Results: This study spanned from March 31, 2021, to November 26, 2021. Eight out of 62 participants discontinued participation. Data collection and analysis have been completed. Significant differences were only observed in the mental health (t_{50}=–3, P=.004), pain ($t_{39.4}$=–3.6, P<.001), social support (t_{50}=–2.7, P=.009), and social activities (t_{50}=2.2, P=.03) domains of the Osteoarthritis Knee and Hip Quality of Life (OAKHQoL) questionnaire with higher scores in the AVbSE group at the end of week 4. At the end of week 8, significant differences were observed in mental health (t_{50}=–2.1, P=.04) and pain ($t_{37.3}$=–2.8, P=.008) measures with higher scores in AVbSE; however, a significantly higher score was observed in the CbSE group for the Quadruple Visual Analog Scale. No significant main effect of time was observed in this study, except in the muscle strength (F_{2100}=1.5, P=.24), social support (F_{2100}=2.5, P=.09), and social activity (F_{2100}=0.7, P=.48) domains of the OAKHQoL questionnaire and activity limitation (F_{2100}=0.1, P=.90), and performance restriction (F_{2100}=1.3, P=.27) domains of the Ibadan Knee and Hip Osteoarthritis Outcome Measure (IKHOAM) questionnaire. There was no significant difference between groups in all OAKHQoL domains except social activities (mean 17.6, SD 1.2 vs 22.8, SD 1.2; P=.003) and average pain (2.8, SD 1.6 vs 2.3, SD 1.6; P=.03) with higher AVbSE mean scores. However, a higher score was observed for the CbSE group in the Quadruple Visual Analog Scale's least pain domain (1.2, SD 0.2 vs 0.7, SD 0.2; P=.04). Also, interaction effects showed that AVbSE scores were significantly higher for the OAKHQoL questionnaire's physical activity and mental health domains at all time points. However, the CbSE score was higher for the physical performance domain of the IKHOAM questionnaire in the eighth week.

XSL•FO
RenderX

Conclusions: CbSE circuit training and its AVbSE variant effectively improve treatment outcomes and increase the quality of life of patients. While AVbSE was associated with higher improvement in most health-related quality of life domains, CbSE led to higher improvement in average pain.

knee osteoarthritis; video; physiotherapy; exercise; mobile phone; telehealth; telemedicine; randomized; controlled trial; asynchronous; rehabilitation; knees; joints; osteoarthritis; musculoskeletal; rheumatology; physical therapy

Introduction

Osteoarthritis is a degenerative joint disease [1] affecting synovial joints and is a leading cause of pain and disability among adults [2]. Knee osteoarthritis is the most common type, with data indicating that 45% of people may develop symptomatic knee osteoarthritis in their lifetime [3]. Accordingly, knee osteoarthritis is the most prevalent type of osteoarthritis in Africans [4], accounting for 65%-78% of cases in hospitals in Nigeria [5]. Epidemiological studies have shown that obesity, microtrauma, knee joint alignment, repetitive use of joints, bone density, muscle weakness, and joint laxity are all local risk factors for knee osteoarthritis [6,7]. Further reports indicate that approximately 10% and 18% of men and women, respectively, present with myriad symptoms and radiological evidence, especially in about 30%-50% of adults aged 65 years and older [8,9]. Osteoarthritis of the knee is a prevalent musculoskeletal condition affecting older people, often accompanied by pain, physical disability, and reduced quality of life (QoL), with considerable economic burden on the health care system [10,11]. Research indicates that knee osteoarthritis occurs earlier in life, affecting younger adults more often than in previous years, likely due to increased obesity and joint injury [12].

The earlier occurrence and rising prevalence of knee osteoarthritis invite concern for effective management strategies to optimize the patient's QoL [11] and the general well-being of the affected individuals [13]. Physiotherapy is a conservative approach that has been consistently recommended in the management of osteoarthritis [14]. The updated European League Against Rheumatism guidelines for the nonpharmacological core management of hip and knee osteoarthritis (recommendation 3) suggest that individuals with hip or knee osteoarthritis should be provided with an exercise program (such as strength, aerobic, flexibility, or neuromotor training) tailored to their physical function, preferences, and available services, with a progressive increase in intensity and level of difficulty [15]. The Osteoarthritis Research Society International guideline for the nonsurgical management of knee osteoarthritis also recommends land- and water-based exercises and muscle strengthening for pain management, improving physical function and QoL [16]. Accordingly, therapeutic exercise is the mainstay of physiotherapy for knee osteoarthritis as it is an effective and well-tolerated treatment [14]. Exercise intervention in knee osteoarthritis alleviates pain, improves physical performance, and optimizes social, domestic, occupational, and recreational participation [17]. Other potential benefits of exercise for this patient group include improvements in mobility and psychosocial health, as well as reduction of fall risk, body weight, and metabolic abnormalities [18]. Muscle strengthening is also a critical component of most exercise regimes for knee osteoarthritis [19]. Research shows that pain and disability can be reduced with aerobic walking and quadriceps strengthening in patients with knee osteoarthritis [20,21]. Self-management has also been increasingly shown to be an essential component of knee osteoarthritis management. Wu et al [22] found that self-management helped manage pain and stiffness and improve QoL in persons with knee osteoarthritis. Uritani et al [23] also found evidence for the benefits of self-management intervention in improving the self-efficacy of persons with knee osteoarthritis in handling pain and other symptoms. Accordingly, both the European League Against Rheumatism and Osteoarthritis Research Society International guidelines for managing knee osteoarthritis also recommend self-management in conjunction with exercise interventions for managing knee osteoarthritis [15,16].

Still, health care access–related issues can impede some patients with knee osteoarthritis from receiving exercise that is vital for their care [24]. Specifically, in medically underserved areas, physiotherapy services can be limited or lacking entirely [24,25]. These issues are particularly salient for individuals with low socioeconomic status, who also bear a greater burden of osteoarthritis [26]. These issues invite the need for innovative platforms that will help improve access to rehabilitative services and encourage self-management for patients with knee osteoarthritis [27].

Recently, telerehabilitation has been advocated to reduce the frequency of clinic visits, clinic waiting time, and costs incurred from transportation to the clinic, especially for patients living far distances from the clinic [24,28]. In addition, telerehabilitation has the potential to improve access to rehabilitation for patients in medically underserved countries like Nigeria and similar sub-Saharan African contexts. Medically underserved regions are characterized by a lack of adequate health care services, a high proportion of the population living in poverty, a high percentage of elderly residents, and a low ratio of health care providers to the population [29]. Africa is still facing a critical shortage of health workers despite dealing with the highest disease burden in the world [30,31]. Therefore, validated telerehabilitation platforms that may help overcome the challenges to accessing care faced by patients with knee osteoarthritis are necessary. Video-based telerehabilitation

XSL•FO
RenderX

applications may effectively provide care in rural and resource-limited settings where internet-enabled digital services may be scarce or unavailable [24,25]. Particularly, asynchronous video-based telerehabilitation interventions can help overcome the time constraints of in-person and remote synchronous care [32]. Asynchronous digital health tools, also known as "store-and-forward" technology, allow for remote, non–real-time communication between providers and patients. This enables both parties to access the platform at their convenience [33]. These tools can address the limitations posed by poor or lack of internet access and coverage, which is common in Africa [34].

Given the prospect of asynchronous video-based telerehabilitation interventions in overcoming the barrier to health care access that persons with knee osteoarthritis may face, we propose an asynchronous video-based strengthening exercise program as a viable alternative. This study, therefore, seeks to compare the effect of a traditional clinic-based strengthening exercise (CbSE) program and an in-home asynchronous video-based strengthening exercise (AVbSE) program on clinical and psychosocial outcomes in patients with knee osteoarthritis. This study hypothesizes that the outcomes related to the in-home AVbSE would be comparable to CbSE over a period of 8 weeks.

Methods

Design

This study used a pretest-posttest quasi-experimental design.

Participants

Eligible participants for the study included patients with radiologically confirmed knee osteoarthritis for not less than 3 months, who were 45 years and older, had a Kellgren-Lawrence grade of II and III, and were without any obvious deformities of the trunk or upper and lower extremities. Exclusion criteria were patients with other comorbidities such as acute inflammation, knee surgery, cardiovascular, respiratory, neurologic, and metabolic diseases, and pregnant women. Non–mobile phone owners after initial contact and screening were also excluded.

Sample Size

Sample size estimation for the study was based on the equation $c\times\pi1(1–\pi1)+\pi2\ (1–1\pi2)/(\pi1–\pi2)^2$ [35], where c=7.9 for 80% power, and π1 and π2 are proportion estimates (π1=0.25 and π2=0.65). Therefore, n=7.9 × (0.25 (1–0.25)+0.65 (1–0.65)/(0.25–0.65)=20.49, which is approximately 21. Hence, the calculated N is 42 (21 per group). To account for 10% possible attrition, the approximate minimum sample size was 46.

Study's Site and Sampling Procedure

This study was conducted at the Physiotherapy Departments of the Federal Medical Centre and Benue State University Teaching Hospital, both in Makurdi, Benue State, Nigeria. The study sites were selected purposefully based on the caseload at both centers and, second, one of the centers had fewer physiotherapists. The center with more physiotherapists was chosen as the control CbSE, while the other was the experimental AVbSE. Using 2 sites in this study was intended to minimize the spillover effect (spillover bias refers to an unintended effect that happens to those for whom the experimental intervention was not designed) by geographically separating the CbSE (control) from the AVbSE group. Also, the single-blind approach minimized the Hawthorne effect (that's a situation where participants in the experimental or control group show exceptionally higher outcome scores or performance just because they are aware they are being studied). Thus, a research assistant who was not involved in the interventions conducted the recruitment and assessments. The study sample was randomly drawn from the list of patients with knee osteoarthritis attending both clinics.

Outcomes

The primary outcomes in this study were pain, range of motion, and muscle strength, while osteoarthritis-specific QoL and physical function were the secondary outcomes. The instruments used in the study were the Quadruple Visual Analog Scale (QVAS), goniometer, tensiometer, and Ibadan Knee and Hip Osteoarthritis Outcome Measure (IKHOAM) questionnaire, and Osteoarthritis Knee and Hip Quality of Life (OAKHQoL) questionnaire.

QVAS

This tool was used to measure pain intensity based on current pain, average pain, least pain, and worst pain, respectively. The QVAS is a segmented numeric alternative to the visual analog scale where a whole number (0-10 integers) that best reflects the intensity of the pain for the different dimensions is chosen by the respondent [32]. The total score of the QVAS is derived by scoring 1+2+4, divided by 3, and multiplied by 10. Pain intensity can then be classified as low intensity (50) or high intensity (50) [36].

Goniometer

A goniometer (12-inch plastic [model 12-1000], Fabrication Enterprises) was used to measure the range of motion at the knee joint. It ranges from 0° to 180°.

Tensiometer

A tensiometer (model and pocket balance) was used to measure quadriceps muscle strength. The scale is from 0 kg to 100 kg.

The IKHOAM Questionnaire

The IKHOAM questionnaire was used to measure the activities of daily living and societal and physical performance. The IKHOAM questionnaire is a 3-domain, 33-item instrument consisting of an activity limitations domain comprising 25 activities of daily living that are performed by individuals with knee and hip osteoarthritis rated on a 5-point (0-4) ordinal scale, a participation restriction domain comprising 3 activities in societal participation rated on a 4 point (0-3) ordinal scale, and a physical performance tests domain including 5 tests rated by a clinician. These tests are (1) 250 m walk test rated on a 6-point (0-5) ordinal scale, (2) single-leg stance test rated on a 6-point (0-5) ordinal scale, (3) stair climbing test rated on a 5-point (0-4) ordinal scale, (4) squat test rated on a 5-point (0-4) ordinal scale, and (5) balance test rated on a 6-point (0-5) ordinal scale.

XSL•FO
RenderX

The maximum obtainable score for the tests is 23 (5 scores for each of the 250 m walk test, 1 single-leg stance test, and one balance test, with 4 scores for the stair climbing test and squat test, respectively). The maximum obtainable score on the IKHOAM questionnaire is 232 (ie, 200+9+23). The score for each participant was calculated in percentage as a score divided by the total possible score and multiplied by 100. A low score on the IKHOAM questionnaire implies a low level of physical functioning ability, and a high score means a high level of physical functioning ability [37].

The OAKHQoL Questionnaire

The OAKHQoL questionnaire was used to assess the QoL. The OAKHQoL is the first specific QoL questionnaire for patients with knee and hip osteoarthritis. It is self-administered and comprises 43 items in 5 dimensions: physical activity, mental health, pain, social support, and social activities, plus 3 independent items. Dimension scores are standardized from 0 (worst QoL) to 100 (best QoL) [38].

Procedure

The participants were recruited consecutively at each study site and followed through until they completed the 8-week treatment program. The participants were informed of the research's purpose at the onset of the recruitment process. An informed written permission form, which was also translated into the local language by professionals, was given to every participant (N=64) who was evaluated for study eligibility. The number of people invited to participate (n=57), the number of people who rejected (n=3), the number of screened patients who were ineligible (n=4), and their justifications for declining participation were all tracked by a research assistant.

Each individual included in the study had a baseline assessment completed. Measurements included anthropometric variables such as height, weight, and BMI. Each participant's information, including their age and gender, was recorded. All the questionnaires were applied, and the measurements of the range of motion of the knee joint and muscle strength (quadriceps) were taken at baseline, week 4, and week 8 of the study. Active graded exercises (active range of motion and quadriceps strengthening exercises) were administered to the patients in the 2 groups (CbSE and AVbSE) for 8 weeks.

The participants recruited into the AVbSE group received an asynchronous video containing exercises, instructions, and demonstrations of each exercise's performance. The AVbSE was developed to be operable on a mobile device with at least an Android OS of 4.1 or an iPhone interface (iOS) for participants who own and could operate a smartphone. The video was also available as a CD drive for those who had or preferred it (n=8). The AVbSE video was an asynchronous video-based intervention intended for usage at home (a safe exercise space). The participants were encouraged to follow the video and complete the tasks thrice weekly. The exercises in the video include a warm-up of active seated knee flexion and extension, quadriceps isometric setting, quadriceps strengthening exercise, hamstring clenches, wall squats, and cool down of active seated knee flexion and extension. The participants in the AVbSE group were telemonitored with voice calls and SMSs to remind them of their exercise schedules and provide symptom reviews and feedback on performance. Also, the telemonitoring was aimed at guiding patients through the exercises and ensuring safety by asking patients to discontinue exercise in case of any adverse event. The CbSE involves the traditional in-person services exercise session led by a physiotherapist trained in the protocols in the AVbSE. The research assistant carried out all baseline treatment outcome assessments (at weeks 4 and 8) for both the CbSE and AVbSE at the clinics. The details of the exercises on the development and feasibility testing of a smartphone video-based exercise program for patients with knee osteoarthritis are already published in an earlier study by Mbada et al [24]. The exercise intervention was developed using a modified Delphi approach, which involved 3 rounds and included a panel of 4 experts and a patient with knee osteoarthritis. After reaching a consensus, the video program for knee osteoarthritis was developed, including 5 main types of exercises: seated knee flexion and extension, quadriceps isometric setting, quadriceps strengthening exercise, hamstring clenches, and wall squats [24]. The highlights of the intervention are (1) warm-up (active range of motion exercises) for 5-10 seconds, and the movement was performed up to 10 times; (2) quadriceps isometric setting repeated up to 10 times; (3) quadriceps strengthening exercise repeated up to 10 times; (4) hamstring clenches held for 10 seconds and then done 10 more times; (5) wall squat held for 10 seconds, then slide back up while keeping their backs firmly against the wall, and the movement was performed up to 10 times; and (6) cool down (active range of motion exercises) for 5-10 seconds, and the movement was performed up to 10 times [24].

Statistical Analysis

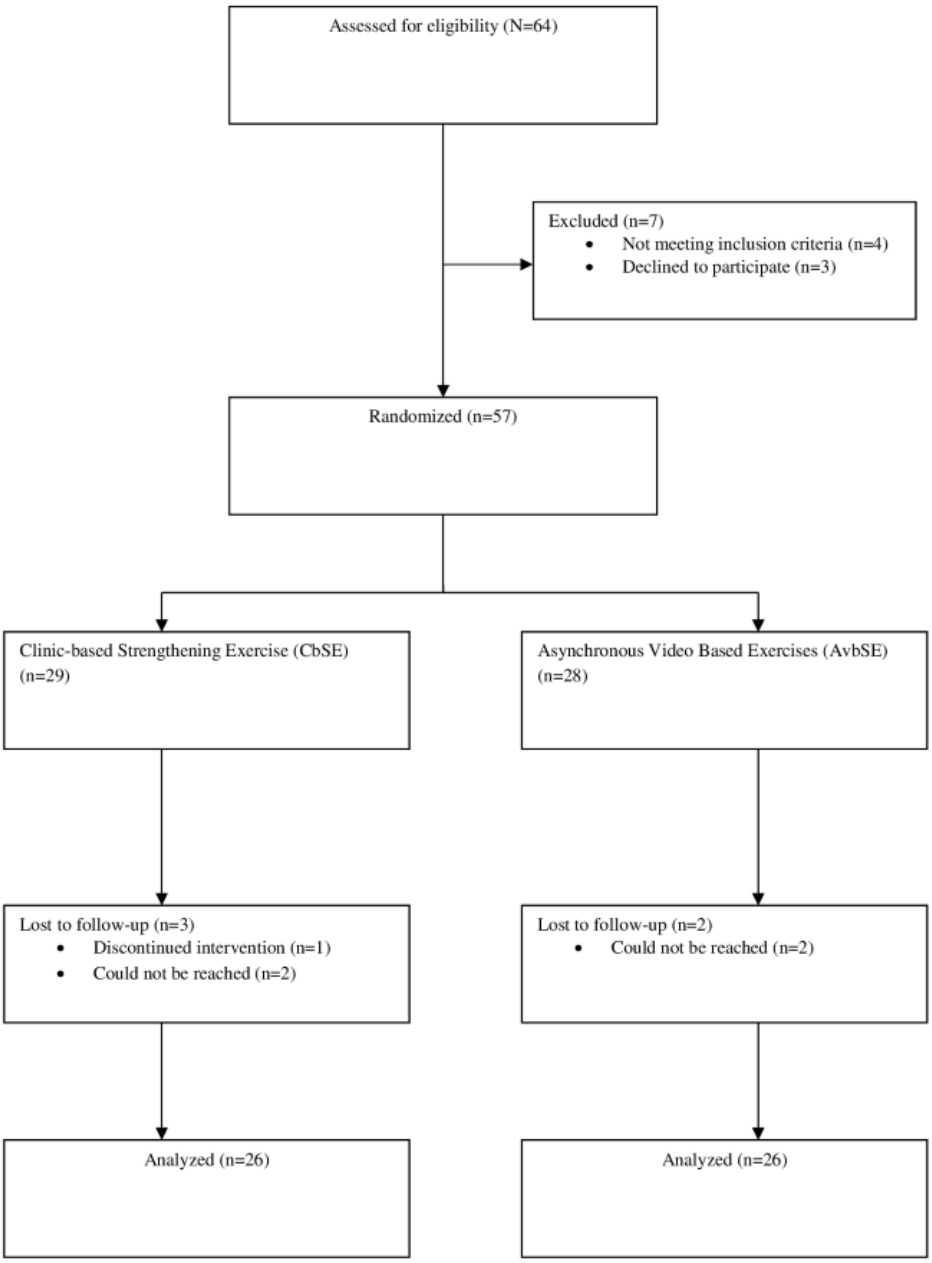
Descriptive statistics of frequency, mean, and SD were used to summarize data, and an independent *t* test was used to compare patients' general and clinical characteristics at baseline. A 2-way mixed-model ANOVA with repeated measures on the time points was used to determine the main effects of the two treatment programs (between-subject factor) and time points (within-subject factor) on the outcome parameters. Parametric tests were used in this study under the assumption that all the measurements are continuous variables on at least an interval scale, are normally distributed, and have equivalent variances. The α level was set at .05. The analysis was done using IBM SPSS (version 27).

Ethical Considerations

This study was conducted according to the guidelines laid down in the Declaration of Helsinki and all procedures involving research study participants were approved by the Health Research Ethical Committee, Federal Medical Centre Makurdi, Nigeria (FMH/FMC/HRE/VL 1-24/03/21). Written informed consent was obtained from all participants.

Results

This study began on March 31, 2021, and ended on November 26, 2021. A total of 64 participants were recruited for the study but 8 participants discontinued. Data collection and analysis have been completed. The CONSORT (Consolidated Standards of Reporting Trials) flow diagram of the study is presented in



XSL•FO
RenderX

Figure 1. Out of 64 patients, a total of 57 patients were found eligible for this study. There was a 12% loss to attrition based on the total number of participants recruited. Thus, 52 of 64 (81.3%) patients completed the study. The mean (SD) age, height, weight, and BMI of the participants were 56.2 (SD 7.5) years, 1.7 (SD 0.1) m, 68.8 (SD 7.6) kg, and 24.8 (SD 2.2) kg/m^2, respectively. Participants in the two groups were comparable in their general characteristics (Table 1). Most participants in both groups were females (31/52, 59%). Civil servants, artisans, and businesspeople or traders comprised 15% (8/52), 21% (11/52), and 63% (33/52), of the participants, respectively. Also, a comparison of baseline measures in the selected outcomes is presented in Table 1. Both groups were comparable at baseline, except in OAKHQoL domains ($t_{39.9}$=–4.1, $t_{42.5}$=–4.7, $t_{38.3}$=–5.8, t_{50}=–4.2, and t_{50}=6; P<.001), the physical performance domain of IKHOAM (t_{50}=–2.2, P=.04), and the least pain domain of QVAS (t_{50}=2.4, P=.02; Table 1).

Within-group effects (comparison of outcomes across baseline, fourth, and eighth week of the study) of CbSE and AVbSE are presented in Tables 2 and 3.

In Table 2, for a particular variable, mean values with different superscripts are significantly different (P<.05). When mean values have the same superscripts, they are not significantly different (P>.05; based on the least significant difference post hoc test).

Participation restriction	6.0 (1.4)	6.5 (1.7)	–1.147 (50)	.26
Physical performance	8.9 (3.1)	10.7 (2.8)	–2.167 (50)	.04

[a]CbSE: clinic-based strengthening exercise.

[b]AVbSE: asynchronous video-based telerehabilitation strengthening exercise.

[c]OAKHQoL: Osteoarthritis Knee and Hip Quality of Life.

[d]IKHOAM: Ibadan Knee and Hip Osteoarthritis Outcome Measure.

In Table 3, for a particular variable, mean values with different superscripts are significantly (P<.05) different. When mean values have the same superscripts, they are not significantly different (P>.05; based on the least significant difference post hoc test).

Results show significant differences in all the outcome parameters across the 3 time points of the study as shown in Tables 2 and 3. Also, a comparison of treatment outcomes between CbSE and AVbSE at weeks 4 and 8 of the study is presented in Table 4. The main effect of time was significant across all outcome parameters except muscle strength (F_{2100}=1.5, P=.24), social support (F_{2100}=2.5, P=.09), and social activities (F_{2100}=0.7, P=.48) of the OAKHQoL questionnaire, as well as the activity limitation (F_{2100}=0.1, P=.90) and performance restriction (F_{2100}=1.3, P=.27) domains in the IKHOAM questionnaire as given in Table 5. Across all dimensions of the QVAS, the mean score reduced significantly from the fourth week to the eighth (F_2=20.9-410.8, P<.001). Physical activities, mental health, and pain also showed a mean decrease across the time points. However, in the physical performance domain of IKHOAM, a significant increase in mean values was observed across the time points (Tables 2 and 3). Similarly, there were no significant differences in the treatment outcome between the two groups at the end of the 8 weeks of the study except for higher mean observed in mental health (17.5, SD 11.5 vs 11.6, SD 8.2; t_{50}=–2.2, P=.04) and pain (23.6, SD 10.9 vs 5.5, SD 3.2; t_{50}=–2.8, P=.008) in AVbSE group compared with CbSE group (Table 4).

A comparison of treatment outcomes between CbSE and AVbSE at weeks 4 and 8 of the study is presented in Table 4. The results of this study show that there were no significant differences in the treatment outcome between the 2 groups at the end of the fourth week of the study except for mental health (t_{50}=–3.0, P=.004), pain ($t_{39.4}$=–3.6, P<.001), social support (t_{50}=–2.7, P=.009), and social activities (t_{50}=2.2, P=.03) domains of the OAKHQoL questionnaire where the AVbSE group had significantly higher mean scores (Table 4). Similarly, there were no significant differences (P>.05) in the treatment outcome between the two groups at the end of the 8 weeks of the study except for a higher mean observed in mental health (17.5 vs 11.6; t_{50}=–2.1, P=.04) and pain (23.6 vs 5.5; $t_{37.3}$=–2.8, P=.008) in AVbSE group compared with CbSE group (Table 4). However, the CbSE group had a higher mean score in the current pain dimension of the QVAS (0.5 vs 0.1; $t_{41.4}$=2.1, P=.04).

[a]OAKHQoL: Osteoarthritis Knee and Hip Quality of Life.

[b]IKHOAM: Ibadan Knee and Hip Osteoarthritis Outcome Measure.

The main effect of the group was found to be significant across all domains of the OAKHQoL measure with corrected *F* test values ranging from F_{150}=21.9 (*P*<.001) on the pain domain to F_{150}=6.4 (*P*=.01) on the physical activities domain. The main effect of the group was also significant for average pain intensity (F_{150}=4.9, *P*=.03) and least pain intensity (F_{150}=4.5, *P*=.04; Table 5). Higher estimated marginal means scores were observed in the AvbSE treatment group across all domains of the OAKHQoL measure except the social activities domain, where the CbSE group was higher (22.8 vs 17.6; F_1-score=9.9, *P*=.003). The average pain dimension of the QVAS score was higher in the AvbSE group (2.8 vs 2.3; F_1-score=4.9, *P*=.03), while a higher mean was observed in the CbSE group for the least pain dimension (1.2 vs 0.7; F_1-score=4.5, *P*=.04). The mean scores showing the difference between groups across all parameters are presented in Table 4.

Discussion

Principal Findings

This study examined the effects of CbSE and AVbSE on clinical and psychosocial outcomes in patients with knee osteoarthritis. The average age of the patients was 56.2 (SD 7.5) years, and most were females. The gender pattern observed in this study might be a coincidence. However, more women are reported to seek care for their musculoskeletal conditions [8,39]. From this study, CbSE and AVbSE significantly improved clinical and psychosocial outcomes in patients with knee osteoarthritis.

Comparison to Previous Work

These findings are consistent with previous reports that exercise interventions have beneficial clinical effects for patients with osteoarthritis in the lower limb [40,41]. The available evidence strongly supports the incorporation of exercise therapy as a fundamental component of nonpharmacological treatment for osteoarthritis of the knee [42]. Numerous studies have demonstrated that muscle strengthening and aerobic exercises can reduce pain and enhance physical function in individuals with mild to moderate knee osteoarthritis [43,44]. A systematic review by Turner et al [45] indicated that resistance training can improve pain and physical function, but the most effective resistance training regimen remains uncertain. Nevertheless, it appears that a total of 24 sessions over 8-12 weeks can yield significant benefits. A meta-analysis of 17 clinical trials involving 1705 patients revealed that resistance exercise contributes to a reduction in pain and stiffness, as well as an improvement in physical function for individuals with knee osteoarthritis [46]. Furthermore, it has been established that strength training exercises carried out over a period of 8 weeks, 3-5 times a week, can be both safe and effective for patients with knee osteoarthritis.

Furthermore, there is evidence for the effectiveness of resistance exercises conducted as a home exercise program for patients with knee osteoarthritis [40,41]. Doi et al [47] conducted a randomized controlled trial involving 142 patients with knee osteoarthritis. They found that a home-based quadriceps strengthening program involving 20 repetitions of a slow knee extension movement implemented 4 times daily for 8 weeks was as effective as nonsteroidal anti-inflammatory drugs for improved pain, stiffness, physical function, and QoL outcomes. However, in a systematic review, Saengpromma et al [48] found that a home exercise program with tracking improves pain and function and increases adherence and changes in behavior in older people compared with the untracked group. Doi et al [47] also corroborate that the effectiveness of home-based exercises in patients with knee osteoarthritis depends on patient adherence. Ettinger et al [49] and Thomas et al [50] submit that adherence to strengthening exercise is a key predictor of response in patients with knee osteoarthritis. However, the best way to deliver in-home strengthening exercises and promote adherence is still unclear.

Few studies emanating from West Africa explored digital rehabilitation for knee osteoarthritis. Odole and Ojo [28] implemented an in-home intervention of standardized exercise programs for patients with knee osteoarthritis, and adherence was monitored using telephone calls. The authors found that in-home telerehabilitation was comparable with clinic-based treatment in terms of improved QoL. Similarly, Ojoawo et al [51] compared clinic-based and telemonitored home-based interventions involving exercise pamphlets and telephone calls. They found that both interventions were effective in managing knee osteoarthritis, but the clinic-based intervention was better than the telemonitored home-based intervention. Both interventions implemented low-tech digital rehabilitation involving preintervention demonstration of exercises and the use of pictorial pamphlets as a guide. This is the first study to implement an asynchronous digital health tool for the rehabilitation of Nigerian patients with knee osteoarthritis. Implementing high-tech digital health interventions in the study setting is hamstrung by many factors, including poverty, lack of needed infrastructure (such as internet availability), and digital illiteracy [52,53].

In-home telerehabilitation creates opportunities to mitigate some of the challenges of home-based interventions (such as lack of support and good communication) using technological platforms

XSL•FO
RenderX

[54]. Technology is not efficacious in itself; it depends on innovative ideas and providers' creative abilities to ensure its use is sustainable [55]. According to Russell [56], telerehabilitation's primary aim is to help patients receive equal access to rehabilitation services via images, sensors, virtual reality, and environments despite their impairments or barriers in accessibility. In physiotherapy, there has been an increase in the adoption of telecommunication technology, such as telephone or videoconferencing, to provide remote access to physiotherapy services when one-on-one contact is not feasible [28,57]. Telerehabilitation is a convenient way for patients to perform basic physiotherapy exercises on their own within their homes to avoid long-distance travel [58]. This study compared an asynchronous video-based telerehabilitation program with a clinic-based intervention. The treatment outcomes between the groups for both interventions are comparable except for average pain and least pain and OAKHQoL domains, where AVbSE produced significantly higher mean change in average pain and all domains of the OAKHQoL except social activities. Also, interaction effects show that the AVbSE had higher mean change across time points for PA and mental health OAKHQoL domain across all time points. Also, the CbSE score was only higher in the physical performance domain of the IKHOAM in the eighth week. Hence, AVbSE is a viable alternative to delivering physiotherapy for patients with knee osteoarthritis. The findings of this study support some related studies. Odole and Ojo [28] documented the efficacy of telephone-based rehabilitation on pain, physical function outcomes, and QoL in knee osteoarthritis. Chandra and Keerthi [58] also reported the efficacy of telerehabilitation using telephonic consultation and videoconferencing for patients with knee osteoarthritis, using exercise as a home-based treatment. Bennell et al [59] investigated the cost and clinical effectiveness of combining a physiotherapist-delivered intervention with a nurse-delivered telephone coaching for people with knee osteoarthritis. Better outcomes were achieved in the group of patients who received physiotherapy treatment and the nurse-delivered telephone coaching than those who received only physiotherapy treatment. According to Adhikari et al [60], telephone-based treatments used in telerehabilitation were both feasible and efficient, significantly reducing pain caused by various musculoskeletal problems in resource-limited settings. Another study by Multani et al [61] found significant improvement in pain, muscle strength, and functional ability within 4 weeks of telerehabilitation in patients with knee osteoarthritis.

This study supports other studies, including reviewed literature that suggest that muscle strengthening interventions improve pain and physical functioning in persons with mild to moderate osteoarthritis of the knee. Also, the study reveals that asynchronous video-based exercises effectively manage patients with knee osteoarthritis and produce comparable effects in physiologic and psychosocial outcomes to conventional clinic-based physiotherapy. Furthermore, the findings of this study confirm an earlier submission by Winters [62] that telerehabilitation brings the hope of enabling access for all, as well as helping address societal challenges in the delivery of rehabilitative services once barriers such as distance and reimbursement are overcome. Also, according to Lamplot et al [63], as technology improves in remote and rural locations, initial knee examination and follow-up visits may also be conducted virtually [63]. The findings of this study support earlier advocacy on the necessity for the development and implementation of telerehabilitation services to support persons with potentially disabling conditions who may have limited access to rehabilitation services [64,65].

Clinical Implications

The study's relevance lies in its provision of evidence on digital rehabilitation to expand access to rehabilitation for individuals with knee osteoarthritis in Nigeria and similar medically underserved contexts. The exercises used in this study were developed based on available evidence and expert opinions following a Delphi study. The interventions were applied in accordance with evidence from a systematic review, which showed that exercise programs lasting 8-12 weeks, with 3-5 sessions per week, are safe and effective for patients with knee osteoarthritis. This study aligns with recent recommendations for self-management in patients with chronic conditions [66], particularly for those with osteoarthritis [67]. Digital interventions have been beneficial in promoting self-management among patients with various conditions [68,69], including osteoarthritis [70,71]. Using asynchronous video-based exercises as digital rehabilitation for patients with knee osteoarthritis would improve access to physiotherapy services, eliminate geographical and distance barriers, and reduce the burden of clinic visits and waiting times.

Study Limitations

This study has some potential limitations that may affect the generalizability of findings. As such, some characteristics of the sample must be considered. First, the significant difference in the baseline parameter between the intervention and control group regarding the OAKHQoL domains, physical performance domain of IKHOAM, and least pain domain of QVAS may be a source of bias on the outcome of the interventions. Second, most participants were primarily middle-aged adults who were largely uneducated; this may affect the ease of use of technological tools. Third, this study used a dual clinical approach to recruiting participants, which could have potential inherent selection bias. Selecting multiple sites for this study may introduce selection bias related to patient demographics or treatment practices, which could independently influence the outcomes of the intervention. However, the findings of the study suggest that the general characteristics of patients at baseline were comparable across groups, indicating that the potential for selection bias is limited. Although both clinics are classified as tertiary health care institutions in Nigeria, the distinctive attributes of teaching hospitals often make them the preferred option for patients seeking specialized and comprehensive health care. As such, the control site, which is the teaching hospital in this case, may have more standardized treatment practices, potentially leading to performance bias and affecting treatment outcomes. Fourth, it is challenging to guarantee the adherence of the participants in the AVbSE group, as it is commonly reported in asynchronous tele-exercise programs, despite the telemonitoring used in this study. Also, asynchronous tele-exercises offer scheduling flexibility to patients but do not provide for real-time interface and response from the provider.

XSL•FO
RenderX

Furthermore, excluding patients without mobile phones from data collection may be a limitation of this study. While mobile phone ownership is relatively high worldwide, it is still a problem in specific populations, such as adults in rural or developing areas, and children [72]. In Nigeria, smartphone penetration is increasing and is expected to reach around 60% by 2025 [73]. However, mobile phone ownership in poorer areas is still limited, with only 58% of Nigerians in urban areas and 32% in rural areas owning smartphones in 2022 [74]. Therefore, the pervasive digital divide or digital poverty in many African settings hinders the continent from fully benefiting from digital technology [75]. For instance, the lack of mobile phone ownership could impede the implementation of mobile health interventions in Africa [76]. Researchers conducting self-report research using mobile phones should be aware that providing a mobile phone to standardize participant response platforms can impact response behavior [72].

Direction for Future Work

Future research investigating the short- and long-term effects of telerehabilitation among a larger population of patients with knee osteoarthritis from multiple sites is recommended to validate the findings of this study.

Conclusion

Clinic-based strengthening exercise circuit training and its asynchronous video-based variant have been found to effectively reduce pain, impairment, and disability and increase patients' QoL. The video-based variant was associated with higher improvement in most health-related QoL domains. In comparison, clinic-based strengthening exercise circuit training led to higher improvement in pain intensity.

Abstract

Background: The rates of sexually transmitted infections (STIs) continue to rise across Australia among 16- to 29-year-olds. Timely testing is needed to reduce transmission, but sexual health clinics are at capacity. This demand, coupled with barriers to getting tested faced by young people, has led to web-based services as a pragmatic solution. However, for young people to use these services, they must be acceptable, attractive, and usable. Social marketing principles combined with end user engagement can be used to guide the development of a web-based service and create a marketing strategy to attract them to the service.

Objective: Working closely with end users and guided by social marketing, this project explored messaging, design elements (imagery), and promotional strategies that will support high usage of a web-based STI/blood-borne virus (BBV) testing service for young people in Victoria, Australia.

Methods: Young people were recruited to participate in half-day workshops via youth organizations and targeted Meta (Facebook/Instagram) advertisements. An initial web-based survey was deployed to inform workshop content. Workshops were held in metropolitan, outer metropolitan, and regional Victoria. Young people were presented with a range of "image territories" developed by a social marketing firm and social marketing messages that were informed by the literature on communicating health messages. Participants discussed the feelings and reactions evoked by the content. Data collected through mixed methods (transcribed notes, audio recording, and physical outputs) were thematically analyzed to understand features of messaging and imagery that would attract young people to use the service.

Results: A total of 45 people completed the initial survey with 17 participating in focus group workshops (metropolitan: n=8, outer metropolitan: n=6, and regional: n=3). Young people preferred messages that highlight the functional benefits (confidential,

XSL•FO
RenderX

affordable, and accessible) of a web-based service and include professional imagery and logos that elicit trust. Young people indicated that the service should be promoted through digital communications (eg, dating apps and social media), with endorsement from government or other recognized institutions, and via word-of-mouth communications.

Conclusions: This study has highlighted the value of applying social marketing theory with end user engagement in developing a web-based STI/BBV testing service. Through the voices of young people, we have established the foundations to inform the design and marketing for Victoria's first publicly funded web-based STI/BBV testing clinic. Future research will measure the reach and efficacy of social marketing, and how this service complements existing services in increasing STI/BBV testing uptake among young Victorians.

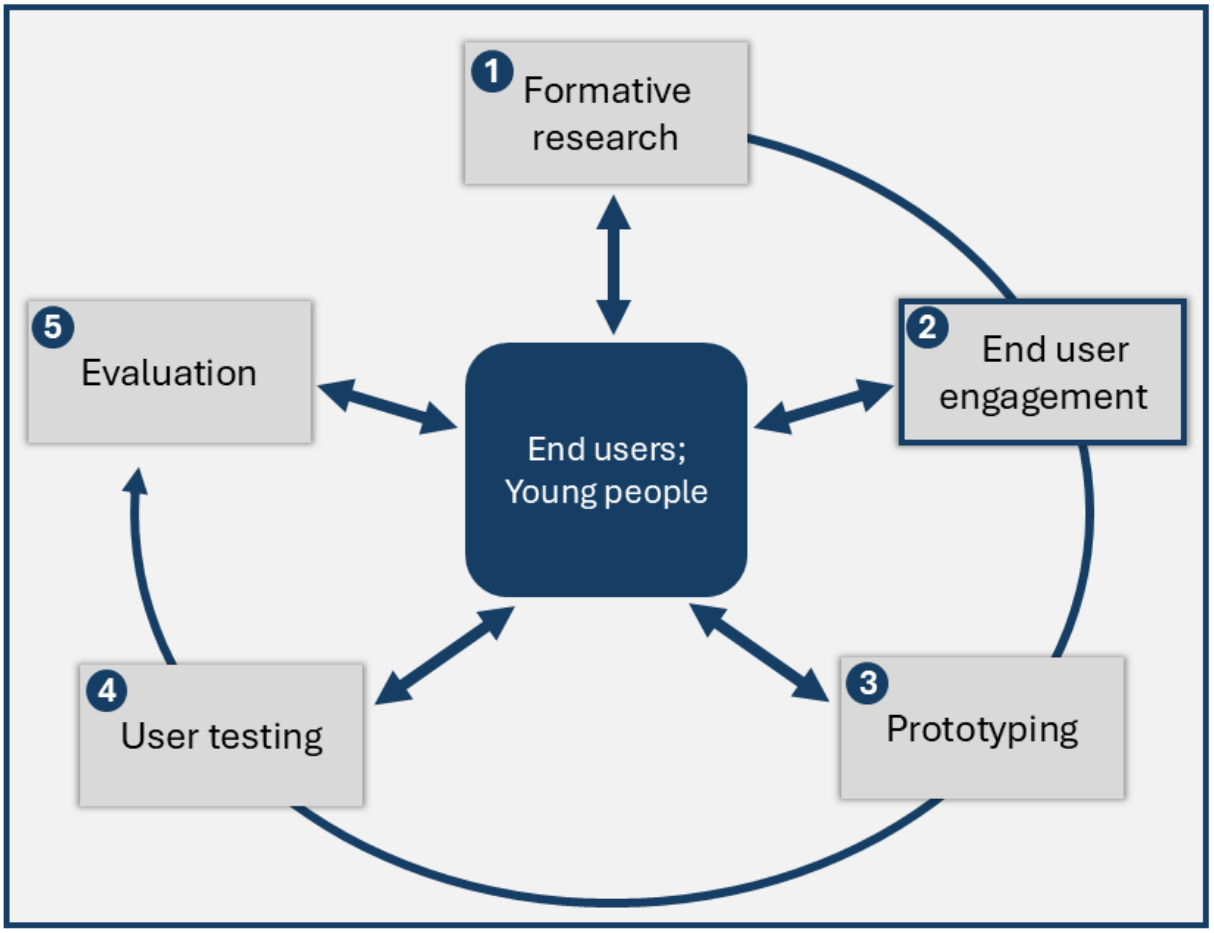
Introduction

Background

After a drop-off during the COVID-19 pandemic, sexually transmitted infections (STI) diagnosis rates are rising again throughout high-income countries and the burden of these infections is particularly high among young people aged 16-29 years [1]. The increased demand for STI and blood-borne virus (BBV) testing has placed a strain on sexual health services and led to the emergence of web-based services that are now increasingly common in the United States, United Kingdom, Canada, and Europe [2] as a solution for increasing access to testing.

While web-based services can be effective at increasing access to STI testing, they are not always acceptable or accessible to particular population groups, such as those living in regional or remote areas, and this is often because they have been developed with little engagement from the end user [3]. This lack of engagement with end users can explain usability problems, low uptake, and high attrition rates [3]—people simply stop using technologies that do not correspond with their daily lives or habits. Social marketing theory [4] and end user engagement [5] approaches are valuable for putting the focus on the end user, increasing the effectiveness, accessibility, and sustainability of web-based technologies [6]. Few studies have applied social marketing theory with end user engagement; however, researchers in the field have acknowledged the use of end user engagement and social marketing theory individually and the potential for synergy when used together [7,8].

Development of a Web-Based STI/BBV Testing Service in Australia



To address the growing demand for access to STI/BBV testing in Australia, we are developing a fully automated web-based STI/BBV testing service to be offered as part of the only specialist sexual health service in Victoria, Australia, based in Melbourne (population of 5 million), the capital city of the State of Victoria (population of 6.7 million). Given the location of the specialist service in Melbourne, people living in regional Victoria have limited access to specialist STI/BBV care, placing them at considerable disadvantage. The aim of our web-based service is to increase STI/BBV testing uptake by providing access to specialist STI/BBV expertise anywhere across the State of Victoria, not just in Melbourne, particularly for young people aged 16-29 years. Our service will allow users to login to a website portal, answer risk-based consultation questions, receive a pathology request according to recommended testing guidelines [9], and have their results sent directly to them.

Development and implementation of our web-based service have five phases: (1) formative research in which we surveyed young people and reviewed existing web-based services in Australia to inform the design of our service [10-13]; (2) end user engagement in which we ran focus group workshops (workshops) to design the content and the tone of voice (language used), imagery, and branding of the service; (3) prototyping in which we are developing digital prototypes based on the findings from phases 1 and 2; (4) user testing in which we test the prototype with end users to assess its usability, acceptability, and refine development; and (5) evaluation in which we implement the web-based service and assess its impact on STI/BBV testing and diagnosis and its cost-effectiveness (Figure 1).

In this paper, we present the methods and results for phase 2, end user engagement, in which we had direct and iterative involvement with young people to explore the messaging and imagery design elements that would attract young people to use a web-based STI/BBV testing service and the best way to promote this messaging to young people. Further publications will detail our research in developing the user experience along the clinical pathway (part of phase 2), user testing of our web-based service (phase 4), and its subsequent evaluation (phase 5).

Figure 1. Five-phase approach to user-centered development of a web-based sexually transmitted infection/blood-borne virus testing service for young people aged 18-29 years in Victoria, Australia.

Methods

Study Design

In phase 2, we have used Andreasen's theory of social marketing [4] to inform our approach to develop the imagery and messaging for our web-based STI/BBV service and have applied Andreasen's six benchmarks as follows:

1. Behavior change: in our context, we want to ultimately increase STI/BBV test uptake among young people using the service; however, this will not be assessed until phase 5.
2. Formative research: we conducted surveys and interviews and reviewed available web-based services to understand young people's experiences, values, and needs of a web-based service.
3. Segmentation: we targeted particular subgroups of young people to capture their views (viz, young people living in metropolitan and regional areas) based on our formative research [12], which showed differences in preferences between regional and metropolitan youth for how web-based STI/BBV services are delivered. By targeting these groups, we sought to understand how these differences would apply to the design and social marketing of our web-based service.
4. Marketing mix: we assess the service we are providing and how to price, place, and promote it.
5. Exchange: we assess what will motivate young people to engage with the service and what service they will get in return.
6. Competition: we assess competing behaviors and strategies to help us understand what would make a young person use our web-based testing service in preference to other testing services [4]. Our formative research showed that young people want to be able to access web-based STI/BBV testing services in addition to in-person services [12] because of limited availability of specialist in-person sexual health services and the time delays and cost often associated with accessing other in-person primary care services in Australia [2,10]. However, there are few web-based STI/BBV testing services in Victoria, and those that are available are rarely free, nor do they offer a comprehensive STI/BBV testing service in which all guideline-recommended tests are available [10].

Although our web-based service will be directed to people aged 16-29 years, people aged 18-29 years living in the State of Victoria were eligible for participation in phase 2 because of consent challenges when working with 16- and 17-year-olds in focus groups. Phase 2 involved three key steps:

XSL•FO
RenderX

1. An expression of interest (EOI) in which young people were invited to express their interest in being involved in the study. The EOI was advertised through youth service organizations across Victoria and targeted advertising on Meta (Facebook and Instagram). Those interested completed a brief web-based survey, which collected information about sociodemographics including their age, gender, sexuality, and residential postcode. The purpose of the EOI was to allow for purposive sampling for the focus group workshops, ensuring diverse representation of young people (eg, gender and sexuality) from across Victoria including metropolitan and regional locations. We reviewed EOIs in real time and placed additional advertisements targeting both young people living in regional areas and heterosexual men to attract more applicants from these demographic backgrounds as needed.
2. A self-administered web-based survey was completed by a select sample of respondents from the EOI. The demographic profile of EOI responses was screened as they were received, with approximately 15 individuals from each geographic location being invited to participate. The survey explored (1) social marketing including the preferred tone of voice, types of messaging, and image territories (group of images representing a design theme) that would attract young people to use a web-based STI/BBV testing service, and (2) the "user experience" along the clinical pathway from establishing a web-based account, answering sexual history questions, and receiving an STI/BBV form for testing. These survey responses were used to refine the messaging and image territories to explore in the focus group workshops. All individuals who completed the survey were invited to participate in the focus group workshops.
3. Focus group workshops, in which we further explored their preferred social marketing and user experience to inform the development of the web-based service with a sample of young people who completed the web-based survey. Workshop participants provided electronic or written consent and were reimbursed for their time. We conducted three 6-hour workshops that were segmented by geographical area with 1 in metropolitan area, 1 in outer metropolitan area, and 1 in regional areas. Metropolitan and outer metropolitan workshops were conducted on the university campus and the regional workshop was conducted at community organization in regional Victoria.

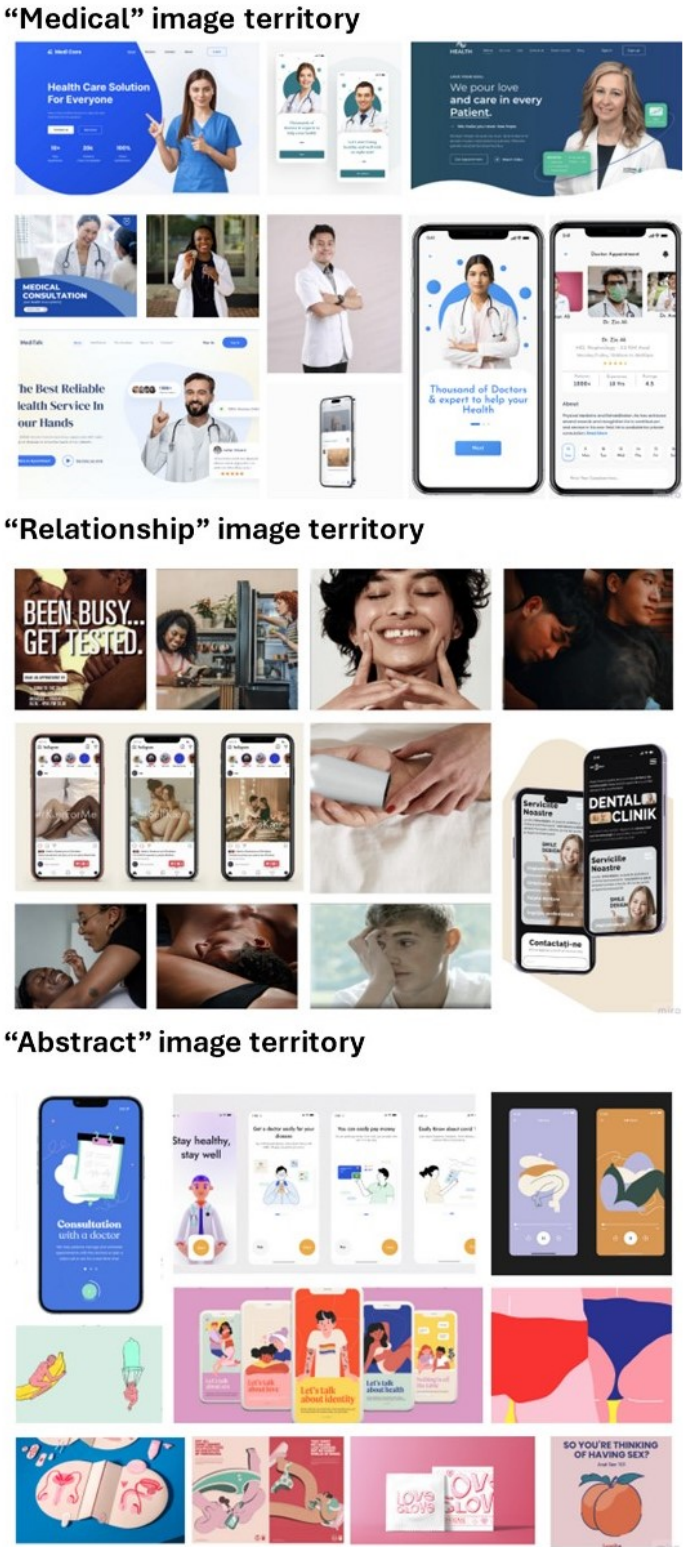
Testing Social Marketing Messaging

The web-based survey explored participants' views about 8 social marketing messages that we developed informed from the literature on communicating health messages to young people [14-16]. Each message included aligns with one of the following approaches to messaging: provision of choice (provides choice between 2 or more behaviors), gain- or loss-framed (emphasizes the advantage or consequence of an action), value based (elicits a sensation of value), and other referencing (focuses on how an individual's choice may affect others) [14-16]. A full list of messages can be found in Multimedia Appendix 1.

Each participant was asked to imagine themselves in 7 different scenarios and then pick the top 3 messages that would encourage them to seek a web-based STI/BBV testing service. Scenarios placed the user in an experience known from the literature as a facilitator or barrier to getting tested, such as stigma, self-efficacy, or risk perception [17-19]. These scenarios were based on the theory of planned behavior and the transtheoretical model [20]. A full list of the scenarios can be found in Multimedia Appendix 1.

The following four messages were the most selected:

- Message 1: Getting tested can protect your partners from STIs.
- Message 2: Confidential, affordable STI testing. Find out more!
- Message 3: Itching. Burning. Rash. Sores. Getting tested is a MUST!
- Message 4: Be healthy. Be safe. Get tested.



In the workshop, participants were presented with each message individually and asked their initial reactions to the message, how it may influence them to use the service, and how it may be improved. After all messages were presented, the participants voted on which of the 4 messages they liked the most.

Testing Image Territories

In our survey, we presented the participants with some examples of web-based service-landing pages (the first web page users see after clicking a link to a testing website) of 2 currently existing sexual health websites and asked them to choose which they liked best (Multimedia Appendix 1). They were then asked what they liked about the website they chose and how it could be improved. We then engaged a social marketing firm that developed 3 "image territories" (medical, relationship, and abstract) to test with young people (Figure 2). During our workshops, we explored how participants felt about each image territory and which one ultimately attracted them most to use this type of service.

XSL•FO
RenderX

Figure 2. Three image territories used to explore design preferences during focus group workshops with young people aged 18-29 years in Victoria, Australia.

Informing a Marketing or Promotion Strategy

To inform a strategy to attract young people to use the service, we explored (1) how participants find out about health services in their day-to-day life, (2) what factors influence their trust of these services, and (3) how they would like to find out about this service.

Analysis

Data collected from the focus group workshops (transcribed notes, audio recording, and physical outputs) were thematically analyzed in Excel by ETC in consultation with SC using an inductive approach [21]. We validated high-level data with those attending the workshop (OW, RP, and TL). Illustrative quotes are presented by geographical location of the workshops. During

XSL•FO
RenderX

the workshops the service was referred to as "online" or "web-based" interchangeably for simplicity.

Ethical Considerations

All activities conducted in this study were approved by the Office of Research Ethics and Integrity at the University of Melbourne (2023-25277-43562-5). All participants were provided with plain language statements and signed an informed consent prior to participation in the study. The consent outlined the activities of the study and informed participants that all data collected would be deidentified and securely stored with password protection. Participants received Aus $20 (Aus $1.00=US $0.63) for completing the initial survey and an additional Aus $100 (Aus $1.00=US $0.63) electronic gift card for each 3-hour workshop they completed for a maximum remuneration of Aus $220 (Aus $1.00=US $0.63).

Results

Participants

A total of 45 individuals completed the initial survey and all were invited to attend a focus group workshop with 17 participating—8 in metropolitan, 6 in outer metropolitan, and 3 in regional locations. Age of workshop participants ranged from 18 to 29 years, with diverse gender (6 women, 9 men, 1 gender diverse, and 1 transgender), sexual orientations (6 heterosexual and 9 same-sex–attracted), and culturally and linguistically diverse backgrounds (7 culturally and linguistically diverse individuals) represented. Results from the focus group workshops are shown in the subsequent section.

Social Marketing Messaging

Four themes emerged from analysis: functional benefits, tone, structure, and altruistic versus individual motivations. These themes were mentioned consistently across all workshops, and there was a general consensus among participants about the messaging they preferred. Participants had more in-depth discussion about the importance of functional benefits and tone than about the themes of structure and individual versus individual motivations.

Functional Benefits—Confidentiality, Affordability, and Accessible Web-Based STI Testing

Functional benefits refer to benefits that particularly relate to the performance of the service and subthemes of confidential, affordable, and specificity (online and STI testing), which were frequently mentioned as important to participants. Participants across all workshops made many comments about the importance of messaging having the functional benefits of the service. They felt that the addition of words "online" or "STIs" would be more descriptive of the service and keep messages from coming off as too "generic."

> *[Be healthy. Be safe. Get tested.] I feel like context is important to make it obvious you're talking about STIs.* [Metropolitan]

It was clear that participants found it important to include aspects of the service that would be seen as valuable to users such as "confidential" and "affordable." This was one of the key reasons for the last message, "Confidential, affordable STI testing. Find out more!" being their favorite.

> *[Confidential, affordable STI testing. Find out more!] Perfect, clear and concise, reiterates the service is confidential, affordable. Assures people can access, like university students.* [Regional]

Although we did not test a message that was specific to accessibility, participants indicated that the word "online" had implicit connotations of being easier to access in comparison with in-person services. In particular, the regional young people spoke about the difficulty of accessing timely health care in their area due to overstretched health care services.

> *Trying to find a doctor in a rural town is very hard because they're not taking new clients.* [Regional]

Tone—Preference for a Nonjudgmental, Comforting Tone

Tone refers to the perception of how the messages come across to the reader with subthemes of commanding, passive, judgmental, comfort, and gimmicky identified. The tone used was brought up across all focus group workshops for every message. Participants did not like messages they perceived to be judgmental or gimmicky. Across all workshops the message, "Itching. Burning. Rash. Sores. Getting tested is a MUST!" was seen as judgmental and not a message they wanted to see. Some participants found certain phrases in the messages to be a bit judgy such as "Be healthy" or gimmicky such as "Find out more!"

> *[Itching. Burning. Rash. Sores. Getting tested is a MUST!] I don't like it at all. If I already had itching and burning, I would already feel uncomfortable and awkward and wouldn't wanted to be shouted at.* [Metropolitan]

In addition, participants discussed the importance of striking a balance between a "passive" and "commanding" tone. The message should not come off as "yelling" or "commanding" but should not be so passive that it does not motivate young people to get tested using the service.

> *[Be healthy. Be safe. Get tested.] I think it's good that it's not fear mongering but maybe too passive.* [Metropolitan]

Structure—Preference for a Short and Snappy Message Structure With Inclusive Wording

Structure refers to the basic elements of the message with subthemes of length, grammar, and wording. The way the message was structured, such as length and grammar, was less important but played a role in how the message was perceived. Participant overall preferred when messages were "short and snappy" and felt that the messages should easily be consumed "if you're walking past." Punctuation was mostly important to participants because it affected the tone of the message. They found that the use of an exclamation and even a period in some places came off as too commanding or gimmicky.

XSL•FO
RenderX

> *[Itching. Burning. Rash. Sores. Getting tested is a MUST!] Exclamation is too much, feels like a WWII poster.* [Metropolitan]

Participants also highlighted the importance of word choice and how certain words such as "partners" may have a "different meaning to different people" and cause some confusion as if the service is right for them.

> *I know a lot of people would just look past it and say, I don't have a partner, I've hooked up with 3 people in 3 days.* [Regional]

Altruistic Versus Individualistic Motivations

This theme refers to participants' comments on the focus of the message being on the individuals themselves or altruistic in nature and how this affects their motivation to get tested. Most comments in this theme related to the message, "Getting tested can protect your partners from STIs." There were mixed opinions from participants as to whether a message focused on the individuals themselves or focused on protecting another person would be more motivating for them.

> *It's focused around other people so I think it would appeal to me more or influence me more to get tested.* [Outer metropolitan]

> *You'll miss selfish people because [they would] possibly be interested in the service for selfish reasons.* [Metropolitan]

Imagery—a Balance of Medical and Abstract Image Territories

Upon thematic analysis, 2 general themes of design neutrality and traditional and modern design emerged across all image territories. Neutral design refers to the generalizability of the design to young people from different backgrounds with young people preferring gender neutral color schemes. Traditional design refers to the professional medical advertisements that have been traditionally used for medical services, where modern refers to more youthful, abstract designs. Participants wanted to find a balance between the 2 as each had its own benefit.

> *I think it's like any other doctor booking website service so if people respond to that then you can use the traditional methods. Why make it look like everything else when it's targeting a niche[r] market.* [Metropolitan referring to the Medical image territory]

There were also themes for each of the image territories. The medical image territory used stock images of medical professionals and traditional depictions of the web-based clinical setting with blue and white color scheme with themes of trust and generic emerging. Although participants found these images to be generic "like any other medical website," they did give participants a feeling of trust for the same reason, as they align with familiar medical service websites.

> *Very professional—too professional. It seems with the doctors and medical professionals makes it reliable and trustable.* [Outer metropolitan referring to the Medical image territory]

The relationship image territory used humanizing images of young people with some appearing to be in relationships and an earth tone color scheme. Participant found the color scheme to be too "luxe" and the images to be overly sexualized like it was "for a dating app."

> *I won't recommend this design at all. I just feel like it would be a dating and relationship website.* [Outer metropolitan referring to the Relationship image territory]

The abstract image territory used an animated approach to imaging with a pastel color scheme and themes of animation and comfort emerged. Participants found the animated images to bring them a sense of comfort as the images are more "relaxed" and relatable to other websites they use and like. However, they did find them feminine and geared toward "young women."

> *Makes me feel more comfortable. I like the animated style, it doesn't feel as daunting. The one thing I didn't like—the colour combos make it feel more targeted to younger females.* [Regional referring to the Abstract image territory]

Promoting and Marketing the Web-Based Service

When asked "How do you find out about health services in your day-to-day life?" participants mentioned social media, word of mouth from friends or health care providers, general searches on Google or specified health engines, and collateral materials posted at various physical locations. Using a search engine and through social media, including advertisements, were mentioned most by young people.

> *I've got ads that were given to me for health services that I wasn't following. I think it's helpful because you're only getting them for a reason.* [Metropolitan]

We then asked participants how they would like to find out about this service particularly. Participants said similar methods to finding out about health services in general but focused more on digital advertising such as social media and dating apps.

> *Dating apps or porn websites; you're going to where your audience is.* [Metropolitan]

We explored what influences their trust in these services. Participants commented that endorsement from friends, partnerships with existing professional organizations, and web-based reviews are important influences for trusting health services, particularly those on the web. It was clear that if participants had a certain level of trust with who they hear about the service from or who it is partnered with they were more likely to trust the service.

> *Word of mouth; people only go to practitioners they've had a good experience with.* [Metropolitan]

> *If it was endorsed by the government or some big hospitals then I would trust.* [Outer metropolitan]

Discussion

Principal Findings

Combining social marketing theory with end user engagement, we were able to identify key messaging and imagery that would attract young people to use a web-based STI/BBV testing service. We found that young people preferred messages that highlight the functional benefits (confidential, affordable, and accessible) of a web-based service and include youthful imagery and professional logos that elicit trust. In addition, we learnt that young people would want this service to be promoted through digital communications (eg, dating apps and social media), endorsement from government or other recognized institutions, and via word-of-mouth communications.

This study is one of the few studies to examine and publish findings from the design phase of developing a digital sexual health intervention and one of the only studies to publish findings on the desired language and imagery of young people as the end user [22-25]. Many studies have outlined the design process but have not clearly defined language or imagery elements of the design [26-28]. However, the summative findings from these studies reflect our findings and establish that young people want to use a web-based service but require a certain level of clarity around the confidentiality and credibility of the service—they want to trust the service [26-28].

Social Marketing and End User Engagement

Social marketing principles informed our study design and end user engagement proved useful for exploring the needs of young people. The workshops were also able to help us reaffirm our earlier findings and assumptions important to designing a service that is attractive and useful for young people. End user engagement has been used for the development of many interventions in sexual health and exemplifies the importance of involving end users and this study is no different [29]. By examining the rationale behind young people's preferences in a focus group setting, we are able to better tailor a youthful yet trustworthy service to young people. It is important to note that this is just the first step in the development of this service. Engaging end users in design is an iterative process and will require further involvement with young people through further user testing of prototypes created and feedback throughout implementation.

In this study, we focused on Andreasen's principles of segmentation, exchange, and the marketing mix (product, place, price, and promotion) (Multimedia Appendix 2). Segmentation was an important principle for us to explore in this study, as our formative research suggested that some populations expressed different preferences for using web-based STI/BBV testing services [12]. While many social marketing researchers have shifted away from the use of geographic and demographic segmentation because of its failure to predict behavior change [30], we included geographic segmentation because our earlier research found that young people living in regional areas expressed a stronger preference for web-based STI/BBV testing services than metropolitan young people [12]. However, in our focus group workshops, we found overall agreement among regional and metropolitan young people on the elements of design and promotion, although regional participants placed more value on the collateral materials (eg, posters) to promote the service. This suggests that while regional youth may be more likely to want to access a web-based rather than in-person service, their preferences for the design of the service are similar to metropolitan youth.

Ideally, we would have also included segmentation on psychographic factors such as personality, social status, or opinions, but this type of segmentation is expensive and time consuming to implement in practice, given the unreliability of and complexity in collecting these data and not possible within the budgetary constraints of our project [31]. In fact, most studies do not even report on segmentation at all [32].

In our exploration of the design of the service (product) and it being web-based (place), we found that young people continuously mentioned the importance of establishing trust among potential users. Whether directly or indirectly, participants made it clear that explicit messages and imagery highlighting the confidentiality and credibility of the service were critical in establishing the level of trust needed to use the service.

Andreasen's benchmark "exchange" (ie, motivation to engage with the service for the offer of something beneficial in return) [4] was indirectly explored throughout the study with the most interesting finding being that our traditional assumption of STI/BBV behavior being intrinsically motivated was not applicable to all participants. Our finding that some participants were more motivated by the extrinsic motivation of "protecting their partner" indicated the need to diversify messaging to extend our reach. Testing a diverse set of messages yielded important additional insights not observed in the initial survey. While the "fear-based" message ("Itching. Burning. Rash. Sores. Getting tested is a MUST!") was one of the top selected messages in the survey, upon deeper discussion with the focus group, this was clearly found to not be a motivating message. Although not intentionally explored in this study, there were some suggestions that the messages presented could be acceptable across multiple platforms (including digital and traditional place-based advertisements). This is something we will explore further in the future.

Competition is another principle often underreported in social marketing interventions [31] and although not directly explored in this study, participants did have some important insights to inform competition. Throughout the workshops, participants made it clear that they wanted a service that had no out-of-pocket costs. This is important given our finding that there are no free web-based comprehensive STI/BBV testing services available in Victoria [10]. Those in regional areas also mentioned the potential for improved access to testing with a web-based service, as it is difficult to access the limitedly available in-person services in their geographic locations. Despite these advantages, we anticipate that strong digital promotion will be needed to compete with existing web-based services that already have high visibility.

XSL•FO
RenderX

Limitations

Although our findings are informed by a diversity of views among young people of different genders, place of residence, and cultural backgrounds, our sample size was relatively small and did not include individuals with disabilities, those younger than 18 years, or many heterosexual men who may have different views about the messaging and imagery of a web-based STI/BBV testing service. As such, our findings may be less applicable to those groups and additional strategies may be needed to improve accessibility for these groups.

Despite the known limitations and lack of insights offered by geographic segmentation [30], we believed that in our context it was important to include this. While our focus groups were limited by lack of segmentation for other factors such as social status, lifestyle, and opinions, we will have the opportunity to explore these during phases 4 and 5 of the project—user testing and evaluation.

In this phase of developing the service, our objective was to explore imagery and messaging of a web-based service that would be acceptable to young people, rather than investigating what would make young people change their behavior and increasingly test. This will be explored during phase 5, the evaluation. We also acknowledge that while we worked directly with young people to design the imagery, messaging, and promotion of our web-based service, the clinical and legal requirements of providing web-based STI/BBV testing service in Australia required that some of the material we presented to the young people was researcher driven, rather than end user driven, potentially introducing researcher bias to the project. However, workshops did allow the young people to introduce new ideas for the design and functionality of the service and its messaging and promotion and gave important insights into young people's intentions, motivations, and interest in web-based STI/BBV testing.

Conclusions

This study has highlighted the value of applying social marketing theory with end user engagement when developing a web-based STI/BBV testing service. We were able to identify that young people are more likely to be attracted to a web-based service that uses messages that highlight the functional benefits of service, and the use of professional imagery and logos within the service can elicit trust. The results of this study will be used to develop and implement a web-based sexual health service for young Victorians, which will be accessible to young people and effectively increase STI/BBV testing uptake. Future research will measure the reach, the efficacy of social marketing strategy, and how this service complements existing services in increasing STI/BBV testing uptake among young Victorians.

Acknowledgments

This project was funded by a National Health and Medical Research Council partnership grant (grant APP2006486).

Abstract

Background: Globally, cardiovascular diseases are leading causes of mortality and disability, with hypertension being a major risk factor. Reducing salt intake and blood pressure are among the most cost-effective health promotion strategies. While mobile health (mHealth)– and school-based salt reduction interventions have proven effective in trials, their impact when scaled up in real-world contexts remains uncertain.

Objective: We evaluated the effectiveness of the real-world implementation of an mHealth- and school-based health education scale-up program to reduce salt intake (EduSaltS [mHealth and school-based education program to reduce salt intake scaling up in China]).

Methods: A parallel cluster randomized controlled trial was conducted from April 2022 to July 2023 across 20 schools in 2 districts and 2 counties within Ganzhou City, Jiangxi Province, China. Schools were randomized 1:1 to intervention or control groups within each district or county. One third-grade class per school and 26 students per class were randomly sampled. One parent, or alternative family member (aged 18-75 years, residing with the student), of each student was invited to join. The EduSaltS intervention, spanning over 1 academic year, incorporated both app-based health education courses and offline salt reduction activities, with participation monitored through the backend management system. The intervention's effectiveness was assessed by comparing changes in salt intake and blood pressure between groups from baseline to 1-year follow-up using surveys, physical examination, and 24-hour urine tests.

Results: Of 524 children (boys: n=288, 54.96%; age: mean 9.16, SD 0.35 years) and 524 adults (men: n=194, 37.02%; age: mean 40.99, SD 11.04 years) who completed the baseline assessments in 10 intervention and 10 control schools, 13 (2.48%) children and 47 (8.97%) adults were lost to follow-up. All schools and participants showed satisfactory intervention adherence. Measured differences in schoolchildren's salt intake, systolic blood pressure, and diastolic blood pressure, between the intervention and control schools, were –0.24 g/day (95% CI –0.82 to 0.33), –0.68 mm Hg (95% CI –2.32 to 0.95), and –1.37 mm Hg (95%

XSL•FO
RenderX

CI –2.79 to 0.06), respectively. For adults, the intervention group's salt intake decreased from 9.0 (SE 0.2) g/day to 8.3 (SE 0.2) g/day post intervention. Adjusted changes in the intervention (vs control) group in salt intake, systolic blood pressure, and diastolic blood pressure were –1.06 g/day (95% CI –1.81 to –0.30), –2.26 mm Hg (95% CI –4.26 to –0.26), and –2.33 mm Hg (95% CI –3.84 to –0.82), respectively.

Conclusions: The EduSaltS program, delivered through primary schools with a child-to-parent approach, was effective in reducing salt intake and controlling blood pressure in adults, but its effects on children were not significant. While promising for nationwide scaling, further improvements are needed to ensure its effectiveness in reducing salt intake among schoolchildren.

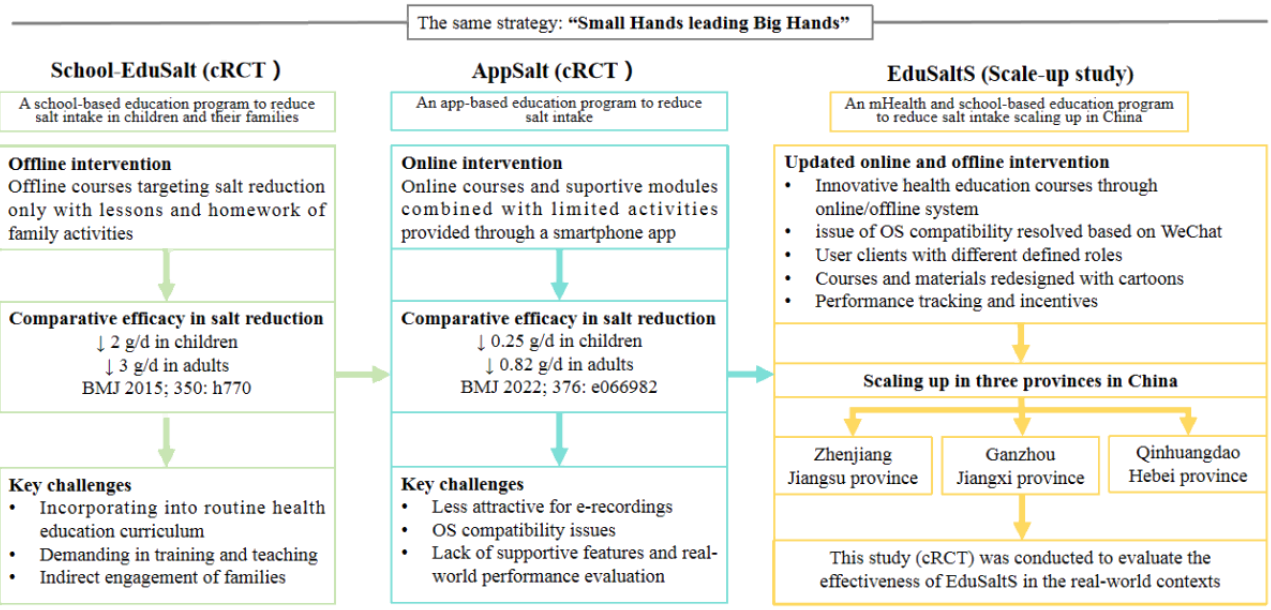
KEYWORDS

school-based health education; EduSaltS; mobile health; salt reduction; cluster randomized trial

Introduction

Cardiovascular disease (CVD) stands as the foremost cause of death and disability worldwide, with hypertension identified as its major risk factor [1-4]. Substantial evidence indicates that excessive salt intake is a key contributor to elevated blood pressure and a significant risk factor for CVD [5-8]. Additionally, the incidence and progression of various noncommunicable diseases, such as chronic kidney diseases, are also linked to salt consumption [9]. Numerous systematic reviews and meta-analyses have demonstrated that reducing salt (sodium) intake can lower the risk of hypertension and CVD [10-13]. The World Health Organization considers reducing salt intake among populations as one of the most effective and economical strategies for health promotion.



China ranks as one of the countries with the highest salt intake, averaging about 11 g/day among adults [14], more than twice the World Health Organization's recommended level of 5 g/day. Unlike developed countries where the majority of salt intake in the population originates from processed foods, approximately 80% of the salt consumption in the Chinese diet comes from the salt added during cooking [6]. Therefore, in addition to reducing sodium in food processing, lowering cooking salt is more crucial. To this end, the Chinese government has initiated policies such as the "Healthy China Initiative (2019-2030)," implementing a national dietary action for healthy living and advocating for "Three Reductions and Three Healthy Conditions," with salt reduction being a primary focus. Meanwhile, a series of scientific studies [15-19] have also been conducted in China to create a supportive environment for salt reduction, optimize public health education and individualized interventions, and further refine comprehensive strategies for reducing salt intake.

Schools, as a critical place for health education, have been proven effective in addressing public health issues concerning smoking, obesity, and CVD [20-22]. The advent of modern information and mobile technologies has also further broadened the scope of health interventions [23,24]. A cluster randomized controlled trial (School-EduSalt [school-based education program to reduce salt intake in children and their families]) was conducted by our team to demonstrate that the "small hands leading big hands" strategy, in which schoolchildren encouraged their parents to collaboratively enhance their knowledge, attitudes, and practices related to salt reduction, effectively reduced salt intake among both children and adults [25]. However, its reliance on specialized offline courses and activities, which demanded considerable training for schoolteachers, limited large-scale implementation. To address this issue, a mobile health (mHealth) platform for salt reduction named AppSalt was developed to provide standardized app-based health education courses and parallel homework assignments for students and their parents. Subsequently, a cluster randomized controlled trial was conducted under close supervision and the results showed that AppSalt was also effective in lowering salt intake among adults [18]. Building on these research findings, an updated development and preliminary implementation study called the mHealth and school-based education program to reduce salt intake scaling up in China (EduSaltS [mHealth and school-based education program to reduce salt intake scaling up in China]) was launched in Ganzhou in Jiangxi province, Zhenjiang in Jiangsu province and Qinhuangdao in Hebei province, for the first time, to refine and scale up the intervention. Compared with the interventions in our previous studies, EduSaltS features a WeChat-based system (Tencent), cartoon-enhanced course materials, role-specific user interfaces, and blended online/offline health education, aiming for a routine yet innovative school-based approach [26]. The evolution of studies from School-EduSalt, AppSalt to EduSaltS can be seen in Figure 1.

Given the uncertainty surrounding the impact of EduSaltS in real-world settings, this study aims to evaluate its effectiveness in reducing salt intake through a cluster randomized controlled trial conducted in Ganzhou, Jiangxi Province in China.

Methods

Ethical Considerations

This study was approved by the Scientific Research Ethics Committee of the First Affiliated Hospital of Gannan Medical College (LLSC-2022011901) and was registered retrospectively at the Chinese Clinical Trial Registry (ChiCTR2400079893). This was due to its embedding in a prospectively registered scale-up intervention study (ChiCTR2000039767) and a lack of timely communication with the overall project team. Nevertheless, this study was identical to the protocol assessed by the Research Ethics Committee, which was prospectively approved on January 19, 2022. Permissions were obtained from the local education authorities and school headteachers. All participants taking part in the outcome assessments gave written informed consent. For children, participant assent and parental written consent were obtained. This report does not contain any identifying information or direct quotes. Due to the nature of the program, this study does not involve details of compensation.

Study Design and Participants

The overall design and framework of EduSaltS program have been published elsewhere [26]. The study was implemented using a cluster randomized controlled trial design within scale-up, spanning across 20 public primary schools in Ganzhou City, Jiangxi Province, over a period from April 2022 to July 2023. The process of this study encompassed (1) determination of research sites, (2) execution of on-site baseline survey and clinical evaluations at the end of third grade, (3) allocation of the schools into 2 groups comprised of 10 schools in the intervention group and an equal number in the control group, (4) implementation of an integrative intervention and its subsequent promotion, conducted over the course of 2 semesters, and (5) undertaking of effect evaluation after intervention at the end of fourth grade.

EduSaltS was implemented in 100 scale-up schools across 9 subordinate districts and counties in Ganzhou city, mobilizing all third-grade students and their parents to participate in a year-long health education course and activities focused on salt reduction. In this context, to assess the effectiveness of the intervention, we first contacted the local education authority through the local Health Commission to gain their opinion, support, and approval for the study. After that, considering the potential diversity between urban and rural areas, 2 districts (Zhanggong and Nankang) and 2 counties (Xinfeng and Yudu) close to the city center were selected as the representative sites for the effectiveness assessments following the principle of proximity [27], which can help minimize the influence of geographical and environmental factors, before the commencement of EduSaltS. The selection of schools involved choosing a total of 20 schools from these 4 areas that were willing to participate in the trial, with an even number of schools from each district or county. These schools were then divided into the intervention or control group within each district or county in a 1:1 ratio. The 10 schools in the intervention group were included in the 100 scale-up schools participating in EduSaltS and received the unified interventions, while the control group was not exposed to the intervention and only received routine health education courses, including physical and mental health as all school in the city, but not covering salt reduction. Details of the scale-up schools participating in EduSaltS and the schools in the trial across different districts and counties are provided in Table S1 in Multimedia Appendix 1.

In each selected school, due to the substantial workload and costs associated with conducting the assessments, a simple random sampling method was used. This involved randomly selecting one third-grade class from each school, followed by the random selection of 26 students from the chosen class to serve as survey participants. Subsequently, one parent of each participating child was recruited. At this stage, invitations and

XSL•FO
RenderX

explanatory materials were distributed to parents through the class teacher. If a parent was unavailable, a family member residing with the child, such as a grandparent, was eligible for selection as an alternative. To mitigate bias arising from sex imbalance, preference was given to selecting an adult of the opposite sex to the student whenever possible. In total, this study planned to recruit 520 students and an equivalent number of adults. The baseline survey and clinical evaluations were completed before the schools were allocated, and the follow-up assessments were conducted after the intervention had concluded.

Inclusion criteria were as follows: (1) willingness to participate in follow-up, (2) no transfer plans during the salt reduction intervention period for students, (3) ages of participating adults being older than 18 years and younger than 75 years, and (4) being able to provide regular feedback and complete outcome measurements. Exclusion criteria included: (1) children with medical conditions or other reasons precluding participation in the assessments or intervention activities, (2) individuals explicitly unable to complete follow-up, and (3) inability or refusal to collect 24-hour urine samples.

Randomization and Masking

Schools in each district or county were randomly assigned to the intervention or control group (1:1) using a stratified method of random digits by researchers from Jiangxi Provincial Center for Patriotic Health and Health Promotion with the support of the local bureau of education. This ensured a balanced and comparable distribution of schools in 2 groups across districts and counties. Additionally, after the random allocation into intervention and control groups, a comparison of the geographic distribution of schools was conducted to prevent potential contamination by ensuring no close proximity between schools in different groups. The final grouping of schools is detailed in Table S2 in Multimedia Appendix 1.

Due to the specificity of the intervention, it was imperative to explicitly inform the intervention group of the relevant details. Therefore, blinding was not feasible for the intervention implementers. However, blinding was employed for data collectors. Following rigorous training, investigators from hospitals and Centers for Disease Prevention and Control, without knowing the group allocations, collected baseline and follow-up data. The technicians who performed urinary electrolyte measurements (KingMed Diagnostics) were unaware of specific groups for individual samples.

Procedure

After selecting the schools and classes for the study, communication with school headteachers and class teachers was initiated. Class teachers were responsible for distributing letters of project introduction and informed consent forms to students and their parents (or guardians), thereby confirming the specific student and parent participants and facilitating the on-site baseline survey and clinical evaluations. The content comprised (1) sociodemographic characteristics (eg, age, sex, education level, and relationship to the participating children) and health behaviors (eg, smoking, alcohol consumption, and physical exercise); (2) measurements including height, weight, and blood pressure, which were conducted using standardized tools by trained staff from the Centers for Disease Control and Prevention and township health centers; and (3) a single 24-hour urine collection conducted on a weekday at the same time for both children and adults. The 24-hour urine collection was used to evaluate urinary sodium excretion, which is the most accurate method to estimate salt intake. All participants were provided with sufficient containers to collect their urine continuously over a 24-hour weekday period, ensuring a total collection time of 20-28 hours. After measuring the total urine volume, the thoroughly mixed sample was analyzed for sodium concentration, which was then multiplied by the total volume (corrected for any minor deviations from 24 hours) to calculate the 24-hour urinary sodium excretion. Salt intake was derived by multiplying the 24-hour urinary sodium excretion by 23 (atomic weight of sodium) and 2.54 (the sodium-to-salt conversion factor). The follow-up investigation was conducted after 1 year of intervention, using the same method.

Intervention

The specific framework, development process, features, and intervention protocol of EduSaltS have been detailed in a previously published paper [26]. The intervention, which spanned 1 academic year, incorporated app-based courses, offline activities, and the establishment of a supportive salt-reduction environment. Quality control was mainly implemented by teachers following standardized training, with guidance from our research team, targeting all fourth-grade students and their families in intervention schools. The concise summary of interventions of EduSaltS is provided in Table S3 in Multimedia Appendix 1, and a detailed demonstration of specific applications and web interfaces can also be seen in our published paper [26].

The online component of this intervention predominantly revolved around the WeChat miniprogram named “Health Cloud Classroom”, delivering a curriculum of salt reduction. In alignment with the “Health Education Guidelines for Primary and Secondary Schools” stipulated by the Ministry of Education of China, the miniprogram disseminated 1 health lesson weekly and 10 lessons for 1 semester. Each video lesson, approximately 10 minutes in duration, was designed for students to watch at home with their family members, followed by a set of 5-10 quiz questions to enhance learning interest and assess comprehension. The curriculum encompassed eight compulsory lessons on salt reduction (covering the dangers of excessive salt intake, misconceptions, and practical techniques about salt reduction) and 12 elective health lessons (such as eye protection, nutritional diet, and influenza prevention). Class teachers had responsibilities for organizing students and their parents or grandparents to use the “Health Cloud Classroom” for course learning. They also used a teacher-oriented miniprogram named “Health Salt Management” (a WeChat app designed for monitoring, managing, and evaluating) to stay informed about the status of course learning and homework completion of all students and their families in each class, ensuring timely adherence to requirements of the curriculum. Each term, students were expected to complete 10 lessons. Moreover, “Health Cloud Classroom” features additionally optional modules designed to facilitate the increase of low-sodium knowledge and encourage

XSL•FO
RenderX

corresponding behavioral changes, such as healthy food selection (explanations of various food nutrients), interactive quizzes on salt-related knowledge for entertainment, and routine assessments of sodium intake levels through self-administered dietary records. These modules were optional, and families were free to choose whether or not to use them without any monitoring of their use. Materials uploaded in this miniprogram for online study, such as cartoons, PowerPoint, and posters, could also be used for offline activities.

The offline component primarily involved salt reduction interactive activities. Integrating existing educational frameworks like health education classes, science practice classes, and themed class meetings, each term featured at least 4 lectures and themed activities concerning salt reduction. Class teachers could use videos, posters, and leaflets provided by "Health Cloud Classroom" to impart knowledge about salt reduction to students. Children were expected to complete related homework and convey salt reduction knowledge, methods, and skills to their family members after class, persuading the person cooking at home to reduce salt use and improve dietary behavior. Additionally, the program includes the construction of an environment of lower sodium and health education regarding reduced-salt school meals, such as displaying salt reduction posters across the campus, broadcasting a series of salt reduction short films and radio dramas within schools, and providing self-learning materials and training once per semester for cafeteria chefs and catering providers to lower the salt content in students' meals.

To render the evaluation of the performance of the process more scientifically effective, a web-based miniprogram in WeChat named "EduSaltS Manager," with regard to backend management and quality control, was developed specifically for researchers and school teachers. This program aided teachers in knowing and overseeing the participation of families and in submitting records related to project implementation. Researchers could also access relevant data through this backend system, regularly monitoring the progress and compliance in participants or specific schools.

Students in the control group received routine health education courses, occasionally delivered by physical education teachers, with no specific content on salt reduction and no family engagement. Due to the citywide publicity of EduSaltS, schools in the control group might have been aware of this project. However, as families in the control group were not provided with accounts to access the intervention miniprogram, there was little risk of contamination.

Outcomes

The primary outcome of this study was the difference between the 2 groups in the change in salt intake among students and adults, before and after the intervention, assessed through 24-hour urinary sodium. The secondary outcome was the change in blood pressure. All measurements and data collections were conducted once at baseline and after completion of the intervention, with consistent survey processes and methods of data collection at each time point and across both groups.

The method for 24-hour urine collection was the same as previous studies, using an electronic data collection system [14]. Tests of all samples were uniformly conducted by a central laboratory (KingMed Diagnostics), with the testing parameters including urinary sodium, potassium, and creatinine concentrations. Urinary volume and creatinine concentration were used to assess the completeness of the 24-hour urine collection. The concentration of urinary sodium and potassium was used to calculate the participants' salt and potassium intake, as well as the sodium-potassium ratio.

Blood pressure measurements were conducted using calibrated Omron electronic sphygmomanometers. After a 10-minute rest in a seated position, trained physicians measured the blood pressure of the right arm of the participants. Blood pressure was measured 3 times for each individual, with at least a 1-minute interval between measurements. The average of the last 2 readings was used for statistical analysis.

This study employed an electronic information platform to support data collection, allowing for the recording of the evidence of key survey indicators through audio recording, video recording, and photography, which standardized the collection of diverse data information.

Sample Size Calculation

A mixed linear model was planned to be applied to analyze changes in effect sizes, with alterations in salt intake (calculated from 24-hour urinary sodium excretion) serving as the primary outcome variable. In accordance with previous research [25], a reduction of 1 g/day of salt intake was set as the target change in effect size, with an SD of 2.15 and an intraclass correlation coefficient of 0.01. Setting α at 0.05, 1-β at 0.9, and considering a 10% loss to follow-up rate, the sample size calculation performed using PASS software indicated that 520 students and 520 parents (cluster size of 26) across 10 intervention and 10 control schools would satisfy the power of the test.

Statistical Analysis

The effectiveness of the intervention was evaluated through an intention-to-treat analysis without imputation due to the very low drop-out rates (13/524, 2.48% for children and 47/524, 8.97% for adults). All students and their family members who completed the baseline assessments were analyzed according to the initial group allocation of their respective schools. Taking into account the hierarchical structure of the data, with 2 measurements (baseline and 2 semesters) for each participant and participants nested within each school, mixed linear models with random intercepts and fixed effect variables (eg, time, group, time×group, and covariates) were applied to analyze the effects of intervention. The time×group interaction term indicated the differential change by groups from baseline to the end of the trial. Potential confounding variables adjusted in the model included district/county areas, age, sex, BMI (body weight in students), education level (the adults' level substituted for their children), and physical exercise (coded as "yes" if someone engaged in moderate physical activities at least 3 times a week and more than 30 minutes each time). Additionally, when analyzing blood pressure changes, outdoor temperature was further included as a confounding factor. In the analysis of

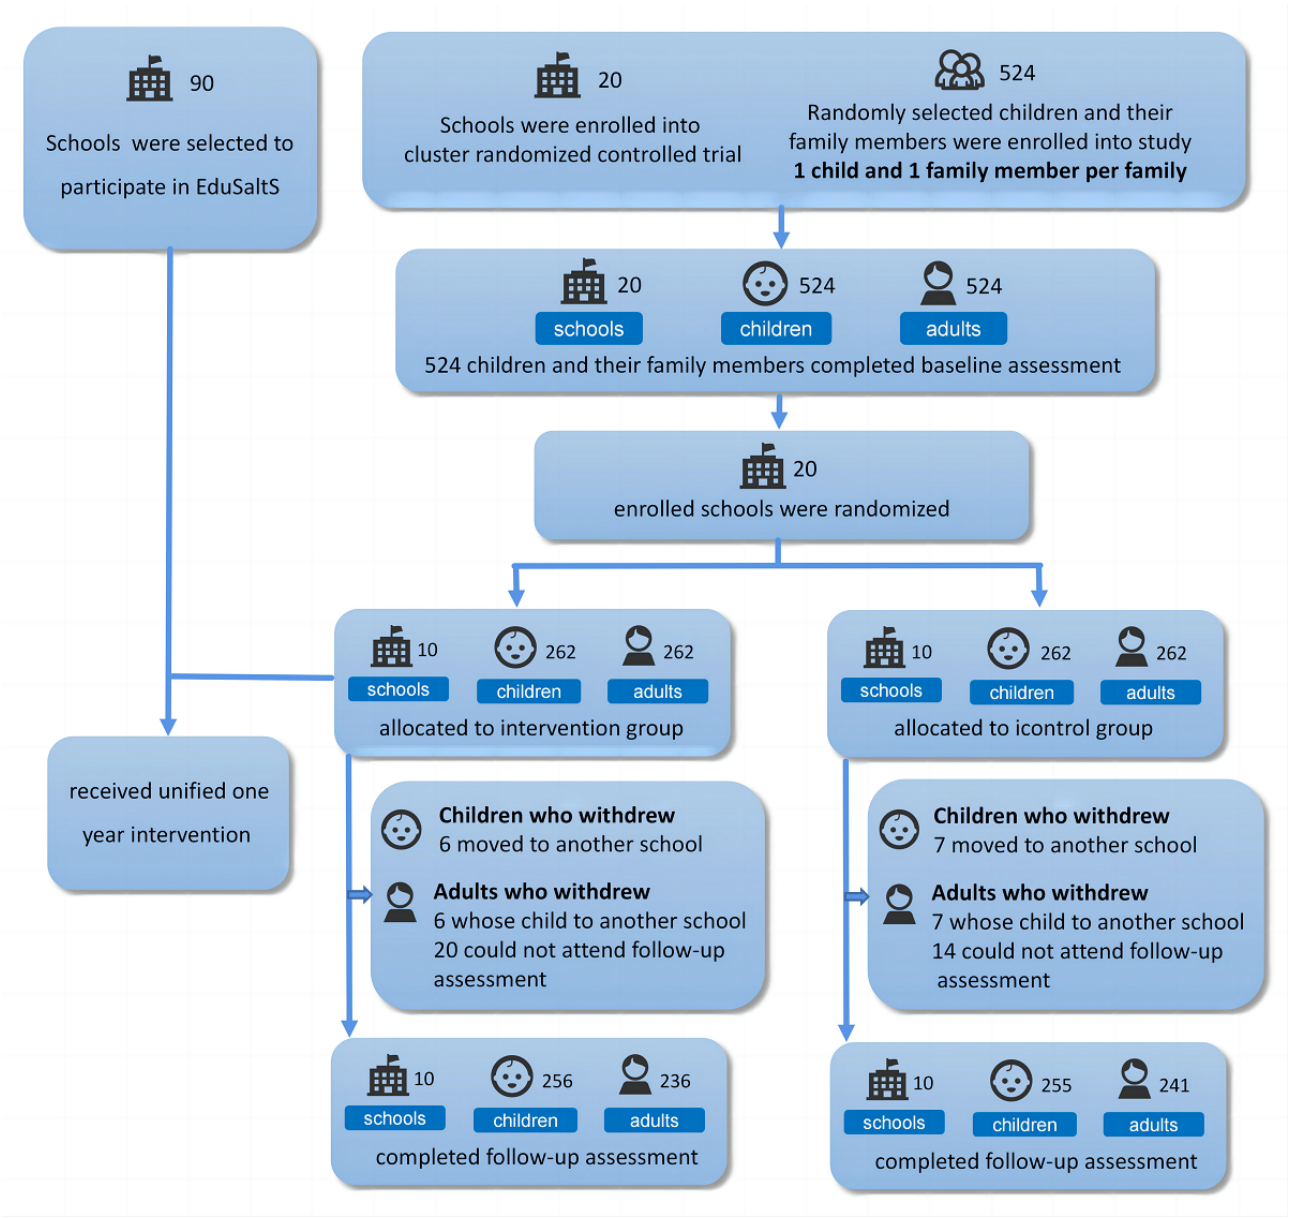
XSL•FO
RenderX

the effect on adults, familial relationships, smoking, and alcohol consumption (coding "occasional" and "regular" as "yes") were added as additional adjustments.

The collection time of 24-hour urine samples was recorded in this study. The urine sample would be excluded if the collection time was less than 20 hours or more than 28 hours. If the duration of the collection was within 20-28 hours, the 24-hour urine volume was calculated as: urine volume (mL per 24 hours) = urine volume (mL) / duration of urine collection (hours) × 24 hours. This adjustment, in conjunction with urinary concentration of sodium and potassium, was used for the calculation of individual salt intake and other related indicators. Urine samples were also considered incomplete and excluded from the main analysis if 24-hour urine volume was <500 mL in adults; 24-hour urinary creatinine was <4.0 mmol or <6.0 mmol in women or men, respectively; 24-hour urine volume was <300 mL in children; or 24-hour urinary creatinine was lower than the fifth centile (<2.27 mmol for girls and <2.43 mmol for boys).

Sensitivity analysis and subgroup analysis were carried out in this study. In the sensitivity analysis, possibly incomplete 24-hour urine collections, assessed by 24-hour urinary volume and creatinine excretion, were included in the analysis based on the intention-to-treat approach. In the subgroup analysis, for students, the effects of intervention across different subgroups based on district/county areas, sex, and education levels of their familial participants were analyzed. For adults, additional analyses of subgroups were performed, which included age groups, education levels, blood pressure status (hypertension was defined as systolic blood pressure [SBP] ≥140 mm Hg or diastolic blood pressure [DBP] ≥90 mm Hg, or self-reported hypertension), smoking, weight status (BMI<24.0 or not), and relationship with their children.

Quantitative data were statistically described using means and SDs, while categorical data were presented as frequencies and percentages. Statistical analyses were executed using SAS (version 9.4; SAS Institute Inc), with a *P* value of <.05 considered statistically significant.



Results

Characteristics of Participants

Twenty schools across 4 districts or counties in Ganzhou City in southeastern China were recruited in this research. Adhering to the specified inclusion and exclusion criteria, a total of 524 families (4 families, beyond our initial expectations, from different schools were enthusiastic about this project, so we enrolled them as well) participated in the study and completed the baseline survey and clinical evaluations. Following randomization and 2 semesters of intervention, the loss to follow-up was 2.48% (13/524) for students and 8.97% (47/524) for adults, due to either the students having moved to another school or adults being unable to attend subsequent assessments, as detailed in Figure 2. Baseline characteristics of those lost to follow-up did not significantly differ from those who completed the study and the loss to follow-up was completely random (*P*>.05 for the Little test for both children and adults). In all families of the intervention and control groups who completed the baseline assessments, the average ages of the students were 9.10 (SD 0.35) and 9.22 (SD 0.34), respectively, while the average ages of adults were 40.96 (SD 11.07) and 41.01 (SD 11.03). Each of the intervention and control groups had 20 adults who self-reported having hypertension, and these individuals were confirmed to be on medication at the time of blood pressure measurement. Demographic and general behavioral characteristics of these 2 randomized groups were basically consistent and well-balanced, as detailed in Table 1.

Evaluation of the Intervention

During the process of intervention implementation, all schools in the intervention group systematically cultivated an environment conducive to low-sodium practices in accordance with the prescribed program. Health education lessons incorporating salt reduction content, which were required to be conducted at least once every 2 weeks, were effectively implemented across all participating schools, offline activities were also carried out successfully. Furthermore, low-sodium materials provided by our research team, including videos, PowerPoint, posters, and pamphlets, were integrated into various educational activities such as health education courses, lectures, as well as thematic class meetings. In addition to these initiatives, we distributed low-sodium picture books and stationery to all families in order to boost the adherence of the participants, garnering a positive reception from students. All families of the intervention group registered and actively engaged with the WeChat-based “Health Cloud Classroom” miniprogram. Timely dissemination of app-based courses was ensured under the collective guidance of researchers and teachers. Finally, 84.7% (222/262) families successfully fulfilled the requirements of the app-based curriculum pertaining to low-sodium education in the “Health Cloud Classroom.” Overall, adherence to the intervention was satisfactory and the process evaluation of EduSaltS could be found in the published paper [28].

Table 2 presents the measurements and changes in salt intake, blood pressure, urinary sodium, potassium, and sodium-potassium ratio for the intervention and control groups. During the study of 2 semesters, there was a slight upward trend in salt intake and SBP among students. The salt intake of students was 5.4 (SE 0.2) g/day and 5.5 (SE 0.2) g/day in the intervention and control group at baseline, and it increased by 0.41 g/day (95% CI 0.01-0.82) and 0.61 g/day (95% CI 0.21-1.02) respectively after 2 semesters. The mean effect comparing the intervention group with the control group was –0.24 g/day (95% CI –0.82 to 0.33) after adjustment for covariates. Similarly, the blood pressure of students showed the same trend. The adjusted mean difference in the change of SBP and DBP for students between intervention and control groups was –0.68 mm Hg (95% CI –2.32 to 0.95) and –1.37 mm Hg (95% CI –2.79 to 0.06), respectively.

For adults, the intervention group showed a reduction in salt intake (g/day) and urinary sodium (mmol/24 hours), while the control group showed a slight increase, resulting in a significant difference. The salt intake in the intervention group decreased from 9.0 (SE 0.2) g/day to 8.3 (SE 0.2) g/day during the study, a change of –0.79 g/day (95% CI –1.33 to –0.25). In contrast, the control group exhibited a slight increase of 0.26 g/day (95% CI –0.27 to 0.80), from 9.1 (SE 0.2) g/day to 9.3 (SE 0.2) g/day. After adjusting for confounding factors, the mean intervention effect between the 2 groups was –1.06 g/day (95% CI –1.81 to –0.30), which was statistically significant. Regarding blood pressure, there were slight changes in the intervention group, whereas the control group showed a marked increase. The adjusted intervention effect, comparing the intervention group with the control group, was –2.26 mm Hg (95% CI –4.26 to –0.26) for SBP and –2.33 mm Hg (95% CI –3.84 to –0.82) for DBP. Further details are available in Table 2.

Table 3 shows the results of the sensitivity analysis. The adjusted mean effects comparing the intervention group with the control group on salt intake in children (–0.27 g/day, 95% CI –0.85 to 0.30) and in adults (–1.01 g/day, 95% CI –1.75 to –0.26) were similar to the main results when potentially incomplete 24-hour urine collections were included.

In the analysis of subgroups, as shown in Table S4 in Multimedia Appendix 1, no significant difference was seen among any of the interactions of subgroups with the intervention effect on salt intake for both children and adults. Relatively, younger adults (age<40 years), males, nonsmokers, being overweight (BMI≥24), and participants who were parents appeared to experience significantly greater effects of intervention. However, these outcomes may lack robustness due to the small sample size. Detailed results of the analysis of subgroups for SBP and DBP can be found in Tables S5 and S6 in Multimedia Appendix 1.

Discussion

Principal Results

This study deployed an mHealth- and school-based health education program for salt reduction (EduSaltS), a hybrid of online and offline methods, tailored for integration into school health education and promotion initiatives, which used a “small hands leading big hands” approach to cultivate awareness and practices of salt reduction among students and their families. It was the first time to evaluate the effectiveness of this scale-up program for salt reduction using an embedded randomized controlled trial.

Currently, salt reduction and hypertension prevention efforts among the general population in China are primarily carried out through public health education activities, such as the “Three Reductions and Three Health” campaign, and the national basic public health services. Although these measures play a pivotal role in salt reduction and hypertension prevention strategies in China, it is challenging for such efforts to reach or impact every household. The EduSaltS approach, however, has the potential to balance both broad coverage and effectiveness, which can serve as a good complement to existing strategies. Our research achieved high levels of participation and cooperation over an academic year, with follow-up rates of students surpassing 95% and adults over 90%. The strength of the EduSaltS intervention lies in its comprehensive strategy that integrates traditional school-based health education with the modern advantages of mHealth technology. This approach was not commonly observed in other school-based cardiovascular interventions, which often focused exclusively on students, for example, interventions such as the Active Smarter Kids physical activity intervention concentrated on increasing physical activity to improve cardiovascular health markers [29]. Similarly, the Salud Integral Program also focused on in-person interventions without integrating mHealth strategies that could have enhanced its overall impact [30]. Moreover, the EduSaltS intervention extended its impact beyond the individual by incorporating the

XSL•FO
RenderX

"small hands leading big hands" approach, which encourages collaborative efforts within families to adopt low-salt dietary habits. In contrast, the interventions such as using SaltSwitch (The George Institute for Global Health) smartphone app [31] and WhatsApp (WhatsApp LLC) [32], while effective in their own right, focused more on direct educational outreach to individuals, without explicitly addressing family or community-level behavior change. In essence, the EduSaltS intervention's combination of app-based engagement and offline activities, along with its emphasis on school and family involvement, positions it as a more holistic and potentially more effective strategy for reducing salt intake at both the individual and population levels.

Despite the relatively small and nonsignificant effect of the intervention on students' salt intake, some effects of the intervention on both salt intake and blood pressure were observed among adults compared with the control group. The intervention period overlapped with a significant shift of the quarantine strategy of COVID-19 in China, from stringent isolation controls in 2022, limiting outings and social gatherings, to a relaxation of restrictions at the beginning of 2023, leading to an increase in dining out and leisure activities. From periods of home isolation to the resumption of regular social interactions, there may have been substantial changes in people's dietary behaviors and work-life habits. In this context, the adult participants in the control group showed a nonsignificant rise in salt intake and an obvious increase in blood pressure, whereas the intervention group experienced a notable reduction in salt intake and a slight decrease in DBP, underscoring the effectiveness of the intervention among adults. Subgroup analysis indicated that the EduSaltS program seemed to be more effective among younger adults and those who are parents compared with grandparents. This result may be attributed to the familiarity of those populations with electronic devices and receptiveness to app-based information [33]. However, given the smaller sample size, the outcome of the subgroup analysis needs cautious interpretation.

The observed nonsignificant effects of the intervention in students may potentially be ascribed to a confluence of multifaceted factors. First of all, the salt intake among students is subject to a myriad of influences, including familial dietary patterns, the dining environment within and around the vicinity of schools, personal preferences, as well as levels of health consciousness. During the implementation of EduSaltS in Ganzhou City, the primary focus was on the family dimension and the completion of app-based courses. However, implementation in the school context, particularly in school catering, was not thoroughly actualized. Concurrently, elementary students exhibit a predilection for high-sodium snacks and fast foods, with their dietary choices markedly swayed by peer influences and personal taste preferences, often at the expense of healthful considerations. Such tendencies are detrimental to achieving the anticipated effectiveness of the intervention. Second, the comprehensive intervention in this study largely relied on the WeChat miniprogram named "Health Cloud Classroom," necessitating parental involvement using smartphones or tablets alongside their children. However, some parents, merely to comply with teachers' requests, operated the program themselves, resulting in interventions that often affected only the parents without the students, hardly obtaining the desired outcome. Furthermore, the same content of health intervention may not be as comprehensively understood by students as by parents. This disparity in comprehension and a less holistic grasp of health concepts are likely to result in an inadequate acquisition of knowledge and a lack of behavioral change among students.

Public Health Implications

It is noteworthy that, although the findings of this study resembled, to some extent, that of our earlier study [14], the intervention incorporated here was broader in scope, more diverse in format, and easier to implement. As a result, the intervention schools have successfully established a supportive environment for salt reduction, and there has been a high level of cooperation among teachers, students, and parents in completing both app-based courses and offline activities. Building upon the already developed health education materials and platforms of intervention, the overall execution was relatively uncomplicated, just requiring primarily efficacious organization by schools and weekly opportune reminders by class teachers following brief training. Additionally, the resources within the system could assist teachers in managing their existing required health education courses and activities more efficiently, thus reducing the need for substantial manpower and resources. Previous research has demonstrated that a reduction of 1 g/day in per capita salt intake could lead to a decrease of nearly 9 million cardiovascular events by 2030 [34]. Furthermore, based on a recent meta-analysis of blood pressure treatment trials [35], the prevented increase of 2.26 mm Hg in SBP, compared with the rise observed in the control group in our study, is projected to reduce the risk of stroke by 5.88% and ischemic heart disease by 3.62%, which would prevent nearly 231,400 strokes and about 126,700 ischaemic heart disease events per year in China if the program was scaled up across the country [36]. Consequently, the initiative of EduSaltS, with its notable practicality, may not only facilitate the enhancement of health education curricula and activities in schools but also significantly curtail the prevalence of CVD within the population, rendering it of substantial value for the guidance of health policies and public health.

Limitations

This study still has some limitations. For instance, during the implementation of the intervention, many aspects required the use of smartphones or tablets, which were not readily accessible in less developed, remote mountain areas, and for students only living with grandparents. Despite the assurance of access to basic public health and health care services in these populations, the digital divide and limitations in school infrastructure may hinder the implementation and effectiveness of the intervention. Thus, we should consider how to promote this mHealth technology–based health education in impoverished and underdeveloped areas, which may serve as a good supplement for the prevention and treatment of hypertension in regions with relatively lower medical care standards. Additionally, a minority of parents perceived this intervention as increasing children's screen time, potentially detrimental to their eyesight, thereby

XSL•FO
RenderX

engendering a degree of resistance. Furthermore, the intervention for school chefs and food service providers was limited to self-learning materials and training once per semester, without monitoring the salt used in school meals. Recording and monitoring salt purchase and use had been suggested but not implemented due to various difficulties. These are what we aim to improve in the future. Subsequent research endeavors will further analyze its generalizability and attempt to evaluate the long-term effects of the intervention. Our team will also incorporate feedback from process evaluations to refine and better integrate the comprehensive intervention strategy into the construction of healthy schools, ultimately enhancing the health levels of students and their parents.

Conclusion

Based on extensive and long-term exploratory efforts, an attractive, appropriate, and comprehensive intervention program for salt reduction (EduSaltS) was developed and implemented in China. Demonstrating favorable feasibility and efficacy, this program is potentially well-suited for nationwide implementation based on collaboration across multiple departments. The intervention, adopting a “small hands leading big hands” approach, effectively reduced the salt intake and blood pressure among adults, while its impact on students was not statistically significant. Future enhancements to the offline components of the intervention, such as improving salt reduction interventions in school catering, could further facilitate the development of low-salt dietary habits in schoolchildren.

Authors' Contributions

LW and PZ led the conception and design of the study. Yinghua Li and FJH contributed to the research design and analysis of data. LL, Yuan Li, RL, DW, LX, LD, and CW were involved in the study implementation and quality control. CW participated in collecting data and jointly performed statistical analyses with NW. NW wrote the first draft of the manuscript and all authors contributed to the revision and approved the final manuscript. LW and PZ (pzhang@bjtjzx.com) contributed equally to this work and should be considered joint corresponding authors.

Conflicts of Interest

FJH is an unpaid member of Action on Salt and World Action on Salt, Sugar, and Health (WASSH). The other authors declare that they have no competing interests.

Editorial notice: This randomized study was only retrospectively registered, explained by authors due to lack of timely communication with the overall project team and that this trial was embedded in a prospectively registered scale-up study (ChiCTR2000039767). The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials, because the risk of bias appears low and the study methods mirrored the prospectively registered scale-up studies methods and receive prospective ethics approval. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: Chronic obstructive pulmonary disease (COPD) primarily originates from exposure to tobacco smoke, although factors, such as air pollution and exposure to chemicals, also play a role. One of the primary treatments for COPD is oxygen therapy, which helps manage dyspnea and improve survival rates. Mobile health (mHealth) technologies have demonstrated significant potential in monitoring patients with chronic diseases, offering new avenues for enhancing patient care and disease management.

Objective: The purpose of this study was to evaluate the efficacy and acceptability of a mobile app designed for the clinical monitoring of patients with COPD and home oxygen (HO) therapy, compared with conventional monitoring in real-world community settings.

Methods: A parallel-group, nonblinded, multicenter randomized controlled trial was conducted with 45 participants; the intervention group (IG), which used the mobile app in addition to conventional monitoring (n=23) and the control group, which received only conventional monitoring (n=22), administered by therapists over a duration of 3 months. The primary outcomes included the chronic obstructive pulmonary disease assessment test (CAT) score, the level of dyspnea measured by the Borg scale, and oxygen saturation percentage, assessed at both the beginning and end of the trial. Secondary outcomes included the frequency of app use, the number of hospitalizations, and survival rates. In addition, a satisfaction survey and an interview were conducted with the IG.

Results: The median use of the mobile app was 21 (IQR 16-28) days. At the end of the follow-up, the Borg dyspnea scale was significantly lower in patients who used the mobile app for HO therapy monitoring (mean 0.6, SD 0.8 vs mean 4.1, SD 1.4; *P*=.001). Regarding the impact of COPD on quality of life, as measured by the CAT, no differences were found in the scores between baseline and end-of-follow-up within the control group. However, a significant decrease was observed in the IG (baseline median CAT 27, IQR 23-31 vs final median CAT 22, IQR 14-28; *P*<.001). In addition, the CAT score was significantly higher

XSL•FO
RenderX

in patients receiving conventional monitoring compared with those monitored with the mobile app (median 30, IQR 23-32 vs median 22, IQR 14-28; *P*=.02).

Conclusions: The use of the mobile app, AppO2 (SINCO), designed for the clinical monitoring of patients with COPD and HO therapy, is associated with improved quality of life. In addition, the app is highly accepted by users, promotes self-care, and fosters patient confidence in managing their own condition.

KEYWORDS

m-Health; chronic obstructive pulmonary disease; quality of life; mobile health applications; home oxygen therapy; mobile phone

Introduction

The main cause of chronic obstructive pulmonary disease (COPD) is exposure to tobacco smoke; however, there are also other associated factors such as air pollution, exposure to chemicals, and a history of respiratory diseases [1]. The World Health Organization considers it the third cause of death worldwide, making it a public health problem [2]. It is estimated that approximately 8% of the Colombian population—equivalent to about 3.6 million people—suffers from COPD [3,4]. Oxygen therapy is one of the main treatments for this disease [5], aiding in the control of symptoms such as dyspnea and improving survival [5]. Mesquita et al [6] found patients with COPD who did not adhere to oxygen therapy experienced a long-term decrease in quality of life compared to those who followed their prescribed treatment [7]. Similarly, several authors [6,8,9] have identified factors such as age, communication barriers between doctor and patient, clinical follow-up, and disease knowledge as significant challenges to adhering to oxygen therapy [6]. Low adherence can lead to exacerbations [10], which deteriorate lung function, negatively affect patients' quality of life, and increase mortality [11].

Furthermore, these exacerbations contribute to substantial health care costs. In Colombia, each exacerbation costs an average of US $98 [12], with costs rising to nearly US $700 if hospitalization is required [12]. In addition, this high cost can be attributed to the fact that once a patient is hospitalized, there is a high risk of rehospitalization or death. For example, Niewoehner [13] found that of 1016 patients hospitalized for COPD, some were rehospitalized and 33% (n=335) died within 6 months of discharge.

Conversely, mobile health (mHealth) technologies hold significant promise for monitoring patients with chronic diseases [14]. These apps offer benefits such as remote monitoring, direct communication with health care professionals, recording of clinical signs, and the development of self-care skills [14]. A Cochrane review [15] suggested that self-monitoring of symptoms through mobile apps positively impacts the development of self-care and self-management skills in patients with chronic diseases [9]. Furthermore, studies, such as the one conducted by Knox et al [16], have focused on designing mobile apps for patients with COPD, concluding that reporting clinical information through these apps can aid in disease management [16].

Some authors emphasize the importance of designing these mHealth apps with a user-centered approach [17,18]. Understanding the perceptions and needs of the end user as well as adapting to their sociodemographic characteristics and level of technological literacy are indispensable strategies for developing mHealth apps that increase adherence to use and, consequently, to treatment and self-care [17-19]. Therefore, evaluating the usability [20] of mHealth apps before their implementation is crucial. Conducting usability tests to assess user performance on specific tasks can identify areas for design improvements and enhance user satisfaction [4,21].

Based on the above, the authors of this study designed and developed a mobile app called AppO2 (SINCO) before conducting the research. This app was created using a user-centered design methodology and underwent usability tests [4,19]. AppO2 facilitates the monitoring of the clinical status of patients with COPD receiving home oxygen (HO) therapy, with 2 user profiles—patients (or their caregivers) and health care professionals [4,19]. The functions of the patient profile are centered on self-care skill development and quality of life improvement. These functions include tutorials on measuring and recording vital signs, accessing information related to the prescription of HO treatment, and communicating and interacting with health care professionals [4,19]. Conversely, the functions of the professional profile are designed to monitor patients' clinical status on a daily basis, record and review clinical changes to inform decision-making, and control the dosage of HO therapy [4,19].

Finally, the functionalities of this mobile app were designed to promote self-care in patients with COPD receiving HO therapy. It also sought to address the primary challenges these patients face in improving adherence to HO treatment, preventing or detecting exacerbations early, and enhancing their quality of life [4,19].

In this context, this study aimed at evaluating the efficacy and acceptability of AppO2 in real community settings compared with conventional home care monitoring for patients with COPD-prescribed HO.

Methods

Study Design and Participants

A 3-month, open-label, 2-arm, parallel-arm, multicenter, randomized controlled, nonblinded, clinical trial was conducted

XSL•FO
RenderX

to determine the efficacy of a mobile app in monitoring the clinical status of patients with COPD receiving HO therapy. The control group (CG) comprised patients receiving HO and monitored using conventional methods, such as weekly home visits by a health care professional. The intervention group (IG) comprised patients who were also monitored through weekly home visits in addition to using the AppO2 mobile app. The clinical trial was conducted in Cali, Colombia, with the participation of 3 home care institutions—TodoMed, Amanecer Médico, and Cuidarte en Casa. The clinical trial protocol was registered in ClinicalTrials.gov (ID NCT04820790) [4].

Patients were recruited from May to December 2023 based on the following inclusion criteria: (1) being ≥18 years old, (2) having a medical prescription for HO for more than 1 year, (3) having a caregiver, (4) owning a smartphone, and (5) consenting to audio recording. The exclusion criterion was patients undergoing mechanical ventilation.

In total, 2 health care professionals were included based on the following inclusion criteria: (1) being ≥18 years old, (2) being respiratory therapists and physiotherapists affiliated with a home care company, (3) having more than 6 months of experience in home care, and (4) having a smartphone. The exclusion criterion was established as professionals with less than 6 months of experience in managing patients receiving HO.

Sample Size

To achieve a 1:1 ratio between the IG and CG, with 80% power (β error=20%) and 95% CI (α error=5%), and estimating that the AppO2 app in the IG would result in a 3% increase self-management of dyspnea, with SD 6 [22], a minimum sample of 32 participants (16 in each group) was estimated. Finally, to minimize the effects of potential patient losses that would reduce statistical power, the sample was expanded to a final size of 45 participants (23 in the IG and 22 in the CG) [4].

Randomization

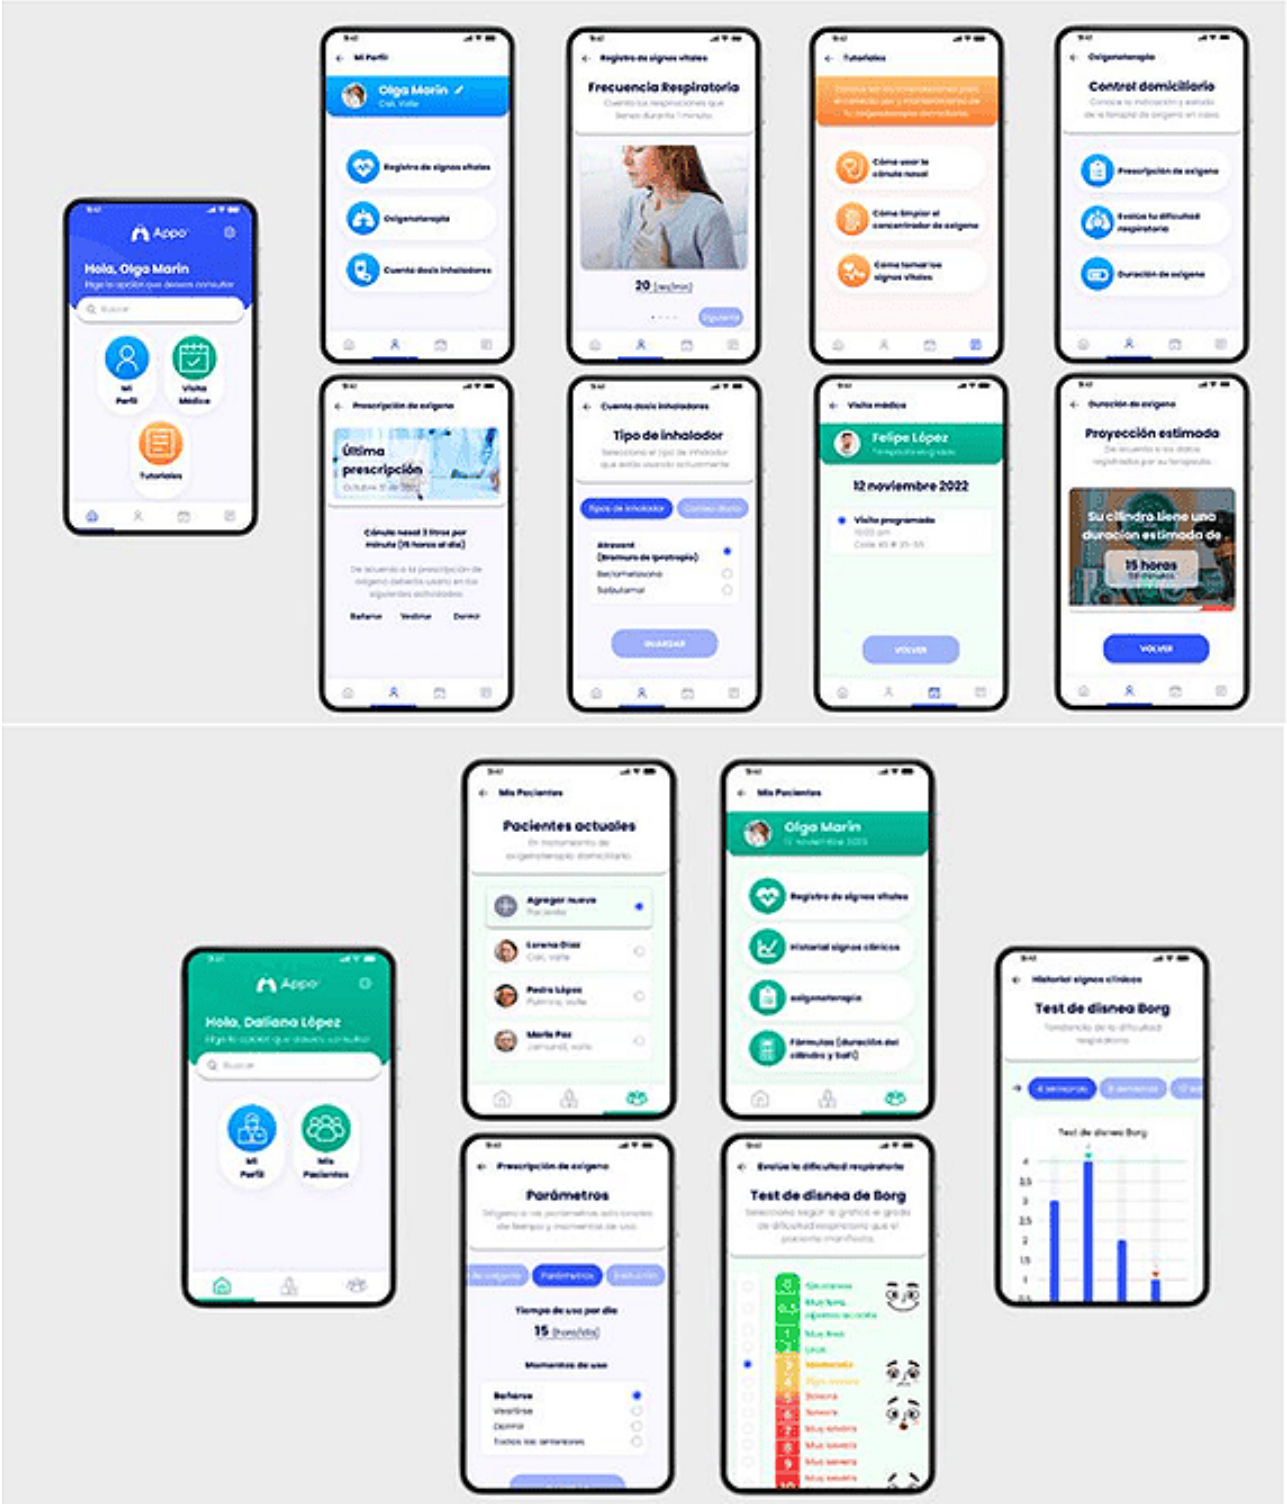
Overview

Participants were equally and randomly assigned to either the IG or CG using a simple randomization method with Epidat 3.1 (Consellería de Sanidade de la Xunta de Galicia, in collaboration with the Pan American Health Organization [PAHO]). Blinding was not possible for participants or health care professionals owing to the intervention method used.

Sample Selection

Consecutive sampling was used to recruit patients and all participants who met the selection criteria and attended consultations at participating institutions were included in the study. Sampling was done until the predetermined sample size was reached.

Intervention



After selecting the trial participants, the IG downloaded the AppO2 app on their mobile phones. The objectives of the investigation and the operation of the app were explained to them. In addition, it was recommended to use the app at least once a week. All recorded information was stored anonymously in a cloud-based database, identifiable by a code only known to the principal investigator. The database was accessible to researchers through a web app for review and analysis.

The AppO2 mobile app consists of 2 user profiles, one for patients and caregivers and another for professionals. There are 3 sections in the patient and caregiver profile, “My Profile,” “Medical Visit,” and “Tutorials.” In the “My Profile” section, patients can record their vital signs and the degree of respiratory difficulty, view the medical prescription for oxygen therapy including the duration of the oxygen therapy regimen, and record the number of daily inhalations if they have a prescription for medication. When recording their vital signs, patients from their user profile receive notifications informing them if vital signs are outside the predetermined ranges. These alerts suggest that they tell their health care professional to adjust treatment as necessary or recommend that they carefully follow medical indications if a slight alteration in vital signs is detected. However, these notifications are not sent to medical staff in real-time. Instead, professionals can view patients’ clinical history as they see fit through their profile [4,19]. This functionality allows them to monitor the behavior of vital signs and make the appropriate adjustments during scheduled home visits, accessible through the “Medical Visit” section. This approach allows for more flexible management and avoids an overload of unnecessary alerts, which could generate “false positives” by prioritizing intervention based on a comprehensive patient assessment. The “Medical Visit” section allowed users to view the schedule of upcoming medical visits and the history of past visits. In addition, the “Tutorials” section featured videos that provided education and instructions on taking vital signs and using oxygen systems [4,19].

Similarly, the professionals’ profile has 2 sections, “My profile,” where they can register their personal data and update their account, if necessary, and “My patients,” where they can record the assessment, prescribe oxygen, and monitor the clinical status of patients. They can also view graphs that display the monthly trends of each vital sign. Through the professionals’ profile, information on HO prescription parameters, visit schedules, and data on the estimated duration of oxygen cylinders are sent to the IG [4] (Figure 1).

Measures

Independent variables, including participants' sociodemographic characteristics (eg, age, sex, marital status, educational level, and place of residence) and other aspects of lifestyle and treatment (such as smoking, biomass exposure, and duration of HO treatment), were obtained from the databases and record systems of the 3 health institutions to which they belonged.

During the home visits, therapists collected information was collected on variables related to vital signs, such as oxygen saturation through pulse oximetry, respiratory rate, central heart rate, number of exacerbations, number of hospitalizations, number of emergency room admissions, survival, inhaler use, and changes in oxygen prescription. Cylinder duration time was calculated considering the conversion factor, oxygen system flow, residual pressure, and cylinder pressure [23]. This calculation was performed manually in the CG, whereas the mobile app was used in the IG. In addition, therapists reminded patients and caregivers to use the app during each visit. Vital signs and the relationship between oxygen saturation and

XSL•FO
RenderX

fraction of inspired oxygen [24] were recorded once a week from the date of randomization until week 12 or until the time of death from any cause, whichever occurred first.

The degree of respiratory distress was determined using the Borg Dyspnea Scale [25], a standardized, validated analog scale in Spanish, widely used since the 1970s. The scale ranges from 0 to 10 and is designed to quickly and easily assess patients' perception of dyspnea. It includes a graph associated with each quantitative value, which helps patients identify their level of respiratory distress, with 10 indicating the highest level of perceived dyspnea [26]. Assessment using the Borg test was conducted from the beginning of the study until week 12 or until the date of death from any cause, whichever occurred first. In addition, the number of days the app was used, access to each screen, and connection time within the mobile app were tracked in the IG.

Questionnaires

The chronic obstructive pulmonary disease assessment test (CAT) questionnaire was used to assess the impact of COPD on patients' quality of life [27]. This questionnaire was administered to both the IG and CG at the beginning and at the end of the intervention. The acceptance of AppO2 was evaluated using the technology acceptance model (TAM) [28], which assessed the perceived usefulness and ease by participants in relation to AppO2 [28]. This questionnaire, along with an interview to gauge the perception of AppO2, was administered to health care professionals and the IG at the end of the follow-up period.

Chronic Obstructive Pulmonary Disease Assessment Test

This is a validated [29,30] and publicly accessible questionnaire consisting of 8 questions, each evaluated on a scale of 0-5 points. The minimum score is 0, and the maximum score is 40 [29,30], reflecting the impact COPD has on a patient's quality of life. The scores are classified as (1) low impact (1-10 points), where most days are "good days"; (2) medium impact (11-20 points), with few "good days"; (3) high impact (21-30 points), with no "good days"; and (4) very high impact (31-40 points), where the disease's limitation is at its maximum. A progressive increase in CAT scores indicates an increase in the impact of COPD on the patient's quality of life [27,29].

AppO2 Acceptance Questionnaire and Perception Interviews

The AppO2 mobile app acceptance questionnaire was administered to patients and professionals. It was based on the TAM [30] designed by Davis [31,32], aimed at evaluating people's perception of usefulness and ease regarding acceptance in the use of devices or software in digital environments. Although several variations have been made by different authors [33-35], it is essential to evaluate the following dimensions: (1) perception of usefulness and (2) perception of ease. Based on these dimensions, 12 items translated and validated into Spanish [36,37] were applied, with minor adaptations in their content for better understanding.

Responses were assessed using a Likert scale, ranging from "totally agree" to "totally disagree" (Multimedia Appendix 1). To determine the acceptance of the AppO2 mobile app, 1 point was assigned to the item with which participants were moderately or totally in agreement, and 0 was assigned to items with which they were moderately or totally in disagreement. Cutoff points for the level of acceptance were obtained by measuring quartiles. Low acceptance was considered if it was in quartile 1 (1-3 points), moderate if it was between quartiles 2 and 3 (4-9 points), and high if it was in quartile 4 (10-11 points). Furthermore, to complete the evaluation of participants' perceptions regarding the AppO2 app, an interview was conducted with both the IG and health care professionals. The objective of the questions was to inquire about what they liked or disliked most about the app, the perceived benefits, and their preferences. These interviews were conducted at the end of the intervention (Multimedia Appendix 2).

Primary and Secondary Outcomes

Primary outcomes consisted of the CAT score, the degree of dyspnea measured using the Borg test, and the percentage of oxygen saturation at the beginning and end of the clinical trial. Secondary outcomes were the frequency of use of the app, number of hospitalizations, and survival.

Statistical Analysis

Data analysis was performed using SPSS Statistics software, version 25.0 (IBM Corp). Initially, a descriptive analysis of the study variables was conducted, characterizing the patients and generating graphs and tables of absolute and relative frequencies for qualitative variables. For quantitative variables, measures of central tendency and position (mean and median) with their respective measures of dispersion (SD and IQR) were calculated.

In the bivariate analysis, the Student *t* test or its nonparametric equivalent (Mann-Whitney *U* test) was used to compare 2 means. For categorical variables, the chi-square test was used. To analyze 3 or more mean values, repeated measures analysis of variance or the Friedman test was used. Crude odds ratios (ORs) were initially calculated to determine variables independently associated (AppO2 use and sex) with the impact of COPD on quality of life, as measured by the CAT. In addition, an analysis of covariance (ANCOVA) was used, which allowed for adjustment of differences in the final Borg dyspnea scores based on the initial baseline score. This ensured that observed changes were attributed to the intervention with the app rather than initial variations in dyspnea.

Finally, a binary logistic regression model was applied, including variables with a P value <.20 in the initial analysis presented or those related to the outcome by biological plausibility. This allowed for estimating the standardized β coefficients, an adjusted coefficient of determination, and the residual values. The binary logistic regression analysis dichotomized the CAT outcome into "low" (patients with a low or medium CAT score) and "high" (patients with a high or very high CAT score). The model was adjusted for possible confounding variables (time of oxygen use and years of cigarette consumption). An α error of ≤0.05 was considered statistically significant, and 95% CIs were calculated.

Ethical Considerations

The clinical trial protocol was approved by the Ethics Committee of the Department of Health of Universidad Santiago de Cali, Colombia, Act No. 02, as well as by the 3 home care institutions in the city of Cali, Colombia. The investigation complies with international regulations, such as the Declaration of Helsinki. All participants gave their written informed consent before inclusion in the study. Informed consent was obtained, and the participants were informed of the possibility of opting out or withdrawing at the time of their choice, if applicable. The data were anonymized so that participants could not be identified, and no amount of compensation was offered or awarded.

Results

Participants were equally and randomly assigned to either the IG or CG using a simple randomization method with Epidat 3.1 (Consellería de Sanidade de la Xunta de Galicia, in collaboration with the Pan American Health Organization [PAHO]). Blinding was not possible for participants or health care professionals owing to the intervention method used (Figure 2). The CONSORT Checklist is included as Multimedia Appendix 3.

Figure 2. Modified CONSORT (Consolidated Standards of Reporting Trials) flow diagram for individual randomized controlled trials of nonpharmacological treatments.

A total of 45 participants were included (23 from the IG and 22 from the CG). The cohort was predominantly female (n=31, 69%) with a mean age of 75.4 (SD 15.9) years (95% CI 70.7-80.0 years). Furthermore, 73% (n=33) of the participants had been exposed to biomass at some point in their lives, and 93% (n=42) had a history of smoking, with a time of consumption that exceeded 15 years in most cases (n=30, 67%). When comparing baseline characteristics between the groups, no statistically significant differences were observed in sociodemographic variables and background except for the "time of oxygen use for more than 15 years," which was greater in the IG (n=17, 74% vs n=9, 41%, *P*=.02; Table 1).

[d]COPD: chronic obstructive pulmonary disease.

Regarding the behavior of vital signs during the 3-month follow-up for patients with conventional follow-up, no significant differences were observed in respiratory rate, heart rate, temperature, saturation, and Borg Dyspnea Scale scores. Likewise, in the IG, no statistically significant differences were found in vital signs, except in the Borg Dyspnea Scale score, which decreased over time (month 1: mean 1.2, SD 0.9; month 2: mean 1.0, SD 0.9; month 3: mean 0.6, SD 0.8; *P*=.01) (Figure 3).

XSL•FO
RenderX

When comparing the clinical variables at the end of follow-up between the groups, it was found that the Borg Dyspnea Scale score was significantly lower in the IG than in the CG (mean 0.6, SD 0.8 vs mean 4.1, SD 1.4; *P*=.001; Table 2).

After adjustment for baseline values, significant differences were maintained in both Borg Dyspnea Scale and CAT final scores, favoring the intervention group, with lower adjusted means (1.3 vs 2.7; *P*=.02 and 22.33 vs 26.69; *P*=.002, respectively; Table 3).

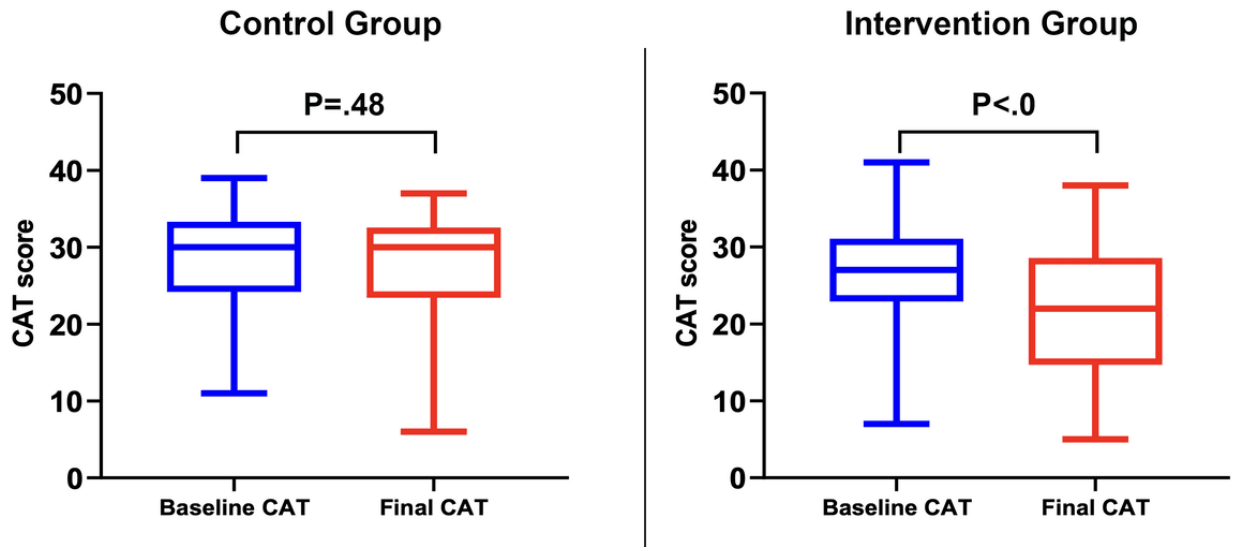
[a]Student *t* test.

[b]Analysis of covariance (ANCOVA).

[c]R^2 adjusted for baseline Borg score: 0.766.

[d]COPD: chronic obstructive pulmonary disease.



Regarding the impact of COPD on quality of life measured with the CAT questionnaire, although no differences were found in the score between the baseline measurement and at the end of follow-up in the control group, a significant decrease was observed in the intervention group (median baseline CAT 27, IQR 23-31 vs median final CAT 22, IQR 14-28; *P*<.001; Figure 4). In addition, the CAT score was significantly higher in patients undergoing conventional follow-up compared with those followed with the mobile app (median 30, IQR 23-32 vs median 22 IQR 14-28; *P*=.02).

When evaluating the record of HO therapy prescriptions in each group, it was found that the proportion of individuals who performed the HO therapy prescriptions correctly was higher in the IG throughout each month of follow-up. The frequency of accessing tutorials or educational records was significantly higher in the IG (95.7% vs 59%; *P*=.003) in the first month of follow-up (Table 4). Furthermore, during the study period, 50% (n=11) of participants in the IG used the mobile app for more than 21 days (median 21, IQR 16-28). The median was greater than 14 days for most variables requiring frequent recording or entry: vital signs recording (median 19, IQR 15-27), Borg scale recording (median 16, IQR 14-22), and oxygen prescription recording (median 14, IQR 11-18; Multimedia Appendix 4).

Satisfaction was mostly observed among users of the AppO2 app, including patients, caregivers, and therapists. Details regarding the measurement of satisfaction with the AppO2 app are presented in Multimedia Appendix 5.

Similarly, in interviews assessing the perception and acceptance of technology using the TAM, the IG reported that the use of the mobile app fostered confidence and improved communication with health care professionals. The group emphasized the value of notifications regarding their vital signs, noting that having access to this information made them more responsible in managing and caring for their disease. Multimedia Appendix 6 presents some expressions reflecting the perceptions and acceptance of AppO2.

Figure 4. Comparison of chronic obstructive pulmonary disease assessment test scores at baseline and at the end of follow-up for control and intervention group patients included in the study. CAT: chronic obstructive pulmonary disease assessment test.

XSL•FO
RenderX

Table 4. Comparison of oxygen therapy recording, education, and oxygen cylinder duration in the control group versus the intervention group.

Variable	Intervention (n=23), n (%)	Control (n=22), n (%)	*P* value
Records oxygen prescription			
Month 1	22 (96)	14 (64)	.006
Month 2	22 (96)	11 (50)	.002
Month 3	22 (96)	10 (48)	.001
Records education or reviews tutorials			
Month 1	22 (96)	13 (59)	.003
Month 2	14 (61)	9 (41)	.18
Month 3	4 (17)	14 (67)	.002
Records duration of oxygen cylinder			
Month 1	6 (26)	2 (9)	.13
Month 2	4 (17)	3 (14)	.72
Month 3	5 (17)	7 (33.)	.44

Finally, the binary logistic regression model was statistically significant (chi-square value=5.9, *P*<.001) and demonstrated a good fit (Hosmer-Lemeshow test=3.92, *P*=.80). The use of the mobile app was the only variable independently associated with the impact on the quality of life of patients with COPD, as measured using the CAT questionnaire (adjusted OR 0.15; 95% CI 0.02-0.82; Table 5).

Table 5. Use of AppO2 and its association with decreased impact of chronic obstructive pulmonary disease on quality of life measured by chronic obstructive pulmonary disease assessment test.

Variable	Crude OR[a] (95% CI)	*P* value	Adjusted OR (95% CI)	*P* value
App usage				
Yes	0.15 (0.02-0.80)	.02	0.15 (0.02-0.82)	.02
No	6.57 (1.21-35.5)	.02	6.57 (1.21-35.52)	.02

Discussion

Overview

A 2-arm randomized clinical trial was conducted to determine the effectiveness and acceptability of the AppO2 mobile app for managing HO therapy in patients with COPD in Cali, Colombia.

The use of health technology tools that offer clinical interventions is emerging as a promising strategy in the health care setting [38,39]. In recent years, self-management interventions supported by smartphone apps have been shown to improve disease management in chronic patients, thus decreasing hospitalizations and emergency room visits and improving quality of life [40].

XSL•FO
RenderX

Quality of Life of Patients With COPD Receiving Home Oxygen When Using AppO2

The main finding of this investigation is that the use of the AppO2 app is associated with a decrease in the score of the impact of COPD on quality of life. This reduction in the CAT score suggests a lower negative impact of the disease on the quality of life of patients and an improvement in their general well-being. We believe that this finding is related to the user-centered design approach of AppO2 [19], which addressed specific needs expressed by patients and their caregivers during the initial stages of the project. Therefore, this app is not only limited to being a clinical monitoring tool, but it also promotes the development of self-care skills and recognition of clinical signs. Wang et al [41], who also used the CAT to assess the impact on patient's quality of life, observed significant improvements in patients who used a mobile app compared with those who received conventional medical care for COPD.

Another important aspect is the improvement in the dyspnea score according to the Borg scale observed in the IG. Participants mentioned that the information provided by AppO2 through images and notifications when determining the degree of dyspnea allowed them to establish a direct relationship with their perception of effort and respiratory difficulty. They also stated that this facilitated communication with therapists through the mobile app and during home visits. These findings are consistent with those reported by Kayyali et al [42], who demonstrated that patients who received clinical information through technological tools, such as mobile apps, could establish correlations with their symptoms and determine when to contact health care professionals.

A Cochrane review [43] suggested that digital tools in health care might improve patients' quality of life, although long-term effects remain unclear. Prolonged use of these digital interventions could improve symptoms such as dyspnea. Our findings align with studies [44,45] that indicate mHealth apps enhance patients' quality of life.

Health Perception and Self-Care of Patients With COPD Receiving Home Oxygen When Interacting With AppO2

Our study found no significant differences between the groups regarding the recording of the clinical signs such as oxygen saturation, respiratory rate, and heart rate. This might be due to the chronic condition [38,40] of the patients, which did not show notable clinical changes during follow-up. However, users in the IG reported that AppO2 improved their health and confidence in recognizing and interpreting vital signs. This suggests that the usefulness of the mobile app extends beyond clinical sign monitoring, positively impacting patients' self-care and their perception of the app's use, as supported by other research on mHealth technologies [42,46,47].

Another point worth mentioning is the interaction of the patients with the oxygen prescription section. The few patients in the IG functionality found it helpful for managing their treatment autonomously by viewing their oxygen prescription at any time, facilitating the use of the HO. Despite previous positive feedback on this feature [4,19], its low usage in this study might warrant its reconsideration or removal. Conversely, the CG only had access to this information during home visits from health care professionals.

Furthermore, patients who used AppO2 mentioned feeling more responsible and confident in managing their disease, emphasizing that access to clinical information aided them in adhering to guidelines for monitoring their clinical signs. This finding aligns with previous investigations [43,47], which indicate that patients with chronic diseases consider the use of digital tools for self-care as a good strategy to access clinical information and optimize disease management.

Acceptability and Connection Time With AppO2

According to the results of the level of acceptability measured using the TAM tool, most patients expressed being completely satisfied with the usefulness and ease of use of AppO2. In addition, patients in the IG expressed feeling safe when using the app. These results are consistent with those of the investigation conducted by Knox et al [16], who designed an app for patients with COPD also using the TAM. They observed that patients demonstrated high motivation and a positive attitude toward using the app, especially in making health-related decisions [16].

On the other hand, while the average use of the app for 21 days over a 3-month period may seem small, it is important to consider that its design does not require continuous daily use to be effective. The app focuses on building patient confidence and promoting self-awareness of their symptoms. Through intermittent but strategic use, patients acquire key tools to monitor and manage their condition more autonomously, potentially contributing to a better quality of life. On the other hand, patients mentioned in interviews that they felt more secure and confident knowing that therapists could access their records at any time, assess their clinical condition, and adjust treatment if necessary. This sense of constant accompaniment helped them to feel "less alone" in the process of their treatment, enhancing their mental well-being.

Likewise, some authors have indicated that certain factors may influence the frequency of AppO2 use. These factors highlight the acquisition of skills and knowledge for self-reporting and managing their disease, which decreases the need to consult tutorials or informative sections. As patients become more familiar with these skills, they experience greater autonomy, leading to more selective use of the app's functions, focusing on those they consider most relevant to their daily routine [48,49].

In this sense, the trend of AppO2 use is reflected in the maximum period of disconnection of 2 weeks observed among the participants, demonstrating a significant engagement with the app. Patients expressed greater confidence and education in recognizing their vital signs. Thus, effective use of AppO2 is not only measured by frequency of access but also by its ability to foster self-management and clinical monitoring.

In previous studies [50-52], it has been documented that adherence to mHealth apps tends to decline over time, especially after an initial phase of intensive use. Perski et al [51] highlight that this decline in user engagement may influence clinical outcomes. However, they also identify factors that may prolong

XSL•FO
RenderX

use, such as personalization and regular reminders. Similarly, Byambasuren et al [52] noted that the "novelty" of mobile apps often wears off after the first few months. However, they suggest that intuitive design [53] and ongoing support from health professionals may improve long-term user retention.

In our study, the median number of app logins was 21 days during the 3-month follow-up period. In addition, we observed that the maximum time offline was 10 days. These data reflect a pattern of use that aligns with the app's design and does not require continuous daily access to be effective. The design's simplicity [53], vital sign notifications, and ease of use have been key factors in maintaining patient engagement.

As mentioned earlier, access to the tutorials in the IG decreased by the third month. The authors attribute this finding to the fact that the content of the videos did not vary over time, which may have led patients to view the education provided as adequate and integrated into their activities. This allowed them to be more selective in choosing the sections that best suited their needs and daily routine. In this sense, it is crucial to explore reinforcement strategies in future studies to ensure continued app use and maximize its clinical impact. This emphasis on continuous improvement in app usage is essential for the long-term success of such interventions [54,55].

Finally, the IG showed a maximum disconnection period of 2 weeks, indicating that the patients continuously interacted with the app. This adherence may be attributed to the high usability of AppO2, achieved through the end-user-centered design methodology applied in this research [4,18,19]. Conversely, the viewing of tutorials decreased in the final month of follow-up in the IG, which could be attributed to patients becoming more adept at self-monitoring and recognizing their vital signs. Similarly, Ding et al [56] reported that the use of the mobile app was more frequent during the first week of launch but decreased over time. Similarly, previous research [48,49] observed that users stop consulting some functions of mobile apps over time. Some factors that may influence this are the acquisition of skills and knowledge for self-registration and management of their disease, which reduces the need to consult tutorials or information sections. The continuous use of the app can also lead to a more selective use of its functions, focusing on those that are essential in their daily routine [48,49].

Principal Results

The findings of this study indicate that the use of the "AppO2" mobile app is associated with a significant improvement in the quality of life for patients with COPD and HO therapy. The high acceptability of the app is evidenced by a notable degree of satisfaction and adherence among users. Furthermore, "AppO2" not only facilitates self-care by enabling patients to manage their treatment more autonomously but also enhances their confidence in self-managing their condition. This contributes to better adaptation to treatment and greater self-care capabilities.

Limitations

The sample size comprised 45 participants. To avoid a lack of statistical power, the study included 3 home care institutions, which helped increase participant representativeness and the generalizability of the results for home health programs.

A limitation of the study is the 3-month duration. Although this period was sufficient to record favorable changes in the CAT score, which measures the impact of COPD on patients' quality of life, as well as their self-care and health perceptions, a longer follow-up could provide insights into the long-term effects.

The ANCOVA results indicated that the use of the app reduced dyspnea, as measured by the Borg scale, at month 3. However, the statistical significance of the initial Borg score (Borg month 1) suggests that the initial levels of dyspnea influenced the final results. The influence of the covariate suggests that other unmeasured variables, such as disease severity or comorbidities, may have affected the results, although this factor was controlled for in the analysis. Similarly, another possible limitation is the Hawthorne effect or observation bias, which occurs when study participants can systematically alter their behavior when they know they are being observed or monitored [50]. This, along with the inability to blind participants, may have influenced participant behavior. Future research should consider more discreet observation methods to minimize these biases.

Conclusions

The use of AppO2 is associated with a better quality of life in patients with COPD receiving HO therapy. The acceptability results for AppO2 show a high degree of satisfaction and adherence to its use. In addition, this mobile app promotes self-care and allows patients to develop confidence in managing their disease.

Acknowledgments

This research has been funded by the Dirección General de Investigaciones of Universidad Santiago de Cali (call 01-2024). This research has also been supported by the Universidad Santiago de Cali (research project 442-621121-3169). We would also like to thank all the patients and their families, as well as the professionals and institutions that participated in this study.

Conflicts of Interest

None declared.

Multimedia Appendix 5
Satisfaction of patients, caregivers, and therapists using the mobile app for home oxygen therapy monitoring (n=24). (A) Perceived usefulness. (B) Perceived ease of use. Question 1: Using this app helps me complete my tasks more quickly. Question 2: Using this app enhances my performance. Question 3: Using this app increases my productivity. Question 4: Using this app enhances the effectiveness of my work or self-care. Question 5: Using this app makes it easier for me to perform my work or self-care. Question 6: I find this app very useful for my work or self-care. Question 7: Learning to use this app was easy for me. Question 8: I find this app easy to do what I need to do. Question 9: My interaction with this app was clear and understandable. Question 10: I find this app flexible to interact with. Question 11: It will be easy for me to become an expert in using the app. Question 12: I find this app easy to use.

Abstract

Background: Tinnitus is a major health issue, but currently no tinnitus elimination treatments exist for chronic subjective tinnitus. Acoustic therapy, especially personalized acoustic therapy, plays an increasingly important role in tinnitus treatment. With the application of smartphones, personalized acoustic stimulation combined with smartphone apps will be more conducive to the individualized treatment and management of patients with tinnitus.

Objective: The aim of this study was to evaluate the efficacy of a new personalized approach known as the digital frequency customized relieving sound (DFCRS) for tinnitus treatment and to explore the factors that may influence its therapeutic effect.

Methods: Patients with subjective tinnitus were enrolled in this study from July 14, 2020, to May 24, 2021, in the tinnitus specialist clinic of Eye and ENT Hospital, Fudan University, Shanghai, China. In this nonrandomized concurrent controlled trial, a total of 107 participants were assigned to listen to personalized DFCRS through our developed app, while the other 77 participants who did not want to download and use the app were assigned to listen to unmodified music (UM). All the recruits were instructed to listen to DFCRS or UM for at least 2 hours a day and complete follow-up assessments at baseline, 1, 2, and 3 months. Multidimensional assessment scales, that is, Tinnitus Handicapped Inventory (THI), Hospital Anxiety and Depression Scale (HADS), Athens Insomnia Scale (AIS), Fear of Tinnitus Questionnaire (FTQ), and Tinnitus Catastrophizing Scale (TCS) were used to evaluate the severity of tinnitus and the quality of life. Linear mixed models were used to test for changes in the THI scores across 3 months of acoustic treatment between group (DFCRS or UM treatment) and time. A multiclass logistic model was built with a stepwise function to determine the influence of the different covariates on the effects of acoustic treatment.

Results: The results of the multidimensional assessment scales after 3 months of treatment showed that DFCRS-treated patients had significant tinnitus relief compared to those in the UM group. Linear mixed models revealed a significant reduction in the THI scores over time (P<.001), with the DFCRS group showing significantly greater improvement than the UM group (P<.001). At 3 months, 92.5% (99/107) of the patients undergoing DFCRS reported tinnitus relief or disappearance, and longer daily treatment time was associated with better outcomes (P=.007). Multiclass logistic regression confirmed that longer treatment time (odds ratio [OR] 13.07-64.78; P<.001) and more severe tinnitus at baseline (OR 10.46-83.71; P<.001) predicted better treatment response. All secondary outcomes (HADS, AIS, FTQ, TCS) showed significant improvements over time (P<.001).

Conclusions: Our study suggests that DFCRS is a new promising and noninvasive therapy for chronic tinnitus, and it can be delivered through a mobile app to bring more convenience to patients with tinnitus.

KEYWORDS

tinnitus; digital frequency customized relieving sound; unmodified music; sound therapy; prospective study; mobile phone

Introduction

Tinnitus, a common concern in the otolaryngology clinic, is described as the perception of sound without a corresponding external stimulus [1]. People can experience tinnitus constantly or intermittently from a single ear, both ears, and within the head. The presence of tinnitus can be annoying, affecting the patients' overall quality of life (QoL) and even negatively impacting their mental health [2]. Epidemiological studies have shown that tinnitus affects approximately 10%-25% of the adults [3,4], and tinnitus-induced anxiety, irritability, depression, sleep disturbances, and concentration disorders seriously threaten the cognitive and neurological health of approximately 1% of the adults [5]. Therefore, the search for an efficient treatment for tinnitus is urgently needed.

To date, there is a lack of approved medications that can eliminate tinnitus or provide a completely satisfactory cure [6,7]. However, there are several intervention strategies that can help patients cope with tinnitus. In recent decades, sound therapy has been broadly applied in exploring clinical treatments for tinnitus [8-12]. According to the sound generation method, sound therapy can be divided into 2 main types: unmodulated and modulated sound therapy [13]. Tinnitus masking and tinnitus retraining therapy are the 2 most commonly used unmodulated strategies, and their ultimate goal is to help patients with tinnitus become accustomed to tinnitus, attenuating excessive attention to it and thus reducing the tinnitus-related negative emotions [14-17]. Although some findings have confirmed their effectiveness in improving the QoL of patients with tinnitus [18], a randomized clinical trial showed no significant difference in the outcomes between tinnitus retraining therapy and placebo-sound treatment control groups [19]. Additionally, the current unmodulated sound therapy does not appear to change the loudness of tinnitus, limiting the possibility of tinnitus elimination [12].

Conversely, customized sound therapy is designed to encourage the reorganization of abnormal neural connections or to inhibit pathological neural activity, which is more promising in effectively eliminating tinnitus [10,20]. Current research has confirmed the superior effectiveness of customized sound therapy over unmodulated therapy [21]. For example, neuromonics tinnitus treatment involves adding or excluding individual broadband frequency sounds to relaxing music to produce intermittent tinnitus perception and facilitate desensitization to tinnitus [22-24]. It is worth noting that tailor-made notched music training [10] and tinnitus pitch-matched therapy [11] used 2 opposite sound-processing strategies; however, both produced positive results [25-27]. Thus, the underlying mechanisms of tinnitus alleviation, which might be linked to the pathogenesis of tinnitus, should be elucidated in the future. Although various sound therapies differ in strategies and effectiveness, there is a consensus that the effects of sound therapy are not immediate and need to be sustained over a period of time. We reviewed the follow-up time of different acoustic treatments [28]. For short ones such as the Heidelberg music therapy, the follow-up time can be 5 days, 1 week, or 3 weeks. In interventions such as tailor-made notched music, pitch-matched therapy, and tinnitus masking, the follow-up time can be 1 month to 3 months. Tinnitus retraining therapy, neuromonics tinnitus treatment, acoustic coordinated reset neuromodulation therapy, tailor-made notched music, and many other studies have a long follow-up time—more than 6 months or even 12 months, 18 months, 36 months, and so on.

To date, the mechanism of subjective tinnitus has not been fully elucidated. Generally, peripheral hearing loss may be the trigger of subjective tinnitus [12,29]. Due to auditory deprivation, the activity of the affected peripheral auditory nerves is reduced, and neuroplasticity directs adaptive changes in the central auditory system when the brain loses input from the ear [30,31]. Based on this, we designed a new personalized tinnitus relief model known as the digital frequency customized relieving sound (DFCRS), which generates 2 surrounding narrow bands (each 1/3 octave) according to the individual's matched tinnitus frequency and then dynamically enhances the intensity of the 2 designated bands by 10 dB on soft and relieving music [32]. With the popularity of mobile smart devices and the improved stability and convenience of mobile apps, which are increasingly being used in the sound therapy of patients with tinnitus [33,34], we developed an app named the Fudan Tinnitus Relieving System (FTRS) [35,36] to run this model for monitoring, management, and follow-up evaluation of tinnitus treatment. In this study, we aimed to investigate the effectiveness of DFCRS by using a self-designed FTRS app compared to that of unmodified music (UM) for treating tinnitus. Furthermore, we explored the possible factors that might influence the treatment effectiveness of DFCRS.

Methods

Study Design

Patients with subjective tinnitus were enrolled from the tinnitus specialist clinic of Eye & ENT Hospital of Fudan University from July 14, 2020, to May 24, 2021. All the included participants were Mandarin speakers, aged over 18 years, and able to communicate with instructors without any hearing aids. The average pure tone threshold (0.5, 1, 2, 4 kHz) should be no more than 55 dB HL of the worse ear. The participants were required to understand the purpose and process of the study, complete at least 3 follow-up visits in the clinic, and sign the informed consent prior to the commencement of the experiment. Patients with pulsatile tinnitus, objective tinnitus, or clear primary causes such as otosclerosis, Meniere disease, and acute stage of sudden sensorineural hearing loss were excluded from this study. Moreover, for safety reasons, patients with severe health issues such as cardiovascular and cerebrovascular diseases or tumors were excluded from this study. This was a nonrandomized concurrent controlled trial, and we followed the TREND (Transparent Reporting of Evaluations with Nonrandomized Designs) guidelines for nonrandomized

XSL•FO
RenderX

controlled trials (Multimedia Appendix 1). A total of 107 eligible patients who tended to use the FTRS app for acoustic therapy received DFCRS, and they were labeled as the experimental group. The other 77 patients who refused to use the app received UM, serving as the control group. The experimental group and the control group were recruited and provided acoustic therapy at the same time. All participants completed 4-timepoint follow-up questionnaires.

Ethics Approval

All tests were approved by the institutional review board of Eye & ENT Hospital of Fudan University (2017048). All patients signed the informed consent forms, and sensitive information relevant to patient privacy was removed before the analysis. Both forms of acoustic therapy did not add any cost to the patient, and each patient could also receive an appointment or a plus number service for the tinnitus specialist clinic.

Patient Assessment

The baseline data were collected mainly from 4 aspects: general information, characteristics of tinnitus, audiological and tinnitus assessments, and results of the multidimensional assessment scales of tinnitus. General information included details on age, gender, medical history, and treatment history. The characteristics of tinnitus included information on position, course, pitch, and correlative factors of tinnitus. Audiological and tinnitus tests included pure-tone audiometry (125 Hz-8 kHz), acoustic immittance, and tinnitus pitch matching. Five standardized questionnaires in the Chinese version were used to evaluate the severity of tinnitus and the QoL of patients with tinnitus from multiple dimensions.

Tinnitus Handicap Inventory

The Tinnitus Handicap Inventory (THI) is a self-report measure first developed in 1996 [37]. It contains 25 items with 0, 2, and 4 points each to quantify the functional, emotional, and catastrophic feedback to tinnitus. The total number of points is up to 100, with a higher score indicating more severe tinnitus-related discomfort and disability.

Hospital Anxiety and Depression Scale

The Hospital Anxiety and Depression Scale (HADS) consists of 14 items, 7 of which belong to the subscale for anxiety (HADS-A) and the other 7 questions indicate the subscale for depression (HADS-D) [38]. Due to the close correlation between tinnitus severity and psychiatric disorders, HADS was introduced to patients with tinnitus to identify emotional disturbances that reflect therapeutic efficacy [39].

Athens Insomnia Scale

The Athens Insomnia Scale (AIS) is commonly used to measure sleep quality [40]. It includes 8 items with a total score ranging from 0 (no sleep disorder at all) to 24 (the most severe insomnia). Changes in sleep disorders—one of the most common concomitant symptoms of tinnitus—can be used to evaluate the effects of tinnitus treatment.

Fear of Tinnitus Questionnaire

The Fear of Tinnitus Questionnaire (FTQ) is a self-report measure containing 17 items, with 1 point each, which intends to assess the levels of fear of tinnitus [41]. Higher scores indicate a greater fear of tinnitus. Researchers can estimate tinnitus status based on patients' attitudes and moods toward tinnitus.

Tinnitus Catastrophizing Scale

The Tinnitus Catastrophizing Scale (TCS) is a 13-item measure developed to assess how catastrophizing respondents are regarding tinnitus [42]. The instrument is rated on a 5-point scale from 0 to 4, with higher scores indicating higher states of tinnitus-specific distress.

Tinnitus Severity Assessment

The Tinnitus Severity Assessment scale divides patients with tinnitus into 4 grades according to subjective tinnitus-related impairment in daily life [2]. Patients with grade I or no impairment are not annoyed by tinnitus, whereas patients who are unable to work or live normally will be confirmed as having grade IV severe impairment.

Acoustic Therapy Procedure

In the DFCRS-treated group, according to precise audiological and tinnitus tests, a series of 4 endpoints of the modulation range adjacent to the tinnitus pitch were calculated using our specific algorithm (Multimedia Appendix 2). Based on these 4 endpoints, 2 specific frequency bands of 1/3 octave intervals below and above the tinnitus pitch were confirmed. Thereafter, with the assistance of the FTRS app, soft and relieving music was processed by dynamically increasing the intensity of both specified bands with a 10-dB gain, thus outputting the personalized relieving sound for tinnitus. Accordingly, in the UM-treated group, the unmodified original music was used.

After baseline data completion at the initial point in time (T0), patients in the DFCRS-treated group were trained to use the FTRS app correctly, while others in the UM-treated group were instructed to listen to UM through their favorite players. All participants were required to listen to the modified or unmodified sound in a quiet environment with a comfortable volume to avoid possible hearing damage.

In this study, the participants were not allowed to receive any other simultaneous treatments that might interfere with sound therapy. To obtain a better effect, all patients were encouraged to be exposed for as much time as possible in the therapeutic sound environment, and the recommended duration was at least 2 h/day. In addition, the participants were instructed to record the time of daily sound exposure accurately and truthfully. Finally, researchers maintained contact with the participants through various accessible means such as phone calls, WeChat, emails, and tinnitus specialist clinic visits.

Tinnitus Counseling and Education

Well-trained otologists implemented counseling and education for all patients with tinnitus. The main topics included the etiology and basic pathogenesis of tinnitus, the relationship between tinnitus and hearing loss, the interpretation of audiological and tinnitus test results, the psychoacoustic characteristics of tinnitus, the relationship between tinnitus and attention, guidance on exploring common methods to divert attention, and relaxation training. During the entire procedure,

XSL•FO
RenderX

the participants' confusion and discomfort with regard to tinnitus were patiently, promptly, and sufficiently dispelled.

Outcome Measures

There were 4 timepoints in total, including the baseline when the participants were enrolled and at 1, 2, and 3 months after commencing treatment. The primary outcome was the THI scores from baseline to follow-up endpoints. In addition, the other assessment instruments (HADS, AIS, TCS, and FTQ) as secondary outcomes also provided longitudinal insights into the efficacy of tinnitus treatment.

Statistical Analysis

Statistical analyses were performed using R software (version 4.1.2; R Foundation for Statistical Computing) with the lme4, nnet, and ggpubr packages. Two-sided values of $P<.05$ were deemed statistically significant. Demographics and baseline characteristics such as age, sex, tinnitus course, location, tinnitus pitch, severity, and assessment instruments (THI, HADS-A, HADS-D, AIS, FTQ, and TCS) were summarized by groups that were defined by the treatment results. We summarized the descriptive statistics of the continuous variables (mean, standard deviation or median, and quartile) and categorical variables (number and proportion of participants in each category). Differences in the characteristics among the groups were tested with chi-square for categorical variables; 1-way analysis of variance was used for normally distributed continuous variables, and the Kruskal–Wallis test was used for nonnormal continuous variables. A 2-tailed *t* test was applied to compare the mean multidimensional assessment data before and after treatment and to determine the differences between subgroups. Linear mixed models were used to test for changes in the THI scores across 3 months of acoustic treatment between groups (DFCRS or UM treatment) and time. A multiclass logistic model was built with a stepwise function to determine the influence of different covariates on the effect of acoustic treatment, and Akaike information criterion/Bayesian information criterion/corrected Akaike information criterion was used to select the best model.

Results

Demographic and Tinnitus Characteristics of the Participants at Baseline

A total of 184 patients with tinnitus (107 in the DFCRS treatment group and 77 in the UM control group) completed the baseline data collection and 3 follow-up visits. After the 3-month treatment, patients were asked to report the effectiveness of tinnitus treatment based on their subjective perceptions. The baseline data are shown in Table 1. In the DFCRS treatment group, 50.5% (54/107) were men and 49.5% (53/107) were women, aged 45 (range 35.5-57) years, with a tinnitus duration averaged at 12 (range 4-24) months. In the UM group, 55% (42/77) were males, the age was 50 (range 37-59) years, and the tinnitus duration was 8 (range 3-42) months. The patients' gender and age did not differ significantly between the experimental group (DFCRS) and the control group (UM). We also compared other baseline data and observed no significant differences in the distribution of tinnitus characteristics involving location, frequency, and severity assessed by multidimensional tinnitus scales (HADS, AIS, Visual Analog Scale, FTQ, and TCS) between the 2 groups. Besides, there were no significant differences in the hearing levels in either ears between the 2 groups. However, the THI scores differed at baseline between the 2 groups (UM group: median 40, range 24-60; DFCRS group: median 48, range 33-66; $P=.01$). The overall baseline data were comparable between the DFCRS group and the UM group, suggesting that the following therapeutic effect was not significantly influenced by pre-experimental demographic information and characteristics of tinnitus.

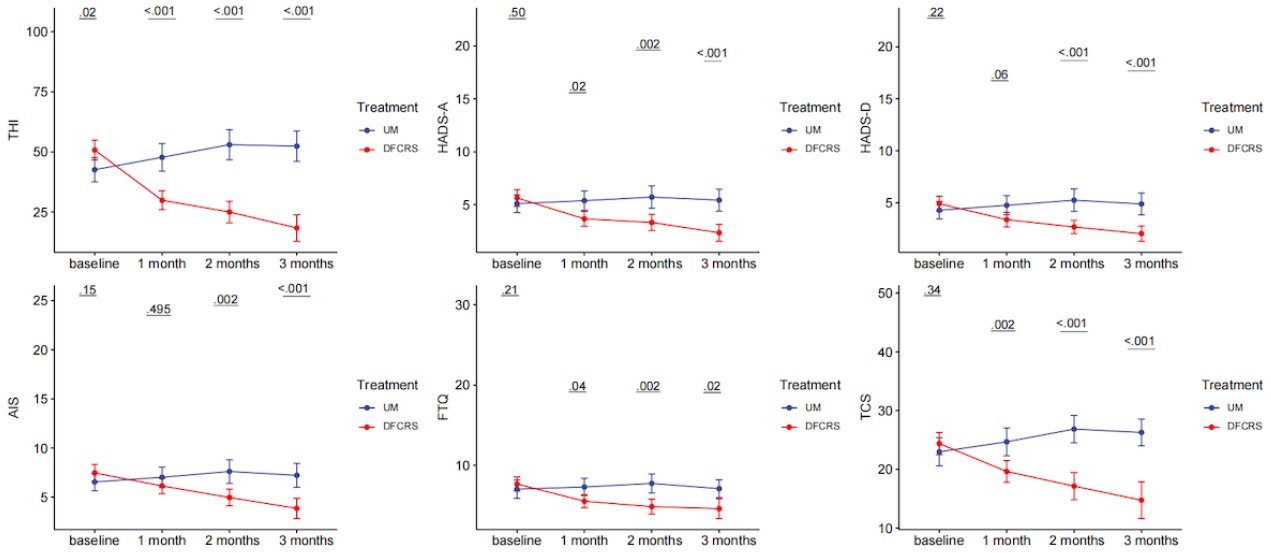
[a]Average air conducted pure tone hearing thresholds of 500, 1000, 2000, and 4000 Hz.

Mixed Effect Model Indicated Effectiveness of DFCRS Treatment

As the primary outcome, the THI scores were calculated using the linear mixed model in both DFCRS and UM treatment groups. The results of the linear mixed model revealed significant main effects of follow-up time (estimate=–0.119; *P*<.001) (Table 2), which showed a general decrease in the THI scores over the trial duration. Besides, there were significant effects in the DFCRS group compared to those in the control group, and the negative value revealed a remarkable treatment effectiveness of DFCRS measured by THI compared to that of UM in the control group (estimate=–16.6469; *P*<.001).



Apart from the follow-up time and treatment procedure, no other factors were found to contribute to a significant effect in the linear mixed model. Comparisons of the multidimensional assessment scales between the DFCRS-treated group and the UM control group at 4 timepoints are shown in Figure 1. During the 3 months of treatment, almost all of the scores on the 6 scales in the DFCRS-treated group showed significant decline compared to those in the UM control group, indicating better effectiveness of DFCRS in managing tinnitus. We found that UM had no significant therapeutic effect on tinnitus (Table S1 in Multimedia Appendix 3). Moreover, the differences were mostly maintained or were even enlarged across time especially after 1 month of treatment. No adverse effects were reported during follow-up in both groups.

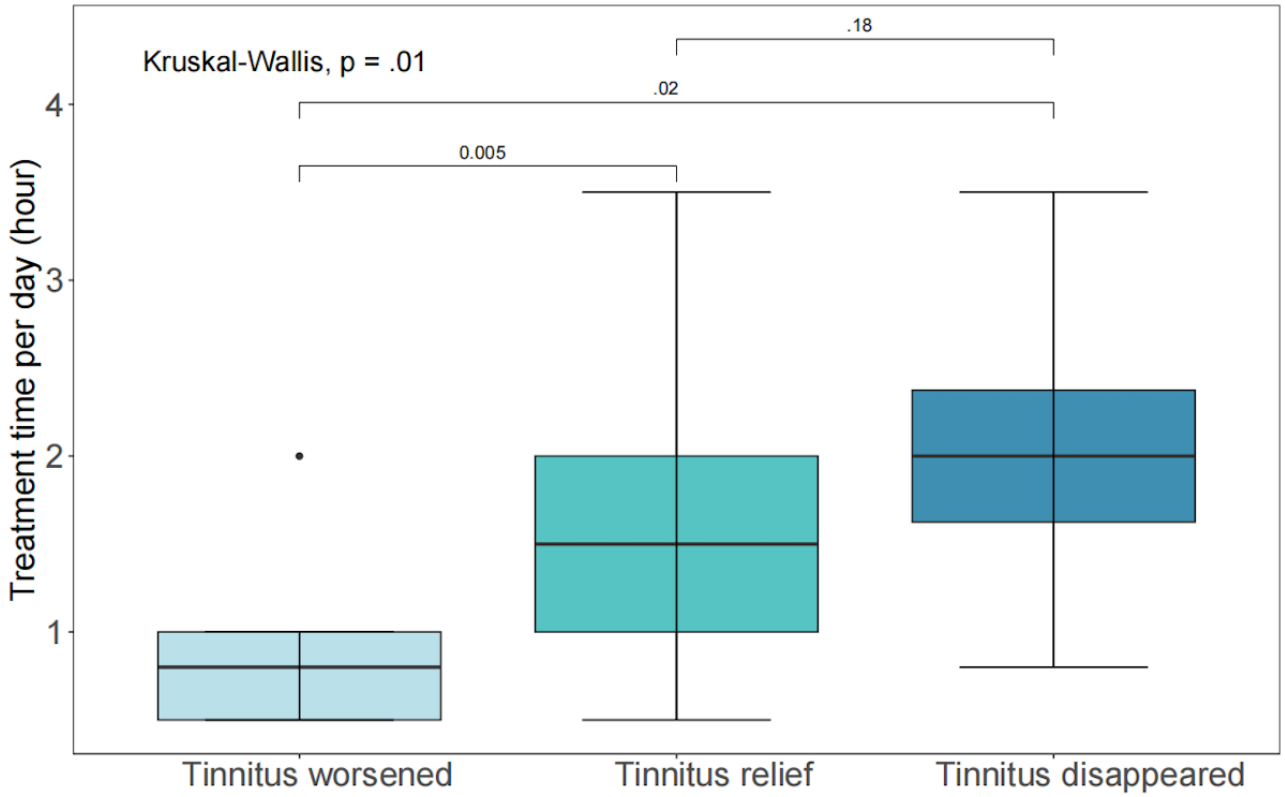
AIS: Athens Insomnia Scale; DFCRS: digital frequency customized relieving sound; FTQ: Fear of Tinnitus Questionnaire; HADS-A: Hospital Anxiety and Depression Scale-subscale anxiety; HADS-D: Hospital Anxiety and Depression Scale-subscale depression; TCS: Tinnitus Catastrophizing Scale; THI: Tinnitus Handicapped Inventory; UM: unmodified music.

Multiclass Logistic Model Predicted Factors That Affect the Effectiveness of DFCRS Treatment for Tinnitus



To further identify the factors affecting the effectiveness of DFCRS, we analyzed the statistical relationships among gender, age, acoustic treatment time per day, various tinnitus characteristics, and treatment results according to patients' subjective reports. After 3 months of DFCRS treatment, 86.9% (93/107) of the patients reported tinnitus relief, 5.6% (6/107) reported that tinnitus disappeared, and 7.5% (8/107) reported worsened tinnitus (Table S2 in Multimedia Appendix 3). The patients' gender and age did not differ significantly among the 3 different treatment outcome groups. There were no significant differences in the distribution of characteristic tinnitus indicators such as location, tone, course, and severity assessed by multidimensional tinnitus scales among the 3 subgroups as well. Interestingly, the data showed that there was a significant difference in the treatment time per day among the 3 groups (*P*=.007). Participants whose tinnitus was alleviated or disappeared received sound therapy for a longer time than those who reported worsening tinnitus, indicating a time-dose–dependent relationship for implementing DFCRS as a tinnitus treatment strategy (Table S2 in Multimedia Appendix 3). We then conducted a two-by-two comparison among the 3 subgroups, and the results revealed that significant differences existed between the worsening tinnitus group and the tinnitus relief group (*P*<.01) as well as the worsening tinnitus group and

XSL•FO
RenderX

the tinnitus disappeared group (*P*<.05; Figure 2). This finding preliminarily confirmed that an increase in the exposure of DFCRS treatment contributed to better efficacy in managing tinnitus.

For more precise analysis, we built a multiclass logistic model to determine the influence of different covariates on acoustic treatment effects (Table 3). The results showed that compared to patients whose tinnitus worsened, patients who reported tinnitus relief had a longer treatment time per day (odds ratio [OR] 13.07, 95% CI 4.19-40.78; *P*<.001), and patients who reported tinnitus disappearance had the longest daily treatment time (OR 64.78, 95% CI 11.63-360.77; *P*<.001). In addition, patients with more severe tinnitus at baseline tended to respond better to acoustic treatment. More specifically, patients with severity III were more likely to have tinnitus relief (OR 40.37, 95% CI 3.42-477.14; *P*<.001) than patients whose tinnitus severity level was I. Similarly, patients with severity IV were more likely to have tinnitus relief (OR 10.46, 95% CI 2.12-51.62; *P*<.001) or tinnitus disappearance (OR 83.71, 95% CI 5.9-1188.28; *P*<.001) than those with tinnitus severity I.

DFCRS Treatment Demonstrated a Dose-Dependent Effectiveness As Measured by Multidimensional Assessment Scales

After 3 months of DFCRS treatment, the scores of all the multidimensional scales significantly decreased compared with the baseline data (*P*<.001 for all scales), indicating the efficacy of DFCRS therapy in managing tinnitus. The THI score decreased from 48.00 (95% CI 32.00-66.00) points at baseline to 30.00 (95% CI 18.00-42.00) points at the 1-month follow-up, to 22.00 (95% CI 12.00-36.00) points at the 2-month follow-up, and finally to 18.00 (95% CI 8.00-30.00) points at the 3-month follow-up. Significant differences were observed between the scores at baseline and 3 consecutive months of follow-up (*P*<.001; Figure 3).

XSL•FO
RenderX

Figure 3. Box and whisker plots for changes in the scores of the multidimensional assessment scales in digital frequency customized relieving sound–treated patients at 4 timepoints. After 3 months of digital frequency customized relieving sound treatment, the scores on all the 6 scales were significantly lower than those at baseline. Data are presented as median (IQR). AIS: Athens Insomnia Scale; FTQ: Fear of Tinnitus Questionnaire; HADS-A: Hospital Anxiety and Depression Scale-subscale anxiety; HADS-D: Hospital Anxiety and Depression Scale-subscale depression; TCS: Tinnitus Catastrophizing Scale; THI: Tinnitus Handicapped Inventory.

By comparing the 3 follow-up scores with the baseline of the other secondary outcomes, we observed that a more significant decline occurred in the following follow-up than in the preceding one (HADS-A, AIS, FTQ: P<.001 at 1-month follow-up, P<.001 at 2- and 3-month follow-ups; and HADS-D, TCS: P<.01 at 1-month follow-up, P<.001 at 2- and 3-month follow-ups). These significant differences suggested that there was a time-dependent increase in the effectiveness during the experimental procedure.

We also analyzed the differences between 2 of the 3 follow-up outcomes of the 6 assessment scales. Regarding THI scores, significant differences were observed between 2 and 3 months of follow-up (P<.05) and between 1 month and 3 months of follow-up (P<.001). In contrast, the THI scores did not decrease significantly from 1 month of follow-up to 2 months of follow-up (P=.07). A similar reduction was also found in the TCS scores (1 month vs 2 months: P=.09; 1 month vs 3 months: P<.01; 2 months vs 3 months: P=.17; baseline vs 3 months: P<.001), indicating that the therapeutic effect of DFCRS on tinnitus impairment and catastrophizing was observed at 2 months and was maintained in the third month.

Discussion

Customized sound therapy is an advanced method for treating subjective tinnitus that can effectively reduce the loudness of tinnitus and alleviate its negative impact on patients [12]. In this clinical trial, we explored the therapeutic effect of a new self-developed acoustic treatment named DFCRS [32] compared to that of UM over 3 months. Based on the changes in the scores of multidimensional assessment scales and patients' subjective judgments of symptom change, we concluded that the DFCRS delivered by our developed FTRS app [36] was more effective than UM in relieving subjective tinnitus and improving the QoL of patients with tinnitus. Moreover, better effects were obtained as the treatment course was extended or if the patients were exposed to the treatment sounds for longer periods.

We first identified more significant efficacy in the DFCRS treatment group compared to that in the UM control group during the treatment program by using linear mixed models. We further analyzed the possible influencing factors according to the different outcomes of tinnitus treatment and observed that those who achieved better therapeutic outcomes tended to adhere to acoustic treatment longer than those who reported aggravated tinnitus (Figure 2). Additionally, as shown in Figure 3, the assessment scores continued to decrease as the treatment proceeded and the total treatment time accumulated, indicating a steady increase in the efficacy of DFCRS. Interestingly, these 2 results on the treatment duration provided evidence from 2 perspectives for a possible positive correlation between the efficacy of DFCRS and treatment duration and were comparable to those reported in a previous 18-month controlled clinical trial study by Bauer and Brozoski [14] and an 18-month randomized controlled trial study by Henry et al [18], which used tinnitus retraining therapy or tinnitus masking sound.

THI, as the primary outcome, showed the treatment effects of functional, emotional, and catastrophic feedback on tinnitus [37,43]. The results showed significant improvement in the first month with a sustained effect in the following 2 months, indicating that the functional impairment caused by tinnitus and the patient's negative emotional state rapidly improved after starting DFCRS treatment. Additional assessments, including HADS-A, HADS-D, AIS, FTQ, and TCS, also showed rapid

XSL•FO
RenderX

and sustained efficacy after 3 months of DFCRS treatment, and the results demonstrated effective improvements in different aspects such as anxiety and depression, sleep disturbance, and other negative emotions related to tinnitus [41,42,44]. We hypothesized that the patient's trust in the treatment strategy gradually decreased the negative emotions such as fear and pain after personalized acoustic treatment and that physiological abnormalities such as sleep disturbances could be resolved [45]. The negative emotional and physiological responses caused by tinnitus and tinnitus itself interact synergistically. The patients benefited from individualized sound therapy, which helped them develop a positive mindset to overcome tinnitus, and the relief of tinnitus, in return, boosted their confidence in conquering tinnitus, which formed a positive feedback loop [12]. This could explain why patients showed significant relief at the first follow-up visit since the start of the experiment, and the efficacy persisted at the next 2 follow-up visits and was long-lasting. The sample size in our study was larger than those in other similar clinical trials [44], and the participants adhered well to the DFCRS strategy, which guaranteed data credibility.

The main limitation of our study, similar to those of other early clinical trials, is the lack of randomized subgroups [15]. In randomized controlled trials, to avoid selective bias, a more validated evaluation of the effect of sound treatment can be obtained compared to that in nonrandomized controlled trials [18]. In fact, a randomized controlled trial of this sound treatment strategy is already underway based on the initial positive results from this trial [32]. In future trials, a longer follow-up period would be necessary to determine whether the efficacy would be more significant after a longer treatment period [15,45]. In addition, the maintenance of efficacy after stopping the intervention also needs to be explored in a longer trial [15].

In conclusion, we have confirmed the efficacy of DFCRS in treating patients with subjective tinnitus, and thus, it could be a promising treatment option for chronic subjective tinnitus. However, future research needs to be conducted in a more controlled setting, even with a randomized controlled trial, to draw a more precise conclusion.

Acknowledgments

This work was supported by the National Key Research and Development Program of China (2023YFC2508401), National Natural Science Foundation of China (82371149), Shanghai Rising-Star Program (23QC1401200), and Shanghai Municipal Key Clinical Specialty (SHSLCZDZK00801). The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author (DT) upon reasonable request.

Authors' Contributions

DT and YP conceptualized this study, contributed to the methodology, and wrote the original draft. DT and HL acquired the funds. DT, YP, DG, and YW reviewed and edited this paper, administered the project, and contributed to the methodology, formal analysis, and validation. DT and HL contributed to the investigation and formal analysis. All authors read and approved the final manuscript. DT, YP, and DG have contributed equally to this study and are credited as co-first authors. DT (tang.dongm@163.com), YW (wgek2018@163.com), and HL (hwli@shmu.edu.cn) are co-corresponding authors for this article.

Abstract

Background: Enhancing self-management in health care through digital tools is a promising strategy to empower patients with type 2 diabetes (T2D) to improve self-care.

Objective: This study evaluates whether the Greenhabit (mobile health [mHealth]) behavioral treatment enhances T2D outcomes compared with standard care.

Methods: A 12-week, parallel, single-blind randomized controlled trial was conducted with 123 participants (62/123, 50%, female; mean age 58.25 years, SD 9.46 years) recently diagnosed with T2D. Participants were recruited face-to-face from primary care centers in Barcelona, Spain, between July 2021 and March 2022. They were randomly assigned to 1 of 2 groups: (1) an intervention group (n=61) instructed to use the Greenhabit mobile app alongside standard care, or (2) a control group (n=62) who received advice on maintaining a healthy diet and followed standard care. The Greenhabit app incorporates serious gaming technology. Participants received daily messages and challenges focused on promoting a healthy lifestyle, including nutrition, exercise, relaxation, a positive mindset, and a supportive social environment. The app encouraged participants to set weekly goals and awarded points for completing challenges. Data on nutrition, anthropometrics, and blood and urine samples were collected at baseline, 6 weeks, and 12 weeks. Questionnaires assessing quality of life, work-life balance, and social environment were administered at baseline and during the final visit. The primary outcomes were HbA1c and fasting plasma glucose (FPG). Repeated-measures analysis of variance was used to compare changes over time (baseline to 6 weeks and baseline to 12 weeks) between the 2 intervention groups. Analysis of covariance was performed to evaluate changes at 6 and 12 weeks, adjusted for baseline levels of each variable. Multiple contrasts were corrected using a Bonferroni post hoc test.

Results: Both groups showed significant reductions in HbA1c after 6 and 12 weeks (mean change in the intervention group [n=50] –0.4%, $P<.001$ vs –0.3% in the control group [n=53], $P=.001$) and in FPG after 6 weeks (mean change in the intervention group –5.3 mg/dL, $P=.01$ vs control group –5.8 mg/dL, $P=.01$). At 12 weeks, the intervention group also showed significant reductions in systolic and diastolic blood pressures (mean change –4.5, $P=.049$ and –2.4 mmHg, $P=.03$, respectively), body weight (mean change –0.8 kg, $P=.03$), BMI (mean change –0.3 kg/m2, $P=.03$), waist circumference (mean change –1.0 cm, $P=.046$),

XSL•FO
RenderX

and triglyceride concentration (mean change –20.0 mg/dL, *P*=.03). There was also a significant increase in high-density lipoprotein-cholesterol concentrations (mean change 2 mg/dL, *P*=.049). Finally, improvements were noted in 3 out of the 5 elements of balance: positivity, social environment, and work-life balance.

Conclusions: The 12-week intervention with the Greenhabit behavioral treatment mHealth app showed beneficial effects on T2D outcomes and reduced the burden of cardiovascular risk factors. Although larger studies are warranted, these results suggest that mHealth apps can be a promising tool for improving T2D self-management.

Introduction

Diabetes is a chronic metabolic disease characterized by hyperglycemia, which results from defects in insulin secretion, insulin action, or both [1,2]. Over time, this condition leads to severe complications, contributing to significant morbidity and mortality worldwide [3].

According to the World Health Organization, diabetes remains a critical public health issue, with 422 million people affected in 2014. The global prevalence of diabetes is steadily increasing, with projections estimating 570 million cases by 2030 and 700 million by 2045, largely driven by rising rates of overweight and obesity [4]. The growing prevalence of type 2 diabetes (T2D) and the expanding population affected underscore an urgent need to develop novel strategies for diabetes treatment, treatment adherence, lifestyle modifications, and care. The rising prevalence of T2D places a significant strain on health care systems, highlighting the importance of empowering individuals to manage their conditions effectively [5]. Consequently, numerous mobile health (mHealth) apps have been developed as innovative tools to enhance self-management of T2D and prevent macrovascular and microvascular complications [6-12].

Patients with T2D require effective diabetes control and self-management skills to adopt a healthier lifestyle. Self-management encompasses daily activities aimed at controlling or reducing the disease's impact on health and well-being, including monitoring blood glucose levels, managing food intake, engaging in physical activity, and managing stress [13]. mHealth apps play a pivotal role in achieving glycemic control, encouraging lifestyle modifications, and promoting self-management among individuals with T2D [14]. Recent research highlights the growing adoption of these apps for managing treatment and care among this population [13]. They empower self-management by supporting dietary adherence, consistent blood sugar monitoring, regular physical activity, reduced medication needs, and lower glycated hemoglobin (HbA_{1c}) levels [15,16]. Additionally, they help reduce face-to-face counseling time and health care expenses [17].

Currently, a wide range of mHealth apps is available to enhance self-management for individuals with diabetes. These apps facilitate close monitoring, provide feedback, and help overcome geographic barriers [14]. Furthermore, a systematic review and meta-analysis have demonstrated the effectiveness of mHealth apps in empowering self-management across various domains of disease management and lifestyle changes [18]. Additionally, the American Diabetes Association guidelines advocate for the use of mHealth apps as a valuable tool for achieving effective lifestyle changes in diabetes prevention [19]. However, the lack of consensus on the definition of self-management interventions for chronic diseases [20,21], combined with diverse outcome measures—such as self-efficacy, health-related quality of life, activity participation, performance of daily living activities, depression, and self-confidence [22]—poses challenges in comparing interventions and interpreting results. Greenhabit is a holistic education program that empowers individuals to take control of their health by fostering sustainable behavior change. Its approach, which addresses the physical, mental, and social aspects of well-being, promotes mental resilience and self-awareness [23]. The Greenhabit method is grounded in 2 key theories: (1) the *McClelland Iceberg model*, which serves as a framework for building content, challenges, and measures for users [24]; and (2) the *Behavioral Change Wheel*, which informs the development of interventions and techniques within Greenhabit [25]. Social integration (through buddies and community) provides motivation and social support to help maintain healthy habits. It encourages individuals to take care of their health by offering nudges related to nutrition, physical activity, and social interactions, all aimed at promoting overall well-being. The game/app incorporates serious gaming technology. The vitality education program is a 12-week journey in which players focus on the 5 elements of Greenhabit: nutrition, exercise, relaxation, positive mindset, and social environment. It leverages the power of brain-based learning through methods such as nudges, content, challenges, rewards, working with a buddy, and engaging the senses with joy. The brain is plastic, allowing us to learn new habits. It takes at least 68 days to establish new habits [26]. After 12 weeks, players report increased awareness, resilience, and energy.

Thus, the primary aim of this study was to assess the efficacy of the Greenhabit app on T2D outcomes, specifically plasma glucose concentrations and HbA_{1c} levels, in patients with a recent diabetes diagnosis. As a secondary aim, we evaluated whether participation in the app led to improvements in blood pressure (BP), plasma lipids, adiposity parameters, and the maintenance of a healthy lifestyle after 12 weeks of use.

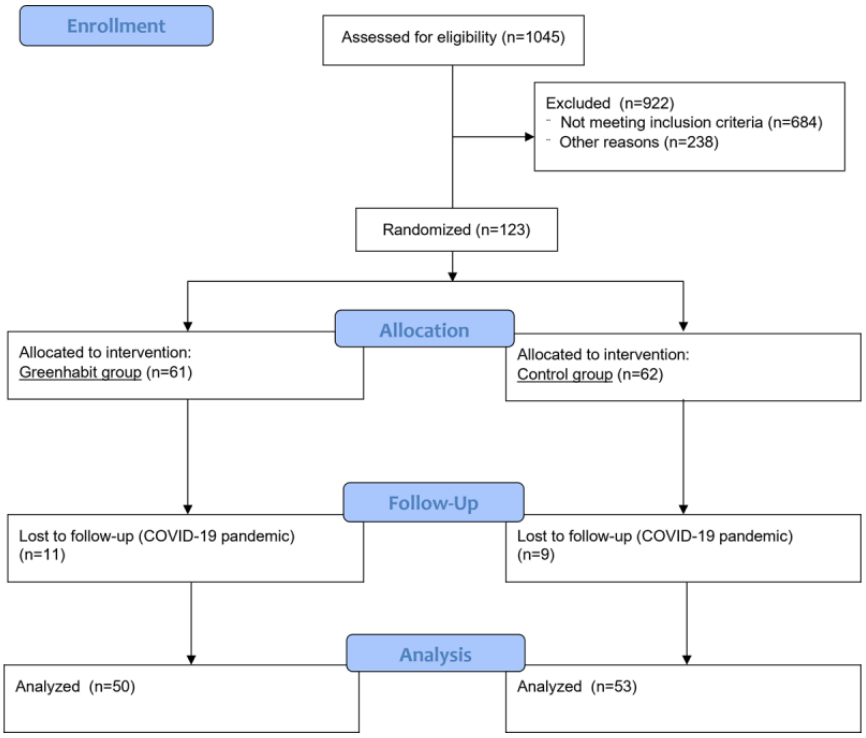
Methods

Study Design

This study is a 12-week, parallel-group, single-blind, single-center, randomized controlled trial (RCT) designed to assess the efficacy of the Greenhabit method on diabetes treatment and management. The intervention, a low-intensity self-management program, focuses on behavior change and incorporates evidence-based approaches to diabetes self-management education and support [27]. The diabetes specialist dietitian and nurse applied principles of motivational interviewing, including a person-to-person, client-centered approach aimed at eliciting behavior change by helping patients explore and resolve ambivalence. Additionally, a successful telephonic intervention, proven to improve diabetes control in urban adults, was incorporated.

Consecutive candidates were randomly assigned to either the intervention or control group after sex stratification, with an allocation ratio of 1:1.



Outcomes

The primary outcome of the trial was the management of T2D, measured by HbA_{1c} and fasting plasma glucose (FPG) concentrations at 12 weeks. The secondary outcomes included the effect of the intervention on cardiovascular risk factors, such as BP, lipid profile, body weight (BW), and adiposity, as well as its impact on dietary habits, stress relief, and psychological factors, assessed using validated questionnaires.

Setting and Participants

As shown in Figure 1, from July 2021 to March 2022, we screened 1045 potential candidates from the databases of primary care centers affiliated with Hospital Clínic of Barcelona, Spain. Of the screened participants, 684 were excluded for not meeting the inclusion criteria of a recent T2D diagnosis, while 238 were excluded for various other reasons: 179 had limited ability to use a smartphone, 48 had a severe chronic disease, 5 faced language barriers, 4 lacked a smartphone, and 2 had difficulty following an appropriate diet. Finally, 123 participants were recruited through a face-to-face interview and randomized, with 61 assigned to the Greenhabit group and 62 to the control group. Randomization was carried out by consecutively assigning participants using sealed envelopes, which were prepared based on a computer-generated random number table. Of these participants, 20 were withdrawn from the trial because they could not attend follow-up visits during the COVID-19 pandemic. As a result, 50 participants in the intervention group and 53 in the control group completed the study.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram of the Greenhabit 12-week randomized controlled trial.

Inclusion criteria were as follows: men and women aged 18-75 years, with a recent diagnosis of T2D (<2 years of treatment with insulin, antidiabetic medications, a combination of both, or a nonpharmacological treatment), and either an HbA_{1c} greater than 6.5%, FPG greater than 126 mg/dL on 2 occasions, or a 2-hour plasma glucose greater than 200 mg/dL after a 75-g oral glucose load.

Exclusion criteria included participants who underwent or planned bariatric surgery during the trial period; individuals with type 1 diabetes; those with a diagnosis of gestational diabetes; and individuals with severe chronic illnesses, alcoholism, or other drug addictions. Also excluded were participants with gastrointestinal diseases that would hinder adherence to a specific diet, those who had taken vitamins or nutritional supplements in the month before recruitment, pregnant women, individuals without their own smartphone,

XSL•FO
RenderX

those unable to attend additional visits, and those already participating in another trial.

Ethics Approval and Consent to Participate

Before starting the study, all participants provided informed consent during a face-to-face interview with the researcher. The study protocol and procedures were approved by the Committee for Ethical Research at Hospital Clínic (Barcelona, Spain) on April 19, 2021, and adhere to the ethical standards of the Declaration of Helsinki. The study was registered with the following code: HCB/2021/0061. The trial was also registered with the International Standard Randomized Controlled Trial Number registry (ISRCTN13456652).

Intervention

Participants in the intervention group were instructed to follow standard care recommendations, similar to the control group, and were provided with personalized, free access to the Greenhabit app via email. Additionally, they received a second free access for a partner (eg, sibling, friend, spouse) to offer extra motivation and mutual support. Participants could choose whether or not to use this second access. Each week, 3-4 days before starting the Greenhabit intervention, participants, grouped into teams of 10-12 individuals, were invited to attend an online group meeting. The purpose of these meetings was to teach participants how to use the app and address any potential technological barriers. Participants could invite friends or colleagues to join their journey for free; these invited individuals could only view the photos selected by the participants. Additionally, participants were encouraged to set weekly goals and log their measurements (eg, steps walked, weight, glucose levels, HbA_{1c}). Each day, participants received a "treasure chest" from Greenhabit, containing messages and challenges related to healthy lifestyle habits (nutrition, exercise, relaxation, positive thinking, and social environment). Participants earned points for each challenge they completed. Various rewards, such as a water bottle for tracking intake, a jump rope, a notebook, and card games, were given throughout the 12-week program upon completing each level.

Participants in the control group received guidance on maintaining a healthy diet and were given written materials prepared by a dietitian. These materials included information on seasonal Mediterranean foods, shopping lists, weekly meal plans, and recipes for a typical week. Additionally, participants in this group received standard care through their primary care center. Usual care included routine health care appointments with providers, as well as access to diabetes management and weight loss education, electronic learning materials, and guidance on how to use the health system's patient portal [28]. The main goal was to equip participants with the skills needed to maintain or improve their health.

Greenhabit Behavioral Treatment Program

The Greenhabit program is a 12-week mHealth cognitive-behavioral education initiative designed specifically to support individuals in managing T2D. Greenhabit is a behavioral change program in which patients receive personalized content (interventions) based on their clinical profile through a recommender system. This system leverages an artificial intelligence–based infrastructure to promote personalized lifestyle changes. Additional information about the questionnaires used can be found in Supplementary Methods S1 in Multimedia Appendix 1 (see also [23-25,29-34]).

Diet and Clinical Measurements

All participants underwent a face-to-face interview with the dietitian at baseline and after 12 weeks of intervention, along with regular phone calls. During these individual sessions, each participant received information on seasonal foods, shopping lists, weekly meal plans, and cooking recipes. Additionally, the individual interviews included a 151-item validated Food Frequency Questionnaire [35] and personalized recommendations for dietary changes aimed at achieving the participant's goals. Participants also completed a 47-item questionnaire on education, lifestyle, medical history, and medication use. To assess adherence to the Mediterranean diet, a validated 14-point Mediterranean diet screener was used [36]. In the intervention group, participants were encouraged to increase their intake of vegetables (≥2 servings/day), fresh fruit (≥3 servings/day), legumes, nuts, and fish or seafood (≥3 servings/week), and to use olive oil for cooking and dressings. The app also promoted physical activity. Energy restriction was not specifically advised for either group.

At baseline (visit 1), 6 weeks (visit 2), and 12 weeks (visit 3), trained personnel (consistently the same dietitian and nurse) collected anthropometric measurements, determined BP, and took biological samples. Height was measured to the nearest 0.1 cm using a wall-mounted stadiometer with participants standing, wearing socks, and with their heads in the horizontal plane. BW was measured to the nearest 0.1 kg, with participants in light clothing and without shoes or accessories, using a high-quality calibrated scale. BMI was calculated by dividing weight (kg) by the square of height (m^2). Waist circumference (WC) was measured midway between the lowest rib and the iliac crest using an anthropometric tape. Hip circumference (HC) was measured at the maximum point below the waist, without compressing the skin [37]. BP was measured in triplicate after at least 5 minutes of rest using a validated semiautomatic oscillometer (Omron HEM-705CP). The mean value of the 3 BP measurements was used in this study. A medical record was also collected. Fasting blood and spot urine samples were obtained for basic hematologic and biochemical analyses for all participants, including HbA_{1c}, glucose, and lipid profile parameters. Additionally, the nurse provided diabetes self-management support to patients as needed.

Technicians and nurses were blinded to the group assignment of each participant.

Quality-of-Life Questionnaires

At baseline and after 12 weeks, participants completed several questionnaires to assess perceived physical and mental health over time, focusing on various aspects of health-related quality of life, including energy, happiness, positivity, social environment, and work-life balance. Additional details about the tests used can be found in Supplementary Methods S1 in Multimedia Appendix 1.

XSL•FO
RenderX

Validity and Reliability

Blood samples were collected at baseline and at the end of the intervention to determine biochemical and nutritional parameters. Hemoglobin was measured by high-performance liquid chromatography, blood glucose by the glucose oxidase method, and total cholesterol and triglycerides by enzymatic procedures. High-density lipoprotein (HDL) cholesterol was assessed after precipitation with phosphotungstic acid and magnesium chloride. All analyses were performed using the Advia 2400 clinical chemistry analyzer (Siemens Healthcare), with reagents provided by the instrument manufacturer. The main outcomes of the trial (HbA_{1c} and FPG levels) were determined at the CORE Laboratory at Hospital Clinic de Barcelona, which meets all required quality standards and holds ISO 9001:2015 certification and ISO 15189 accreditation for certain tests.

The instruments used for dietary assessment are both validated and have been utilized in large randomized clinical trials and cohort studies (see [35,36]).

Regarding quality of life, all the questionnaires are detailed in Supplementary Methods S1 in Multimedia Appendix 1. These questionnaires are divided into 5 components: energy, happiness, positivity, social life, and work-life balance. To assess these components, we used validated questionnaires tailored to the Spanish population, and further details of these questionnaires are extensively presented in Multimedia Appendix 1. In brief, the International Physical Activity Questionnaire, in its Spanish version, was used to assess physical activity [38,39]. The 36-item Short Form Health Survey was used to measure quality of life. This generic scale is applicable to both patients and the general population, providing a comprehensive profile of health status. The questionnaire includes 8 scales: Physical Function, Physical Role, Body Pain, General Health, Vitality, Social Function, Emotional Role, and Mental Health. The Spanish version is a validated instrument, suitable for both medical research and clinical practice [40]. The Hospital Anxiety and Depression Scale is a validated, rapid self-assessment screening tool. Although not intended for diagnostic purposes, it is highly convenient for evaluating anxiety and depression in patients with somatic or mental health issues [41]. This test has been widely used in patients with T2D [42]. Additionally, the Life Orientation Test assesses the psychometric properties of an optimism scale and has been adapted for the Spanish population using the multidimensional graded response model. This 10-item scale evaluates an individual's life expectations, including 3 positive and 3 negative items. The test has also been widely used in individuals with T2D [43]. Finally, the Duke-UNK Functional Social Support Questionnaire is an objective tool that measures "perceived functional social support." It is a self-administered, validated instrument for the Spanish population [44].

Statistical Analysis

The total number of participants included was 123. Power calculations, based on an estimated intervention-induced intergroup difference of 0.8% in HbA_{1c} with an SD of 2.75, indicated that 104 individuals were needed to detect a statistically significant difference of .05 units (α risk=.05 and β risk=.2 in a bilateral test). A follow-up loss rate of 10% was anticipated. A reduction in HbA_{1c} greater than 0.5% is considered clinically significant, as diabetes-related complications are directly proportional to blood HbA_{1c} levels [45].

We used descriptive statistics, presenting the mean (SD) for the baseline characteristics of the participants. Categorical variables are expressed as percentages. For baseline characteristics, the Pearson chi-square test was used for categorical variables, and 1-way analysis of variance (ANOVA) was applied for continuous variables to compare between groups. Differences in biochemical parameters, anthropometric measures, food, and nutrient intake at baseline, 6 weeks, and 12 weeks of intervention were assessed using ANOVA. Changes in biochemical parameters and anthropometric variables after 6 and 12 weeks of intervention were assessed using analysis of covariance (ANCOVA), adjusting for baseline levels of each variable, age, sex, use of hypoglycemic treatment (yes/no), and BMI. BMI was categorized according to World Health Organization classifications: normal weight (<25 kg/m^2), overweight (25 to <30 kg/m^2), obesity class 1 (30 to <35 kg/m^2), obesity class 2 (35 to <40 kg/m^2), and obesity class 3 (≥40 kg/m^2). Significant interactions were analyzed using simple-effect analysis, and multiple contrasts were adjusted using a Bonferroni post hoc test. Within- and between-group differences were expressed as estimated means with 95% CIs. The significance level was set at $P<.05$. All analyses were conducted using SPSS version 20.0 (IBM Corp.).

Results

Study Population

Of the 123 participants assessed (Figure 1; Multimedia Appendix 2), 31 in the Greenhabit group (n=61, 51%) and 31 in the control group (n=62, 50%) were female. The mean BMI was 31.8 (SD 6.14) kg/m^2 for the Greenhabit group and 32.4 (SD 6.49) kg/m^2 for the control group. Participants in the Greenhabit group were slightly younger, with a mean age of 56.0 (SD 10.8) years, compared with 60.5 (SD 8.11) years in the control group. No significant between-group differences were observed (Table 1).

XSL•FO
RenderX

No changes in medication (glucose-lowering agents) were reported after the 12-week intervention, and no comorbidities associated with T2D were observed.

Blood Pressure, Cardiovascular Risk Factors, and Adiposity

Table 2 (adjusted variables) and Table S1 in Multimedia Appendix 1 (unadjusted variables) present baseline values and changes in anthropometric measures and cardiovascular risk factors at 6 and 12 weeks by the intervention group. Participants in both groups showed reductions in systolic BP at 12 weeks (P=.049 and P=.02 in the intervention and control groups, respectively), FPG at 6 weeks, and HbA_{1c} at both 6 and 12 weeks (P<.001 for both). At 6 weeks, participants in the intervention group demonstrated a significant improvement in diastolic BP (P=.007). By 12 weeks, they also showed significant reductions in triglyceride concentrations (P=.03), BW (P=.03), BMI (P=.03), WC (P=.046), and HC (P=.049), along with a significant increase in HDL-cholesterol levels (P=.049).

XSL•FO
RenderX

Table 2. Changes in blood pressure, cardiovascular risk factors, and adiposity, at baseline and after 6 and 12 weeks of follow-up in the 2 study groups of the Greenhabit randomized controlled trial[a].

Variables	Greenhabit (n=50)	Control (n=53)	Differences between groups (Greenhabit vs control)
Systolic blood pressure (mmHg)			
Baseline	141.3 (19.5)	142.5 (18.5)	N/A[b]
Changes after 6 weeks	–3.7 (–8.0 to 0.5)	–1.8 (–5.9 to 2.3)	4.0 (–7.6 to 15.6)
Changes after 12 weeks	–4.5 (–9.0 to 0.0)[c]	–5.0 (–9.4 to –0.7)[c]	1.3 (–10.2 to 12.8)
Diastolic blood pressure (mmHg)			
Baseline	84.9 (10.6)	81.2 (10.1)	N/A
Changes after 6 weeks	–2.9 (–5.0 to –0.8)[c]	0.5 (–1.5 to 2.5)	–6.3 (–11.3 to –1.3)[d]
Changes after 12 weeks	–2.4 (–4.4 to –0.3)[c]	–0.4 (–2.5 to 1.6)	–3.5 (–8.9 to 1.8)
Fasting plasma glucose (mg/dL)			
Baseline	125.7 (29.1)	132.4 (38.0)	N/A
Changes after 6 weeks	–5.3 (–9.6 to –1.0)[c]	–5.8 (–10.1 to –1.5)[c]	–0.09 (–9.0 to 8.8)
Changes after 12 weeks	–4.0 (–9.3 to 1.2)	–1.4 (–6.5 to 3.6)	–2.7 (–14.3 to 8.9)
Glycated hemoglobin (%)

[a]Values are expressed as mean (SDs) or mean differences (95% CI). Comparisons between groups with 1-way analysis of variance and comparisons between groups after 6 and 12 weeks of intervention with analysis of covariance adjusted for baseline levels of each variable, age, sex, use of hypoglycemic treatment (yes/no), and BMI are presented.

[b]N/A: not applicable.

[c]*P*<.05 between before and after the intervention.

[d]*P*<.05 between-group changes.

[e]*P*<.001 between before and after the intervention.

[f]BMI was classified according to the World Health Organization categories: normal weight: <25 kg/m^2; overweight: 25 to <30 kg/m^2; obesity class 1: 30 to <35 kg/m^2; obesity class 2: 35 to <40 kg/m^2; and obesity class 3: ≥40 kg/m^2.

Dietary Intake of Key Foods and Nutrients

As shown in Table S2 in Multimedia Appendix 1, after 12 weeks of intervention, the Greenhabit group exhibited significant increases in the consumption of virgin olive oil (*P*<.001), nuts (*P*=.008), and legumes (*P*=.04). By contrast, the control group experienced a significant reduction in vegetable intake (*P*=.02), along with a significant increase in the consumption of refined cereals (*P*=.049), red wine (*P*=.001), and pastries, cakes, or sweets (*P*=.02). The 14-item Mediterranean Diet adherence score improved by 0.4 points in the intervention group after 12 weeks; however, this increase did not reach statistical significance (*P*=.16).

Regarding nutrient intake (Table S3 in Multimedia Appendix 1), the intervention group showed a significant increase in the consumption of total fat (*P*=.049) and monounsaturated fatty acids (*P*=.009). Between-group comparisons confirmed that the intervention group had higher consumption of total fat and monounsaturated fatty acids compared with the control group (*P*=.02 and *P*=.01, respectively).

Adherence to the Greenhabit Intervention

The data from the app revealed that users spent an average of 8 minutes per day online, with participants achieving an average of 372 challenges over the 12-week period. Based on the app data for each Greenhabit participant, dietitians offered personalized nutritional and lifestyle advice to address areas where participants scored lower.

As shown in Table 3 and Table S4 in Multimedia Appendix 1, the control group experienced a significant reduction in perceived social support (*P*<.001), along with a significant increase in anxiety (*P*=.03) and body pain perception (*P*=.049). By contrast, the intervention group demonstrated an improvement in social functioning.

[a]Values are expressed as mean (SDs) or mean differences (95% CI). Comparisons between groups with 1-way analysis of variance and comparisons between groups after 6 and 12 weeks of intervention with analysis of covariance adjusted for baseline levels of each variable are presented.

[b]N/A: not applicable.

[c]$P<.05$ between before and after the intervention.

Finally, physical activity significantly increased in both groups, but only the International Physical Activity Questionnaire test revealed significant changes in MET-walked minutes per day for participants in the intervention group ($P=.048$).

Data from the app are presented in Figure S1 in Multimedia Appendix 1. After 12 weeks, all participants in the Greenhabit group showed improvements in their quality of life: increase in energy (10/76, 13%), happiness (11/85, 13%), positivity (14/78, 18%), social engagement (7/81, 9%), and work-life balance (6/62, 10%).

Participant Retention

Notably, of the 61 participants, 46 (75%) used the app, with 38 using it daily and participating in the challenges offered. Among the 46 active participants, 15 exhibited intermittent use of the app. The data provided by the app revealed that the average daily time spent online was 8 minutes, and the average number of challenges completed during the 12 weeks was 372.

Discussion

Principal Findings

The primary goal of our RCT was to evaluate the effectiveness of the Greenhabit method in promoting self-management and self-care among patients aged 18-75 years recently diagnosed with T2D. Significant improvements in HbA_{1c} and FPG concentrations were observed in both the intervention and control groups at 6 and 12 weeks. However, notable between-group differences were evident in secondary outcomes, particularly in WC after 12 weeks. Additionally, the Greenhabit group showed significant improvements in BP, triglycerides, HDL-cholesterol, BW, HC, and overall quality of life following the 12-week intervention period.

Notably, the Greenhabit app proved more effective in significantly reducing anxiety, fostering positive emotions, improving coping with body pain, and enhancing participants'

XSL•FO
RenderX

perception of health. By contrast, the control group showed either no improvement or worsening trends in these areas.

Changes in T2D Parameters

Results indicate that telemedicine, particularly through the Greenhabit app, effectively reduced FPG and HbA_{1c} levels within 6 weeks of intervention, with these effects sustained at 12 weeks. However, no significant differences were found between the intervention and control groups. The app's visual representation of blood glucose values may have contributed to participant motivation.

Comparison with other studies showed similar HbA_{1c} reductions in the intervention group, but no significant differences between groups [46,47], suggesting that the app alone may not drive sufficient lifestyle changes, at least in the short term. The effectiveness may be enhanced through health care provider support and a personalized follow-up plan, which many patients may require to achieve their goals [48]. Several factors may explain the lack of differences in HbA_{1c} levels between groups as the primary outcome. The Hawthorne effect, where awareness of being observed influences behavior, may have led to improved self-management in both groups [49]. Additionally, baseline HbA_{1c} levels below 8% and the potential for increased attention from general practitioners during the RCT could have influenced the outcomes [50,51].

In patients with T2D, diet and exercise play a vital role in glycemic control and the prevention of cardiovascular risk [26,52-55]. However, conventional education may be insufficient to improve self-care, as patients with T2D often resist changing unhealthy behaviors [56]. This point will be explored further later.

It is important to highlight that the high costs associated with T2D are often due to the condition being accompanied by additional health-related complications. Moreover, health-related quality of life has been found to be significantly lower in individuals with T2D-related complications compared with those without such complications [57]. A 1% reduction in HbA_{1c} has been reported to significantly decrease microvascular and macrovascular complications in patients with T2D [58]. In our study, the intervention group showed a reduction in HbA_{1c} below 7%, which is associated with maximum cardiovascular benefits [59]. After 12 weeks, we hope participants will feel more aware, resilient, and energized, enabling them to maintain these habits long-term, though this would require further evaluation.

Changes in Cardiovascular Risk Factors

Remarkably, the mHealth intervention with Greenhabit led to improvements in cardiometabolic parameters, including systolic and diastolic BP, triglycerides, and HDL cholesterol, as well as adiposity indicators such as BMI, WC, and HC after the 12-week intervention. These findings are consistent with those of Hamaya et al [60], who reported significant reductions in BW and HbA_{1c} and an increase in HDL-C among 12,602 healthy participants (mean age 44.1 years, SD 10.2 years) using the Kencom mHealth app. A Chinese meta-analysis [61] and a recent systematic review [62] indicated that mHealth app interventions were associated with significant improvements in metabolic measures (HbA_{1c}, BW, BP, lipid profile, and physical activity) in patients with T2D. This suggests that mHealth apps, even when used by older individuals, can provide valuable support to enhance diabetes self-care and thereby improve clinical outcomes.

Cognitive and Behavioral Improvements

Participants in the intervention group reported a more positive outlook, improved coping with body pain, and favorable changes in their perception of health. These positive outcomes are attributed to the social support provided by the app environment, including the role of supportive peers and the broader social network. While no changes in social aspects were observed in the intervention group, the control group showed a significant decrease. Notably, there were differences between the groups in terms of anxiety, with a tendency to decrease in the intervention group and an increase in the control group. This aligns with previous findings suggesting that implementing support mechanisms can reduce anxiety [63,64].

The primary objective of this mHealth app targeting anxiety or depression is centered around cognitive-behavioral education. The Greenhabit method is based on educating individuals to cultivate enduring habits. By adopting a holistic approach that encompasses physical, mental, and social dimensions, it fosters resilience and self-awareness, thereby promoting the adoption of healthy habits. Moreover, fostering social engagement empowers individuals to take control of their health. Human interactions, particularly with medical physicians or health care professionals, along with the provision of social support and an appealing mHealth app interface, play pivotal roles in enhancing compliance, adherence, dropout rates, and treatment efficacy [12]. First, the combination of automatic information through the Greenhabit app, face-to-face visits with a dietitian, and regular phone calls during the 12-week intervention likely contributed to maintaining healthy behaviors such as diet. Furthermore, the critical support provided by nurses proved invaluable when participants encountered personal difficulties. The nurse served as a supporter, helping to motivate the patients. Interactions also created accountability, focus, and awareness of how behaviors impacted the participants' health. Thus, the combination of nursing assistance and the mHealth app demonstrated short-term effectiveness in enhancing diabetes self-efficacy and significantly increasing physical activity within the intervention group. These support mechanisms may explain the observed reductions in FPG and HbA_{1c} levels, as well as improvements in anxiety and general health status. The interaction with health care providers and the use of devices seem to enhance feelings of support for some individuals [65]. Second, while the influence of social support and its resultant outcomes may resemble those observed in conventional standards of care, a distinguishing characteristic of the digital social support offered by this mHealth app is the provision of anonymity and accessibility. The capability to exchange comparable lived experiences of anxiety or depression among peers, coupled with being accountable to an authoritative figure (eg, health care professional) for symptom monitoring or assessment, holds the potential to bolster engagement and

XSL•FO
RenderX

adherence to the mHealth app. Finally, the Greenhabit app demonstrates attributes of easy navigation, relatability, engagement, and aesthetic appeal, ensuring greater user engagement.

Adherence to the Intervention

The observation that not all participants consistently used the app (46/61) concurs with findings from Torbjørnsen et al [66], indicating varying acceptability of T2D self-management apps based on factors such as sex, age, education, expectations, and ease of use. Some participants viewed the app as more of a time-waster than a helpful tool, citing forgetfulness or excessive time requirements. Despite this, most participants expressed satisfaction (43/49, 88%) and considered the app useful (42/49, 86%), noting that it established new routines resulting in an improved lifestyle.

Influence of the mHealth App on Diabetes Self-Management and Treatment

The level of self-management may vary between individuals with T2D and those with type 1 diabetes, potentially influenced by treatment intensity and the necessity for regular blood glucose monitoring, particularly among insulin-dependent individuals [67]. To underline, most of our participants indicated that they were already self-monitoring their blood glucose levels at the outset of the study, implying a preexisting engagement in self-management practices regardless of insulin use.

To achieve a meaningful improvement in HbA_{1c} levels and cardiovascular risk factors in participants with T2D through self-management interventions, it is essential to first enhance healthy eating habits, promote engagement in physical activity, and ensure consistent adherence to medication. It is well-known that patients with T2D usually show higher resistance to changing their unhealthy behaviors, particularly when it comes to increasing physical activity and improving dietary habits [13,26]. It has been demonstrated that physical activity may contribute to a 30%-50% reduction in the development of T2D [68]. While both groups showed similar changes in T2D management strategies, including diet and physical activity, only the intervention group demonstrated a significant improvement in exercise. The control group did not show significant improvement in overall diet and displayed reduced adherence to the Mediterranean Diet. These findings are consistent with those of other studies [53-55].

Neither significant differences in dietary habits were noted between the intervention and control groups nor were significant changes observed in dietary habits after 12 weeks. This may be attributed to limited app usage, consistent with findings by Agarwal et al [11], and the inherent challenges in altering dietary habits influenced by external (food industry) and internal (long-term preferences) factors [69]. Additionally, participants using the Greenhabit app had to manually input data, which posed a barrier for some, leading to dropouts, including those aged 60 years and above and younger individuals who never used the app. A Norwegian RCT reported preferential app usage by older compared with younger participants [12].

However, the acquisition and maintenance of a healthy lifestyle, based on a healthy dietary pattern and physical activity programs, could be insufficient. As the intrinsic motivation of participants plays a key role, it may be recommended to include a motivational approach to bring about behavioral change [56]. Participants allocated to the Greenhabit group are more aware of what they eat and the daily exercise they perform, which may explain better control of the disease.

Chronic diseases carry severe consequences, including reduced quality of life, health emergencies, complications, and death [70]. Managing them poses significant challenges and costs for health care systems globally, with chronic diseases accounting for 71% of all deaths annually [71]. These diseases exacerbate inequality, disproportionately affecting socially disadvantaged individuals and hindering poverty reduction efforts [30]. Improving patients' health not only enhances their quality of life but also alleviates societal economic burdens. Effective management relies on understanding the impact of chronic diseases on patients' daily lives and empowering them to self-manage and make informed decisions [14]. This approach aligns with national health care strategies emphasizing personalized medicine and self-management [72]. Patient empowerment involves actively engaging in health responsibilities and promoting meaningful involvement in treatment decisions [70]. In this regard, mHealth emerges as a cost-efficient tool to support self-management and foster empowerment.

Limitations and Strengths

The study's primary strength lies in its design as an RCT, which allows for causal inference. Other strengths include a sizable and diverse sample (ages 18-75 years, gender-balanced), standardized data collection conditions for anthropometric and blood measurements, and the option for participants to involve a mate in app usage for mutual support. The app's holistic approach—addressing diet, physical activity, positive thinking, relaxation, and social aspects—distinguishes it from other mHealth strategies. This comprehensive strategy potentially explains its success in reducing cardiovascular risk factors. Our study stands as one of the few RCTs that specifically investigated the impact of using a mobile phone app as a digital diabetes diary to enhance quality of life.

Our study also has limitations. It was short-term (12 weeks) and conducted in a single center, which means findings may not be generalizable to non-T2D populations and could be subject to selection bias among patients with T2D. Additionally, technological challenges, particularly for older individuals, could hinder the app's use as a public health strategy. Furthermore, individuals from low-resource areas may struggle to access smartphone technology due to associated costs, in both acquiring the device and downloading paid apps. Additionally, selection bias occurred because participants were required to possess a smartphone. These financial barriers can limit access to mHealth interventions, exacerbating inequalities in health care access. The findings might not be applicable to cohorts with lower levels of motivation or limited technological knowledge. The observed increase in skill and technique acquisition may imply a heightened capability among participants to alleviate symptoms related to T2D and effectively manage their overall health. This enhancement may encompass

XSL•FO
RenderX

improved utilization of technical aids. Although our study did not incorporate a specific health education impact questionnaire, the integration of validated health-related quality-of-life assessments could provide valuable insights into the observed improvements in self-management abilities. Finally, while HbA_{1c} is crucial for long-term glycemic control, the exclusion of glycemic variability assessment limits a comprehensive understanding of glycemic status. Combining HbA_{1c} and glycemic variability could enhance diabetes management strategies [3]. More RCTs with longer follow-up times should be conducted to evaluate the long-term effect of diabetes-related mobile apps on glucose control and quality of life and to confirm that the outcomes seen in initial studies are sustainable over time.

Conclusions

Chronic illnesses can have significant consequences, often necessitating patients to depend on lifestyle choices and effective coping strategies for management. Self-management, which empowers patients to take control of their own health, is crucial. Studies on self-management highlight the importance of patient empowerment, enhancing their autonomy in health-related decisions. mHealth offers an economical means to enhance self-management and empower individuals. The integration of the Greenhabit app into clinical practice has the potential to positively impact glycemic control, reduce anxiety, and improve overall health status in individuals with T2D. Therefore, the Greenhabit app could be an additional supportive tool in the comprehensive management of patients with T2D within clinical settings.

The use of tailor-made interventions supported by an artificial intelligence–based infrastructure to enhance health and achieve sustainable behavior change represents a significant and promising approach for T2D self-management. However, larger studies are required to validate the effectiveness of these interventions.

Acknowledgments

We thank all the volunteers who participated in the study. We also express our gratitude to Giulia Maria Antonietta Trevisan for her assistance in the development of the project. We would also like to extend our sincere gratitude to the team of Logmeal, Marc Bolaños, and Eric Verdaguer for their dedicated support and collaboration on the project which was instrumental to the success of this study. CIBERobn is an initiative of the Instituto de Salud Carlos III, Spain. The Institut de Recerca en Nutrició i Seguretat Alimentaria (INSA-UB), University of Barcelona, Barcelona, Spain, is recognized as a Maria de Maeztu Unit of Excellence (grant CEX2021-001234-M), funded by MICIN/AEI/FEDER, UE. This work was fully supported by EIT Digital 2021 (21105). SCB received support from the University of Barcelona through the Margarita Salas postdoctoral fellowship. The funders had no role in the design or conduct of the study; the collection, management, analysis, or interpretation of the data; or the preparation, review, or decision to submit the manuscript for publication.

Data Availability

Data availability for the Greenhabit trial is restricted due to signed consent agreements, which permit data sharing only with external researchers conducting studies aligned with the project's aims. Researchers interested in accessing the Greenhabit trial data used in this study may contact the corresponding author.

Authors' Contributions

RC, PR, and RE contributed to the conceptualization of the study. AMRL, RC, SCB, SAG, FCG, ES, and APG were responsible for the methodology and investigation. Validation, review, and editing of the manuscript were carried out by AMRL, RC, SCB, PR, and RE. Formal analysis and original draft preparation were conducted by AMRL, RC, and SCB. PR provided resources and secured funding. Data curation was performed by RC, SCB, and RE, while RC and RE supervised the study. RC and RE contributed equally to this work and should be considered co-corresponding authors.

Conflicts of Interest

RE reports receiving grants from the Fundación Dieta Mediterránea (Spain) and Cerveza y Salud (Spain), as well as personal fees for lectures from Brewers of Europe (Belgium), the Fundación Cerveza y Salud (Spain), Pernod Ricard (Mexico), Instituto Cervantes (Albuquerque, United States), Instituto Cervantes (Milan, Italy), Instituto Cervantes (Tokyo, Japan), Lilly Laboratories (Spain), and the Wine and Culinary International Forum (Spain). Additionally, RE received nonfinancial support for organizing a National Congress on Nutrition and for feeding trials with products from Grand Fountain and Uriach Laboratories (Spain). The remaining authors have no conflicts of interest to declare.

Abstract

Background: Despite the increasing popularity of electronic devices, the longitudinal effects of daily prolonged electronic device usage on brain health and the aging process remain unclear.

Objective: The aim of this study was to investigate the impact of the daily use of mobile phones/computers on the brain structure and the risk of neurodegenerative diseases.

Methods: We used data from the UK Biobank, a longitudinal population-based cohort study, to analyze the impact of mobile phone use duration, weekly usage time, and playing computer games on the future brain structure and the future risk of various neurodegenerative diseases, including all-cause dementia (ACD), Alzheimer disease (AD), vascular dementia (VD), all-cause parkinsonism (ACP), and Parkinson disease (PD). All the characteristics of using mobile phones and playing computer games were collected through face-to-face interviews at baseline, and outcomes were extracted from the algorithmic combinations of self-reported medical conditions, hospital admissions, and death registries. In addition, a group of participants underwent magnetic resonance imaging (MRI) at follow-up. Cox regression and linear regression were performed.

Results: The study included over 270,000 participants for risk analysis, with a mean baseline age of approximately 55.85 (SD 8.07) years. The average follow-up duration was approximately 13.9 (SD 1.99) years. Lengthy mobile phone use was associated with a reduced risk of ACD (2-4 years: hazard ratio [HR] 0.815, 95% CI 0.729-0.912, *P*<.001; 5-8 years: HR 0.749, 95% CI 0.677-0.829, *P*<.001; >8 years: HR 0.830, 95% CI 0.751-0.918, *P*<.001), AD (5-8 years: HR 0.787, 95% CI 0.672-0.922, *P*=.003), and VD (2-4 years: HR 0.616, 95% CI 0.477-0.794, *P*<.001; 5-8 years: HR 0.729, 95% CI 0.589-0.902, *P*=.004; >8 years: HR 0.750, 95% CI 0.605-0.930, *P*=.009) compared to rarely using mobile phones. Additionally, lengthy mobile phone use was linked to a decreased risk of ACP (5-8 years: HR 0.747, 95% CI 0.637-0.875, *P*<.001; >8 years: HR 0.774, 95% CI 0.663-0.904, *P*=.001) and PD (5-8 years: HR 0.760, 95% CI 0.644-0.897, *P*=.001; >8 years: HR 0.777, 95% CI 0.660-0.913, *P*=.002) in participants older than 60 years. However, higher weekly usage time did not confer additional risk reduction compared to lower weekly usage of mobile phones. The neuroimaging analysis involved 35,643 participants, with an average duration of approximately 9.0 years between baseline and neuroimaging scans. Lengthy mobile phone use was related to a thicker cortex in different areas of the brain.

Conclusions: Lengthy mobile phone use is associated with a reduced risk of neurodegenerative diseases and improved brain structure compared to minimal usage. Our research provides valuable background knowledge for future studies on the impact of modern electronic devices on brain health.

KEYWORDS

electronic device; parkinsonism; dementia; aging; brain MRI; magnetic resonance imaging

Introduction

Aging and digitalization are two key issues of the current era. The prevalence of neurodegenerative diseases is projected to increase with the aging of the population in the future [1]. Dementia and parkinsonism rank as the top two most prevalent neurodegenerative diseases, with Parkinson disease (PD) being the fastest growing among them [2]. Since disease-modifying treatments are still under research, early detection and prevention of neurodegenerative disease risk factors are crucial for reducing the disease burden on the health care system worldwide.

As digital technologies develop, the use of electronic devices is becoming increasingly popular, raising concerns about their impact on health. However, previous studies have reported controversial results. Electronic devices produce low-intensity electromagnetic fields and microwave radiation during operation, with mobile phones being particularly relevant due to their proximity to the head during use. Hypotheses have been proposed suggesting that low-intensity electromagnetic fields are associated with an increased risk and younger onset age of neurodegenerative diseases [3-5]. Conversely, some argue that exposure to low-intensity electromagnetic fields reduces the risk of Alzheimer disease (AD) [6]. Studies examining the association between mobile phone use and dementia risk have reported conflicting findings, with some suggesting a decreased risk, while others propose no association or even an increased risk [7,8]. Animal and in vivo studies have also yielded conflicting results, further complicating the understanding of the relationship between electronic device use and neurodegenerative diseases [9-11]. Studies on PD specifically have provided mixed evidence, with 1 study reporting no association, while another suggested a potential protective effect in males [8,12].

Overall, controversial hypotheses have been put forward by different studies, and there is a lack of convincing real-world evidence on this topic, especially in neuroepidemiology research. Furthermore, although changes in the brain structure and activity related to excessive phone use have been widely studied, less attention has been paid to the effects of daily electronic use [13,14]. For individuals who are not addicted to electronic devices, the impact of daily electronic use on the brain remains unclear. Compared to previous studies, this research further explored the details of the habit of electronic device use and its relationship with brain aging in participants of different ages.

To address the aforementioned research gaps, our study was designed to meet the following objectives: (1) the relationship between baseline usage of mobile phone/computers and the risk of developing neurodegenerative diseases and (2) the relationship between baseline daily usage of mobile phones/computers and the subsequent individual brain structure to explore the association between mobile phone/computer usage and brain aging. Clinical and imaging data were sourced from the UK Biobank. The findings of our study will offer valuable insights into the influence of electronic device usage on neurodegenerative processes.

Methods

Participants

The UK Biobank is a comprehensive longitudinal population-based cohort that enrolled 502,376 participants from 2006 to 2010 in the United Kingdom. In this study, we included participants who had baseline electronic device usage data and covariate data. The exclusion criteria were a history of the following diseases at baseline: dementia, stroke, PD, multiple sclerosis, demyelinating disorders, and other neurodegenerative diseases.

Ethical Considerations

The UK Biobank was approved (number 21/NW/0157) by the North West Multi-centre Research Ethics Committee (MREC). Consent were acquired from participants at the recruitment center for the study. Compensation and consent details are available on the UK Biobank website [15]. This manuscript was approved for publication by the UK Biobank, and data in the UK Biobank were accessible for health-related research with the approval of the UK Biobank Ethics Advisory Committee. All the data used in the study were anonymized, and no identifiable features were included.

Electronic Device Use

Data on the use of electronic devices were extracted from the UK Biobank database [16] and transferred into category variables: plays computer games (3 levels: never/rarely, sometimes, often) and length of mobile phone use (5 levels: never used a mobile phone at least once per week, 1 year or less, 2-4 years; 5-8 years, >8 years). For those who used mobile phones, the following data were extracted: weekly usage of mobile phones in the past 3 months (2 levels: <5 minutes, ≥5 minutes), hands-free device/speakerphone use with mobile phones in the past 3 months (2 levels: never/almost never, used), differences in mobile phone use compared to the previous 2 years (3 levels: no change, more frequent, less frequent), and usual side of the head for mobile phone use (3 levels: left, right, equally left and right). For details of the answer to each question and their form in the models, see Multimedia Appendix 1.

Neuroimaging

The details of the magnetic resonance imaging (MRI) performed can be found on the UK Biobank website and in previous studies [17-19]. In brief, participants were invited to attend the research centers for follow-up and further neuroimaging assessment from 2014. Imaging scans were conducted in 3 imaging centers with identical scanners and fixed platforms to minimize heterogeneity. Those who had a neurological disease before the imaging scan were excluded from the analysis.

Brain imaging was acquired with 3T Siemens Skyra (software platform VD13) using a 32-channel receive head coil. T1 images were collected at 1 mm isotropic resolution using 3D MPRAGE

XSL•FO
RenderX

acquisition, with the superior-inferior field of view being 256 mm. Several structural metrics were provided by the UK Biobank using Freesurfer. The most segmented brain imaging metrics were selected to obtain the most detailed changes. We used metrics processed by Destrieux (a2009s) parcellation in Freesurfer to assess the area, mean thickness, and volume of the brain in 148 areas [20].

Diffusion tensor imaging (DTI) is an advanced MRI technology that can detect microstructural abnormalities in white matter (WM) before the visual injury emerges. Diffusion data were collected with 2 b-values (1000 and 2000 s/mm^2) at 2 mm spatial resolution, with a multiband acceleration factor of 3. Fifty distinct diffusion-encoding directions were acquired for each diffusion-weighted shell. The diffusion preparation was a standard ("monopolar") Stejskal-Tanner pulse sequence. We used 5 DTI metrics provided by the UK Biobank: fractional anisotropy (FA), mean diffusion (MD), orientation dispersion (OD), intracellular volume fraction (ICVF), and isotropic (free) water volume fraction (ISOVF) [17]. FA and MD were calculated by fitting a voxel-wise diffusion tensor model through DTIFIT in FSL. The OD, ICVF, and ISOVF were calculated by fitting neurite orientation dispersion and density imaging models using accelerated microstructure imaging via convex optimization [21,22]. Low FA or high MD indicate a higher overall deficit in WM fiber integrity. Specifically, OD represents the overall coherence of fibers, the ICVF represents axonal/neurite density, and the ISOVF indicates the free-water fraction [22].

Diagnosis

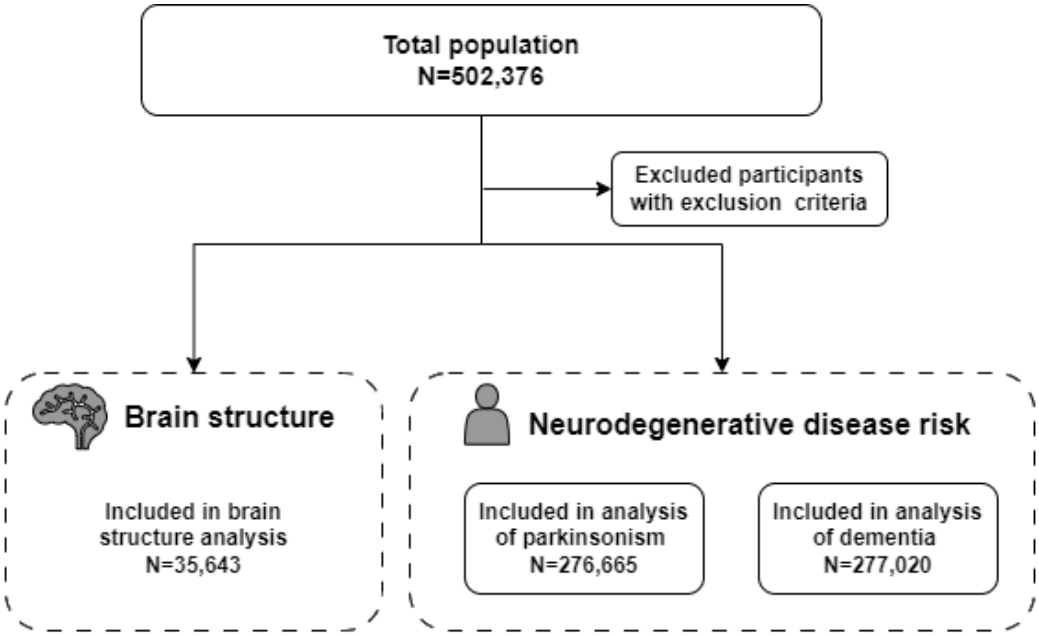
We used the diagnosis of neurodegenerative diseases (dementia outcomes and parkinsonism outcomes) from category 47 and category 50: all-cause dementia (ACD), AD, vascular dementia (VD), all-cause parkinsonism (ACP), and PD. These outcomes were defined through algorithmic combinations of self-reported medical conditions, hospital admissions, and death registries [23].

Statistical Analysis

Data were described as mean (SD) values for continuous variables and counts (percentages) for category variables. Continuous variables were compared using the *t* test, and category variables were compared using the chi-square test or the Fisher exact test. We used Cox regression analysis to evaluate the risk of dementia. Participants were considered at risk for dementia or parkinsonism from baseline (2006-2010) and were followed up to the date of the first diagnosis, death, loss of follow-up, or the last hospital admission.

The covariates included age, sex, the BMI, smoking (ever or never), drinking (ever or never), hypertension, diabetes, education (college/university degree or lower degree), the polygenic risk score, socioeconomic status (Townsend deprivation index, a score calculated according to the output area in which participants' postcodes were located and the preceding national census output areas), the average total household income before tax, the mental health score, and physical activity. Using scaled Schoenfeld residuals to test proportional hazards, there was no indication of a violation of the hypothesis. In the sensitivity analysis, we further conducted several models: (1) model 1 excluded those diagnosed with outcome diseases within 5 years from baseline to exclude the potential reverse causality, (2) model 2 only included diagnoses that were from the hospital or death registration; (3) model 3 was used to replace the polygenic risk score (PRS) with the status of the *apolipoprotein ε4* gene, and (4) model 4 divided patients into 2 groups according to age (60 years old) at baseline to exclude the influence of age.

Linear regression models were used with variables using electronic devices as independent variables and neuroimaging metrics as dependent variables. Sex, age, ethnicity, the BMI, smoking, drinking, hypertension, diabetes, education, socioeconomic status, the WM hyperintensity volume, the whole WM volume, handedness (only for the usual use of the side of the mobile phone), and the average total household income before tax were included as covariates [24]. In the sensitivity analysis, we further adjusted the mental health score and physical activity. The variance inflation factor was tested and controlled under 5 to avoid multicollinearity. We used Bonferroni-corrected *P* values to determine the statistical significance: .05/5 for disease risk analysis, .05/(48 tracts×5 metrics) for DTI, and .05/148 regions for the surface, thickness, and volume in linear regression models. All analyses were performed using R version 4.1.2 (R Foundation for Statistical Computing).



Results

Demographic Characteristics of Participants Included in Risk Analysis

The inclusion flowchart is displayed in Figure 1 (detailed version in Multimedia Appendix 1), and the demographic characteristics of the participants are shown in Table 1. A total of 277,020 and 276,665 participants were included in the Cox regression model for dementia and parkinsonism, respectively. The mean age of the dementia and parkinsonism analysis groups at baseline was 55.85 (SD 8.07) years and 55.86 (SD 8.07) years, respectively. Half of the included participants (dementia group: n=139,166, 50%; parkinsonism group: n=139,276, 50%) were female. The mean duration of follow-up was 13.90 (SD 1.99) years and 13.89 (SD 2.01) years for the dementia and parkinsonism groups, respectively. We further compared the characteristics of the included and excluded participants (Tables S1 and S2 in Multimedia Appendix 1). The participants in the included risk analysis were younger, had higher education, a lower Townsend deprivation index, and a higher income compared to those excluded from the analysis.

[a]AD: Alzheimer disease.

Relationship Between Electronic Device Use and Dementia

In the follow-up, we included 3007 (1.1%) participants with ACD, 1231 (0.4%) with AD, and 631 (0.2%) with VD. Lengthy mobile phone use (≥2 years) at baseline was related to a lower risk of ACD and VD compared to never using a mobile phone at least once per week (Table 2 and Table S3 in Multimedia Appendix 1). Additionally, participants who had used mobile phones for 5-8 years had a significantly lower risk of AD.

To exclude the influence of reverse causality, several sensitivity analyses were conducted. After excluding participants who developed outcomes within 5 years after baseline, we found that lengthy mobile phone use was related to a lower risk of ACD (mobile phone use≥2 years), VD (mobile phone use=2-4 years), and AD (mobile phone use=5-8 years), as shown in Table S4 in Multimedia Appendix 1. After excluding participants whose source of outcomes was not from the hospital or death registration, we found that lengthy mobile phone use (≥2 years) was related to a lower risk of ACD and VD (Table S5 in Multimedia Appendix 1). To analyze the influence of *apolipoprotein ε4*, we adjusted the status of *apolipoprotein ε4* instead of the PRS and found that lengthy mobile phone use was related to a decreased risk of ACD (mobile phone use≥2 years) and VD (mobile phone use=2-4 years), as shown in Table S6 in Multimedia Appendix 1.

To exclude the influence of age, we conducted a separate analysis based on participants' age at baseline. We found that lengthy mobile phone use was related to a decreased risk of ACD (mobile phone use≥2 years) and AD (mobile phone use≥5 years) in participants younger than 60 years (Table S7 in Multimedia Appendix 1). Lengthy mobile phone use was also related to a decreased risk of ACD (mobile phone use≥2 years), AD (mobile phone use≥5 years), and VD (mobile phone use≥2 years) in participants older than 60 years (Table S8 in Multimedia Appendix 1).

Relationship Between Electronic Device Use and Parkinsonism

In the follow-up, we included 1578 (0.6%) participants with ACP and 1415 (0.5%) with PD. Often playing computer games was related to a lower risk of ACP (hazard ratio [HR] 0.604, 95% CI 0.425-0.859; *P*=.005) and PD (HR 0.574, 95% CI 0.392-0.841; *P*=.004) compared to never or rarely playing computer games (Table S9 in Multimedia Appendix 1). However, after excluding those who developed outcomes within 5 years, none of the above results remained statistically significant (Table S10 in Multimedia Appendix 1). We excluded participants whose source of outcomes was not from the hospital

XSL•FO
RenderX

or death registration and reached a similar result that often playing computer games was related to a lower risk of ACP and PD (Table S11 in Multimedia Appendix 1). After age stratification, in participants younger than 60 years, we found that the association between often playing computer games and a lower risk of ACP did not reach statistical significance (HR 0.393, 95% CI 0.175-0.844; *P*=.02; Table S12 in Multimedia Appendix 1). However, lengthy mobile phone use (≥5 years) was related to a decreased risk of ACP and PD in participants older than 60 years (Table S13 in Multimedia Appendix 1).

Demographic Characteristics of Participants Included in Neuroimaging Analysis

The demographic characteristics of participants who underwent neuroimaging analysis are displayed in Table S14 in Multimedia Appendix 1. A total of 35,643 participants were included, 48% (n=17,109) of them were male, and the mean age at baseline was 54.77 (SD 7.51) years. The mean duration between baseline and the neuroimaging scan was 8.97 (SD 1.73) years.

Relationship Between Electronic Device Use and the Brain Structure

Areas where the brain structure metrics at follow-up were related to the use of electronic devices at baseline are displayed in Tables 3 and 4. Using mobile phones for a long duration (≥2 years) was related to a thicker cortex in the left superior temporal sulcus. In addition, lengthy mobile phone use (≥8 years) was related to a significantly higher volume of the parahippocampal gyrus and thicker left orbital gyri, left precuneus, left superior temporal sulcus, right posterior-dorsal part of the cingulate gyrus, right middle temporal gyrus, and right subparietal sulcus (Table 3). Lengthy mobile phone use (2-4 years, ≥8 years) was related to higher mean FA in the pontine crossing tract on the FA skeleton (Table 4). Often playing computer games was related to a higher volume in the left anterior part of the cingulate gyrus and sulcus and the left triangular part of the inferior frontal gyrus, while sometimes playing computer games was related to a lower volume of the parahippocampal gyrus (Table 3). In addition, often holding a mobile phone on the right side of the head was related to larger areas in the bilateral posterior division of the middle temporal gyrus, bilateral anterior division of the cingulate gyrus, and a larger area of several regions compared to those who usually held their phones on the left side of the head (Table 3). Results of sensitivity analyses of neuroimaging are displayed in Tables S15-S17 in Multimedia Appendix 1.

Discussion

Principal Findings

In our study, we found evidence suggesting that the use of electronic devices is associated with a reduced risk of neurodegenerative diseases. Specifically, we observed that using mobile phones for 2 or more years is linked to a decreased risk of ACD and VD compared to never/rarely using mobile phones. Upon conducting sensitivity analyses, we confirmed the stability of the association between long mobile phone use and a lower risk of ACD and VD. Moreover, individuals aged 60 years and older appeared to benefit from extended duration of mobile phone use with a reduction in the risk of AD, ACP, and PD. Furthermore, our neuroimaging analysis revealed that various electronic device use habits, including the duration of mobile phone use, the frequency of computer use, and the preferred side of the head for holding mobile phones, were associated with distinct characteristics in the gray matter and WM structures of several brain regions over the follow-up period.

XSL•FO
RenderX

Comparison With Prior Work

Our findings suggest that using a mobile phone for more than 2 years is associated with a reduced risk of ACD and VD in the middle-aged population, with no significant impact of weekly mobile phone use. Previous studies using UK Biobank data have reported an association between mobile phone use and a lower risk of ACD in individuals over 60 years old [7]. Our study builds upon this knowledge by focusing on specific types of dementia and details of mobile phone use. We found that a long weekly time of mobile phone use (≥5 minutes) does not alter the risk of dementia compared to a shorter weekly time (<5 minutes). However, the duration of mobile phone use affects the association between mobile phone use and reduced risk of dementia. Using a mobile phone enriches the user's social and mental activities, potentially leading to improved cognition in later life [25,26]. The association between mobile phone use and a decreased risk of dementia is partly mediated by rich social support and flourishing leisure activities [7]. Additionally, prior research has suggested that registering a mobile phone decreases the risk of PD [8]. Our study further revealed that this association is observed only in populations aged 60 years and older, where a long duration of mobile phone use decreases the risk of developing ACP and PD compared to those who rarely use mobile phones.

The benefits of using electronic devices can be reflected in improved brain structure. We found that long durations of mobile phone use are associated with a thicker cortex in multiple areas of the brain. Specifically, individuals who use mobile phones for more than 8 years exhibit a higher volume of the parahippocampal gyrus, a region crucial for memory function [27]. This finding is particularly significant as atrophy in the parahippocampal gyrus is observed in the early stages of AD, serving as an early pathological biomarker [28,29]. Previous studies have shown that daily mobile phone use for less than 1 hour is associated with lower functional connectivity in certain brain regions, such as the superior temporal sulcus, and higher functional connectivity in others, like the cingulate [14]. In this study, we observed that only weekly mobile phone use of 5 minutes or more is associated with a decreased volume and area in the right posterior transverse collateral sulcus compared to less than 5 minutes of weekly use. However, no significant results were found in other areas or the DTI analysis. These findings suggest that daily mobile phone use, without reaching problematic levels, has minimal impact on the user's brain structure. Interestingly, we found inconsistent effects of occasional or frequent computer usage on the brain structure. Often playing computer games is associated with a higher brain volume, while sometimes playing computer games is related to a lower brain volume. For those who sometimes play computers, the related shortcomings, such as sedentariness, are more prominent and result in cortical atrophy [30].

Strengths and Limitations

This study has several strengths. First, we adjusted for covariates that may have influenced the results using comprehensive data from the UK Biobank, which is the largest population-based cohort in the world. This allowed us to provide important information on the use of electronic devices. Second, the cohort's follow-up duration was notably extensive, allowing sufficient time for patients to reach the point at which diseases developed. Additionally, the duration between baseline and neuroimaging scans offered crucial insights into the long-term effects of electronic device use on brain health.

There was 1 limitation that should be mentioned. The mobile phone use in this study was limited to receiving calls. The rapid advancement and evolution of electronic devices in recent years have transformed the usage patterns of mobile phones, heightening the potential for dependency [31,32]. However, the evolution happened years after the launch of the UK Biobank cohort. Our study still provides important insights into the long-term influence of electronic device use. The time that people spend on mobile phones now is much longer than it was decades before [31,33]. However, this study found that there are no additional benefits of longer weekly usage. In addition, playing games on the mobile phone is popular nowadays [33]. We found an association between playing computer games and decreased neurodegenerative disease risk, but the association is unclear if game devices change from computers to mobile phones. Future studies should record the details of the daily time and the type of function of mobile phone use to analyze the impact of modern electronic devices on brain health.

Conclusion

In conclusion, our study revealed that individuals with long duration of mobile phone use are associated with a decreased risk of ACD and VD compared to those who rarely use mobile phones. The protective effect of mobile phone use is also observed in individuals older than 60 years, who experience a reduced risk of AD, ACP, and PD. However, spending more time on mobile phones per week may not further reduce the risk of neurodegenerative disease. Our findings also indicate that electronic device use can impact the brain structure. Specifically, using a mobile phone and often playing computer games are associated with a better brain structure, while sometimes playing computer games is linked to a poorer brain structure. These results highlight the complex relationship between electronic device use and neurodegenerative disease risk, as well as the influence on the brain structure. Future studies should concentrate on the mechanism underlying the influence of using mobile phones and computers and new electronic devices on health.

Abstract

Background: Traditional in-clinic methods of collecting self-reported information are costly, time-consuming, subjective, and often limited in the quality and quantity of observation. However, smartphone-based ecological momentary assessments (EMAs) provide complementary information to in-clinic visits by collecting real-time, frequent, and longitudinal data that are ecologically valid. While these methods are promising, they are often prone to various technical obstacles. However, despite the potential of smartphone-based EMAs, they face technical obstacles that impact adaptability, availability, and interoperability across devices and operating systems. Deficiencies in these areas can contribute to selection bias by excluding participants with unsupported devices or limited digital literacy, increase development and maintenance costs, and extend deployment timelines. Moreover, these limitations not only impede the configurability of existing solutions but also hinder their adoption for addressing diverse clinical challenges.

Objective: The primary aim of this research was to develop a cross-platform EMA app that ensures a uniform user experience and core features across various operating systems. Emphasis was placed on maximizing the integration and adaptability to various study designs, all while maintaining strict adherence to security and privacy protocols. JTrack-EMA+ was designed and implemented per the FAIR (findable, accessible, interpretable, and reusable) principles in both its architecture and data management layers, thereby reducing the burden of integration for clinicians and researchers.

Methods: JTrack-EMA+ was built using the Flutter framework, enabling it to run seamlessly across different platforms. This platform comprises two main components. JDash (Research Centre Jülich, Institute of Neuroscience and Medicine, Brain and Behaviour [INM-7]) is an online management tool created using Python (Python Software Foundation) with the Django (Django Software Foundation) framework. This online dashboard offers comprehensive study management tools, including assessment design, user administration, data quality control, and a reminder casting center. The JTrack-EMA+ app supports a wide range of question types, allowing flexibility in assessment design. It also has configurable assessment logic and the ability to include supplementary materials for a richer user experience. It strongly commits to security and privacy and complies with the General Data Protection Regulations to safeguard user data and ensure confidentiality.

Results: We investigated our platform in a pilot study with 480 days of follow-up to assess participants' compliance. The 6-month average compliance was 49.3%, significantly declining (P=.004) from 66.7% in the first month to 42% in the sixth month.

Conclusions: The JTrack-EMA+ platform prioritizes platform-independent architecture, providing an easy entry point for clinical researchers to deploy EMA in their respective clinical studies. Remote and home-based assessments of EMA using this

XSL•FO
RenderX

platform can provide valuable insights into patients' daily lives, particularly in a population with limited mobility or inconsistent access to health care services.

(J Med Internet Res 2025;27:e51689) doi:10.2196/51689

digital biomarkers; mobile health; remote monitoring; smartphone; mobile phone; monitoring; biomarker; ecological momentary assessment; application; costly; user experience; data management; mobility

Introduction

Self-reported information in psychiatric disorders plays a crucial role in clinical decision-making. They are often gathered through traditional questionnaires or verbal conversations during clinic visits [1]. These visits are infrequent, costly, and inaccessible to everyone [2]. The self-reports from in-clinic visits may also be subject to higher recall bias, notably when asked to recall memories and past events [3].

The need to reduce reliance on traditional in-clinic visits and the widespread adoption of smart devices (such as smartphones and smartwatches) have increased their potential for use in clinical settings. Health-related data collected from these devices are often called digital biomarkers (DBs) [4-6]. DBs include a wide range of measurements, with ecological momentary assessments (EMAs) being one of the most widely accepted and used [7]. EMA involves using experience sampling methods, which are brief assessments administered in real time in naturalistic settings to study the moment-to-moment fluctuations of states and behaviors [8]. EMA offers several advantages over traditional in-clinic visits, including a higher sampling frequency, the ability to collect longitudinal data, enhanced engagement, lower costs, and increased ecological validity [1,9]. Smartphones are often equipped with a range of sensors such as location, pedometer, proximity, and luminance sensors. These sensors can be used to trigger surveys based on different physical activities or environmental factors. For instance, a survey can be automatically triggered when the user visits new locations or there is a change in weather conditions in the user's location. This type of EMA is commonly referred to as event-contingent EMA [10,11].

Assessment questions, supporting material (eg, images, videos, and explanatory text), managing assessment logic (ie, scheduling, inclusion or exclusion criteria, validating input answers, recording timestamps, and storing and transferring assessments), and providing assessment completion reminders [12] are among the main features typically integrated into EMA apps. These advanced capabilities offer an excellent opportunity for collecting DBs in remote assessments. However, their implementation comes with several technical challenges and obstacles. These challenges include but are not limited to privacy and security, memory and battery usage, patient acceptance, scalability, and interoperability with different devices and operating systems. Although there are various apps intended to meet many of the abovementioned criteria [13-17], interoperability with different operating systems, adaptability, and configurability are still lacking. Several operating systems are available for mobile (Android and iOS) and desktop (Windows and macOS) devices. Each of these has its own paradigms and programming languages. Therefore, separate developers and experts are required for each, significantly increasing the cost and development time. Additionally, restricting the apps to a specific operating system may lead to a selection bias. A platform-independent architecture addresses these limitations. This motivated us to introduce JTrack-EMA+ as a cross-platform, configurable app that also complies with the General Data Protection Regulation (GDPR). It consists of an EMA app and an online management tool facilitating assessment management and data quality control. It is integrated into our previously introduced sensor-based DBs ecosystem, "JTrack" [18]. In this paper, we also evaluated a pilot study using JTrack-EMA+ in a population of parents with a newborn to investigate participants' compliance with the assessment protocols.

Methods

Study Design

Here, we describe the primary component of the JTrack platform (Figure 1), which includes a smartphone-based app JTrack-EMA+ (Figure 2A-H), and an online management app, JDash (Figures 3A-E and 4A-E). JTrack-EMA+ was developed based on platform-independent architecture using the Flutter framework [19]. Flutter is a cross-platform framework developed by Google that allows developers to build native apps from a single codebase. There are different cross-platform technologies such as React Native (Meta Platforms, Inc) and Xamarin (Microsoft). However, Flutter has several advantages that make it an irresistible choice for JTrack-EMA+. Flutter uses its rendering engine, which provides better performance and a more consistent look and feel across platforms compared to React Native, which relies on native components. Flutter's hot reload feature enables faster iteration and testing during development, improving the overall development workflow and Flutter's widget-based approach to user interface development promotes a consistent and cohesive user experience across platforms. Additionally, Flutter has a more active and growing community, with strong support from Google, ensuring continued development and improvement of the framework.

Platform-independent design reduces development and maintenance time, provides a consistent performance and user experience, and enables instant delivery of new feature updates and enhancements across multiple platforms.

(A) Create a new assessment, (B) display the main screen of the assessment and related information, (C) add a new question to the assessment, (D) add answers to the question from the previous step, and (E) modify and add logic to the question. EMA: ecological momentary assessment.

Adaptability and Configurability

The behavior and performance of software are significantly impacted by rapidly evolving operating systems. Being able to adapt to these changes in agile is a crucial trait that the platform-independent architecture of JTrack-EMA+ provides. Besides architectural benefits, JTrack-EMA+ constructs evaluation materials and logic using a JSON file to facilitate reusability and configurability.

The use of a JSON file providing the configurations for each specific study can simplify the process of reusability in an app by centralizing configuration fields in a single file. This approach allows for efficient management and modification of app settings without the need to alter the codebase. By storing configuration details such as logging credentials, user and study IDs, and survey-related data in a JSON file, study owners can quickly update these settings as needed without modifying the app code. This approach enhances flexibility, scalability, and maintainability by separating configuration from the app logic. It makes it easier to reuse the same configuration across different environments or instances of the app. Using such a configuration file approach, study owners can modify the app settings from the study management interface without further need to alter the app codebase, making it easier to manage and maintain.

After users register with the provided QR codes, the assessment is generated based on a study-specific JSON file received from the server. Additionally, assessments can be updated remotely using this file without updating the app. The browser-based study management dashboard JDash has a built-in EMA creator to generate these JSON files making the design and configuration of an EMA study quite simple and versatile (Figure 4).

JTrack-EMA+ supports a wide range of assessment formats, such as binary, multiple-choice, text, or numeric user input; date and time; and sliding questions (Figure 2). The system has a flexible assessment logic that includes conditions, categories,

XSL•FO
RenderX

and customizable frequency on a question-by-question basis. This functionality is vital in determining whether to ask or skip certain questions, based on predetermined criteria such as the time elapsed since the assessment began, the present time of day, and the value or date of the participant's response (conditional questions). By categorizing questions, different conditions can also be applied within each category (ie, only show the first n questions for each category). Additionally, the system allows for defining the frequency at which the questions should be displayed to users (such as on-demand, daily, or weekly).

JTrack-EMA+ supports two distinct paging styles: page view and list view. With page view, participants will see a single question at a time, whereas list view shows all questions as a list, allowing participants to expand (choose) a question to answer. While page view ensures the visibility of each question, list view is especially helpful in situations where many questions are shown or only specific questions are relevant.

Data Quality, Privacy, and Security

Quality, security, and privacy of the collected data are important considerations when designing a novel EMA app. To address the data quality, syntactic input validation is deployed to ensure that only properly formed data is entered. Additionally, to prevent possible data loss, we adopted the "local-first" data storage method, where data are stored locally on the device and only synced to the server when connected to the internet. In addition, to mitigate the impact of potential interruptions (eg, by other programs, battery drain, or phone restart) on saving data, we implemented an auto-saving mechanism.

To ensure data privacy and security and to comply with the European Union GDPR, JTrack-EMA+ deployment does not require any identifiers or personal data. All data are assigned to a JDash-generated user ID allowing for fully anonymized and pseudonymized data collection. Secure channels are used for communication between servers and devices, and data integrity is protected against unintended corruption and potential interruptions using message-digest algorithms. Moreover, the distribution of the app through official channels (ie, Google Play Store and Apple App Store) provides convenience to the participants and creates a sense of security and confidentiality.

QR code-based registration, embedding control, and authentication methods streamline the registration process (these codes are generated when a study is created in JDash). In addition, we have provided a "leave study" option in the app, which enables all participants to withdraw from the study at any time.

Study Management

JDash is an online study management app designed to assist JTrack study owners in creating new studies and managing ongoing ones (Figure 3A-E). It allows study owners to create and modify all study aspects, such as the duration, addition of assessment materials (eg, images), data quality checks, removal of participants from a study, ending of a study, and management of the study owner's access level. Python (Django and Web Server Gateway Interface) was chosen as the implementation technology. JDash consists of a user interface and a backend. While the backend app programming interface serves as an end point for receiving, saving, and authentication requests arriving from the app, the frontend interface can also be used to create and design an assessment (Figure 1).

The JDash was developed to be easy to use and deploy. It incorporates flawless design principles to provide a range of features for clinicians to establish their assessments intuitively. The design principles used in the app ensure that clinicians can navigate and use the assessment tools efficiently, without further help from a technical team, enhancing the overall user experience. By focusing on such design principles, the app aims to streamline the assessment process for clinicians, making it user-friendly, clear, and consistent (eg, similar design patterns). This approach aligns with best user interface design and usability practices, ultimately benefiting users by simplifying their workflow and improving the effectiveness of their assessments.

In addition to an open-source software license, JDash uses an automated deployment model that is efficient, easy to use, and requires fewer configurations (for instruction on deployment, readers may refer to the documentation on our GitHub page [20]). In addition, JDash has a comprehensive notification system to ensure periodic reminders based on a predetermined schedule, avoiding unwanted (eg, overnight) alerts. This notification is designed to operate as a push notification (online) that can be sent to participants' devices from the dashboard. This module is integrated into JDash to deliver reminders to participants' devices, either individually or based on their status (ie, no data sent in a few days). This regular reminder has the potential to minimize the high dropout rate of EMA-based assessments [9].

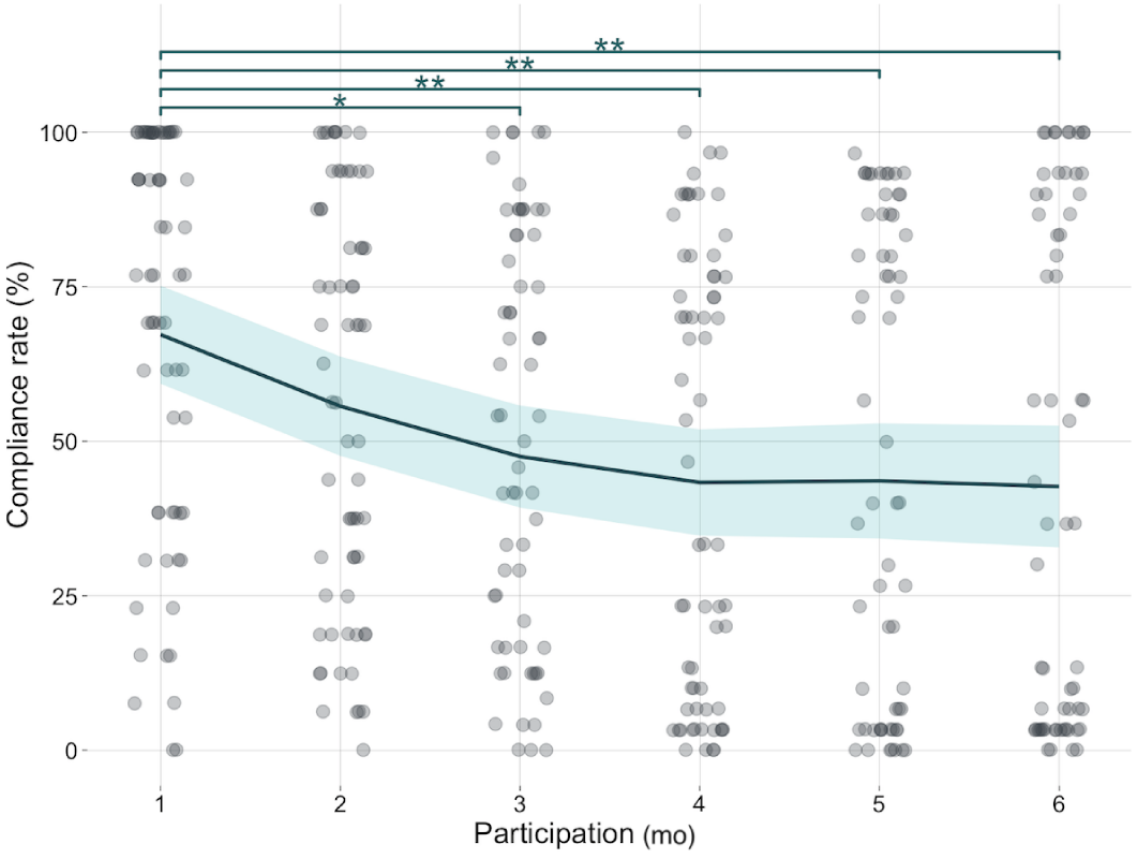
Finally, most research programs aim to share data with colleagues or along with research results to promote transparency, encourage collaboration, and accelerate research. To facilitate this goal, we have used DataLad [21] as a data management infrastructure on our servers to manage data according to FAIR (findable, accessible, interpretable, and reusable) principles [22]. DataLad offers essential features such as data versioning, metadata handling, structured formatting, and change tracking under an open-source license which contributes to enhanced security and privacy of collected data. This integration in the data management layer also accelerates reproducible science, a key element of scientific methods.

Pilot Study

We deployed the JTrack-EMA+ app in a pilot study involving 179 parents with newborns followed up for 480 days. Parents were asked to install the JTrack app on their phones (75 iOS and 104 Android). The pilot study includes weekly assessments of children's physical and mental development. These questions are designed to appear based on their defined frequency and the time since participants joined the study. Furthermore, the yes or no questions deactivate when the answer is "Yes." To illustrate the development questions, a picture was shown for each question. Martin Pawlusiak designed the pictures. Additionally, an appropriate notification time was chosen to avoid receiving assessment reminders early in the morning or late at night.

XSL•FO
RenderX

We have been conducting the pilot study since November 2021, and it is set to run until November 2023. As of now, we have released the preliminary compliance data that we have gathered over the first 14 months of the study. We calculated the compliance rate as a percentage of completed surveys compared to what was expected. In total, 65 participants completed assessments for at least 6 months and were included in the compliance analysis. Monthly compliance was computed as the number of received data points divided by the number of expected data points. Monthly average compliance was compared using the Friedman test, followed by pairwise comparisons using the Wilcoxon rank sum test.



Ethical Considerations

The studies involving human participants were reviewed and approved by the ethics committee at the medical faculty, Heinrich-Heine-Universität Düsseldorf, Germany (2021-1500_1). The patients or participants provided written informed consent to participate in this study. The data were anonymized. Participants did not receive any compensation for this study.

Results

Figure 5 displays the fluctuation of average compliance rates across the 6 months of the pilot study. The overall average compliance rate across this period was 49.3%. The between-group comparisons of the average compliance rate show a significant decrease from 66.7% in the first month to 46.9% (P=.01), 42.6% (P<.001), 42.9% (P=.002), and 42% (P=.004) in the third, fourth, fifth, and sixth months, respectively.

Figure 5. Compliance rate for an exemplary study. Each dot represents a participant with a corresponding compliance rate (calculated as a percentage of completed surveys out of expected surveys), and a solid line is the average compliance for a corresponding month with a 95% CI. *P<.05, **P<.01.

Discussion

Principal Findings

Here, we introduced JTrack-EMA+, a smartphone-based, real-time EMA app. This platform-independent architecture of the app reduces the disparity in user experiences and functionality across different operating systems. It complies with the GDPRs and official app distribution channels while providing all features required for designing and deploying EMA-based evaluations.

The online dashboard serves as a central study management interface. It visualizes and summarizes the study information (ie, duration, the number of subjects, and supplementary information). This information is used for data streaming and quality checks and to interact with participants in case of missing or invalid data via push notifications. Researchers can control the access to the specific information of the study to their research partners through the user access level control provided by the dashboard. The open-source solution DataLad [21] is used for data management in JDash, and the abovementioned functionalities reduce reliance on third-party apps and services such as Amazon Web Services.

The traditional development architecture used by existing platforms is limited by its shortcomings [13-17]. A lack of

XSL•FO
RenderX

support and disparities in user experience and app functionality across platforms are among the most significant contributors. Therefore, most EMA platforms are either available for a single operating system (ie, ULTEMAT is only available for Android [16], and iHabit is only available for iOS [17]) or have different features depending on the operating system (ie, AWARE, Remote Assessment of Disease and Relapse–base, and SEMA3 have two distinct apps for each platform [13,15]).

To the best of our knowledge, the JTrack-EMA+ stands out as a pioneer in prioritizing platform-independent architecture. This platform offers extensive configurability, which sets it apart from the existing platform. It also provides a flexible and dynamic environment instead of being limited to a single problem-oriented solution.

The effectiveness of EMA depends on the participants' motivation and adherence to assessment protocols [12,23]. Poor compliance and missing data can adversely impact the quality of the collected data and introduce bias in the sample, thereby hindering the success of clinical apps. Our results revealed an overall average of 49.3% with a significant decrease in compliance rate after 2 months. Although there is a large degree of heterogeneity in compliance rates reported in various studies [24], considering our inclusion time constraint (6 months) and the target demographic (parents with busier routines who dedicate more time to their newborn), this compliance rate can be considered an acceptable rate. Importantly, there is no definitive recommendation for a minimum or appropriate rate of compliance as it is highly dependent on the specific patient or participant population and the actual frequency, duration, and comprehensiveness of the specific assessments, as well as the actual research question. As long as sufficient representation of the individual day-to-day variability in the respective EMA assessments is achieved, the respective EMA measures could be considered useful. Overall, our results demonstrate the potential to use our platform compared to the paper-and-pencil EMA assessment (which was shown to have a significantly lower compliance rate), particularly in participants with limited mobility or restricted access to health care services [24].

A limitation of our platform is its ability to detect and respond to various events and contexts, such as environmental and physical activities. Although we consider this a limitation here, it is carried out on purpose to simplify the ethics and data privacy required by sensory and contextual assessment; required in addition to EMA. Additionally, despite the attempts to keep performance and user experience consistent across all operating systems, background work constraints in iOS may influence the app's internal reminders on these devices, so automated push notifications implemented by JDash can be a better choice for such devices.

Finally, JTrack-EMA+ is an active project regularly updated to add new features and improve the platform's functionality. The features described here are part of the version 1 release. Therefore, later versions may have additional functions which will be documented with the respective releases. The most updated JTrack-EMA+ versions are released via the official distribution channels (ie, Google's Play Store and Apple's App Store). All study management functionalities to deploy JTrack-EMA+ are implemented as open source and can be accessed from our GitHub repository under an open-source license.

Conclusions

In this paper, we covered the key concepts associated with EMA apps and the technical constraints of existing platforms. Then we launched a platform-independent JTrack-EMA+ app to reduce the gap in user experience and app functionality across different operating systems while adhering to security, privacy, and GDPR requirements.

In a pilot study, we also demonstrated participants' compliance rate with assessment protocols and how it fluctuated over a 6-month course of study. We conclude that remote and at-home assessment using this platform results in an acceptable rate of compliance that may not be possible using the conventional in-clinic visit method, particularly in a population with limited mobility or a busy schedule—as were the participants in our pilot study.

Incorporating EMA apps into clinical practice can significantly improve patient monitoring in real time, reaching a wider population and enhancing ecological validity. It can lead to personalized treatment interventions by providing comprehensive and dynamic insights into individuals' health behaviors and experiences. JTrack-EMA+ was originally designed for clinical studies, but it can also be used in different areas where EMA measures may be required such as market research, education, government, public policy, event planning, and feedback and engagement. While using smartphone-based EMA technologies offer many potential benefits, certain populations may face barriers to effectively accessing and using these apps. Some key challenges include access to smartphones or the internet in underresourced regions, older adult individuals, individuals with disabilities, and low digital literacy. A multipronged approach is needed to address these challenges, such as providing alternative low-tech EMA options, designing highly accessible and intuitive interfaces, improving digital literacy through training, and ensuring affordable access to required technologies. In this regard, the future version of JTrack-EMA+ will improve integration for web-based users as an alternative to smartphone-based EMA. Additionally, it will include conditional assessment support and additional features to analyze the collected data directly in a browser-based dashboard (JDash).

Finally, we concluded that platform-independent architectures provide comparable functionality and user experience and save development and maintenance costs over time. These principles are critical to EMA-based assessments' effectiveness and applicability in clinical trials.

Data Availability

On the iOS platform, this app is published as JTrack-EMA.

Authors' Contributions

MSF developed the JTrack-EMA+ app and performed all analyses. MSF wrote this paper with the support of JD. JMF and MN developed the online dashboard app. JD designed the overall study. SBE and TM contributed to the overall design of this study. DS contributed to the development of questions for the pilot study. RR and SS recruited probands and the clinic. All authors contributed to this paper and approved the submitted version. This study was supported by the Human Brain Project, funded by the European Union’s Horizon 2020 Framework Programme for Research and Innovation under the Specific Grant Agreement 785907 (Human Brain Project SGA2).

Abstract

Background: Few studies have explored the relationship between macronutrient intake and sleep outcomes using daily data from mobile apps.

Objective: This cross-sectional study aimed to examine the associations between macronutrients, dietary components, and sleep parameters, considering their interdependencies.

Methods: We analyzed data from 4825 users of the Pokémon Sleep and Asken smartphone apps, each used for at least 7 days to record objective sleep parameters and dietary components, respectively. Multivariable regression explored the associations between quartiles of macronutrients (protein; carbohydrate; and total fat, including saturated, monounsaturated, and polyunsaturated fats), dietary components (sodium, potassium, dietary fiber, and sodium-to-potassium ratio), and sleep variables (total sleep time [TST], sleep latency [SL], and percentage of wakefulness after sleep onset [%WASO]). The lowest intake group was the reference. Compositional data analysis accounted for macronutrient interdependencies. Models were adjusted for age, sex, and BMI.

Results: Greater protein intake was associated with longer TST in the third (+0.17, 95% CI 0.09-0.26 h) and fourth (+0.18, 95% CI 0.09-0.27 h) quartiles. In contrast, greater fat intake was linked to shorter TST in the third (–0.11, 95% CI –0.20 to –0.27 h) and fourth (–0.16, 95% CI –0.25 to –0.07 h) quartiles. Greater carbohydrate intake was associated with shorter %WASO in the third (–0.82%, 95% CI –1.37% to –0.26%) and fourth (–0.57%, 95% CI –1.13% to –0.01%) quartiles, while greater fat intake was linked to longer %WASO in the fourth quartile (+0.62%, 95% CI 0.06%-1.18%). Dietary fiber intake correlated with longer TST and shorter SL. A greater sodium-to-potassium ratio was associated with shorter TST in the third (–0.11, 95% CI –0.20 to –0.02 h) and fourth (–0.19, 95% CI –0.28 to –0.10 h) quartiles; longer SL in the second (+1.03, 95% CI 0.08-1.98 min) and fourth (+1.50, 95% CI 0.53-2.47 min) quartiles; and longer %WASO in the fourth quartile (0.71%, 95% CI 0.15%-1.28%). Compositional data analysis, involving 6% changes in macronutrient proportions, showed that greater protein intake was associated with an elevated TST (+0.27, 95% CI 0.18-0.35 h), while greater monounsaturated fat intake was associated with a longer SL (+4.6, 95%

XSL•FO
RenderX

CI 1.93-7.34 min) and a larger %WASO (+2.2%, 95% CI 0.63%-3.78%). In contrast, greater polyunsaturated fat intake was associated with a reduced TST (–0.22, 95% CI –0.39 to –0.05 h), a shorter SL (–4.7, 95% CI to 6.58 to –2.86 min), and a shorter %WASO (+2.0%, 95% CI –3.08% to –0.92%).

Conclusions: Greater protein and fiber intake were associated with longer TST, while greater fat intake and sodium-to-potassium ratios were linked to shorter TST and longer WASO. Increasing protein intake in place of other nutrients was associated with longer TST, while higher polyunsaturated fat intake improved SL and reduced WASO.

Introduction

Dietary intake patterns vary widely depending on the lifestyle. Brain imaging reveals that these patterns are associated with mental health, cognitive function, blood and metabolic biomarkers, overall brain structure, and white matter integrity [1]. Diet and sleep are closely linked [2]. A systematic review partially revealed that overeating, especially meals high in fat, can extend sleep latency (SL), increase wakefulness after sleep onset (WASO), and ultimately reduce total sleep time (TST) [3-5].

Dietary intake and sleep are known to have a bidirectional relationship [2]. The intake of healthy foods is associated with improved sleep quality, whereas consuming processed foods and foods high in free sugars has been shown to deteriorate sleep quality [6]. Several hypotheses have been proposed to explain this relationship [7-9]. One hypothesis suggests that an increased dietary intake of tryptophan can promote the production of serotonin and melatonin, potentially leading to improved sleep quality [7]. Additionally, sleep deprivation can decrease leptin levels and increase ghrelin levels, a hormone that stimulates appetite, and may trigger overeating, especially at night, creating a negative spiral [7-9].

The importance of assessment methods in examining the relationship between diet and sleep has been emphasized in numerous studies [2,3,10]. Subjective methods, such as dietary diaries, 24-hour recalls, and food frequency questionnaires, rely heavily on the participants' memory and can be prone to recall bias. In contrast, objective methods, such as digital apps that record dietary intake in real time, can reduce bias; however, they still face challenges related to technology use and data accuracy [11]. Furthermore, automated systems have been introduced to eliminate recording and subjective biases, allowing users to register menus or scan the barcodes of commercially available products, which automatically calculates the nutritional components [12]. Similarly, sleep assessments also face challenges. Subjective sleep assessments, such as sleep diaries or self-reported questionnaires, are prone to recall bias, sleep-state misperception, and underreporting. Objective assessments, including polysomnography, portable electroencephalogram devices, and wearable devices such as accelerometers, provide more accurate data but are often costly, require technical expertise, or can be intrusive for users [11,13-15]. Each method has its own set of limitations, making it important to carefully choose the appropriate assessment method based on the research context.

Observational studies investigating the relationship between diet and sleep often rely on subjective assessments of nutrition and sleep, with many highlighting the potential for recall bias [2,3]. Many studies have focused on the intake of individual nutrients, such as specific proteins, carbohydrates, fatty acids, and vitamins [16-20]. Specifically, increased protein intake has been reported to improve subjective sleep quality [16,17], while carbohydrate intake affects the sleep stages, SL, and WASO; however, further research is warranted on its long-term impact [21]. Imbalances in polyunsaturated fatty acids have been linked to a higher prevalence of sleep disorders and shorter TST [19,20]. Additionally, vitamin D deficiency has been associated with sleep disorders and shorter TST [18]. However, macronutrients that contribute to the total energy intake (such as carbohydrates, proteins, and fats, including saturated and unsaturated fatty acids) are interdependent and interact with each other [22]. Although recent research has considered these interdependencies and their relationship with health status [22-24], research on how these interdependencies affect sleep is limited. In particular, these methods, which consider the interdependencies of nutrient components, are expected to attract more attention in the future but have not yet been fully explored [25].

Understanding these complex relationships is crucial before transitioning to intervention studies, as it provides a foundational understanding of how nutrients work together to influence health outcomes. Therefore, an approach that accounts for the interdependent relationships between nutrients is necessary. This cross-sectional study using real-world data from smartphone apps aimed to examine the hypothesis that there are relationships among macronutrients, dietary components, and sleep parameters. We also investigated the relationships between sleep and macronutrients while considering their interdependencies using compositional data analysis.

Methods

Study Design and Participants

This retrospective, cross-sectional study used data from 6052 users who consented to participate between January 19 and 31, 2024. During this period, in-app messages were sent to all the users of the Asken app (Asken Inc), which is designed for dietary management and recording, requesting permission to

XSL•FO
RenderX

use their stored data. The goal of the Asken app was to gather detailed information on dietary intake, enabling us to assess the participants' nutritional habits.

At the same time, users who also used Pokémon Sleep (The Pokémon Company), a sleep-tracking app, were asked to provide their user IDs in their electronic informed consent. This linking of data was crucial for analyzing the relationship between the objective sleep data collected from the Pokémon Sleep app and the dietary data from the Asken app.

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board of Sapporo Yurinokai Hospital, Japan (approval 030). Informed consent was obtained from all participants involved in the study. Participants used both apps concurrently from July 2023 to January 2024. Furthermore, data were extracted only from the overlapping period between the start and end dates of both apps, and average values were considered representative of each participant's typical sleep habits and nutritional intake status. To ensure participant privacy and confidentiality, all data were deidentified before analysis, and no personally identifiable information was included in the dataset. The dataset was securely stored and accessible only to authorized researchers. Participants were not provided with monetary compensation for their participation in the study. However, they were fully informed about the study's purpose and significance, and their voluntary participation was obtained based on informed consent.

Dietary Intake Patterns Assessment

We calculated dietary intake patterns using the Asken smartphone app. Participants logged their meals by selecting food items and portion sizes from a database containing over 100,000 menu items. Participants entered the details of each meal into the app. For commercial products, the nutritional information was automatically recorded by scanning the barcode. The nutritional values were calculated based on the *2020 Standard Tables of Food Composition in Japan (eighth edition)* [26]. The recording and calculation methods used by the participants are detailed in a previous study [12]. The Asken dietary recording app and traditional paper-based questionnaires have been reported to have a reasonably good correlation coefficient of 0.80 for nutrient intake [12,27,28].

In this retrospective, cross-sectional study, data were only included from days when participants reported consuming all three meals, as it was not possible to distinguish between missed recordings and actual skipped meals. Asken allows for the calculation of various macronutrients and dietary components, including total energy, protein, total fat (including saturated, monounsaturated, and polyunsaturated fats), carbohydrate, sodium, potassium, calcium, magnesium, phosphorus, iron, zinc, copper, manganese, vitamin A, vitamin D, vitamin E, vitamin K, vitamin B1, vitamin B2, niacin, vitamin B6, vitamin B12, folate, pantothenic acid, vitamin C, cholesterol, dietary fiber, and alcohol intake.

Based on previous research [29,30], we selected and analyzed the following components reportedly associated with sleep: total energy, protein, total fat (including saturated, monounsaturated, and polyunsaturated fats), carbohydrate, sodium, potassium, and dietary fiber intake, and calculated the sodium-to-potassium ratio. Macronutrients were energy adjusted by calculating the percentage of total energy intake. The absolute daily intake was calculated for other dietary components.

Sleep Assessment

We calculated the TST, SL, and percentage of WASO (%WASO) derived from the Pokémon Sleep, which uses the Cole-Kripke algorithm for sleep-wake determination [31], as publicly disclosed [32]. Although accelerometer-based sleep determination integrated into smartphones lacks the ability to distinguish sleep stages [33,34], it provides a certain level of accuracy in determining sleep and wakefulness [22,23]. Although there may be a slight underestimation of SL, the overall TST and nocturnal awakenings showed good agreement with traditional actigraphy [34,35]. As previously mentioned, Natale et al [35] used the Cole-Kripke algorithm with smartphone accelerometers. Briefly, sleep-wake determination was performed using accelerometer data with 10-second epochs per minute. The decision was based on a 7-minute window of accelerometer data (from 4 min before to 3 min after the reference point [0 min]). A value greater than 1 indicates wakefulness and a value less than 1 indicates sleep [31]. SL was defined as the time from going to bed (start of the recording) to the first instance of being determined as sleep.

Statistical Analysis

Descriptive analysis was conducted to summarize the basic characteristics of the participants, including sleep status and dietary nutrient intake. The multivariable regression analysis, isotemporal substitution model, and compositional data analysis were performed using the *lmtest*, *deltacomp*, *Compositions*, *robCompositions*, and *ggplot2* R packages, respectively [25,36-38]. All regression models were adjusted for age, sex, and BMI.

First, multivariable regression analysis using the forced-entry method was used to determine the association among macronutrients, dietary components, and objective sleep variables (TST, SL, and %WASO). We conducted quartile categorization for total energy intake, energy-adjusted macronutrients (protein intake, total fat intake including saturated, monounsaturated, and polyunsaturated fats, and carbohydrate intake), sodium intake, potassium intake, dietary fiber intake, and sodium-to-potassium ratio. All the quartile range information for each variable is presented in Table S1 in Multimedia Appendix 1. Dummy variables were created for each nutrient based on the first quartile.

Second, to investigate the linear relationship between macronutrient intake and sleep parameters, we used an isotemporal substitution model and compositional data analysis [22-24]. In the isotemporal substitution model, when one macronutrient component is replaced with another on a one-to-one basis, the other components remain constant [22,23]. Compositional data analysis, in contrast, considers the overall composition and estimates the changes in sleep variables when the proportion of a specific macronutrient component is increased or decreased within the total composition [25]. Both

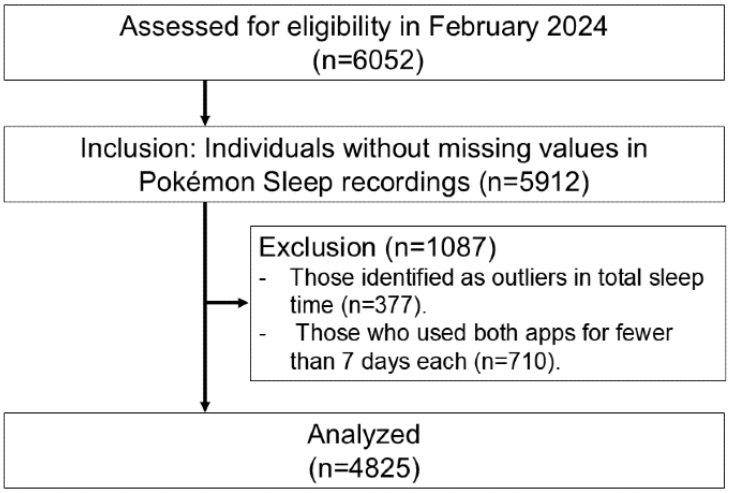
XSL•FO
RenderX

methods have been used in studies that consider the interdependencies of factors contributing to a total composition of 100% (eg, dietary nutrient intake, 24-h physical/sedentary activity, and TST) [22,23,37,38].

We calculated the macronutrient intake (in grams) by multiplying each intake by its respective calorie contribution (ie, 4 kcal for carbohydrates and protein and 9 kcal for each type of fat), ensuring that the sum equals 1 (ie, total energy intake). Nutrient intake data were transformed into compositional data using an additive log-ratio transformation. Nutrient intake data were transformed into compositional data using an additive log-ratio transformation. This transformation was necessary to account for the relative proportions of macronutrients and facilitate subsequent analyses. The log transformation helps meet the assumptions required for compositional data analysis [25]. The variability in the data, in terms of the variability of each macronutrient intake relative to the variability of other components and the total variance of the whole composition, is described in Table S2 in Multimedia Appendix 1 through a variation matrix within each component. A value close to zero implied that the intake of the two macronutrient components was highly proportional.

The compositional data were then subjected to an isometric log-ratio (ilr) transformation to facilitate the application of the linear regression models. The ilr transformation was conducted using default and customized orthonormal bases for different nutrients. Linear regression models were constructed to evaluate the association between sleep parameters and the ilr-transformed nutrient composition after adjusting for sex, age, and BMI (Table S3 in Multimedia Appendix 1). The mean nutrient composition was calculated, and predictions for sleep parameters were made using a linear regression model. The compositional ratios of macronutrients among the participants are presented in Table S4 in Multimedia Appendix 1. Because of the isotemporal substitution model and compositional data analysis, it was not possible to replace values below the minimum composition. Therefore, in this study, we replaced values exceeding the upper limit of 6% (Table S4 in Multimedia Appendix 1).

To assess the impact of altering the nutrient composition, specific changes (eg, increasing monounsaturated fat and decreasing polyunsaturated fat) were applied, and new predictions were obtained. CIs for the differences in the predicted sleep parameters were computed using the residual standard error, model matrix, and critical value from the *t*-distribution. Hypothesis tests were conducted to examine the significance of the associations between individual nutrients and sleep parameters. Different ilr transformations were applied, each focusing on a specific nutrient (protein, carbohydrate, saturated fat, monounsaturated fat, or polyunsaturated fat), and the corresponding linear models were analyzed for significance.



Ramsey regression equation specification error test confirmed the linearity assumption for all models (TST, SL, and %WASO). Variance inflation factor values ranged from 1.10 to 4.65, indicating no multicollinearity. The Durbin-Watson test showed no autocorrelation in the residuals, and the Breusch-Pagan test confirmed homoscedasticity. Although the Shapiro-Wilk test showed significant *P* values, W-values between 0.996 and 0.997 indicated that the residuals were close to normally distributed.

All descriptive and statistical analyses were performed using R (version 4.4.0; R Foundation for Statistical Computing), with statistical significance assessed at the level of .05.

Results

Of the 6052 participants who consented, 140 individuals were excluded from the analysis due to missing sleep records, 377 were excluded due to being outliers in the TST (ie, participants who did not fall within the average SD 3 range), and 710 were excluded because they used both apps for fewer than 7 days each. Therefore, the final analysis included 4825 participants (mean age 36.7, SD 10.4 years; BMI 24.8, SD 4.8 kg/m^2; 3938/4825, 81.6% were female; Figure 1 and Table 1).

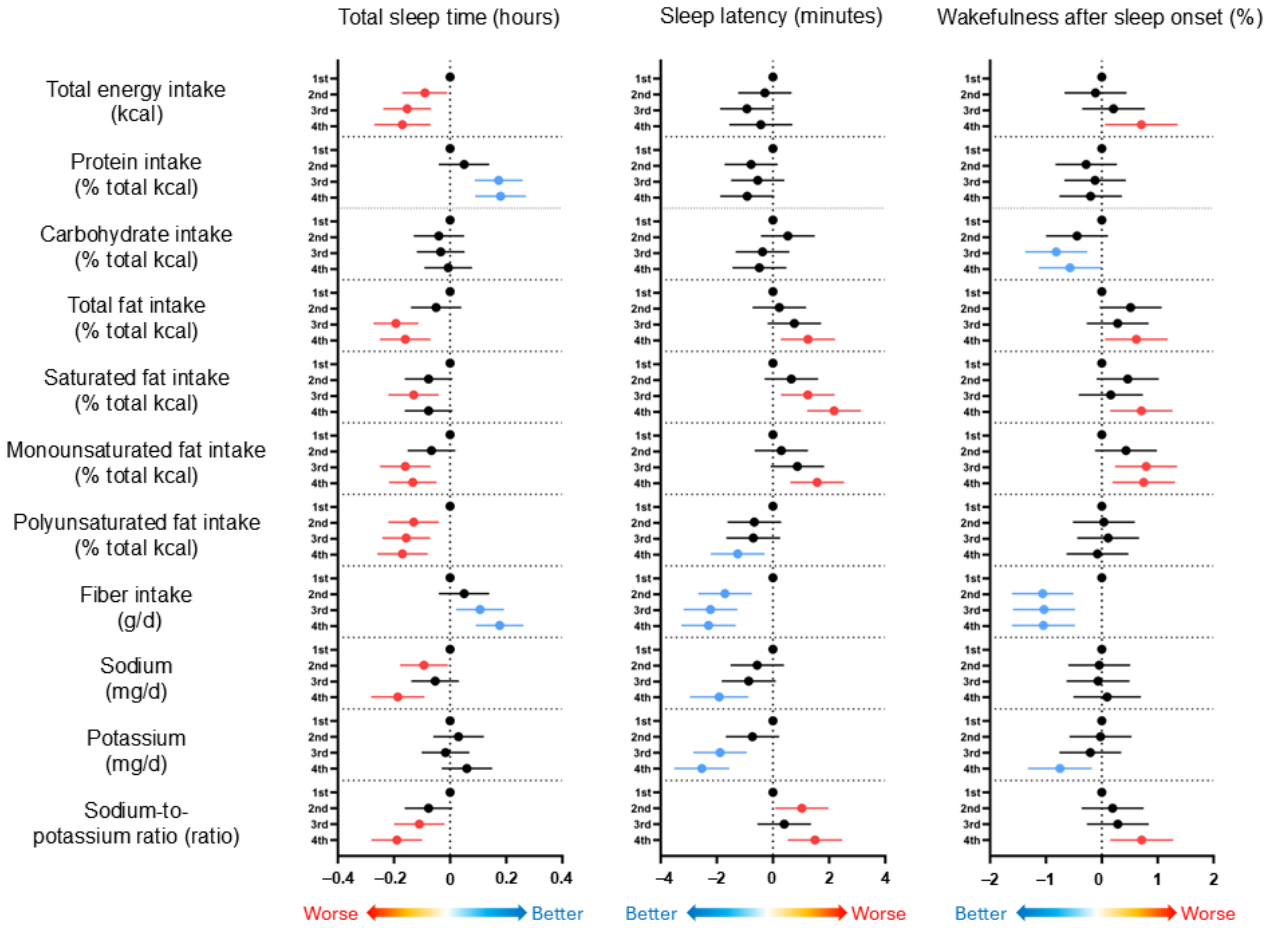
Table 1. Characteristics of participants.

Variables	All participants (n=4825)	Male participants (n=887)	Female participants (n=3938)
Basic characteristics			
Age (years), mean (SD)	36.7 (10.4)	38.4 (10.8)	36.3 (10.2)
BMI (kg/m^2), mean (SD)	24.8 (4.8)	26.0 (4.5)	24.6 (4.8)
Physical activity level (inactive), n (%)	4381 (90.8)	775 (87.4)	3606 (91.6)
Sleep status, mean (SD)			
Number of days of Pokémon Sleep recording	134.0 (54.5)	135.7 (56.0)	133.7 (54.2)
Total sleep time (hours)	6.7 (1.1)	6.5 (1.1)	6.7 (1.1)
Sleep onset latency (minutes)	21.5 (12.1)	23.5 (13.6)	21.1 (11.7)
Percentage wakefulness after sleep onset (%)	9.9 (7.2)	13.1 (9.1)	9.2 (6.4)
Nutrient status, mean (SD)			
Number of days of Asken data recording (days)	85.8 (63.6)	93.2 (67.3)	84.1 (62.7)
Total energy intake (kcal)	1662.6 (330.3)	2055.1 (349.2)	1574.2 (252.4)
Protein intake (% total kcal)	17.7 (3.7)	18.8 (4.8)	17.5 (3.4)
Carbohydrate intake (% total kcal)	51.7 (5.5)	50.3 (5.9)	52.0 (5.3)
Total fat intake (% total kcal)	32.3 (4.3)	31.4 (4.8)	32.6 (4.2)
Saturated fat intake (% total kcal)	9.5 (1.8)	8.8 (1.8)	9.7 (1.8)
Monounsaturated fat intake (% total kcal)	11.5 (2.0)	11.3 (2.2)	11.5 (1.9)
Polyunsaturated fat intake (% total kcal)	6.3 (1.0)	6.1 (1.2)	6.3 (1.0)
Dietary fiber intake (g/day)	11.7 (3.5)	10.7 (2.7)	11.9 (3.6)
Sodium (mg/day)	3486.6 (881.0)	4230.7 (996.7)	3319.1 (758.1)
Potassium (mg/day)	2295.3 (602.1)	2625.0 (692.4)	2221.0 (553.3)
Sodium to Potassium ratio	1.6 (0.4)	1.7 (0.5)	1.6 (0.4)



The mean macronutrient composition was as follows: protein, 18.2%; carbohydrates, 53.8%; and total fat, 28% (saturated fat at 9.7%, monounsaturated fat at 11.8%, and polyunsaturated fat at 6.5%; Table S4 in Multimedia Appendix 1).

Figure 2 and Table S5 in Multimedia Appendix 1 present the results of multivariate regression analyses comparing each nutrient across quartiles to the first quartile in relation to sleep variables. Specifically, in terms of macronutrients, the TST was significantly shorter in the second, third, and fourth quartiles compared with the first quartile with lower total energy intake. Greater intake ratios of total fat, including saturated, monounsaturated, and polyunsaturated fats, were associated with shorter TST. In contrast, greater protein intake levels in the third and fourth quartiles were associated with longer TST compared with those in the first quartile.

Regarding SL, greater levels of total, saturated, and monounsaturated fat intake were linked to longer SL, while greater intake of polyunsaturated fats showed a tendency toward shorter SL. Greater total energy and total fat intakes were associated with longer %WASO, whereas greater carbohydrate intake indicated a tendency towards a shorter %WASO. Greater dietary fiber intake consistently showed associations with longer TST, shorter SL, and shorter %WASO, suggesting its beneficial effect on sleep quality. Greater sodium intake was associated with shorter TST, and both greater sodium and potassium intake were linked to shorter SL. Notably, a greater sodium-to-potassium ratio was related to shorter TST, longer SL, and %WASO (Figure 2 and Table S5 in Multimedia Appendix 1).

XSL•FO
RenderX

Figure 2. Multivariable regression analysis of macronutrients and dietary components on sleep variables.

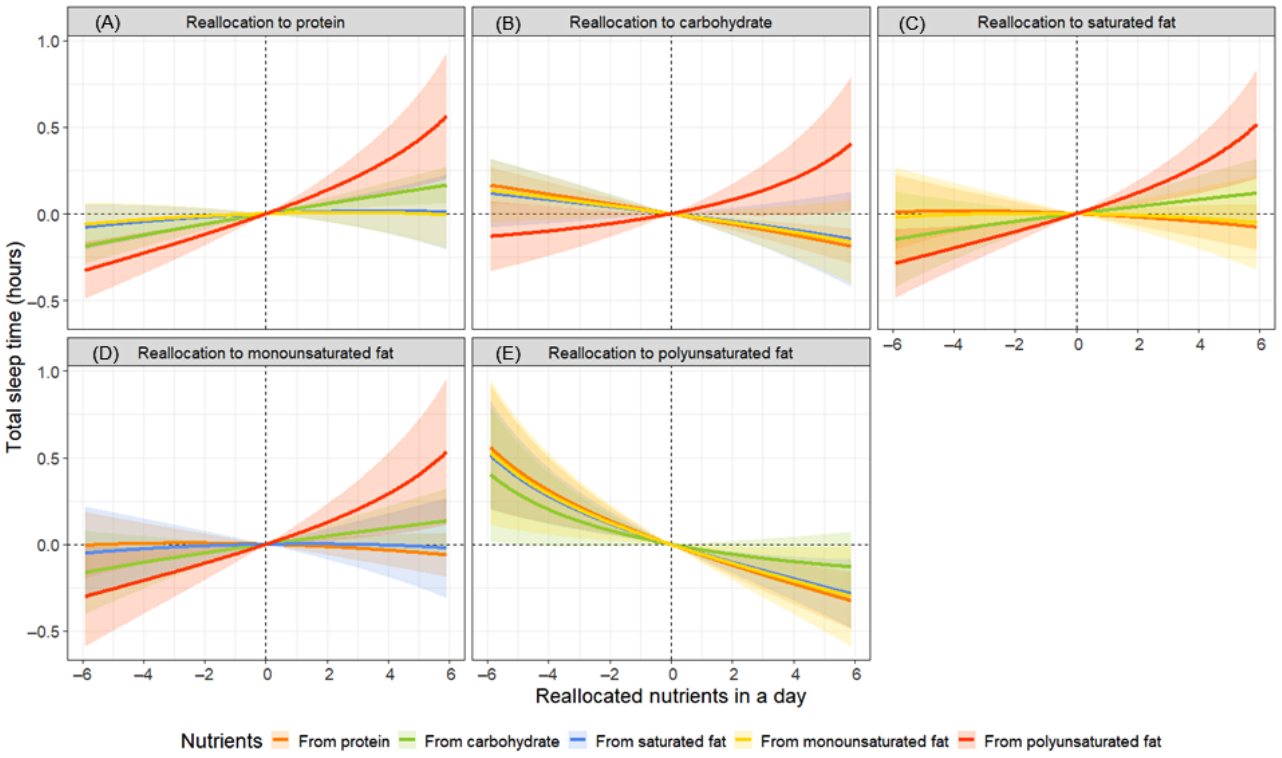
The results of the isotemporal substitution model showed that replacing 6% of total energy intake from protein with carbohydrates was significantly associated with a reduction of 0.2 hours in TST. Conversely, replacing 6% of polyunsaturated fat with equivalent amounts of protein, carbohydrates, saturated fat, and monounsaturated fat was significantly associated with changes in the TST by +0.6, +0.4, +0.5, and +0.6 hours, respectively (Figure 3 and Table S6 in Multimedia Appendix 1). Regarding SL, replacing 6% of proteins or carbohydrates with monounsaturated fat was significantly associated with a change of +2.4 and +2.8 minutes, respectively. Conversely, replacing 6% of monounsaturated fat with equivalent amounts of protein, carbohydrates, and saturated fat was significantly associated with SL changes of –3.7, –4.1, and –3.2 minutes, respectively. Additionally, replacing 6% polyunsaturated fat with equivalent amounts of protein, carbohydrates, saturated fat, and monounsaturated fat was significantly associated with changes in SL of +10.3, +9.9, +10.8, and +12.7 minutes, respectively (Figure 4 and Table S6 in Multimedia Appendix 1). For %WASO, replacing 6% of protein with monounsaturated fat was significantly associated with a +1.2% change, whereas replacing saturated fat with monounsaturated fat was significantly associated with a +2.3% change. Conversely, replacing 6% of monounsaturated fat with equivalent amounts of protein, carbohydrates, and saturated fat was significantly associated with changes in %WASO by –1.8%, –1.7%, and –2.5%, respectively. Additionally, replacing 6% polyunsaturated fat with equivalent amounts of protein, carbohydrates, saturated fat, and monounsaturated fat was significantly associated with changes in %WASO of +4.3%, +4.5%, +3.7%, and +5.5%, respectively (Figure 5 and Table S6 in Multimedia Appendix 1).

In the compositional data analysis, changes in protein by –6% of the overall macronutrient composition were significantly associated with changes in the TST by –0.6 hours, whereas changes in polyunsaturated fat by –6% were significantly associated with changes in the TST by +0.5 hours. Conversely, changes in protein by +6% from the overall macronutrient composition were significantly associated with changes in TST by +0.3 hours, while changes in polyunsaturated fat by +6% were significantly associated with changes in TST by –0.2 hours (Table 2). Regarding SL, changes in monounsaturated fat by –6% from the overall macronutrient composition were significantly associated with a change of –10.5 minutes, whereas changes in polyunsaturated fat by –6% were associated with a change of +10.7 minutes. Conversely, changes in monounsaturated fat by +6% were significantly associated with a change of +4.6 minutes, and changes in polyunsaturated fat by +6% were significantly associated with a change of –4.7 minutes (Table 2). For %WASO, similar to SL, changes in monounsaturated fats by –6% of the overall macronutrient composition were significantly associated with a change of –5.0%, whereas a –6% change in polyunsaturated fats was significantly associated with a change of +4.5%. Conversely,

XSL•FO
RenderX

changes in the monounsaturated fat content by +6% were significantly associated with a change of +2.2%, and changes in the polyunsaturated fat content by +6% were significantly associated with a change of –2.0% (Table 2).

Figure 3. Simulated changes in total sleep time when reallocating fixed amounts of other nutrient components among each nutrient component: (A) protein, (B) carbohydrate, (C) saturated fat, (D) monounsaturated fat, and (E) polyunsaturated fat, while keeping the remaining components constant at compositional percentages. All estimates have been adjusted for age, sex, and BMI.



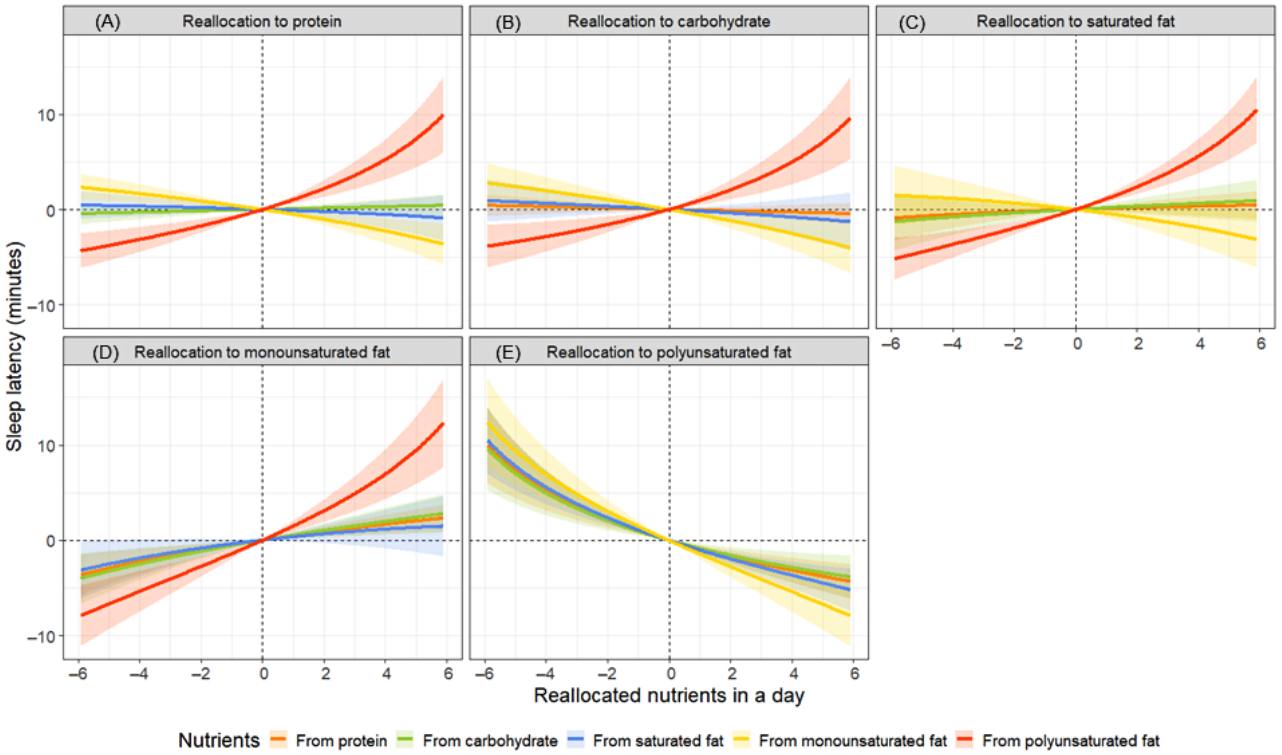


Figure 4. Simulated changes in sleep latency when reallocating fixed amounts of other nutrient components among each nutrient component: (A) protein, (B) carbohydrate, (C) saturated fat, (D) monounsaturated fat, and (E) polyunsaturated fat, while keeping the remaining components constant at compositional percentages. All estimates have been adjusted for age, sex, and BMI.

Discussion

Principal Findings

This study examined the relationship between nutritional intake and sleep using multivariate regression analysis, isotemporal substitution models, and compositional data analysis. Overall, the findings are consistent with those of previous research on individual nutrients and sleep [3-6,16-21]. As shown in Figure 2, greater total energy, fat, and sodium intakes were associated with shorter TST, whereas greater protein and dietary fiber intakes were linked to longer TST. Furthermore, the main findings of this study, based on compositional data analysis considering interdependencies, demonstrated that increasing protein while reducing other factors is associated with an elevated TST, whereas an increase in the polyunsaturated fat

XSL•FO
RenderX

with a reduced TST (Table 2). Regarding SL and WASO, monounsaturated fat and polyunsaturated fat exhibited opposing relationships (Table 2). The differences in the compositional data analysis results, compared with individual macronutrients (eg, carbohydrates), likely reflect the strong interdependent relationships among various nutrients.

Dietary fiber intake was consistently associated with improved SL and %WASO. Additionally, greater sodium intake was correlated with shorter TST, whereas greater potassium intake was associated with shorter SL. Notably, polyunsaturated fats demonstrated potential benefits for SL and %WASO compared with other types of fat. Studies suggest that dietary fiber can affect sleep by influencing microbiota [39,40]. When dietary fibers are fermented by microbiota in the large intestine, they produce short-chain fatty acids, such as acetate, propionate, and butyrate, which enhance serotonin release. Furthermore, administering tributyrin, a compound made of three molecules of butyric acid and glycerol, to mice resulted in a 50% increase in nonrapid eye movement sleep for 4 h [40]. The results of this study support those of previous studies [39,40].

Previous studies have established that greater total energy intake and poor dietary quality are associated with lower subjective sleep quality [7,41]. Specifically, higher protein intake correlates with improved sleep, whereas a higher intake of fatty acids is linked to worse sleep [41]. This study also found variations in the effects of lipid intake on sleep, depending on the type (eg, saturated, monounsaturated, or polyunsaturated fats). The mechanism by which proteins affect sleep following acute feeding may involve tryptophan; tyrosine; and the synthesis of brain neurotransmitters, such as serotonin, melatonin, and dopamine [42]. Although no significant differences were observed in SL or %WASO, a greater protein intake was positively associated with longer TST.

However, the specific mechanisms underlying the relationship between monounsaturated fat, polyunsaturated fat, and sleep remain unclear. A meta-analysis found an association between a greater intake of hexadecenoic acid, a saturated fatty acid, and subjective difficulty falling asleep [43]. Conversely, difficulties falling asleep were linked to a lower intake of dodecanoic acid, a monounsaturated fat, and butanoic acid, a saturated fatty acid [43]. Additionally, a reduced intake of dodecanoic acid was associated with subjective difficulties in maintaining sleep [43]. An epidemiological study involving adults evaluated the relationship between two polyunsaturated fatty acids, ω-6 and ω-3, and found that ω-6 fatty acids were related to the risk of sleep disorder, based on self-reported data, in an inverse U-shaped manner [19]. The ω-6:ω-3 ratio was positively and linearly associated with the risk of sleep disorders [19]. The underlying mechanisms involving ω-3 fatty acids and sleep are discussed, noting that a deficiency in ω-3 intake may affect cortical neuron oscillatory activity and sleep-wake patterns [20].

Additionally, the timing of fat intake may influence sleep; one observational study based on polysomnography suggested that consuming high-fat foods close to bedtime may be associated with increased WASO [44]. Continued consumption of a high-fat diet has been partially understood to reduce physical activity and increase rapid eye movements and sleep fragmentation through dopaminergic dysregulation [45]. Research involving mouse models and pregnant women has suggested a potential positive association between monounsaturated fat intake and sleep [46,47]. However, other studies have indicated a negative association between monounsaturated fat and sleep, whereas polyunsaturated fat has shown a positive association with sleep [48-50]. Previous studies have often focused on dietary fiber levels and comparisons between high- and low-saturated-fat diets [45,48]. Future studies should explore the impact of unsaturated fats, including monounsaturated and polyunsaturated fats.

Sodium and potassium have been reported to impact health individually [51,52], and a high sodium-to-potassium ratio (indicating relatively high sodium intake) has been associated with higher all-cause mortality [53]. Sodium intake is known to be correlated with sleep, indicating that greater sodium intake is associated with shorter subjective TST and worse sleep quality [30,50]. This relationship is attributable to the potential effect of sodium on nocturnal urination [51,52]. However, in this study, a greater intake of sodium alone was associated with a shorter TST, although no significant differences were observed in %WASO. Moreover, greater sodium intake was associated with shorter SL. Greater potassium intake was associated with shorter SL and reduced %WASO. All sleep variables were adversely related when considering the balance between sodium and potassium, which indicates an unhealthy dietary pattern (ie, relatively greater sodium intake). In this study, sodium intake was used as a basis for analysis, while the sodium-to-potassium ratio was also evaluated (Figure 2). Therefore, the results linking sleep outcomes with the sodium-to-potassium ratio are considered reasonable, as they provide a more comprehensive perspective on the impact of both minerals on sleep.

Recent studies suggested that changes in the gut microbiota may influence sleep and nutrient absorption [39,54,55]. Disrupted gut flora in patients with celiac disease has been linked to sleep disturbances [56]. Future research is warranted especially focusing on patients with celiac disease. Additionally, digital health tools offer the potential for health monitoring and early diagnosis [57].

Limitations

In this study, we investigated the association between daily nutrient intake and sleep using isotemporal substitution models and compositional data analyses to account for the interdependencies [25]. These approaches enabled us to assess how substituting macronutrients and considering the overall composition ratio affect sleep outcomes. Nonetheless, this study had several limitations. First, this cross-sectional study does not provide causal explanations. As noted above, previous studies have reported bidirectional relationships between these factors [58]. Additionally, the isotemporal substitution model and compositional data analysis are merely statistical inferences [25]. The findings of this study underscore the need for future interventions and longitudinal studies to establish causal effects definitively.

Second, this study may have included a highly health-conscious group that uses both health management apps simultaneously. Therefore, although values around the second and third quartiles,

XSL•FO
RenderX

as shown in Table S1 in Multimedia Appendix 1, correspond to Japanese macronutrient standards [59] and suggest the possibility of representing the general population, caution is needed when generalizing the findings to broader populations, owing to the inclusion of this health-conscious group.

Third, the sleep assessment method used in this study involved applying gamified elements. Some users may have exhibited sleep patterns different from their habitual patterns to achieve specific goals within the game. Moreover, because users have their own smartphones, the reliability of accelerometer measurements varies across different device models. In the future, integrating alternative methods, such as tappigraphy for sleep-wake rhythms, actigraphy, or in-home electroencephalogram devices could provide more objective evaluations [13-15].

Fourth, retrospective studies like this one are inherently prone to recall bias, as participants may inaccurately report their dietary intake and sleep patterns based on memory. It should also be noted that dietary intake was not cross-checked, and this study did not separately account for weekdays and weekends in assessing overall nutrient intake. Finally, because this study was retrospective, we could not adequately capture confounding factors related to sleep and nutrition. We collected basic demographic information, such as age, sex, height, weight, and physical activity level. However, other confounding factors, such as alcohol and smoking habits, employment status (including shifts and night shifts), marital status, cohabitation status, medical history, and medication use, were not considered. Therefore, since we could not fully eliminate concerns regarding internal validity, the presence of selection bias cannot be ruled out. Although this is an observational study with a large sample size of real-world data, it is essential to exercise caution in interpreting the results owing to these limitations.

Conclusions

We found that a greater intake of polyunsaturated fats was associated with better SL and reduced WASO, while saturated and monounsaturated fats were correlated with longer SL and wakefulness. Dietary fiber intake was positively associated with improved sleep quality, and a greater sodium-to-potassium ratio was linked to worse sleep outcomes. Furthermore, our compositional data analysis, which accounted for the interdependencies between nutrients, suggested that increasing the protein intake in place of other nutrients could improve the TST, and similar effects were observed for polyunsaturated fats on SL and WASO. Although this study is cross-sectional, the results highlight the complex potential role of dietary factors in sleep regulation and suggest the possibility of dietary interventions to enhance sleep health.

Acknowledgments

We express our gratitude to the personnel of The Pokémon Company (Tokyo, Japan), Asken Inc (Tokyo, Japan), and S'UIMIN Inc (Tokyo, Japan) for their contributions to data preparation. We also thank Editage for the English language editing. This work was supported by the World Premier International Research Center Initiative (WPI) from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) to MY; Japan Agency for Medical Research and Development (AMED) (JP21zf0127005) to MI and MY; and the COI STREAM initiative launched in 2013 by MEXT, as well as the COI-NEXT initiative launched in 2020 by MEXT (JPMJPF2017) to JS.

Data Availability

The data used in this study belong to The Pokémon Company (Tokyo, Japan) and Asken Inc (Tokyo, Japan). These data are not publicly available but can be used in future projects. Proposals and requests for data access were sent to the corresponding authors via email.

Authors' Contributions

JS, MI, and MY contributed to the conceptualization of the study. The methodology was developed by JS, MI, and MCTK, while JS and MI conducted the formal analysis. JS was responsible for data curation. JS prepared the original draft, with JS, MI, MCTK, and MY contributing to its review and editing. JS handled visualization, while MI and MY provided supervision. Funding acquisition was managed by MY. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

MY was paid by The Pokémon Company (Tokyo, Japan) for a consultation to develop the Pokémon Sleep app. The authors declare no conflicts of interest.

Abstract

Background: Oura Ring is a wearable device that estimates ovulation dates using physiology data recorded from the finger. Estimating the ovulation date can aid fertility management for conception or nonhormonal contraception and provides insights into follicular and luteal phase lengths. Across the reproductive lifespan, changes in these phase lengths can serve as a biomarker for reproductive health.

Objective: We assessed the strengths, weaknesses, and limitations of using physiology from the Oura Ring to estimate the ovulation date. We compared performance across cycle length, cycle variability, and participant age. In each subgroup, we compared the algorithm's performance with the traditional calendar method, which estimates the ovulation date based on an individual's last period start date and average menstrual cycle length.

Methods: The study sample contained 1155 ovulatory menstrual cycles from 964 participants recruited from the Oura Ring commercial database. Ovulation prediction kits served as a benchmark to evaluate the performance. The Fisher test was used to determine an odds ratio to assess if ovulation detection rate significantly differed between methods or subgroups. The Mann-Whitney *U* test was used to determine if the accuracy of the estimated ovulation date differed between the estimated and reference ovulation dates.

Results: The physiology method detected 1113 (96.4%) of 1155 ovulations with an average error of 1.26 days, which was significantly lower (U=904942.0, P<.001) than the calendar method's average error of 3.44 days. The physiology method had significantly better accuracy across all cycle lengths, cycle variability groups, and age groups compared with the calendar method (P<.001). The physiology method detected fewer ovulations in short cycles (odds ratio 3.56, 95% CI 1.65-8.06; P=.008) but did not differ between typical and long or abnormally long cycles. Abnormally long cycle lengths were associated with decreased accuracy (U=22,383, P=.03), with a mean absolute error of 1.7 (SEM .09) days compared with 1.18 (SEM .02) days. The physiology method was not associated with differences in accuracy across age or typical cycle variability, while the calendar method performed significantly worse in participants with irregular cycles (U=21,643, P<.001).

Conclusions: The physiology method demonstrated superior accuracy over the calendar method, with approximately 3-fold improvement. Calendar-based fertility tracking could be used as a backup in cases of insufficient physiology data but should be used with caution, particularly for individuals with irregular menstrual cycles. Our analyses suggest the physiology method can reliably estimate ovulation dates for adults aged 18-52 years, across a variety of cycle lengths, and in users with regular or irregular cycles. This method may be used as a tool to improve fertile window estimation, which can aid in conceiving or preventing pregnancies. This method also offers a low-effort solution for follicular and luteal phase length tracking, which are key biomarkers for reproductive health.

Introduction

With advances in wearable technology, an increasing number of women are leveraging continuous, automated sensor data to track ovulation [1]. Ovulation tracking serves multiple purposes; notably, it can be used to delineate the end of the fertile window to optimize the timing of intercourse for conception or contraception. Studies have shown that ovulation tracking can increase the likelihood of conception by approximately 40% for those trying to conceive [2-5]. Conversely, fertility awareness–based methods for contraception, although less effective than hormonal contraception methods [6-8], is increasing popular as the use of hormonal contraception declines [9-12]. Beyond fertility, the ovulation date, alongside period start dates, can be used to measure a cycle's follicular and luteal lengths. These phase lengths have been identified as biomarkers of menstrual health [13], with early research suggesting they may provide insights into fecundity [14], systemic inflammation [15], endometrial development [16], and ovarian aging [17].

Approximately 75% of individuals attempting to conceive use some method to estimate their ovulation date; these methods include cervical mucus monitoring, detecting a rise in basal body temperature (BBT), and feeling for changes in the cervix [18]. These methods vary in accuracy across subgroups including cycle regularity, compliance, and interpretation [19]. Among these, cervical mucus tracking is associated with the highest reported accuracy, with 48% to 76% of ovulations correctly estimated within 1 day of the reference ovulation [19,20]. Approximately 21% of women trying to conceive use the BBT method [18], which, although less precise than cervical mucus tracking at predicting imminent ovulation, has been found to accurately detect that ovulation has occurred [21-23]. All these methods—cervical mucus tracking, feeling for changes in the cervix, and BBT—require significant user knowledge and active participation. In contrast, wearable-based ovulation tracking may provide a more convenient alternative for those seeking a less labor-intensive approach to monitoring ovulation [1].

Previous research has shown that wearables can detect ovulation-related physiological changes. These include wrist-worn devices like Ava [24], an in-ear thermometer [25], vaginal biosensors [26,27], and Oura Ring [28]. While temperature remains the primary continuously measured physiological metric for ovulation detection, other metrics such as heart rate, breath rate, and heart rate variability have also shown predictive value [1]. Studies indicate that intraoral and ear-based temperature methods are generally less accurate for ovulation detection compared with wrist and ring-based wearables [29], which provide more stable temperature readings, especially when measuring distal temperature during sleep [6,24,30]. The primary objective of these wearable technologies, thus far, has been to support conception or offer nonhormonal contraception by using changes in ovulation-related physiology to identify fertile days in a user's cycle.

We assess the performance of the physiology method using Oura Ring of ovulation estimation against the traditional calendar method [31]. We hypothesized that the physiology method would outperform the calendar method in participants with high cycle variability, and the physiology method's ovulation detection rate would decrease with participant age, reflecting age-related declines in progesterone levels and consequently luteal temperature rise magnitude [32]. Ultimately, we aim to review the strengths, weaknesses, and limitations of using Oura Ring physiology for ovulation date estimation.

Methods

Reference Ovulation Dates

Oura Ring commercial users can choose to self-report the results of home luteinizing hormone (LH) tests through the Oura Ring app. Positive LH test results served as the benchmark reference for algorithm performance testing. The reference ovulation date was defined as the day after the last positive LH test in the menstrual cycle [19,33].

Data Inclusion and Exclusion Criteria

Participants were selected for the study if they self-reported a positive LH test result between January 1, 2019, and April 15, 2024. Inclusion criteria required the positive LH test date to be logged within a complete menstrual cycle, such that menses start and end dates were both logged. The self-reported menses and reference LH test dates were required to demarcate biologically plausible cycle phase lengths. Acceptable ranges were 10-90 days for the follicular phase and 8-20 days for the luteal phase [33]. If a single user had multiple complete menstrual cycles containing an LH test reference, these were included as long as the algorithm input window did not overlap. These inclusion criteria resulted in 121 users with 2 or more observations, for a total of 1209 ovulatory menstrual cycles from 1051 unique users.

We excluded menstrual cycles from the analysis based on insufficient physiology data, hormone use, or self-reported pregnancy. Insufficient data were defined as more than 40% of missing physiology data in the last 60 days. Hormone use was self-reported by a questionnaire, where participants were asked to report any hormone intake that could influence ovulation, including hormonal birth control, hormone replacement therapy, or fertility medications. Of these exclusion criteria, 47 cycles were excluded due to insufficient physiology data, 6 due to hormone use, and 1 due to pregnancy. The resulting dataset contained 1155 ovulatory cycles from 1007 unique participants.

Ovulation Detection Algorithms

Calendar Method

We estimated each cycle's ovulation date using the calendar method as a comparison with the physiology method results. The calendar method estimates the ovulation date by subtracting the typical luteal length from the user's typical cycle length. The population mean is used as the typical luteal length, that is, 12 days [33,34]. One additional day is subtracted because we define the ovulation date as the last follicular day, which is standard in the literature [33,34]. The user's typical cycle length is defined here as the median cycle length across the last 6 months, with outliers shorter than 12 days or greater than 90 days excluded.

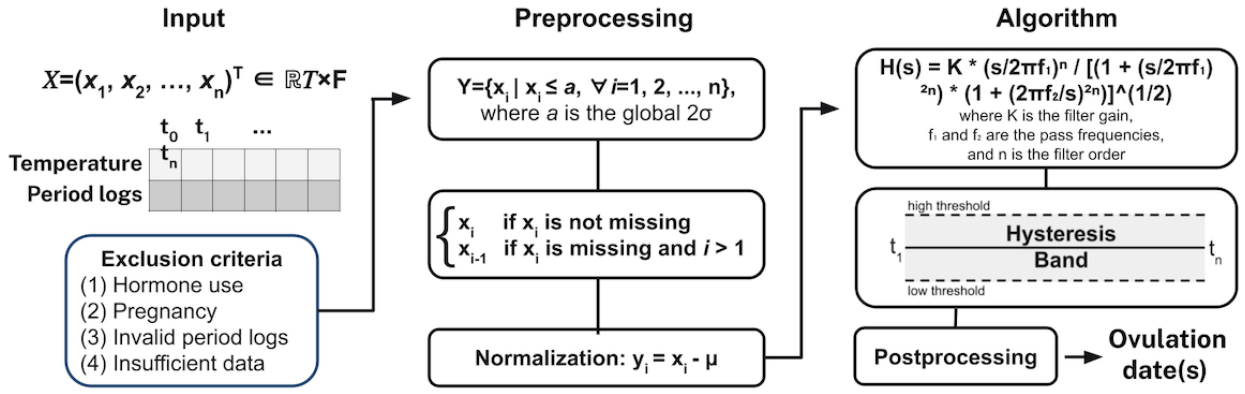
RenderX



Physiology Method

The physiology method is an algorithm written in Python that uses signal processing techniques to analyze continuously recorded finger temperature from Oura Ring to estimate the date of the most recent ovulation event. The ring contains negative temperature coefficient thermistors, which are used to measure skin temperature. Users are instructed to wear Oura Ring on a finger where the ring feels tight but not uncomfortable.

The algorithm was developed by assessing a separate training dataset of 30,000 menstrual cycles, which contained no overlapping users or menstrual cycles as the test set presented here. The algorithm aims to identify a maintained rise in skin temperature by around 0.3-0.7 °C, which has shown to be a robust postovulatory change following the regression of the dominant follicle [32]. The algorithm was tuned using a grid search across a set of parameters on the training dataset to optimize for detecting the rise in temperature following ovulation, as determined based on visual inspection. The physiology algorithm first normalizes the dataset by centering it around 0. Then, outliers were rejected, defined as >2 SD from the population average. Any missing or rejected data were then imputed using a linear fill. A Butterworth bandpass filter was then applied, with the low pass, high pass, and order set as parameters to be tuned in the grid search. Finally, hysteresis thresholding was used to determine the likely follicular and luteal phase days of the cycle, the parameters of which were also tuned in the grid search.

Algorithm postprocessing included combining the temperature-estimated luteal phase with self-reported period start logs. The algorithm rejects ovulation detections if they resulted in biologically implausible phase lengths [33,35], that is, luteal phases outside the range of 7-17 days or follicular phases outside the range of 10-90 days. In these cases, the physiology algorithm labels these cases as failures to detect ovulation. For details, refer to Figure 1.

Figure 1. The physiology algorithm pipeline.

Statistical Analysis

Detection Rate

The ovulation detection rate was defined as the proportion of ovulatory cycles in which the algorithm correctly identified an ovulation. We calculated the 95% CI for the detection rate using the *z*-score–based margin of error for proportions [36]. To assess statistical differences in the ovulation detection rate across subgroups, we used the Fisher exact test. This nonparametric statistical method is well-suited for comparing proportion data, especially in datasets where subgroups vary in sample size [37]. For each subgroup of interest, such as cycle variation, we designated a reference group and used the Fisher exact test to compare the detection rates between the reference group with all other groups. For example, participants with irregular cycles were compared with participants with regular cycles as a reference group. Adjustments for multiple comparisons were made using the Bonferroni correction [38].

Accuracy

The ovulation date error was defined as the number of days between the algorithm's estimated ovulation date and the reference ovulation date. The reference ovulation date was determined as the day following the last positive or peak LH surge reported in that cycle. To quantify the typical accuracy, we calculated the mean absolute error (MAE). The 95% CI on this mean was estimated using 1.96 times the SEM [39]. To evaluate statistical differences in ovulation date error across various subgroups, we used the Mann-Whitney *U* test. This test is preferred for providing a robust analysis with minimal influence from outliers and nonnormal distributions, in contrast to parametric methods. For each subgroup of interest, such as cycle variation, one group is designated as the reference group to be compared against all other groups. For example, we compare participants with irregular cycles to participants with regular cycles as a reference group. Adjustments for multiple comparisons were made using a Bonferroni correction [38].

Subgroups

Cycle Length

Detection rate and accuracy were broken down by cycle length to compare ovulation estimation performance in menstrual cycles of various lengths. Cycle length was defined as the number of days between 2 menses onsets. The cycle length was classified as abnormal if it was shorter than 21 days or longer than 35 days [40]. Of the remaining cycle lengths, we defined

XSL•FO
RenderX

a “short” cycle as lasting between 21-26 days, a “typical” cycle as lasting between 27-31 days, and a “long” cycle as lasting between 32-35 days (Table 1). To statistically compare ovulation detection performance metrics across groups, we compared performance metrics in cycles of typical length with all other cycle length groups.

Table 1. Cycle length.

Cycle length	Days, n	Cycles (n=1155), n (%)	Physiology method			Calendar method	
			Detection rate (%), mean (SEM)	MAE[a], mean (SEM)	Within 2 days (%)	MAE, mean (SEM)	Within 2 days (%)
Abnormally short	≤21	2 (<1)	—[b]	—	—	—	—
Short	22-26	176 (15.2)	93.2 (3.7)	1.34 (.09)	84.8	2.84 (0.21)	51.7
Medium	27-31	662 (57.3)	98.0 (1.1)	1.18 (.04)	90	3.02 (0.13)	51
Long	32-35	223 (19.3)	97.3 (2.1)	1.26 (.08)	88	3.57 (0.28)	55.6
Abnormally long	≥36	92 (8)	90 (6)	1.70 (.18)	77	7.32 (1.07)	35

[a]MAE: mean absolute error.

[b]Not applicable.

Cycle Variability

Detection rate and accuracy were broken down by a participant’s cycle variability to compare performance in these groups. Cycle variability was defined as the median of the absolute value of cycle length differences between consecutive cycles, across the past 6 months. Abnormal cycle variation is defined as cycle variation larger than 7 days. Of the normal cycle variation, we defined a “typical” cycle variation as between 0-3 days and a “moderately irregular” cycle variation as between 4-7 days (Table 2). To statistically compare ovulation detection performance metrics across groups, we compared the typical cycle variability group with all other groups.

Table 2. Cycle variability.

Cycle variability	Variation (days)	Cycles (n=975), n (%)	Physiology method			Calendar method	
			Detection rate (%), mean (SEM)	MAE[a], mean (SEM)	Within 2 days (%)	MAE, mean (SEM)	Within 2 days (%)
Typical	0-3	648 (67)	97.5 (1.2)	1.23 (0.05)	88.3	2.51 (0.08)	55.9
Moderately Irregular	4-7	210 (21)	96.0 (2.7)	1.23 (0.08)	90.7	3.48 (0.22)	43.8
Abnormally Irregular	>7	117 (12)	94.0 (4.3)	1.48 (0.14)	81.8	6.63 (0.65)	32.5

[a]MAE: mean absolute error.

Age

Age was binned into 4 groups. Specifically, our groups consisted of 18-26 years, 27-34 years, 35-43 years, and ≥44 years (Table 3). Because the group with the most participants fell into “27-34 years” age group, this was designated as the reference group for statistical analysis.

Table 3. Age.

Age group (years)	Cycles (n=1155), n (%)	Physiology method			Calendar method	
		Detection rate (%), mean (SEM)	MAE[a], mean (SEM)	Within 2 days (%)	MAE, mean (SEM)	Within 2 days (%)
18-26	134 (11.6)	97.0 (2.8)	1.35 (0.11)	86.9	3.64 (0.48)	53
27-34	592 (51.3)	96.6 (1.5)	1.29 (0.05)	87.1	3.39 (0.48)	55.4
35-43	373 (32.3)	96.0 (2.0)	1.17 (0.06)	89.1	3.46 (0.21)	45
≥44	56 (5)	95 (6)	1.19 (0.13)	91	3.30 (0.31)	34

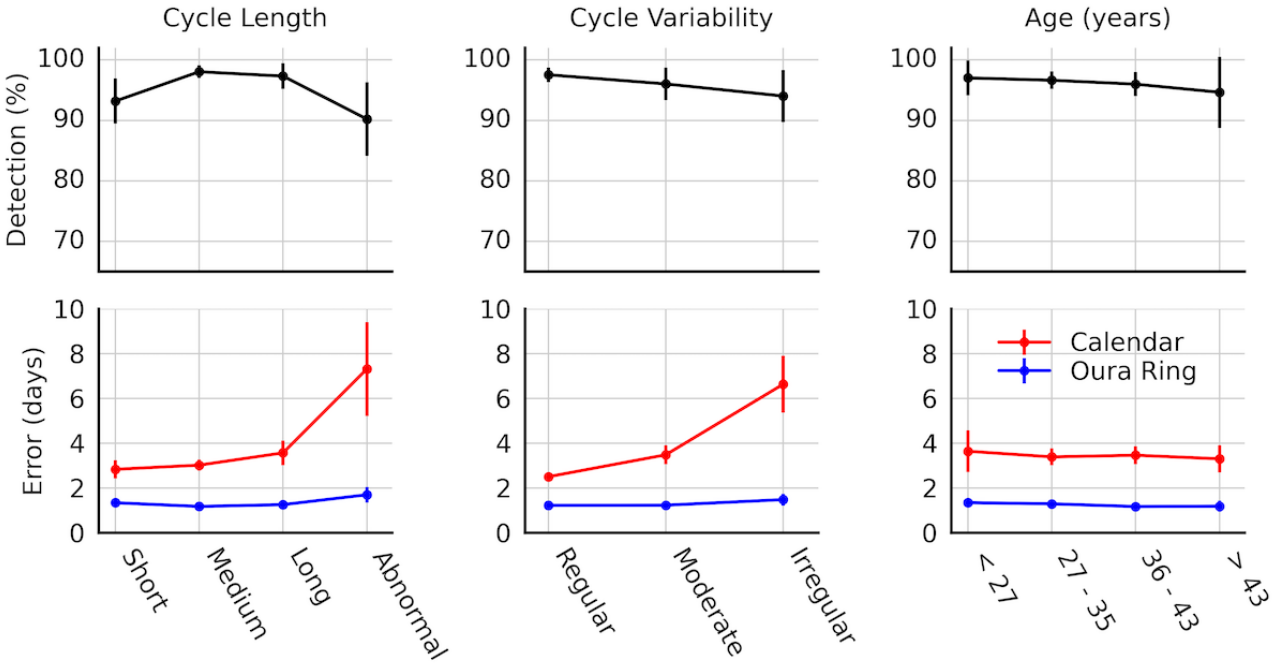
Ethical Considerations

Data from adult Oura Ring users were selected from the Oura Ring commercial database. Oura Health Oy (Oulu, Finland)

XSL•FO
RenderX

collected the data in accordance with their terms of use and privacy policy. By agreeing to the privacy policy, the Oura Ring users had also agreed to the use of their data to perform analysis. The data analysis study protocol was reviewed and approved by ŌURA's science and legal team, which is responsible for ethics and regulatory adherence for studies. The study was deemed exempt as the analysis used aggregate data without individual identifiers. All data that were made available were deidentified and are anonymous. Additional protections included allowing data access only upon request for the purpose of ensuring the analyses presented are accurate and complete. Compensation for study participation was not provided.

Results



Participants

The study sample consisted of 964 female participants. Participants had a mean age of 32.8 (SD 5.5) years and a mean self-reported cycle length of 29.1 (SD 3.4) days.

Algorithm Performance

The physiology method from Oura Ring correctly detected 1113 (96.4%) of 1155 ovulatory cycles observed (95% CI 95.3-97.4%). The estimated ovulation date MAE was 1.26 (SEM 0.02) days. Of the total 1155 ovulatory cycles, 1097 (95%) of ovulations were detected within 3 days, 1015 (87.9%) were detected within 2 days, and 785 (68%) were detected within 1 day. By comparison, the calendar method's ovulation MAE was 3.44 (SEM 0.07) days. In total, the calendar method detected 768 (66.5%) of ovulations within 3 days, 585 (50.7%) within 2 days, and 371 (32.2%) within 1 day. The physiology method estimated ovulation with significantly improved accuracy compared with the calendar method (U_{1154}=904942, P<.001, Cliff δ=0.46). Refer to Figure 2 for a breakdown of the algorithm's performance by cycle length, cycle variability, and age.

Figure 2. Ovulation estimation performance metrics across subgroups.

Cycle Length

Ovulation detection rate was impacted by cycle length. The Fisher test for detection rates suggests the odds of detecting ovulation were 3.56 times higher in medium cycle lengths compared with short cycle lengths (odds ratio 3.56, 95% CI 1.65-8.06, P=.008). Long (P=.99) and abnormally long (P=.59) cycle lengths did not statistically differ relative to medium cycle lengths. Accuracy did not significantly differ across regular cycle lengths (short, medium, or long) when using the physiology method (short vs medium: P=.41; long vs medium: P=.99). However, abnormally long cycle lengths ≥36 days) were associated with increased error (U=22,383, P=.03, δ=−0.17) with an MAE of 1.7 (SEM .09) days compared with 1.18 (SEM .02) days. The calendar method also performed significantly worse in abnormally long cycles (U=21,184, P<.001, δ=−0.30), with an MAE of 7.32 (SEM .54) days compared with 3.02 (SEM .07) days.

Cycle Variability

Neither detection rate nor accuracy differed significantly based on cycle variability when using the physiology method (for detection rate, moderate vs regular: P=.33 and irregular vs regular: P=.07; for accuracy, moderate vs regular: P=.99 and irregular vs regular: P=.15). However, the calendar method was associated with significantly worse accuracy for moderately irregular cyclers (U=54,093.5, P<.001, δ=−0.17) and even worse accuracy in irregular cycles (U=21,643, P<.001, δ=−0.43) when compared with typical cycle variability.

XSL•FO
RenderX

Age

Neither the physiology method nor the calendar method was associated with differences across age in ovulation detection rate or estimated ovulation date error.

Discussion

Principal Findings

Finger temperature collected from Oura Ring was formulated as a physiology-based method of estimating the ovulation date. To assess the performance of this algorithm, we compare the physiology method with the calendar method in 1155 ovulatory cycles. The physiology method correctly detected ovulation in 1113 (96.4%) of 1155 cycles with an MAE of 1.26 days. This method was significantly more precise than the calendar method, which exhibited an MAE of 3.44 days, representing a 2.7-fold increase in error. In practical applications, Oura Ring primarily uses the physiology-based method to estimate a cycle's ovulation date. However, the calendar method is used as a secondary approach when the physiology-based method cannot estimate the ovulation date, for example, in instances of excessive missing data. Thus, a thorough understanding of the strengths and limitations of both methods is critical. We also assessed if subgroups including age, cycle variation, and cycle length impact the accuracy of ovulation date estimation.

Age did not influence the accuracy of estimated ovulation dates within the assessed age range of 18-52 years, using either physiology-based or calendar methods. This finding aligns with the existing literature suggesting that age should not significantly affect the performance of the calendar method, as the luteal phase length remains consistent across age groups, and the calendar method estimates ovulation day by subtracting the luteal phase length from the user's typical cycle length [31]. Although it was hypothesized that the physiology method may be less accurate across age due to variations in the magnitude of the postovulatory temperature rise [32,41], our analysis indicates that age did not significantly impact performance. However, ovulation estimation using Oura Ring has not yet been tested in individuals younger than 18 years and thus accuracy should not be assumed for adolescents.

Cycle variability significantly impacted the performance of the calendar method, but not the physiology method. Specifically, participants with irregular cycles experienced poorer performance using the calendar method, with an MAE of 6.63 days. This is a 2.6-fold decrease in accuracy relative to regular cyclers using the calendar method, and a 4.5-fold decrease in accuracy relative to the physiology-based method in irregular cyclers. When framing this as a window of days where the ovulation is 95% likely to have occurred, in irregular cyclers, that window is reduced from 14.2 days to 3.4 days. The superior accuracy of the physiology method likely stems from its independence from follicular phase length, which predominantly drives cycle variability and thus increases error in the calendar method [33,42].

Cycle length significantly influences ovulation estimation performance. Using the calendar method, longer cycles were associated with decreased accuracy, such that the MAE reaches 7.32 days in abnormally long cycles (ie, cycles exceeding 36 days in length). With the physiology method, statistical differences are evident both in the ovulation detection rate and the accuracy of the estimated ovulation date. Specifically, in cycles shorter than 26 days, which constitute 15% of our sample, the detection rate falls to 93%, compared with 98% in cycles of typical length. Furthermore, accuracy diminishes in abnormally long cycles with an MAE of 1.7 days versus 1.18 days in typical cycles. Consequently, users with shorter cycles may experience fewer detected ovulations, while those with abnormally long cycles may experience slightly worse accuracy when using the physiology method. Nevertheless, across all cycle categories, the physiology method significantly outperforms the calendar method.

Comparison With Previous Work

Compared with wrist-worn devices with reported ovulation detection rates between 54% to 86% [43,44], Oura Ring exhibited superior performance, detecting 96.4% of ovulations. Oura Ring accuracy was similar to that of cervical mucus tracking, with 68% of estimations within 1 day of the reference ovulation date compared with 48% to 76% [19,20]. Oura Ring achieved favorable accuracy to BBT, which has a reported 20% detection rate [19,23], with an accuracy of 22% of ovulations correctly falling within 1 day of the reference ovulation [22,23]. Notably, BBT shows a marked decrease in performance in irregular cycles with a 34% drop in accuracy compared with regular cycles [45], while Oura Ring accuracy remained stable. Direct comparisons between studies should be approached with caution, as they are based on datasets with varying compositions of participant subgroups known to influence accuracy; notably, most studies exclude irregular cycles and cycles of abnormal length for performance analysis. The primary objective of this study is to identify conditions that may hinder the performance of Oura Ring ovulation estimation, rather than directly comparing it with other devices.

Limitations

The primary limitation of this study is that our dataset consisted solely of ovulatory cycles and thus we cannot address ovulation estimation performance in anovulatory cycles. Without an estimate of the false alarm rate, a lack of detected ovulation by the algorithm should not be interpreted as indicative of an anovulatory cycle. The algorithm is not intended for use in individuals who frequently experience anovulatory cycles or who do not ovulate due to factors such as hormonal contraceptives.

Another limitation of this study is that our reference ovulation date is based on self-reported positive LH surge from participants using ovulation predictor kits (OPKs). While OPKs impose a lower participant burden, the gold standard for ovulation reference is a transvaginal ultrasound, which offers higher accuracy [19]. Given that our approach for collecting LH test results relied on self-report, the ovulation reference labels used here are susceptible to inaccuracies introduced by human error and subjective reporting biases. This approach also limits our sample to individuals who both use an Oura Ring and opt to take OPKs, and thus our cohort may not be representative of the broader population with menstrual cycles. Furthermore,

XSL•FO
RenderX

the absence of data on negative OPK results precludes our ability to assess anovulatory cycles. In addition, it is not uncommon for an OPK to return a positive LH surge across multiple days; therefore, if participants logged only 1 positive LH surge and did not test on subsequent days, our reference ovulation day might be prematurely assigned.

A further limitation is that we did not collect data on whether participants had a history of menstrual cycle disorders. This is of particular concern in the 12% of participants with irregular cycles, who may have various underlying causes. A potential factor that could impact the accuracy of Oura Ring ovulation estimation is luteal phase deficiency (LPD), characterized by insufficient progesterone exposure [46]. LPD could influence the magnitude of the postovulatory temperature rise and thus impair the algorithm's ability to estimate ovulation dates. Until future research is conducted, the estimated ovulation dates provided by the Oura Ring should be interpreted with caution in individuals with menstrual cycle disorders, particularly conditions associated with LPD, such as polycystic ovary syndrome [47,48], thyroid and prolactin disorders [49], and during in vitro fertilization cycles [50].

Conclusions

Overall, the results suggest that Oura Ring offers significantly improved accuracy over the traditional calendar method for estimating ovulation date. Furthermore, the physiology method is associated with relatively robust accuracy across various ages, cycle variability, and cycle lengths, with only small drops in detecting rate for shorter cycles (<26 days) and slight drops in accuracy in abnormally long cycles (>36 days). This is significantly improved compared with the calendar method, which was associated with large accuracy decreases in users with long cycles and irregular cycles. Based on previous reports, Oura Ring ovulation estimation appears to be outperforming other wearables and BBT-based ovulation estimation methods and on par with the cervical-mucus tracking method, although those results should be compared cautiously given that the performance was measured on different datasets. Furthermore, we posit that widespread ovulation tracking could have broad use beyond its use in conception and nonhormonal contraception. Specifically, continuous monitoring of follicular and luteal phase lengths throughout the reproductive lifespan could benefit a wider demographic interested in menstrual cycle–related biomarkers. These biomarkers hold promise for the early detection of disorders related to the menstrual cycle and fertility.

Data Availability

The dataset analyzed during this study is not publicly available due to privacy protections for participants but may be made available at Oura's sole discretion.

Authors' Contributions

NT designed the algorithm, implemented the algorithm in Python, aggregated the dataset for analysis, conducted the analyses, wrote the first draft of the manuscript, and generated figures. NT and XZ contributed to algorithm design iterations, analysis plan iterations, and data interpretation. All authors contributed to manuscript editing.

Conflicts of Interest

The authors are employees of Oura Health, but this work represents their individual opinions and initiatives. We aim to provide a clear and impartial analysis to ensure that users and research partners are well-informed about the capabilities and limitations of the algorithm.

Abstract

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common and debilitating adverse effect of neurotoxic chemotherapy characterized by symptoms such as numbness, tingling, and weakness. Effective monitoring and detection of CIPN are crucial for avoiding progression to irreversible symptoms. Due to the inconvenience of clinic-based objective assessment, CIPN detection relies primarily on patients' reporting of subjective symptoms, and patient-reported outcomes are used to facilitate CIPN detection. Our previous study found evidence that objective functional assessments completed within a smartphone app may differentiate patients with and those without CIPN after treatment.

Objective: This prospective, longitudinal observational cohort study aimed to determine the feasibility and accuracy of app-based remote monitoring of CIPN in patients with cancer undergoing neurotoxic chemotherapeutic treatment and to conduct exploratory comparisons of app-based functional CIPN monitoring versus patient-reported outcome–only monitoring.

Methods: The NeuroDetect app (Medable Inc) includes subjective EORTC (European Organization for Research and Treatment of Cancer) Quality of Life Questionnaire (QLQ)–20-item scale (CIPN20) and 6 objective functional assessments that use smartphone sensors to mimic neurological examinations, such as walking, standing, and manual dexterity tests. The functional assessment data were collected from patients with cancer undergoing neurotoxic chemotherapy, and a neurological examination was conducted at the end of treatment to diagnose CIPN in the feet (CIPN-f) or CIPN in the hands (CIPN-h). Various classification models including NeuroDetect features only (NeuroDetect Model) CIPN20-only (CIPN20 Model) or a combination of both (Combined Model) were trained and evaluated for accuracy in predicting CIPN probability.

Results: Of the 45 patients who completed functional assessments and neurological examinations, 24 had CIPN-f, and 29 had CIPN-h. The NeuroDetect Model could discriminate between patients with and those without CIPN-f (area under the curve=83.8%, comparison with no information rate P=.02) but not CIPN-h (area under the curve=67.9%, P=.18). The rolling rotation features from the eyes-closed phase of the Romberg Stance assessment showed the greatest contribution to CIPN-f (40% of total variable importance) and the Finger Tapping assessment showed the greatest contribution to CIPN-h (85% of total variable importance). The NeuroDetect Model had numerically, and at some time points statistically, superior performance to the CIPN20 Model in both CIPN-f and CIPN-h, particularly before and early in treatment. The Combined Model numerically, though not statistically,

XSL•FO
RenderX

outperformed either assessment strategy individually, indicating that the combination of functional and patient-reported assessment within a smartphone may be optimal to CIPN detection.

Conclusions: Our findings demonstrate the feasibility of integrating subjective and objective CIPN assessment into a smartphone app for remote, longitudinal CIPN monitoring. Studies of larger patient cohorts are needed to refine the app-based CIPN detection models and determine whether their use in practice improves CIPN detection.

Introduction

Chemotherapy-induced peripheral neuropathy (CIPN) is a common adverse effect of chemotherapy, affecting up to 70% of patients receiving taxanes for breast, lung, ovarian, and other cancer types [1]. CIPN typically presents with numbness or tingling in the feet or hands that may progress to motor weakness and impairment [2,3]. In some cases, CIPN can be irreversible, resulting in long-term gait imbalance and impaired manual dexterity, which hinder daily activity, reduce independence, increase fall risk, and reduce quality of life [4,5].

Detecting CIPN during treatment is critical to avoid these potentially irreversible adverse effects [4,5]. Detection of CIPN during neurotoxic chemotherapy treatment primarily depends on patients self-reporting symptoms during routine appointments with their medical oncology team [6]. Objective CIPN assessment may be useful to detect symptoms but is not commonly used in practice due to logistical barriers, including the need for additional trained personnel, time, space, and equipment [7]. As an alternative, validated patient-reported outcome (PRO) questionnaires have been developed to enable convenient subjective CIPN assessment. One such tool is the CIPN Quality of Life Questionnaire developed by the European Organization for Research and Treatment of Cancer (EORTC), which includes a 20-item scale (CIPN20) [8]. PROs may be an improvement over routine physician assessments via the National Cancer Institute Common Terminology Criteria for Adverse Event grading, but PROs lack objective measurement and rely on patients' willingness to accurately report CIPN symptoms [9]. Consequently, there remains an unmet need to develop strategies for objective CIPN assessment that are feasible and accurate.

Smartphone and wearable sensor-based technology have been increasingly used to advance the detection and monitoring of various diseases [10], for example, smartphone apps can monitor gait and balance changes and provide valuable insights for patients with progressive Parkinson disease [11]. Similar to Parkinson disease, objective evidence of CIPN includes impaired gait, increased sway, and reduced manual dexterity, all of which can be detected through functional assessments using wearable or smartphone sensors [12,13]. Our previous study of the first version of NeuroDetect (Medable Inc) used off-the-shelf smartphone sensor–based functional assessments and showed feasibility in differentiating patients with and those without CIPN posttreatment [13]. Integrating PRO data with objective assessments within a smartphone app could achieve remote and objective CIPN monitoring and enhance the detection of CIPN with minimal inconvenience and cost [14]. The objective of this longitudinal study was to determine the feasibility of conducting longitudinal, remote smartphone-based functional assessments that emulate certain aspects of a formal bedside neurological examination and investigate whether these functional assessments can detect CIPN during neurotoxic treatment. Exploratory analyses in this unpowered feasibility study investigated the sensitivity and specificity of an app-based approach compared with or combined with PRO-only CIPN assessment.

Methods

NeuroDetect App

NeuroDetect is an iOS (Apple Inc) app that incorporates both subjective and objective evaluations of CIPN. The subjective evaluations include EORTC Quality of Life Questionnaire (QLQ)–CIPN20, a validated PRO questionnaire for the collection of CIPN sensory, motor, and autonomic symptoms on a 4-point Likert scale (1=not at all, 2=a little, 3=quite a bit, and 4=very much) [8,15]. The objective functional assessments were customized from the available activities in the ResearchKit (Apple Inc) framework to replicate certain aspects of the neurological examination [16]. The 6 NeuroDetect functional assessments use embedded sensors within the smartphone including an accelerometer, gyroscope, and touchscreen to monitor speed, sway, accuracy, and rhythm during gait and balance tasks (natural walk, tandem walk, tandem stance, and Romberg stance) and manual dexterity tasks (finger tapping and hole-peg test). For both natural walk and tandem walk, the user is asked to place their phone in their back pocket while taking 10 steps forward, turning around, and then walking 10 steps back at their usual pace [16,17]. For both tandem stance and Romberg stance, the user is asked to stand as still as possible for 10 seconds. In tandem walk and tandem stance, the user's feet are lined up with 1 foot directly in front of the other while walking or standing, respectively [17-19]. In Romberg stance, the user stands still for 10 seconds with their eyes open and then for another 10 seconds with their eyes closed [18,19]. In finger tapping, the user taps 2 buttons on the screen of their phone with their index and middle fingers, alternatively for 100 taps or 100 seconds (whichever comes first) [16]. In the hole-peg test, which is adapted from the standard 9-hole peg test, the user repeats the process of placing a "peg" (indicated by a closed

XSL•FO
RenderX

circle) into a "hole" (indicated by an open circle) on the phone screen and then removing it 4 times [13,20].

Study Participants

Patients scheduled to begin taxane or platinum treatment for breast or colorectal cancer were identified by the Breast or Colorectal Clinical Research Teams within the University of Michigan Rogel Cancer Center. After the medical oncologist approved recruitment of the patient, the study team called the potential participant up to 3 times to describe the study and assess their eligibility and interest in participating. Patients who were interested in participating in the study were screened during the phone call to confirm that they (1) had consistent access to an iPhone (Apple Inc) and (2) did not have baseline neuropathy, defined as any score >1 in the first 4 items of the CIPN20, which ask about tingling or numbness in the fingers or toes [21]. After screening, interested participants completed verbal informed consent to participate and were provided email instructions to download NeuroDetect and complete the integrated written informed consent, a baseline CIPN20, and the 6 functional assessments.

Patients were asked to repeat the CIPN20 and functional assessments within 24 hours before each chemotherapy cycle. Depending on the chemotherapy regimen, the evaluations ranged from every 2 to 4 weeks and the timing was adjusted to accommodate treatment delays or early discontinuations. Patients were also allowed to complete additional evaluations during treatment.

Within 1 week before or 2 weeks after the end of chemotherapy treatment, patients underwent a structured clinical neurological history and examination that included assessment of neuropathic symptoms, signs, and reflexes, which was conducted by neuromuscular specialists (BC and AS) on the study team. CIPN signs and symptoms were diagnosed based on the Toronto Consensus Definition of possible clinically evident distal symmetrical polyneuropathy, which was considered the gold-standard CIPN definition for this study [22,23]. Each patient was clinically assessed for sensory symptoms (numbness, dysesthesias, hypersensitivity to touch, or pain), muscle strength, sensory function of small and large fibers, gait and coordination, and reflexes. From these data, the clinician determined whether the patient had symptoms, sensory exam findings, or decreased reflexes consistent with polyneuropathy. If at least 1 of these 3 were present, a patient is considered to have possible CIPN and thus was considered a CIPN case for this analysis. CIPN cases were then classified as experiencing CIPN in the hands (CIPN-h) or CIPN in the feet (CIPN-f) based on the location of the symptom or sensory or reflex exam finding that caused them to be considered a CIPN case.

Data Preprocessing

Sensor data from the walking and standing samples were filtered and preprocessed before feature extraction. Walking forth and back were treated as 2 samples. Walking samples with durations of less than 7.5 seconds in natural walking or 10.5 seconds in tandem walking were discarded as these indicate the patient stopped the walking task rather than completing it. Walking samples were trimmed to keep only the active walking phase without interruption, including turning around. Walking and standing samples were rotated to the global reference frame to adjust for individual variations in the orientation of the patient's phone in their pocket or the direction the patient faced while walking.

A total of 3700 features were generated from the 6 functional assessments (Table S1 in Multimedia Appendix 1). An open-source tool, mhealthtools in R (Posit), was used to extract statistical or informational features from sensor data of walking, standing, and finger-tapping assessments [24]. For walking and standing data in each of the 3 dimensions of acceleration (side-to-side, forward-backward, and up-and-down) and rotation (pitch, yaw, and roll), empirical 2-mode decomposition transformation and empirical wavelet transformation were used, respectively, to generate features in time-domain (signal amplitude and distribution) and frequency-domain (signal composition in different frequencies) [24]. For finger-tapping data, features of tapping intervals and drifts were generated to characterize both dominant and nondominant hand movements [24]. The mean and SD of the duration of placing and removing pegs were calculated for hole-peg tests in R.

Features were filtered using an ensemble method of minimum redundancy maximum relevance through mRMRe in R to account for multicollinearity [25]. The number of features to select was based on the number of features with a positive score, which means the relevance to the outcome was higher than redundancy with any previously selected features. Feature selection was determined by majority voting among multiple solution sets through 3 steps. First, baseline features were filtered within each assessment and voted among 5 solution sets. Second, end-of-treatment features were filtered together with selected baseline features within each assessment and voted among 5 solution sets to remove features correlated with the baseline. Third, all selected end-of-treatment features were further filtered and voted on among 15 solution sets to remove features correlated with each other between different assessments.

NeuroDetect Model Training and Testing

In total, 2 elastic net classification NeuroDetect Models were built to filter feet and hand features, respectively, and to achieve the highest area under the curve (AUC) in detecting CIPN-h and CIPN-f [26]. NeuroDetect Models were trained using 70% of the end-of-treatment data set with repeated cross-validation through caret and glmnet in R, and the performance was evaluated in the unbiased 30% testing data set [27,28]. The numbers of repeats and folds were the square root of the sample size. Optimal model parameters were first searched using sequences automatically generated by the glmnet package based on the range of input data, which were then fined-tuned to the same magnitude [28]. Infinite values were imputed with 1.5 times the maximum value. All input values were centered and scaled before training and testing. Variable importance was calculated using the caret package based on regression coefficients [27].

NeuroDetect Model performance was evaluated via AUC and accuracy, which was compared with the accuracy that could be

XSL•FO
RenderX

obtained by always predicting the majority class (ie, Yes CIPN-f or CIPN-h), referred to as the no information rate.

Contribution of Functional Assessments in NeuroDetect Models

The contribution of each functional assessment (eg, natural walk, Romberg stance, and finger tapping) to NeuroDetect Model classification was assessed by building and evaluating exploratory models that included only a single functional assessment and models that included all but 1 of the functional assessments using a similar process as that used to build the NeuroDetect Models. The AUC of each exploratory model was compared with the NeuroDetect Models using all functional assessments by a 1-sided bootstrap method with 400 permutations.

Comparisons With CIPN20 Models and Combined Models

To compare the performance between functional assessments and PROs to detect CIPN-f and CIPN-h, a similar process was used to build models for CIPN-f and CIPN-h that included either CIPN20 items only (CIPN20 Models) or the combination of CIPN20 items and NeuroDetect features (Combined Models). A 2-sided bootstrap method with 400 permutations was used to compare the AUCs of these models for detecting CIPN-f or CIPN-h at the end of treatment.

To evaluate the performance of each model for detecting CIPN at earlier time points during treatment, data collected from NeuroDetect Models, CIPN20 Models, and Combined Models at months 0 (M0, before day 0), 1 (M1, from day 0 to day 29), 2 (M2, from day 30 to day 59), and 3 (M3, day 60+) were used, and the AUC for detecting CIPN-f and CIPN-h was calculated and compared using the same 2-sided bootstrap method. The earliest time point a model could differentiate patients with and those without CIPN is estimated based on the first consecutive day that there was a statistically significant association between the model classification and CIPN diagnosis using a Fisher exact test. Multiple comparisons for testing each day throughout treatment were accounted for using the Benjamini and Hochberg false discovery rate.

Ethical Considerations

This study was approved by the University of Michigan IRBMed (HUM00171478). All participants completed oral informed consent before downloading NeuroDetect and then completed comprehensive written informed consent within NeuroDetect. All data were collected within secure databases accessible only to the study team. Clinical data were collected within REDCap (Research Electronic Data Capture; Vanderbilt University) and NeuroDetect data were collected within the secure data environment provided by Medable. Patients were compensated US $50 if they completed at least 3 NeuroDetect assessments and the clinical neurological assessment, otherwise, they did not receive compensation and were replaced in the study. No identifying information for individual participants is included in this manuscript.

Results

Patient Enrollment and CIPN Data Collection

Of the 85 eligible patients who indicated interest in participating, a total of 66 patients enrolled and completed CIPN20 and functional assessments at baseline and at least once during treatment, and 45 completed a neurological examination at the end of treatment (Multimedia Appendix 2). Among these 45 patients, 24 had CIPN-f and 29 had CIPN-h (Table 1). On average, each patient performed each gait and balance assessment 7.5 times, each manual dexterity assessment 7.4 times, and CIPN20 7.4 times during treatment. Most patients (40/45, 80%) completed NeuroDetect assessments and CIPN20 questionnaires every 3 weeks. After data cleaning, the walking and standing data had 567 unique samples throughout treatment, including 70 samples at the end of treatment, and the finger tapping and hole-peg test data had 318 samples throughout treatment, including 41 samples at the end of treatment. A total of 333 CIPN20 questionnaires were collected including 45 at the end of treatment.

NeuroDetect Models for Detecting CIPN at the End of Treatment

From the 3700 features generated from the 6 functional assessments (Table S1 in Multimedia Appendix 1), minimum redundancy maximum relevance selected 300 gait and balance features and 20 manual dexterity features, of which elastic net selected 182 gait and balance features and 19 manual dexterity features to be included in the final NeuroDetect Models of CIPN-f and CIPN-h, respectively (Tables S2 and S3 in Multimedia Appendix 1). The NeuroDetect Model accuracy was significantly higher than no information rate for CIPN-f (80% vs 53%, *P*=.02, Table 2, Figure 1) but not CIPN-h (82% vs 64%, *P*=.18).

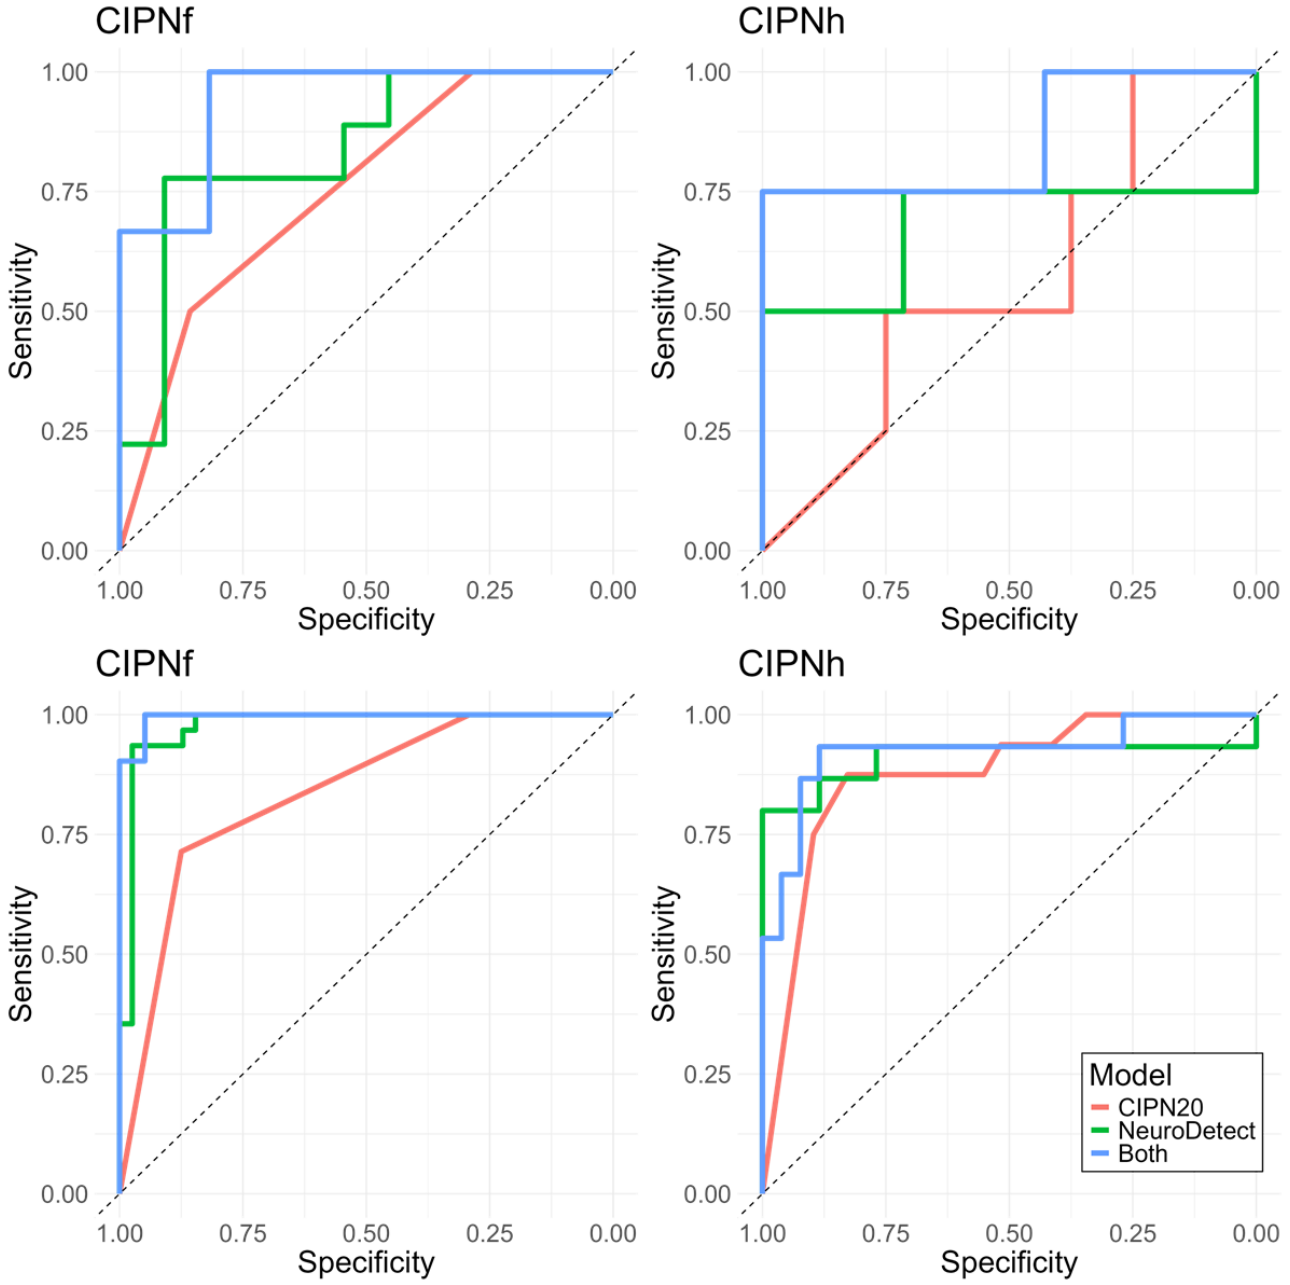
Figure 1. Predicted chemotherapy-induced peripheral neuropathy probability of NeuroDetect models at the end of treatment. CIPN: chemotherapy-induced peripheral neuropathy; CIPNf: chemotherapy-induced peripheral neuropathy in the feet; CIPNh: chemotherapy-induced peripheral neuropathy in the hands.

All data were collected within a prospective observational study of 45 patients with cancer receiving neurotoxic chemotherapy treatment who completed NeuroDetect functional assessments during treatment and a clinical neurological assessment at the end of treatment. The NeuroDetect models were used to estimate the likelihood (y-axis) that each patient had CIPN-f (left panel) and CIPN-h (right panel) at the end of neurotoxic chemotherapy treatment. Patients are reordered in descending order of the strength of the CIPN prediction probability from NeuroDetect. There was strong concordance between these estimated probabilities and the clinical diagnosis from the clinical neurological examination; red circles indicate patients who were diagnosed with CIPN, and blue circles indicate patients who were not. Closed and open circles indicate the 2 walking phases, forth and back, respectively, which were connected by a line for each patient. There was strong agreement between CIPN-f probability estimated between the 2 walking phases in all except a single patient.

The final NeuroDetect Models are enriched for features from Romberg stance (40.2% of total variable importance in CIPN-f) and finger tapping (84.7% of total variable importance in CIPN-h, Table S4 in Multimedia Appendix 1) assessments. The 3 most important CIPN-f features are all rolling rotations from tandem walk and Romberg stance assessments (Table S2 in Multimedia Appendix 1). The most important CIPN-h feature is the autocorrelation of the nondominant hand-tapping interval during the finger-tapping assessment (Table S3 in Multimedia Appendix 1). In CIPN-f detection, the model built using only features from Romberg stance had the best performance and had higher AUC than the model built using all functional assessments (AUC=98% vs 83.8%, *P*=.04, Table S5 in Multimedia Appendix 1). Similarly, the detection performance of the CIPN-f model declined most when removing Romberg Stance features (Table S6 in Multimedia Appendix 1), indicating that Romberg stance had the highest contribution to CIPN-f detection. Neither finger tapping nor hole-peg test had a



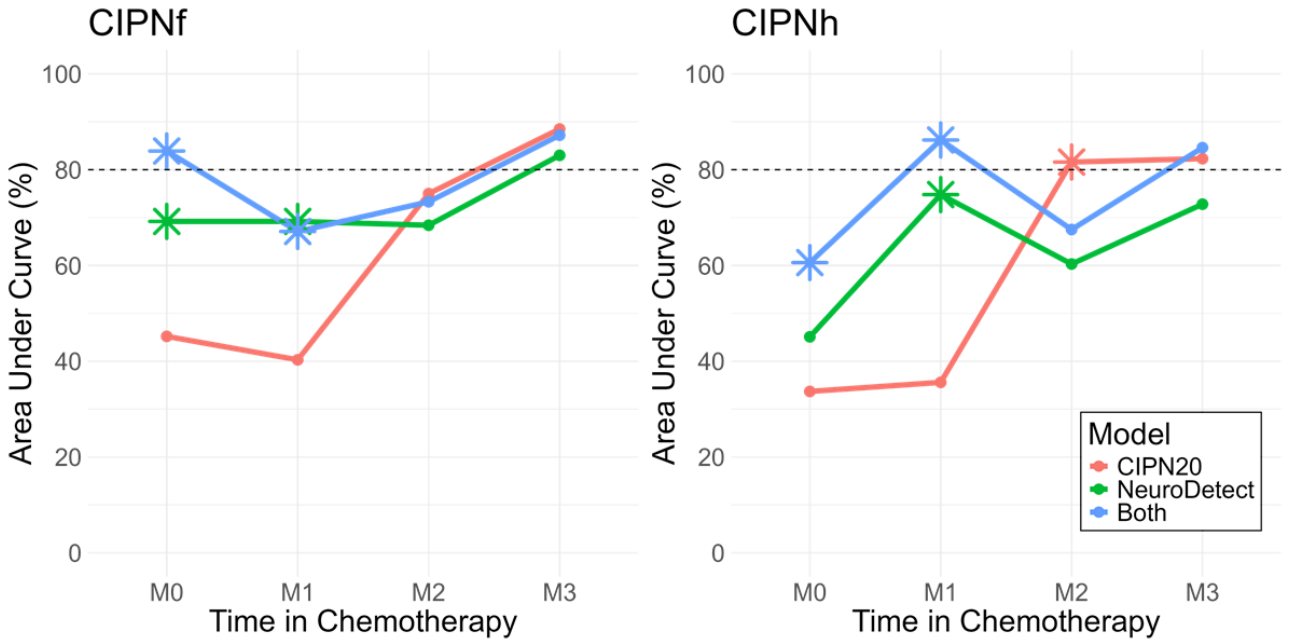
XSL•FO
RenderX

significant independent contribution to CIPN-h classification (Tables S5 and S6 in Multimedia Appendix 1).

Comparisons Between NeuroDetect, CIPN20, and Combined Models

In exploratory analyses comparing end-of-treatment CIPN detection between models, NeuroDetect Models had numerically, but not statistically, superior performance to CIPN20 Models in both CIPN-f (AUC=84% vs 76%, *P*=.55, Table 2 and Table S7 in Multimedia Appendix 1) and CIPN-h (AUC=68% vs 56%, *P*=.67). Combined Models numerically, but not statistically, outperformed either independently (Figure 2, Table S7 in Multimedia Appendix 1).

Figure 2. Receiver operating characteristic curves for chemotherapy-induced peripheral neuropathy detection at the end of treatment. CIPN20: 20-item scale; CIPNf: chemotherapy-induced peripheral neuropathy in the feet; CIPNh: chemotherapy-induced peripheral neuropathy in the hands.



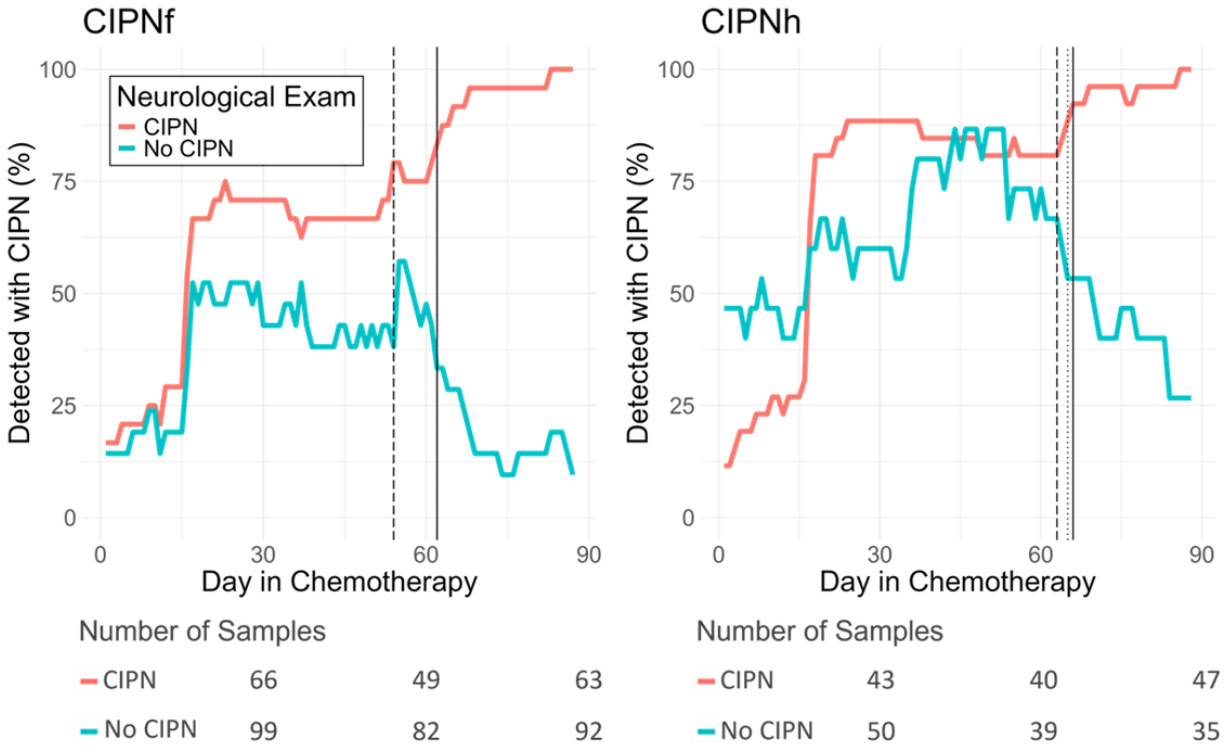
All data were collected within a prospective observational study of 45 patients with cancer receiving neurotoxic chemotherapy treatment who completed NeuroDetect functional assessments during treatment and a clinical neurological assessment at the end of treatment. Models built using only the features generated from the functional assessments conducted within NeuroDetect (NeuroDetect Models), only from the patient-reported CIPN20 questionnaire items (CIPN20 Models), or the combination of both (Combined Models) were compared for their accuracy in detecting CIPN-f and CIPN-h at the end of treatment. CIPN-f and CIPN-h are based on a clinical neurological assessment. The top 2 panels present the sensitivity and specificity of the CIPN-f (left) and CIPN-h (right) models in only the unbiased independent testing data set (30% of the entire data set, not used in model training). The bottom 2 panels present similar results for the entire data set, including both the training and testing data. Colored lines indicate results from the NeuroDetect Models (green), CIPN20 Models (red), and Combined Models (blue).

XSL•FO
RenderX

NeuroDetect Models had a good AUC with balanced sensitivity and specificity. In CIPN-f classification, the NeuroDetect and Combined Models had a greater AUC than the CIPN20 Model.

Models were then compared on their ability to detect CIPN at earlier time points using the patient data at months 0, 1, 2, and 3 of treatment. NeuroDetect and Combined models were numerically, and in most cases statistically, superior to CIPN20 models at M0 (pretreatment) and at M1, but the models were similarly accurate by month 2 (Figure 3 and Table S7 in Multimedia Appendix 1).

Figure 3. Area under the curve of models over the course of treatment. CIPN20: 20-item scale; CIPNf: chemotherapy-induced peripheral neuropathy in the feet; CIPNh: chemotherapy-induced peripheral neuropathy in the hands.



All data were collected within a prospective observational study of 45 patients with cancer receiving neurotoxic chemotherapy treatment who completed NeuroDetect functional assessments during treatment and a clinical neurological assessment at the end of treatment. Data before treatment (M0) and during months 1 (from day 0 to day 29), 2 (from day 30 to day 59), and 3 (from day 60 to day 89) of treatment were used to evaluate the performance of the CIPN detection models. Models were generated using only the NeuroDetect objective assessments (green), only the patient-reported CIPN20 questionnaires (red), and a Combined Model using both (blue). The data from each model collected before and throughout treatment were used to estimate model performance through AUC. The true CIPN-f and CIPN-h were based on the clinical neurological assessment conducted at the end of treatment. Asterisk dots indicate significantly higher AUC than at least 1 of the other 2 models by a bootstrap method. NeuroDetect and Combined Models were superior to CIPN20 Models before treatment (M0) and at M1, but models generally had nonsignificantly different performance after M2. These analyses suggest that CIPN detection before and early in treatment can be improved by using NeuroDetect functional assessments in addition to patient-reported questionnaires.

Finally, analyses were conducted to determine at what point in treatment the NeuroDetect and other Models could discriminate between patients with and those without CIPN. For CIPN-f, the NeuroDetect Model could statistically discriminate between patients with and those without CIPN on day 62 (Figure 4), which was numerically though not statistically later than the CIPN20 Model and similar to the Combined Model (indicated in Figure 4, raw data not shown). For CIPN-h, the NeuroDetect Model reached significance at day 65 (Figure 4), which was not statistically different from that of the CIPN20 or Combined Models.

XSL•FO
RenderX

Figure 4. Percentage of patients detected with chemotherapy-induced peripheral neuropathy over time. CIPN: chemotherapy-induced peripheral neuropathy; CIPNf: chemotherapy-induced peripheral neuropathy in the feet; CIPNh: chemotherapy-induced peripheral neuropathy in the hands.

All data were collected within a prospective observational study of 45 patients with cancer receiving neurotoxic chemotherapy treatment who completed NeuroDetect functional assessments during treatment and a clinical neurological assessment at the end of treatment. Data collected during treatment were used to estimate the earliest time point the Models created from only the NeuroDetect functional assessments could statistically differentiate patients with and those without CIPN. Similar analyses were conducted for the models generated from only the CIPN20 patient-reported questionnaires and the combination of both data types (Combined Model) for comparison (raw data not shown). Red lines indicate the group of patients diagnosed with CIPN from neurological examinations conducted at the end of treatment and blue lines indicate the group not diagnosed with CIPN. For CIPN-f, the NeuroDetect Model reached statistical significance at day 62 (P=.003, solid vertical line), which is the same day that CIPN discrimination was significant for the Combined model (dotted vertical line not visible due to overlay with solid line). The CIPN20 Model discrimination was significant at day 54 (dashed vertical line), though this difference was not statistically significant. For CIPN-h, the NeuroDetect Model reached statistical significance at day 66 (solid vertical line), which was not statistically different from the day the CIPN20 (day 63, dashed vertical line) and Combined (day 65, dotted vertical line) Models reached statistical significance.

Discussion

Principal Results

Tremendous advancements in the development of smartphone and wearable sensor–based technology in health care enable various apps relating to disease and treatment [10], including monitoring gait, balance, and manual dexterity changes in Parkinson disease [11]. Like Parkinson disease, CIPN is associated with changes in gait and balance, and reductions in manual strength and dexterity. Detecting CIPN is essential to prevent its progression to debilitating symptoms that can irreversibly diminish function and quality of life [4,5]. The current approach to CIPN detection, which relies on patient's reporting symptoms during appointments, has limitations that are not addressed by currently available clinic-based objective assessment or PRO subjective assessment strategies. Our previous NeuroDetect V1.0 cross-sectional study revealed evidence that a single timepoint remote, smartphone sensor–based functional assessments after neurotoxic chemotherapy treatment can differentiate patients with and those without CIPN [13]. Building upon our previous study, the objective of this NeuroDetect V2.0 longitudinal study was to determine the feasibility of completing longitudinal app-based functional assessments that emulate certain aspects of the neurological examination that can detect CIPN during neurotoxic treatment. In addition, we conducted exploratory comparisons of functional assessments collected via NeuroDetect V2.0 with CIPN20 questionnaires. The results demonstrated the feasibility of integrating subjective and objective CIPN assessment into a smartphone app for remote, longitudinal CIPN monitoring.

Comparison With Previous Work

In this longitudinal observational cohort study, the NeuroDetect Model effectively distinguished patients with and those without end-of-treatment CIPN-f based on gold-standard clinical assessment by neuromuscular specialists, while maintaining an acceptable false discovery rate. The features contributing the most in the final CIPN-f NeuroDetect Model were rolling rotation, which is intertwined with the side-to-side swaying movement features from balance assessments. These features

XSL•FO
RenderX

during the eyes closed period of the Romberg stance assessment showed the greatest contribution to CIPN-f detection. Furthermore, 2 previous studies used smartphone or smart device sensors to monitor CIPN [13,29]. One study did not detect any correlation between CIPN and a small set of gait and balance features [29]. Alternatively, in our cross-sectional study of NeuroDetct V1.0, a side-to-side swaying acceleration pattern during a normal walk assessment indicated diminished balance in patients with CIPN [13]. Side-to-side swaying features were also identified in studies with open-eye and closed-eye balancing assessments using commercial or self-designed wearable devices and software [30-32] or other clinic-based balance assessments [12,14]. Previous studies have also reported shorter step lengths in patients with CIPN [4,13,32]. This analysis could not be conducted since NeuroDetect V2.0 does not estimate step length.

The CIPN-h NeuroDetect Model was not able to distinguish patients with and those without end-of-treatment CIPN-h, which might suggest a more sensitive functional assessment is needed. Our NeuroDetect V1.0 and V2.0 studies are the only attempts to our knowledge to objectively evaluate manual dexterity using a remote app-based strategy [13]. The hole-peg test is an on-screen assessment that is supposed to mimic the 9-hole peg test, which is often used to assess manual dexterity, in which patients physically pick up pegs and stick them into a hole on a board [20]. In our cross-sectional study of NeuroDetect V1.0, features from the hole-peg test were indicative of CIPN. However, user feedback indicated that the hole-peg test was confusing to operate on a screen [13], which was also reported by patients within poststudy interviews conducted in this longitudinal study (data not included). In the longitudinal study of NeuroDetect V2.0, the newly added finger-tapping assessment was more informative than the hole-peg test, but the overall performance remained poor. Finger tapping is also used as an objective manual strength assessment in neurological disorders and hereditary peripheral neuropathy [33,34], although its use in CIPN has not been validated to our knowledge. Adding other screen-compatible manual dexterity assessments, such as line tracing, might improve the ability of smartphone sensor–based assessments to detect diminished manual dexterity indicative of CIPN-h [35]. One potential challenge will be to develop manual dexterity assessments that are specific for CIPN symptoms without the interference of other chemotherapy toxicities, such as cognitive impairment [36].

In exploratory model comparisons, combining both NeuroDetect features and CIPN20 items together in a Combined Model numerically outperformed each Model individually early in treatment. This finding indicates that integration of sensory-based functional assessments with PRO may improve CIPN detection, which is consistent with previous research and statements that support combining subjective and objective CIPN assessments to improve CIPN detection [37]. The potential benefits of a combined strategy are further supported by our exploratory analysis, which suggested that CIPN20 differentiates between patients with and those without CIPN 2-8 days earlier than NeuroDetect. Currently available hybrid assessment strategies can be time-consuming and require specialized equipment and trained professionals [37] and have not been demonstrated to improve CIPN detection compared with using only PROs [32,38]. On the other hand, NeuroDetect might provide a convenient option for objectively monitoring CIPN by a smartphone [39] that can be completed at home, where the patient is comfortable, and at a time that is convenient, with no added cost for purchasing equipment since most patients own a smartphone. Objective functional assessments can accurately detect CIPN without being influenced by a patient's tolerance for living with CIPN symptoms [40].

Although there is no effective treatment for CIPN, detecting CIPN can prompt early interventions, such as physical therapy referrals, chemotherapy dose reductions, or drug switching, to prevent severe and irreversible CIPN [41]. Interestingly, our results indicate that pretreatment functional NeuroDetect assessments, but not PRO assessments, may be able to identify patients who are likely to experience CIPN during treatment. This is consistent with other evidence that pre-existing neuropathy, such as that resulting from hereditary neuropathy conditions, diabetes, or advanced age, is a major risk factor for treatment-limiting CIPN [1,41], perhaps due to treatment-related exacerbation of subclinical symptoms. If this is validated in future studies, NeuroDetect may be a particularly convenient screening tool to identify potential participants for interventional trials of CIPN prevention or treatment, including approaches like acupuncture, cryo-compression, and exercise therapy [42], which could ameliorate the disparity in CIPN among non-White patients [43].

Limitations

This study advanced the development of app-based functional CIPN assessment by using a longitudinal study design and gold-standard clinical neurological history and examination for CIPN diagnosis. It also used contemporary machine learning modeling for complex multidimensional data and conducted comparative and integrative analyses to evaluate the benefits of using NeuroDetect alone or in combination with PRO. Despite these strengths, several limitations are worth considering. First, this was a small cohort with many features extracted. Rigorous data processing and model training were used to prevent overfitting and provide evidence of feasibility. Much larger clinical studies are needed to validate a NeuroDetect app and CIPN detection model for clinical use and to further investigate the benefits of adding functional NeuroDetect assessment to PRO CIPN monitoring. Second, in longitudinal analysis, the model classification during treatment could only be compared with the neurological diagnoses at the end of treatment, rather than a direct comparison with the CIPN at that moment. Collecting longitudinal objective CIPN outcomes, perhaps using a hybrid assessment such as the Total Neuropathy Score [37], is crucial for future studies attempting to develop real-time CIPN detection or outcome trajectory prediction. Third, remote functional assessments inherently rely on patient understanding and adherence to instructions, but the nonsupervised process and nonstandardized environments can introduce undesirable variability and missingness in data. This can be mitigated by simplified tasks, clear instructions, and regular reminders and is a trade-off we have accepted to gain convenience of remote CIPN detection without specialized equipment. Finally, given the small patient cohort, we did not make any attempt to conduct subgroup analyses or adjust for

XSL•FO
RenderX

other important clinical variables such as age or neurotoxic chemotherapy regimen (eg, taxane vs platinum). Our analysis did not detect statistically significant differences in age in patients who were CIPN-h or CIPN-f cases versus those who were controls (data not shown). However, since age likely affects patient's performance of functional assessments, age will be explored in detail for potential incorporation into the NeuroDetect models built within larger patient cohorts. It is also possible that other clinical consequences of treatment, such as general fatigue, would contribute to worsening performance on functional tasks, though these data were not collected within the study so this could not be explored.

Conclusions

Our findings demonstrate the feasibility of integrating subjective and objective CIPN assessment into a smartphone app for remote, longitudinal CIPN monitoring. Future work will build NeuroDetect V3.0 and generate validated CIPN-f and CIPN-h detection models in much larger patient cohorts with longitudinal CIPN assessment. Eventually, prospective randomized controlled trials will be needed to investigate whether app-based CIPN monitoring via NeuroDetect improves CIPN detection and treatment outcomes, such as reducing persistent CIPN, in patients with cancer.

Acknowledgments

This study was funded by a MICHR Pathway award through a grant from the National Center for Advancing Translational Science (NCATS; UL1TR002240).

Data Availability

All data and code will be made available upon reasonable request to the corresponding author. Due to the preliminary nature of these findings, these models are not intended to be used to detect CIPN or guide treatment in clinical practice. Researchers interested in contributing to the ongoing development of NeuroDetect should contact the corresponding author.

Authors' Contributions

DLH and MPD conceived the presented idea. SA, AS, and BC collected the patient and neurological examination data. C-SC developed the methods, performed the analyses, and drafted the first manuscript. DLH supervised the work. C-SC and DLH edited the first manuscript. All authors discussed the results and contributed to the final manuscript.

C-SC contributed to data analysis and manuscript writing and review. MPD, JJG, RJ, MS, and BC contributed to project conceptualization and manuscript review. SA and AS contributed to data collection and manuscript review. BC contributed to data collection. DLH is the principal investigator and contributed to project conceptualization, data collection, and manuscript writing and final review.

Conflicts of Interest

BC receives research and editorial support from the American Academy of Neurology, consults for DynaMed, and performs medical legal work including the vaccine injury compensation program. Unrelated to the current work, RJ has stock options as compensation for her advisory board role in Equity Quotient, a company that evaluates culture in health care companies; she has received personal fees from the Greenwall Foundation, Doris Duke Charitable Foundation, the National Institutes of Health, the Blue Cross Blue Shield Association, Physicians Education Resource, and the American Medical Association; and grants or contracts from the National Institutes of Health, the Doris Duke Charitable Foundation, the American Cancer Society, and the Susan G. Komen Foundation. She has served as an expert witness for Kleinbard, LLC and Hawks Quindel Law.

Abstract

Background: The increasing prevalence of problematic smartphone use (PSU) among university students is raising concerns, particularly as excessive smartphone engagement is linked to negative outcomes such as mental health issues, academic underperformance, and sleep disruption. Despite the severity of PSU, its association with behaviors such as physical activity, mobility, and sociability has received limited research attention. Ecological momentary assessment (EMA), including passive data collection through digital phenotyping indicators, offers an objective approach to explore these behavioral patterns.

Objective: This study aimed to examine associations between self-reported psychosocial measures; app-based EMA data, including daily behavioral indicators from GPS location tracking; and PSU in university students during the examination period.

Methods: A 6-week observational study involving 243 university students was conducted using app-based EMA on personal smartphones to collect data on daily behaviors and psychosocial factors related to smartphone overuse. PSU was assessed using the Korean Smartphone Addiction Proneness Scale. Data collected from the Big4+ app, including self-reports on mood, sleep, and appetite, as well as passive sensor data (GPS location, acceleration, and steps) were used to evaluate overall health. Logistic regression analysis was conducted to identify factors that significantly influenced smartphone overuse, providing insights into daily behavior and mental health patterns.

Results: In total, 23% (56/243) of the students exhibited PSU. The regression analysis revealed significant positive associations between PSU and several factors, including depression (Patient Health Questionnaire-9; odds ratio [OR] 8.48, 95% CI 1.95-36.87; *P*=.004), social interaction anxiety (Social Interaction Anxiety Scale; OR 4.40, 95% CI 1.59-12.15; *P*=.004), sleep disturbances (General Sleep Disturbance Scale; OR 3.44, 95% CI 1.15-10.30; *P*=.03), and longer sleep duration (OR 3.11, 95% CI 1.14-8.48; *P*=.03). Conversely, a significant negative association was found between PSU and time spent at home (OR 0.35, 95% CI 0.13-0.94; *P*=.04).

XSL•FO
RenderX

Conclusions: This study suggests that negative self-perceptions of mood and sleep, along with patterns of increased mobility identified through GPS data, increase the risk of PSU, particularly during periods of academic stress. Combining psychosocial assessments with EMA data offers valuable insights for managing PSU during high-stress periods, such as *examinations*, and provides new directions for future research.

Introduction

Background

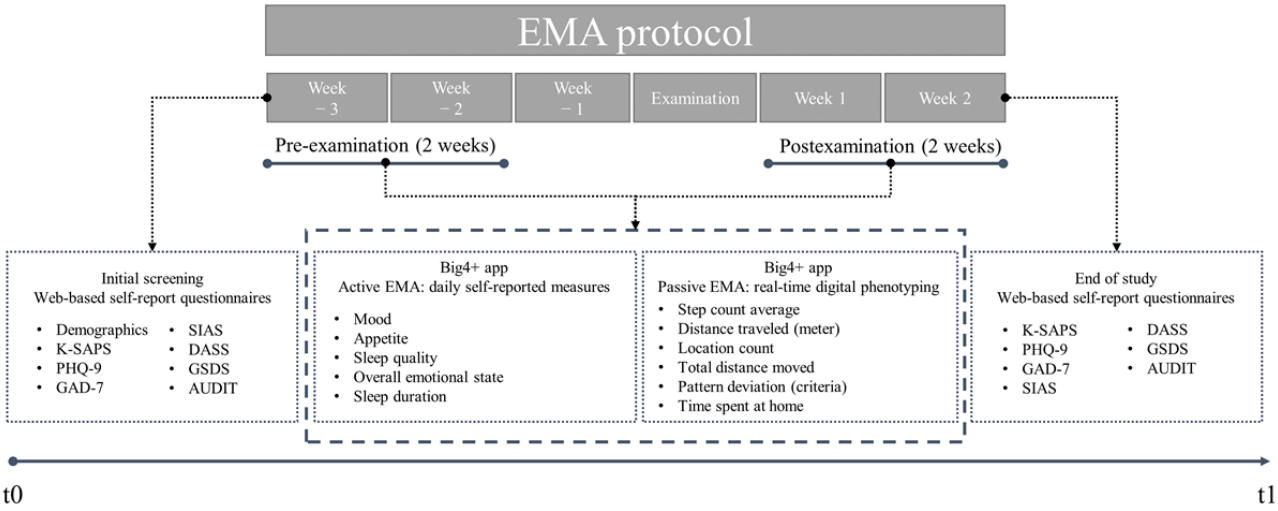
Smartphones are integral to modern life [1-3], embedding themselves into daily routines owing to their advanced features [4,5] and seamless connectivity to web-based services [6,7]. Convenience and accessibility make smartphones indispensable for many, leading to habitual use and, in some cases, unchecked overreliance [5]. Therefore, excessive smartphone use has raised concerns over its potential adverse effects [6] on interpersonal relationships [6,8], physical [5,9-11] and mental health [12], and daily functioning [13,14]. Research shows that problematic smartphone use (PSU) is linked to negative outcomes, including psychopathology [15], poor academic performance [16], and sleep disturbances [17]. However, PSU is not currently classified as a distinct disorder in major diagnostic manuals, such as the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, and *International Classification of Diseases, 11th Revision*, highlighting the need to comprehensively explore its impact and influencing factors [14,18,19].

Ecological momentary assessment (EMA) is a methodological approach to capture people's moods [20,21] and behaviors in their natural environments [22-26]. Recently, EMA has expanded beyond self-report data to include smartphone sensor data [27]. This is known as passive EMA, which describes EMA systems where sensor-based data are collected without any user interaction [26-28]. GPS location–derived features are examples of passive EMA that allow researchers to explore correlations with mental health, such as the proportion of time spent at home [26,29-31]. Recent research has highlighted a significant relationship between increased time spent at home and the severity of depressive symptoms in individuals with major depressive disorder. For instance, an analysis of data from 164 participants using geolocation technology showed that those who spent more time at home during a 2-week period reported more severe depressive symptoms [32,33]. These findings suggest that time spent at home may be an important indicator of mental health, reinforcing the potential of digital phenotyping. By conducting frequent assessments in real-world settings, continuous monitoring through active and passive EMA reduces potential biases associated with traditional self-report methods, which often rely on single-point recollection and introduce inaccuracies [26,28,34,35].

The prevalence of mental health issues among university students is increasing, particularly during examination periods when stress levels peak [36,37]. Academic stress, characterized by increased pressure to perform, has been linked to various challenges, including heightened risks of depression, anxiety, and sleep disturbances [6,38-40], and is positively associated with internet addiction [41,42]. Research indicates that stress can cause excessive use of internet-based devices, potentially resulting in PSU [43]. Studies have also shown a correlation between stress and addictive behaviors related to smartphone use [36]. Moreover, PSU is highly prevalent among university students, with prevalence rates ranging from approximately 10.4% to 70%, depending on demographic and regional factors [44,45]. However, the relationship between PSU and behavioral patterns, such as physical activity, mobility, and sociability, remains underexplored. Limited research has examined how smartphone overuse affects college students' functionality during examinations. Thus, predicting mental health outcomes using smartphone use and sensor data presents a valuable research opportunity.

Objectives

This study aimed to investigate the prevalence of PSU among university students and validate previous findings on its associations with depression, anxiety, and sleep disturbance during examination periods. Furthermore, it integrated smartphone sensing data, including GPS-derived behavioral patterns, with self-reported mental health status to explore the impact of PSU on behavior and mental health as well as potential relationships with app-based EMA data.



Methods

Study Design

The study used a prospective observational design to investigate factors related to PSU among university students for 6 weeks. The data were collected during the 2 weeks preceding and following the examinations. Active EMA involved daily self-reported measures, whereas passive EMA captured real-time digital phenotypes. Key psychosocial measures were assessed at baseline and 2 weeks after the examinations (Figure 1). Additional details of the psychosocial assessment tools and EMA measures used in this study are provided in Multimedia Appendix 1.

Figure 1. Study design, data collection protocol, and study timeline. AUDIT: Alcohol Use Disorders Identification Test; DASS: Depression Anxiety Stress Scale; EMA: ecological momentary assessment; GAD-7: Generalized Anxiety Disorder-7; GSDS: General Sleep Disturbance Scale; K-SAPS: the Korean Smartphone Addiction Proneness Scale; PHQ-9: Patient Health Questionnaire-9; SIAS: Social Interaction Anxiety Scale.

Participants

Participants were recruited in 2 waves from the Ulsan National Institute of Science and Technology in Korea during the fall semester, using both web-based and offline posters. Eligibility criteria included being a university student, aged between 19 and 28 years, a native Korean speaker, and owning a smartphone with either Android or iOS. Participants who objected to data collection or had recent suicidal ideation, severe mental illnesses (eg, schizophrenia and intellectual disability), or organic brain disorders were excluded. The study included a web-based survey that collected basic demographic information and responses using validated psychosocial screening tools. All participants provided informed consent, ensuring anonymity. In the first wave, data from 135 participants were collected from September 25 to November 6, 2023, whereas in the second wave, from November 20 to December 31, 2023, data from 108 participants were collected. On completion, participants received a personalized report summarizing their psychosocial assessments and digital phenotype analyzed by a psychiatrist.

Procedures

Web-Based Self-Report Questionnaires

Validated instruments were used to assess the psychological constructs related to smartphone use and mental health. The Korean Smartphone Addiction Proneness Scale (K-SAPS) evaluates excessive smartphone use through 15 items rated on a 4-point scale (ranging from 1 [not at all] to 4 [extremely]), categorizing use as high risk (scores ≥44), at risk (scores 40-43), or normal use (scores <40), with a Cronbach α of 0.814 [46].

The Patient Health Questionnaire-9 (PHQ-9) measured depressive symptoms over the past 2 weeks with 9 statements rated from 0 (not at all) to 3 (nearly every day), yielding a total score between 0 and 27, with higher scores indicating more severe depression [47].

Anxiety levels were assessed using the Generalized Anxiety Disorder-7 (GAD-7), which comprises 7 items scored from 0 to 3, with the total score reflecting the severity of anxiety symptoms [48].

To gauge social interaction anxiety (SIA), the Social Interaction Anxiety Scale (SIAS), comprising 20 items rated from 0 (not at all) to 4 (extremely), was used [49].

The Alcohol Use Disorders Identification Test (AUDIT) was used to screen for alcohol consumption and dependence using 10 statements. Scores >20 for men and >10 for women indicated high-risk drinking, with a Cronbach α of 0.92 [50].

Sleep quality was assessed using the General Sleep Disturbance Scale (GSDS), comprising 21 items on sleep problems experienced over the previous week, rated from 0 (never) to 7 (every day), with total scores ranging from 0 to 147; scores ≥43 indicate significant sleep disturbances [51].

Finally, stress levels were measured with the Depression Anxiety Stress Scales (DASS), which includes 14 items rated on a 4-point scale, ranging from 0 (did not apply to me at all) to 3 (applied to me very much or most of the time), with higher total scores indicating greater stress levels [52].

Smartphone Sensing and EMAs

All study participants were required to download and install the EMA digital phenotype data collection app *Big4+*, developed by the Department of Psychiatry, Yongin Severance Hospital, and Digital Medic, on their smartphones before the study began. Throughout the 6-week study period, the Big4+ app continuously collected digital phenotype data, such as distance traveled, step count, and sleep duration, while administering daily EMA surveys that assessed participants' mental health (mood, appetite, sleep, and overall condition). Participants could monitor the collected data directly through the app. Active EMA measures involved daily responses to 4 mental health–related questions concerning mood, appetite, sleep duration, and sleep quality via the Big4+ app. Each response was collected using a 7-point Likert scale and required approximately 2 minutes to complete. Examples of questions include "How was your mood?" and "Total hours slept last night." To facilitate engagement, app push notifications reminded users to complete

XSL•FO
RenderX

their daily EMA surveys. In parallel, passive EMA data were gathered through the app, which leverages digital phenotyping data from previous research [30]. Data collection commenced once participants provided consent and began using the app, capturing location data every 5 minutes to measure travel distances. This passive data acquisition included metrics such as step count, activity recognition, and sleep data. All the collected data were encrypted and securely stored in a server database. A comprehensive summary of the detailed digital phenotypes is presented in Textbox 1.

Textbox 1. Description of the digital phenotypes.

Digital phenotype and description

- Step count average: the average number of steps taken over a 5-minute interval
- Distance traveled (m): the average distance traveled over a 5-minute interval (m)
- Location count: the number of unique locations visited per day
- Total distance moved: the total distance traveled per day (km)
- Pattern deviation (criteria): the percentage of times a daily routine deviates by >100 m from the established pattern
- Time spent at most frequented location (home): The total time spent (minutes) at the location where the participant spent most of their time during the day

Statistical Analysis

To explore the factors related to PSU among university students before and after examinations, the participants with K-SAPS scores ≥40 were classified as the PSU group, while those with scores <40 were classified as the non-PSU group. Age-, gender-, and wave-matched participants without PSU were selected, resulting in a total of 112 participants, including 64 (57.1%) men and 48 (42.9%) women. Independent samples *t* tests (2-tailed) were used for numerical variables, and chi-square tests were used for categorical variables. Continuous variables were reported as mean SD, and categorical variables were reported as n (%).

To identify predictors of PSU, backward multivariable logistic regression analysis was conducted. PSU was the dependent variable, and significant variables in univariate analyses ($P<.05$) were the independent variables. Binary variables were created for each participant to indicate whether their scores on the PHQ-9, GAD-7, SIAS, DASS stress, GSDS, K-SAPS, and AUDIT met or exceeded standardized cutoff values, categorizing participants as “at risk” or “not at risk.” Cutoff values were set at ≥9 for PHQ-9; ≥5 for GAD-7; ≥34 for SIAS; ≥15 for DASS stress; ≥33 for GSDS; and ≥10 and ≥6 for AUDIT for men and women, respectively. In addition, EMA variables were categorized using median split, resulting in “above median” and “below median” groups.

A 2 (group)×2 (time) repeated measures ANOVA was performed to examine the between-group effect (PSU vs non-PSU), within-group effect (pre- and postexamination), and time×group interaction effect. Paired *t* tests compared pre- and postexamination scores within groups, and independent *t* tests assessed group differences at both time points, applying the Bonferroni correction ($P<.025$). All analyses were conducted using SPSS (version 27.0; IBM Corp) for Windows, with a significance of $P<.05$.

Ethical Considerations

This study is part of a collaborative project between the Department of Psychiatry at Yonsei University and the Department of Biomedical Engineering at Ulsan National Institute of Science and Technology. It was approved by the Ulsan National Institute of Science and Technology Institutional Review Board (UNISTIRB-23-040-A), and it adhered to the principles of the Declaration of Helsinki. All participants were informed about the study’s aims, methods, and data collection procedures and provided their written informed consent before participation. All collected data were anonymized to ensure participant privacy. Participants who completed the 6-week study were compensated with KRW 80,000 (approximately US $60) for their time and effort.

Results

Participants’ Demographic Information

A total of 243 students participated in the study, comprising 124 (51%) men and 119 (49%) women aged between 18 and 28 (mean 21.9, SD 1.9) years. The prevalence of PSU was 23% (56/243), with 31 (55%) participants with at-risk level of use (scores ≥40 and <43) and 25 (45%) participants with high-risk level of use (scores ≥43). Out of 243 participants, 56 participants with PSU were identified. To ensure comparability, a matched sample of 56 non-PSU participants was selected based on age, gender, and wave of data collection, resulting in a total matched sample size of 112 participants. This matched sample was used for detailed analyses in the study. Additional demographic characteristics are provided in Table 1.

XSL•FO
RenderX

Table 1. Descriptive characteristics of the study population.

	Total participants (N=243)	Study sample (n=112; 1:1 age, gender, and wave matched)[a]
Sample (N=243), n (%)	243 (100)	112 (46.1)
Age (y), mean (SD)	21.9 (1.9)	21.7 (1.8)
Gender, n (%)		
Man	124 (51)	48 (42.9)
Woman	119 (49)	64 (57.1)
Wave, n (%)		
Midterm	135 (55.1)	68 (60.7)
Final	108 (44.1)	44 (39.3)

[a]The study sample consists of 56 participants with problematic smartphone use (PSU) and 56 non-PSU participants matched 1:1 based on age, gender, and wave of data collection. Matching was conducted to ensure comparability between the groups.

Comparison Between the PSU and Non-PSU Groups at Baseline

The analysis revealed significant differences between the PSU and non-PSU groups in several measures: K-SAPS scores (mean 23.70, SD 5.18 vs mean 44.25, SD 4.22; *P*<.001), PHQ-9 (mean 3.59, SD 4.37 vs mean 6.39, SD 5.51; *P*=.004), GAD-7 (mean 2.18, SD 3.07 vs mean 5.05, SD 5.03; *P*<.001), SIAS (mean 23.21, SD 71.15 vs mean 37.16, SD 17.06; *P*<.001), DASS stress (mean 5.7, SD 8.5 vs mean 11.3, SD 12.2; *P*=.006), GSDS (mean 38.75, SD 17.74 vs mean 48.59, SD 17.27; *P*=.004), and AUDIT (mean 4.91, SD 3.60 vs mean 6.98, SD 4.04; *P*=.005), with the PSU group scoring significantly higher in these assessments. In addition, marginally significant differences were observed in the average distance traveled over a 5-minute interval (mean 157.79, SD 119.24 vs mean 221.87, SD 199.50; *P*=.046). However, daily mood, appetite, sleep, and overall emotional state scores derived from EMA surveys were lower in the PSU group than those in the non-PSU group, although these differences were not significant (Table 2).

Factors Associated With PSU in the Univariate Analysis

Univariate analysis revealed significant associations between PSU and multiple psychosocial measures (PHQ-9, GAD-7, SIAS, and DASS stress: all *P*<.01; GSDS: *P*=.02), with no significant difference for AUDIT (*P*=.08). Notably, the PSU group had higher rates of exceeding cutoff scores across the PHQ-9, GAD-7, SIAS, and GSDS. In relation to the digital phenotypes, a significant association was found only for the average distance traveled over a 5-minute interval (*P*=.02). Furthermore, in the active EMA data, only appetite was significantly associated with PSU (Table 3).

Independent Predictors of PSU in Multivariable Logistic Regression

Table 4 summarizes the results of the multivariable logistic regression analysis exploring factors associated with PSU based on K-SAPS scores. This analysis included psychosocial measures and digital phenotype data from passive and active EMA, using baseline data collected 3 weeks before the examination. The final model (R^2=0.424) identified several independent predictors of PSU: PHQ-9 score above the cutoff (B=2.138; odds ratio [OR] 8.480, 95% CI 1.950-36.872), SIAS score above the cutoff (B=1.481; OR 4.398, 95% CI 1.592-12.148), GSDS score above the cutoff (B=1.234; OR 3.436, 95% CI 1.146-10.298), time spent at home below the median (B=–1.066; OR 3.436, 95% CI 1.146-10.298), and sleep duration above the median (B=1.134; OR 3.436, 95% CI 1.146-10.298). The variable “mean distance traveled per 5-minute interval” was not significant (*P*>.05) but was retained in the model. Higher levels of depressive symptoms, SIA, and lower sleep quality, along with less time spent at home, were associated with an increased risk of PSU before the examination.

Table 4. Multivariable logistic regression analysis of the effect of the factors on problematic smartphone use.

	B (SE)	Wald	*P* value	OR[a] (95% CI)
Patient Health Questionnaire-9	2.14 (0.75)	8.13	.004	8.48 (1.95-36.87)

Comparison of Pre- and Postexamination Psychosocial Measures and EMA Data Between PSU and Non-PSU Groups

Repeated measures ANOVA compared changes in smartphone addiction proneness, depression, SIA, sleep disturbance, time spent at home, and sleep duration between the PSU and non-PSU groups before and after the examination. The results revealed a significant group×time interaction effect for smartphone addiction proneness ($F_{1,\ 110}$=370.29; *P*<.001; p^2=0.771), indicating differing patterns of change (Table 5). Specifically, the PSU group exhibited a decrease in average smartphone addiction scores from 44.25 (SD 4.22) to 41.52 (SD 6.72), while the non-PSU group showed an increase from 23.70 (SD 5.18) to 25.13 (SD 6.58). In addition, significant differences were found in depression and SIA. Depression scores in the PSU group decreased from 6.39 (SD 5.51) to 4.48 (SD 5.19), and SIA scores decreased significantly from 37.16 (SD 17.06) to

XSL•FO
RenderX

33.71 (SD 18.52). In contrast, depression scores in the non-PSU group significantly decreased from 3.59 (SD 4.37) to 2.55 (SD 3.13), with no substantial change in SIA scores (Table 6). Furthermore, a repeated measures ANOVA revealed significant changes in sleep disturbance, sleep duration, and time spent at home in both groups before and after the examination. A significant main effect of time for sleep disturbance ($F_{1,110}$=5.13; P=.02) and a significant group effect ($F_{1,110}$=10.94; P=.001) were observed. However, the group×time interaction was not significant ($F_{1,110}$=.062; P=.80; Table 5). Specifically, sleep disturbance or time spent at home did not differ significantly (both P values >.05); although sleep duration changed significantly (P=.03), it was not significant after applying the Bonferroni correction. In the non-PSU group, while sleep disturbance did not differ significantly (P=.07), time spent at home did (P=.03), although this was also nonsignificant after correction. However, a significant difference in sleep duration was observed (P=.01) (Table 6). Overall, while significant main effects of time were observed for sleep disturbance, time spent at home, and sleep duration (Table 5), paired t test results revealed no significant pre- to postexamination differences in sleep disturbance or time spent at home for the groups. However, only the non-PSU group demonstrated a significant increase in sleep duration after the examination, with no change observed in the PSU group (Figure 2; Table 6).

Discussion

Principal Findings

This study identified significant associations between PSU and both questionnaire-based demographic and psychosocial measures as well as daily EMA that were either actively or passively collected from a large sample of university students in South Korea. Independent predictors of PSU from psychosocial assessments at baseline included depression, SIA, and sleep disturbance. Conversely, data collected using app-based EMA from baseline to 2 weeks leading up to 1 week before the examination highlighted less time spent at home and longer sleep duration as significant predictors. These findings provide valuable insights into individual daily patterns through real-time, naturalistic measures.

Comparison With Prior Work

The prevalence of PSU in this study was 23% (56/243), comparable to the 21.7% prevalence reported among Serbian medical students [14] but slightly higher than the prevalence reported among Korean university students [1,53,54]. However, it was lower than the 39.7% prevalence reported by Liu et al [6] regarding smartphone addiction in China. The prevalence of smartphone addiction may vary due to several factors, including differences in measurement scales (eg, cutoff values), sociocultural background, educational environment, sample size, distribution, and technological advancements. Rapid technological progression has likely led individuals to become increasingly accustomed to smartphone use, potentially contributing to the higher prevalence observed in recent research.

Comparison of psychosocial characteristics revealed that the PSU group exhibited significantly higher levels of negative emotions, including depression, anxiety, and stress, as well as more severe sleep disturbances than the non-PSU group. These results suggest a correlation between higher PSU and increased psychological distress and disrupted sleep, consistent with prior findings linking PSU to emotional dysregulation and reduced sleep quality [8,17,55-57]. A significant association was found between PSU and clinical risks for adverse mental health, with a larger proportion of the PSU group classified as being “at risk” for depression, anxiety, stress, and general sleep disturbances compared to the non-PSU group. This suggests a greater likelihood for individuals with PSU to meet clinical thresholds for psychological distress. These findings align with those of a study involving Turkish college students [17], which similarly reported significant associations between smartphone use and elevated depression, anxiety, and poor sleep quality. In addition, recent studies provide evidence of consistent links between smartphone use and psychological factors such as stress, anxiety, and depression [58-61]. Our study reinforces these findings, demonstrating significant associations between PSU and increased risks of depression, anxiety, stress, and sleep disturbances.

Analyzing app-based daily active and passive EMA, this study found distinct GPS-derived movement patterns in individuals with PSU compared to those without it. The digital phenotype

XSL•FO
RenderX

data of the PSU group revealed distinct movement patterns, including greater average distances traveled over 5-minute intervals, spending less time at home, and more frequent deviations from their habitual routes, with some movements exceeding 100 m. These patterns, including deviations >100 m from regular paths, may suggest behavioral tendencies such as impulsivity, emotional avoidance, or a heightened pursuit of immediate rewards. Similarly, although the PSU group traveled shorter total distances compared to the non-PSU group (PSU: mean 45.8, SD 34.3 km vs non-PSU: mean 57.9, SD 136.8 km), participants traveled significantly greater distances within 5-minute intervals (PSU: mean 221.9, SD 199.5 m vs non-PSU: mean 119.2, SD 157.8 m). This suggests that while the PSU group covered less ground overall, their movement patterns, characterized by traveling further in shorter periods, may reflect higher impulsivity. The contrast highlights the complex relationship between PSU and impulsive behavior, suggesting that those with PSU may exhibit more erratic movement patterns. These findings align with those of previous studies that link impulsivity to smartphone overuse and related movement behaviors. For example, Pérez de Albéniz Garrote et al [62] found that individuals with high impulsivity often seek novelty and have increased smartphone engagement. Schulz van Endert and Mohr [63] suggested that GPS-tracked movement data can offer objective insights into impulsivity-related smartphone use. Although these studies did not focus explicitly on GPS data, they support our observation [62,63].

The study identified independent significant predictors of PSU in college students before examinations, including psychosocial factors such as elevated levels of depression, SIA, and sleep disturbances. The digital phenotype features extracted from passive EMA revealed that a longer average “distance traveled” (mean distance covered per 5-min interval, measured in meters) and less “time spent at home” (total daily duration at the primary location, measured in minutes) were distinguishing characteristics for students with PSU. In addition, longer sleep duration was an independent predictor in the PSU group. Together, these findings suggest that students with PSU exhibit distinct mobility and sleep patterns before examinations, potentially indicative of broader behavioral tendencies associated with smartphone overuse. Studies on impulsivity and movement patterns [64,65] have shown that individuals with high impulsivity tend to exhibit irregular movement patterns and greater range in travel, supporting the notion that impulsive behaviors may be tied to broader, real-world activity patterns. This could reflect their use of erratic behaviors as a coping mechanism for stress or emotional avoidance.

Specifically, after the examination, smartphone addiction proneness, SIA, and depression were significantly reduced in the PSU group, suggesting that pre-examination PSU may serve as an avoidance coping strategy for academic stress. These results indicate that academic stress can exacerbate mental health vulnerabilities, leading to PSU or worsening existing addiction. Deteriorating mental health is one of the primary risks for smartphone addiction, with addictive behaviors to manage stress and alleviate negative emotions. PSU students may use smartphones to reduce stress and improve mood, increasing the risk of addiction. This finding aligns with previous findings on stress-related digital dependence behaviors. For example, Choi [66] suggests that stress influences smartphone addiction through self-regulation. Moreover, this result is consistent with Kardefelt-Winther’s [67] compensatory internet use model, which proposes that smartphones can help individuals disengage from stress-inducing social situations, with the need for such behavior diminishing as academic pressures ease. These findings are consistent with those of previous studies [68], showing that as stress decreases, smartphone dependence for emotional regulation may also decline. In contrast, the non-PSU group showed a significant increase in sleep duration after examinations, reflecting distinct adaptation mechanisms between the 2 groups.

Another key finding of this study is that SIA was a strong independent predictor of PSU in the students. Unlike general anxiety, SIA is particularly linked to maladaptive smartphone behaviors, potentially due to mechanisms unique to social anxiety that intensify under academic pressures. The heightened vulnerability of students with PSU seems to be compensated for by the portability and flexibility of smartphone apps, which allow individuals to supplement deficiencies in real-life social interactions [6]. These results suggest that high levels of SIA may negatively impact the mental well-being and behavior of students, emphasizing the need for targeted interventions that specifically address SIA. Addressing SIA during examination preparation may be particularly beneficial in supporting the mental health and academic success of students. This finding aligns with reports by Beidel and Turner [69] and Wong et al [70], highlighting the impact of social anxiety on behavioral and academic outcomes, further validating the importance of addressing social interaction challenges within educational settings [69-72].

The findings from this study highlight distinct shifts in smartphone addiction proneness and psychosocial factors between the PSU and non-PSU groups, especially around examination periods. This work demonstrates how varying psychosocial vulnerabilities and coping mechanisms shape smartphone use patterns, with those having PSU exhibiting higher susceptibility to stress and a tendency to rely on smartphones for emotional regulation. Our results emphasize the impact of PSU on mental health and behaviors, linking it to changes in SIA and depression as well as to physical mobility and sleep. These findings are consistent with previous research [67], suggesting that individuals may use digital devices as coping mechanisms for emotional stress. Moreover, the effects of PSU reach beyond digital habits, influencing real-life routines, as shown by studies on movement patterns [64,65]. In conclusion, this study supports the need for interventions focused on reducing SIA and fostering healthy coping strategies among students, aiming to improve both their mental well-being and academic outcomes. Future research should examine the complex interaction between digital behaviors and real-world outcomes, paving the way for a comprehensive understanding of the broader impact of PSU.

Limitations

This study has several limitations. The generalizability of this study is limited, as the sample comprised students from a single 4-year undergraduate university in Ulsan, South Korea. Consequently, these findings should be applied to different geographical areas or cultural contexts with caution. The sample's unique characteristics, particularly the fact that all students resided in dormitories, are likely to have resulted in restricted movement patterns, with most mobility occurring within the campus or its immediate vicinity. As all students shared the same institutional environment, they were subject to a uniform set of norms and rules that regulate and constrain behavior, including mobility patterns. This homogeneity extends beyond sociodemographic characteristics to encompass behavioral consistency [73,74], particularly during examination periods. During these high-stress academic periods, shared examination schedules, the necessity of efficient time management, and social pressures to engage in study routines further amplified similarities in daily patterns. Consequently, the findings should also be interpreted within the unique context of academic stress in this demographic, as examination-related pressure is known to influence mobility behaviors and psychosocial factors. While this homogeneity provides methodological advantages, such as reduced variability and enhanced internal validity, it limits the study's applicability to more diverse populations [73]. To address this limitation, future research should incorporate diverse geographic, educational, and cultural samples to strengthen the external validity of these findings. Including participants from various universities, regions, and cultural contexts would allow for a more comprehensive assessment of the broader applicability of the results. Expanding the sample to include nonstudent populations or community-based cohorts would also help determine whether the observed relationships are unique to undergraduate students or generalizable to individuals with more varied daily routines and environmental constraints.

This study used both active and passive EMA to capture real-time data and digital phenotypes, focusing primarily on GPS-based movement patterns. However, it did not include objective smartphone use metrics, such as screen time or app use patterns. Previous research underscores the critical role of passive smartphone sensing in identifying impulsive behaviors and self-regulation deficits, which often underlie excessive smartphone use [55,75-79]. For instance, hallmark features of PSU, such as compulsive checking and loss of control over smartphone use, can be quantified through objective metrics, providing clearer insights into behavioral manifestations [76,77]. Wen et al [76] presented preliminary evidence linking impulsivity traits to mobile device use. Passive measures, including call logs, battery consumption, and screen time, were found to predict various aspects of impulsivity and impulsive behaviors in nonclinical populations. These findings highlight the importance of integrating diverse passive smartphone metrics into PSU research. Despite the growing body of evidence supporting the utility of passive sensing methods, our study encountered technical challenges in fully using these data sources. Although we successfully extracted passive smartphone metrics, such as app use and screen time, discrepancies in data accessibility between Android and iOS devices limited their integration. For instance, detailed app-level metrics, such as background use and screen time, were available on Android devices but not on iOS devices, which only provided generalized metrics, such as screen-on and screen-off duration. This platform-specific limitation prevented the harmonization of these data streams, ultimately leading to their exclusion from the final dataset. Addressing such technical barriers, including enhancing the cross-platform generalizability of mobile sensing models, is crucial for future research [76]. Overcoming these limitations would enable researchers to integrate diverse data streams, reduce reliance on self-reports, and provide a more accurate and nuanced assessment of PSU.

The results of this study identify significant independent predictors of PSU, including depression, SIA, and sleep disturbance, through regression analysis. While these findings suggest robust associations after adjusting for potential confounders, they are correlational and should not be interpreted as causal. The cross-sectional nature of the baseline psychosocial assessments limits our ability to infer temporal or causal relationships. Future studies using longitudinal or experimental designs will be necessary to establish causality and to explore the underlying mechanisms of these associations. While this study revealed significant differences in GPS-derived movement patterns between the PSU and non-PSU groups, interpreting these patterns as primarily driven by impulsivity or emotional avoidance remains speculative. Several alternative explanations warrant consideration. First, these movement patterns may reflect stress-related coping strategies, wherein individuals engage in physical displacement to manage heightened stress or anxiety during examination periods. Previous research has demonstrated that traveling longer distances is associated with lower levels of stress, greater positive affect, and reduced anxiety. On a daily basis, participants traveling longer distances reported lower levels of stress and anxiety and more positive emotions, while higher levels of routine activity were linked to lower rates of depression and loneliness [80,81]. These findings align with the results of our study. In this study, the non-PSU group traveled significantly longer total daily distances compared with the PSU group; reported significantly lower levels of depression, anxiety, and stress; and exhibited significantly lower rates of routine deviations. The PSU group exhibited shorter total daily distances traveled, but when averaged over 5-minute intervals, participants covered greater distances. This pattern indicates that the PSU group tended to travel farther within shorter periods, suggesting that such increased high-density (short-time long-distance) travel or movement may act as a behavioral response to stress, providing temporary relief or distraction. Second, environmental or lifestyle factors may also contribute to these patterns. Variations in daily schedules, modes of transportation, and academic routines could influence mobility behaviors. For example, students commuting by car or bike may exhibit different movement patterns than those traveling on foot. Similarly, evening activities such as part-time jobs or social gatherings could explain deviations from habitual routes [81]. Third, personal traits, such as conscientiousness or agreeableness, may influence these behaviors. Previous studies have shown that highly agreeable individuals tend to engage in more social

XSL•FO
RenderX

interactions and visit a greater variety of locations, whereas those with high conscientiousness often follow structured routines and visit fewer places. These traits may interact with PSU, affecting both mobility and smartphone use behaviors [80]. To further investigate the underlying mechanisms, future studies should incorporate additional behavioral and psychological measures, such as momentary assessments of stress, anxiety, and smartphone use during movement episodes. Integrating these data with GPS metrics could help clarify the roles of impulsivity, emotional avoidance, and other psychological factors in driving these patterns. While this study primarily focused on behavioral patterns, it did not directly assess personal traits such as impulsivity or coping mechanisms, which could provide deeper insight into the psychological factors influencing PSU and mobility. Future research should incorporate validated scales for impulsivity and coping styles, alongside EMA, to better understand how students manage stress and emotional challenges through smartphone use.

Conclusions

Despite these limitations, the contributions of this study to understanding the relationship between smartphone use and mental health during academic examination periods are significant. First, it was identified that a significantly higher proportion of students with PSU have high risk for depression, anxiety, stress, and sleep disturbances. This underscores the heightened vulnerability of students with PSU under examination-related stress. In addition, this study is among the first to combine active and passive EMA over a 2-week, pre-examination period to capture real-time data on students' mobility and digital phenotypes. This innovative approach enabled a detailed comparison of movement patterns and behaviors between PSU and non-PSU groups, revealing new insights into how PSU may present in daily life, particularly during high-stress periods. Finally, by including both pre- and postexamination data, this study observed fluctuations in behavioral patterns and mental health outcomes over time, offering a dynamic perspective on the interactions between smartphone use and mental health during critical academic events. These findings align with the concerns raised in the background regarding the negative consequences of PSU. Specifically, this study demonstrated that PSU is associated with heightened risks of depression, anxiety, and stress as well as disrupted sleep patterns, which often exacerbate each other during high-stress periods such as examinations, leading to a compounded negative impact on overall well-being. These results support existing evidence linking PSU to emotional dysregulation, reduced sleep quality, and increased psychological distress. Moreover, the significant associations observed between PSU and clinical risks highlight the importance of addressing these vulnerabilities, particularly during high-stress periods such as examinations. By contextualizing PSU as both a symptom and a contributor to psychological distress, this study emphasizes the need for targeted interventions aimed at mitigating the broader impacts of PSU on students' mental health and academic performance. Together, these findings represent a meaningful step forward in understanding the real-world implications of PSU in students under academic pressure, providing a foundation for future research in this area.

Acknowledgments

This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant: RS-2024-00439193).

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JSA contributed to conceptualization, data curation, formal analysis, methodology, visualization, and writing—original draft preparation. IJ contributed to data curation and investigation. SP and JL contributed to data curation and software. MJ contributed to resources. GD contributed to resources and software. SL contributed to conceptualization and resources. DJ contributed to conceptualization, funding acquisition, project administration, supervision, validation, and writing—reviewing and editing. JYP contributed to conceptualization, funding acquisition, project administration, supervision, validation, and writing—reviewing and editing. All authors take responsibility for data integrity, and all authors have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Mobile digital wellness and health apps play a significant role in optimizing health and aiding in cancer management and decision-making.

Objective: This study aims to identify the factors influencing the use of mobile health and wellness apps among cancer information seekers in the United States.

Methods: We conducted a cross-sectional study using data from the Health Information National Trends Survey. Our analysis focused on 4770 participants who sought cancer information. We performed weighted univariate and multivariable logistic regression to determine the association between the use of health and wellness apps and socioeconomic factors, medical history and conditions, and lifestyle and behavioral factors.

Results: A total of 4770 participants who sought cancer information were included in the final analysis. Of these, 80.9% (n=2705) were health and wellness app users, while 19.1% (n=793) were nonusers. In the final adjusted model, participants with household incomes ≥US $50,000 had 49% higher adjusted odds of using these apps than those with incomes <US $50,000 (adjusted odds ratio [aOR]=1.49, 95% CI 1.02-2.14). College graduates and those with higher educational levels were avid users compared to those with a high school diploma or less (aOR=1.87, 95% CI 1.30-2.67). Internet users had over 3 times the odds of using these apps compared to nonusers (aOR=3.28, 95% CI 1.70-6.33). Participants within the age group 18-34 years were 3.70 times more likely (aOR=3.70, 95% CI 1.90-7.23) to use a health and wellness app compared to participants within the age group of 75 years and older.

Conclusions: Age, education, household income, and use of the internet are the major determinants of the adoption of digital health and wellness apps among seekers of cancer information. Hence, public health programs could be directed toward addressing these factors to improve cancer diagnosis, treatment, and management using these apps.

Introduction

Cancer is a major health problem worldwide and the second leading cause of death in the United States [1]. According to the World Health Organization (WHO), there were about 10 million deaths from cancer in 2020 [2]. According to the National Cancer Institute, in January 2022, about 18.1 million survivors of cancer were estimated in the United States, and by 2032, the number of survivors of cancer would increase to 22.5 million [3]. In the United States, the increasing cancer survival rates can be largely attributed to advances in screening, early diagnoses, and treatment of cancers, as well as a growing and aging US population [4]. Many survivors of cancer tend to seek health information in addition to the information provided by their physicians [5]. A study reported that survivors of cancer seek more information about good diet, exercise, and weight management while undergoing treatment [6]. Nearly 50% of Americans and over 60% of survivors of cancer seek cancer-related information from at least 1 source, including mobile wellness and health apps [5,7-9].

According to WHO, mobile health (mHealth) includes using smartphones, sensors, PDAs, wireless monitoring devices, or other wireless devices for public health and medical practices [10]. The Center for Democracy and Technology categorizes health apps into 4 types: health reference, fitness tracker, diagnostic, and disease management [11]. Mobile health apps are software programs running on smartphones and tablets to promote health and primary disease prevention [12,13]. They are used to oversee, improve, and maintain the health of their users at individual and community levels [14]. Furthermore, these health apps are very useful in facilitating medication adherence, monitoring symptoms, clinical decision-making, and behavioral changes [15-17]. Among patients with cancer, mobile digital health is an important consideration when seeking ways to optimize their mental health [18].

A study has shown that mHealth apps can help in primary prevention, such as screening, as well as early diagnosis, management, survivorship, and end-of-life care among patients with cancer [19]. Another study reported promising use of digital health solutions for promoting and managing the cancer care continuum within a patient-centeredness framework [20]. Furthermore, research has shown that mHealth apps can aid health care providers and patients in cancer diagnosis, managing psychological distress, facilitating follow-up care, devising treatment plans, delivering cancer-related information, promoting drug adherence, and addressing side effects [21].

Socioeconomic variables such as education level and income, marital status, gender, and age, are important predictors of choice of health information source among survivors of cancer in the United States [9]. A study that assessed the disparities in access to mobile health devices and eHealth literacy among survivors of breast cancer found that older age, lack of access to mobile devices, and a lower education level had a lesser association with eHealth literacy [22]. This study also showed that younger women with higher education levels and from less deprived areas were more likely to access smartphones and tablets [22]. Another study also found that mHealth users were more likely to be younger, have higher education, reported excellent health, higher income, and intention to change diet and physical activity [23]. A recent review suggested the positive effect of mHealth apps on health outcomes among those enduring chronic diseases [24]. Furthermore, research revealed that older adults exhibited diminished self-efficacy when using mHealth apps often stemming from a deficiency in technical skills and resulting in a decreased inclination to engage with the technology [25]. An analysis of the moderating effect of different age groups suggests that the perceived ease of use and vulnerability were associated with the use of mHealth apps among middle-aged and elderly people [26].

Despite the growth and promise of using mobile apps to deliver information and interventions to patients with cancer and those with other chronic diseases, the factors influencing the use of mHealth apps have been well-studied primarily among survivors of cancer. However, there is limited research on these factors among the broader US population seeking cancer information. Therefore, the purpose of this study is to identify the factors that impact the usage of health and wellness apps among those seeking cancer information here in the United States. By using a sequential modeling approach, this study aims to provide a deeper understanding of the factors associated with mobile app usage in this specific population, ultimately informing targeted interventions and strategies to effectively support cancer information seekers, both survivors and nonsurvivors.

Methods

Data Source, Study Design, and Setting

This cross-sectional study analyzed data from the Health Information National Trends Survey (HINTS), a nationwide representative survey of US adults aged 18 years and older in 2020 and 2022. HINTS has been conducted periodically since 2003. HINTS collects information on access to and usage of health-related information, health-related behaviors such as perceptions, knowledge of disease and cancer screening as well as telehealth among US adults. The HINTS uses a complex sampling design to ensure the representativeness of the adult population in the United States. The survey uses a sampling frame provided by Marketing Systems Group of addresses in the United States. To enhance the response rate and ensure the sample's representativeness, HINTS conducts several follow-up mailings for nonrespondents. Detailed information about the methodology, sampling, and weighting is available on the web [27]. This study is reported following the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [28].

Study Population

This study included adults aged 18 and older in the United States. Using consistent weighting algorithms, we merged data from HINTS 5 (Cycle 4, 2020) and HINTS 6 (2022) to increase

XSL•FO
RenderX

the precision of estimates and power of this study. This resulted in a total population of 10,117 respondents from the 2 surveys. Individuals' cancer-seeking behavior was assessed through a single question: Have you ever looked for information about cancer from any source? The response options were "yes" or "no." Those who answered "yes" were classified as having sought cancer-related information. Hence, this study included 4770 participants who actively sought cancer-related information in the analysis.

Study Variables

Outcome

The outcome variable was using health and wellness apps categorized as "yes" or "no." Two sequential survey questions were used depending on the outcome. Participants were asked if they owned tablets, computers, or smartphones. Those who owned any were further asked if they had health and wellness apps on these devices, with response options of "yes," "no," or "do not know." If they answered "yes," they were then asked if they had used these apps in the past 12 months.

Independent Variables

Based on previous literature, the sociodemographic characteristics: age (18-34, 35-49, 50-64, 65-74, or 75 years and older), gender at birth (male or female), insurance (yes or no), educational level (high school or less, some college, or college graduates and more), household income (<US $50,000 or ≥US $50,000), use of the internet (yes or no) and race or ethnicity (Hispanic, non-Hispanic Asian or non-Hispanic other, non-Hispanic Black, or non-Hispanic White); medical history and disease conditions: presence or absence of cancer (yes or no), general health status (fair or poor, good, or excellent and very good), family history of cancer (yes or no), depression (yes or no), diabetes (yes or no), hypertension (yes or no), heart condition (yes or no), chronic lung disease (yes or no), and number of disease condition (none, one, or two or more), and lifestyle or behavioral characteristics; BMI (underweight, normal weight, overweight, or obese) and physical activity were included in this study. Physical activity was assessed by the number of days per week and duration of moderate-intensity exercise, classified based on the WHO's recommendation of 150 minutes/week [9,22-27].

Statistical Analysis

We used weighted frequencies and percentages to present participants' sociodemographic characteristics, medical history, disease conditions, lifestyle, and behavioral traits by mobile health app usage status. We used the Pearson chi-square test to assess the statistical significance (P<.05) of the relationship between mobile health and wellness app usage and independent variables. We conducted bivariate and multivariable logistic regression analyses to evaluate the association between the outcome and covariates.

We fitted 4 sequential modeling approaches in the multivariable analysis. Model 0 included the crude effects of each covariate on health and wellness app usage. Model 1 incorporated the effects of sociodemographic characteristics on health and wellness app usage. Model 2 adjusted for all covariates from model 1 and medical history and disease conditions, such as cancer, general health status, family history of cancer, depression, diabetes, hypertension, heart conditions, chronic lung disease, and the number of chronic diseases. The final (model 3) included model 2 and lifestyle and behavioral characteristics, such as BMI and physical activities.

This sequential modeling strategy aimed at determining the degree to which mHealth app use was explained by each group of variables among seekers of cancer information. We further explored the relative importance of medical history and disease conditions on sociodemographic factors and how medical disease conditions are related to the use of mobile apps (model 2). We also looked at the specific importance behavior and lifestyle have in the final model (model 3). For this study, we chose to adjust for physical activity and BMI because these variables are potential factors for the usage of wearable devices [29,30].

All statistical analyses were performed using SAS software (version 9.4; SAS Institute), with significance set at a P value <.05 and a 95% CI.

Ethical Considerations

The administration of HINTS received approval from the institutional review board at Westat Inc and was designated as exempt by the National Institutes of Health Office of Human Subjects Research (45 CFR 46.104 and Project # 6632.03.51) [27]. This exemption applies to this study. HINTS data are accessible to the public, and additional information regarding the survey methodology is available on the HINTS website. This study's participants were deidentified and there was no patient contact.

Results

A total of 4770 participants were seeking cancer information. Only 3498 participants had complete information on the use of mobile apps. Of these, 80.9% (n=2705) were health and wellness app users, while 19.1% (n=793) were nonusers. Overall, more than half (n=2894, 58.4%) of the participants were female, and 78% were between the age group 18-64 years. A larger percentage of participants were college graduates (n=2606, 41.5%), identified as non-Hispanic White (n=2936, 69.3%), had a household income exceeding US $50,000 (n=2854, 69.9%), and rated their general health as excellent or good (n=2256, 49.1%). Most participants had no history of cancer (n=3538, 84.7%), had insurance (n=4453, 92.1%), were internet users (n=4376, 93.3%), had heart conditions (n=460, 92.4%), and lung diseases (n=3961, 86.7%; Table 1).

[c]Not applicable.

From the bivariate analysis, age, level of education, household income, use of the internet, history of cancer, reported health status, physical activity, hypertension, and diabetes status showed a significant association with the use of health and wellness apps (*P*<.05). More than two-thirds (85.1%) of participants within the age group 18-64 years used health and wellness apps compared to (14.9%) of participants within the age group 65+ years. A significant proportion of college graduates (n=1666, 48.2%) and individuals with household incomes of US $50,000 or more (n=1853, 77.2%) were found to use health and wellness apps. Among participants who use health and wellness apps, 87.3% (n=2098) had no history of cancer, 97.9% (2632) were internet users, 52.2% (n=1378) reported their general health status as excellent or very good, and 67.6% (n=1594) were hypertensive.

From the multivariable results in Table 2 and the final model (model 3), factors associated with the use of health and wellness apps included age, household income, use of the internet, higher educational level, and physical activity. We observed that as participant's age increases, the odds of using health and wellness

XSL•FO
RenderX

apps decrease. Participants within the age group 18-34 years were 4 times more likely (adjusted odds ratio [aOR]=3.70, 95% CI 1.90-7.23) to use a health and wellness app compared to participants within the age group of 75+ years. Compared to participants with household income below US $50,000, participants in the higher income category ≥US $50,000 had 49% higher odds of using mobile digital health and wellness apps (aOR=1.49, 95% CI 1.02-2.14).

Furthermore, consistent internet use significantly influenced the use of health and wellness apps across all 3 models. Internet users had 28% higher odds (aOR=3.28, 95% CI 1.70-6.33) of using mobile digital health and wellness apps compared to noninternet users. As the level of education increases, the odds of using health and wellness apps also increase. The participants with college graduate degrees and higher had 1.87 times the odds (95% CI 1.30-2.67) of using health or wellness apps compared to individuals with a high school diploma or less. Physical activity was the only lifestyle and behavioral factor found to be associated with the use of health and wellness apps. Compared to participants who engaged in less than 150 minutes of physical activity per week, those who exercised 150 minutes or more per week had 1.94 times higher adjusted odds (95% CI 1.40-2.70) of using health and wellness apps (Table 2).

Discussion

Principal Findings

This study aimed to investigate the use of digital health and wellness apps among seekers of cancer information and identify factors predicting their use. Our results indicate a high prevalence of app usage among individuals seeking cancer information (81%), highlighting the potential of public health interventions to promote cancer prevention measures (for example, screening) and treatment through these platforms. Age and education emerged as the most significant predictors, with younger and more educated individuals showing a greater inclination toward the usage of these apps.

This finding aligns with similar studies [23,31], including one carried out among the Dutch population, which showed that younger age groups and individuals with higher education are more likely to use mHealth apps [32]. The reason may be that older patients generally describe themselves as not highly skilled

XSL•FO
RenderX

in the use of mobile phones and other mobile devices [33]. In addition, older adults may face barriers such as a lack of trust in the apps, concerns about data privacy, and fear of misdiagnosis [34]. Moreover, other factors, such as age-related reduction in health functions such as memory, vision, and touch sensitivity, may hinder the effective use of mobile health apps [35]. The age disparity in mobile app use implies that older adults may experience worsened health outcomes and limited access to cancer health information due to lower engagement with digital tools. To address this, mobile apps can be designed to be more user-friendly for older adults, and digital health education programs should be implemented to encourage their adoption. Consistent with the Pew survey, which found that women were more likely to use health apps, gender differences were also observed in this study, with females being more likely to use health and wellness apps [36].

In a previous study, higher incomes were correlated with digital technology ownership and usage [37]. Our study found a similar association in which participants with household incomes greater than or equal to US $50,000 were more likely to use digital and wellness apps than participants with less than US $50,000. This suggests that income may strongly influence the use of digital and wellness apps even when other factors are considered. The finding that seekers of cancer information who met weekly recommendations for physical activity were more likely to use mHealth apps compared to those who engaged in less physical activity is consistent with previous studies [23,38]. This implies using health apps may enhance the achievement of physical activity health goals which has the potential to prevent chronic diseases [39].

Engaging in health information-seeking behavior, such as downloading mHealth apps, is acknowledged as a crucial activity during the “preparation stage” that may lead to changes in health behavior [40]. Use of the internet was found to be consistently associated with the usage of health and wellness apps among seekers of cancer information in our study. A similar study found that most internet users indicated a greater likelihood of using at least one eHealth tool to address a health issue over 12 months with a preference for YouTube videos, a peer-to-peer support website, or a smartphone app [41]. This implies that using the internet has the potential to empower individuals, enabling them to play a more active role in their health care and fostering changes in health information–seeking behavior by providing easy access to mHealth apps. Previous studies have shown that increased exposure to internet use and other web-based activities promotes the seeking of health information on the web [42]. The findings of our study confirm the impact of the internet on the use of health and wellness apps. Overall, our findings underscore the potential of mobile digital wellness and health apps in supporting cancer awareness and management.

Clinical Practice Points and Implication

Technological interventions in cancer, specifically those using mobile digital wellness and health apps hold great promise to enhance patient outcomes and improve quality of life. Understanding factors that influence use is vital for creating impactful interventions. Apps should be developed to meet some specific health requirements such as phases of cancer treatment, as personalized intervention content is more likely to engage users and encourage behavioral changes, including social support features that allow users to communicate with caregivers, health care professionals, or individuals with similar health challenges will also go a long way toward heightening app usage and serve as a useful tool for interventions. Social support networks within the app can help users feel more connected and encouraged to share their experiences. Language and cultural differences should be considered to guarantee applicability and accessibility to a wide range of people. Enhanced engagement and effectiveness can also be achieved by providing content in multiple languages and taking cultural norms into account.

Strengths

The major strength of our study was the comprehensive dataset we used. The samples used are fully representative of the noninstitutionalized US population, which enhances the generalizability of our results. Another strength of our study is its targeted population, specifically focusing on individuals who actively seek cancer information. This dataset was created by combining information from multiple survey cycles which boosted the sample size, thereby increasing the power and precision of our study. Additionally, the use of preexisting data minimized selection bias and allowed for proper comparisons with the existing literature. Finally, the consistency of our results with prior research further validates the reliability of our findings.

Limitations

Despite the strengths of our study, it has limitations that warrant due consideration, the dataset used for our study was harmonized data from different HINTS cycles which were obtained from self-administered questionnaires. This method of data collection may introduce information bias, emphasizing the importance of more rigorous study designs in establishing causal relationships. Prospective studies and clinical trials are recommended to further explore the factors influencing digital health and wellness app usage among the general population and seekers of cancer information, and their impact on health outcomes among diverse populations. Additionally, our study did not take into account health literacy, provider recommendations, or health motivation. These factors should be considered in future research on the use of health and wellness apps. Another limitation of our study is the lack of data on the specific types of cancer information sought by participants. While this did not impact our goal of exploring factors influencing the use of mobile health and wellness apps among those seeking cancer information, there is a need for the HINT’s researchers to include a variable that focuses on the type of cancer information for further exploration by future studies.

Conclusion

This study evaluated various factors that could impact the use of mobile health and wellness apps among cancer information seekers. Among the factors assessed; age, education, household income, use of the internet, history of cancer, and optimal health

XSL•FO
RenderX

status were significantly linked to app usage. The results from this study suggest that individuals who have cancer could benefit remarkably from health apps, however, they were least likely to use the apps when compared to other factors. These apps may have the potential to address health care challenges, reduce disparities, and empower patients to manage their health more efficiently. Interventions can be tailored to enhance app use and improve health outcomes as we used retrospectively collected data in this cross-sectional study.

Acknowledgments

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors. The authors would like to take this opportunity to thank the University of Texas School of Public Health for providing student emergency support for the article processing fee.

Data Availability

The data access requests are publicly available on the Health Information National Trends Survey (HINTS) website. The code generated and used during this study is available upon request.

Authors' Contributions

OJE handled the conceptualization, methodology, data curation, supervision, and formal analysis. OKA and AAO worked on the methodology, writing of the original draft, and review and editing of the writing. PF aided in the supervision and methodology. All authors assisted with the writing of the original draft and review and editing of the writing.

Conflicts of Interest

Abstract

Background: Mobile health (mHealth) apps are increasingly being used by community members to track symptoms and manage endometriosis. In addition, clinicians use mHealth apps for continued medical education and clinical decision-making and recommend good-quality apps to patients. However, poor-quality apps can spread misinformation or provide recommendations that are not evidence-based. Therefore, a critical evaluation is needed to assess and recommend good-quality endometriosis mHealth apps.

Objective: This study aimed to evaluate the quality and provide recommendations for good quality endometriosis mHealth apps for the community and clinicians.

Methods: PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines informed the search of mHealth apps on the Google Play Store and Apple App Store. The search terms included “endometriosis,” “adenomyosis,” and “pelvic pain.” mHealth apps were eligible if they were (1) related to the search terms, (2) were in the English language, and (3) were available free of cost. Only the free content of the eligible mHealth apps was assessed. ENLIGHT, a validated evaluation tool for mobile and web-based interventions, was used to assess the quality across 7 domains such as usability, visual design, user engagement, content, therapeutic persuasiveness, therapeutic alliance, and general subjective evaluation. mHealth apps with a total score of ≥3.5 were classified as “good” according to the ENLIGHT scoring system and are recommended as good-quality mHealth apps for endometriosis care.

Results: In total, 42 mHealth apps were screened, and 19 were included in the quality assessment. A total of 6 good-quality mHealth apps were identified (QENDO, Bearable, Luna for Health, Matilda Health, Branch Health: Pain Management, and CHARLI Health). These apps provided symptom-tracking functions and self-management support. A total of 17 apps were designed for community use, while 2 apps provided a digital endometriosis classification tool to clinicians. Most mHealth apps scored well (≥3.5) in the domains of usability (16/19, 84.2%), visual design (14/19, 73.7%), user engagement (11/19, 57.9%), and content (15/19, 78.9%). Few eHealth websites scored well on therapeutic persuasiveness (6/19, 31.6%), therapeutic alliance (9/19, 47.4%), and general subjective evaluation (6/19, 31.6%).

Conclusions: Although time and geographical location can influence the search results, we identified 6 “good-quality” endometriosis mHealth apps that can be recommended to the endometriosis community. mHealth apps designed for community

XSL•FO
RenderX

use should evaluate their effectiveness on user's endometriosis knowledge, self-recommended management strategies, pain self-efficacy, user satisfaction, and user quality of life. Digital technology should be leveraged to develop mHealth apps for clinicians that contribute to continued medical education and assist clinical decision-making in endometriosis management. Factors that enhance usability, visual design, therapeutic persuasiveness, and therapeutic alliance should be incorporated to ensure successful and long-term uptake of mHealth apps.

KEYWORDS

adenomyosis; endometriosis; m-health apps; mobile apps; digital health; pelvic pain; self-learning; clinicians; mHealth; application; endometriomas; chocolate cysts; uterus; womb; pain management; digital health; women's health; mobile phone

Introduction

Endometriosis is a chronic condition characterized by the growth of endometrial-like tissue outside the uterus, causing pain and fertility problems in 190 million women and those assigned female at birth globally [1]. Associated with delayed diagnosis and requiring long-term, individualized care, access to health resources and services is critical to overcoming the negative impact of endometriosis on quality of life and overall well-being [2]. To address this community need, an increasing number of endometriosis mobile health (mHealth) apps [3] have been developed to provide rapid mobile access to symptom assessment and tracking, education, appointment management, and support networking [4]. The value of these mHealth resources in endometriosis care became particularly apparent during COVID-19 lockdowns, when access to doctors and surgery was limited, and elevated endometriosis-related symptoms were observed [5].

As patients increasingly seek digital health information and education [6], medical consultations are progressively more likely to reference mHealth apps. Joint sharing of digital information improves communication between patients and clinicians and enables people to become partners in their health care [4,7,8]. Advancements in digital technologies and the application of machine learning algorithms have led to the development of mHealth interventions [9] to provide more personalized health management [10]. Ball et al [11] trialed a mHealth app intervention to assess the effectiveness of a mindfulness program on chronic pelvic pain in women [11]. In other chronic conditions, including type 1 and type 2 diabetes and hypertension, the integration of digital health strategies led to demonstrable improvements in treatment compliance, disease outcomes [3,11,12], and self-management [13-15].

Clinicians benefit by being informed of the quality and function of endometriosis mHealth apps, as they can provide recommendations to endometriosis community members in a time-efficient, evidenced-based way. There is evidence that mHealth apps can facilitate the diagnosis of endometriosis [16]. The Nezhat Endometriosis Advisor app was trialed to screen populations for the risk of endometriosis, which can assist in early diagnosis [16]. mHealth apps are effective tools that significantly improve medical knowledge and skills among health care providers [17]. The majority of doctors (86%, 170/198) working in pediatric emergency departments across the United Kingdom and Ireland reported using mHealth apps on their phones for clinical decision-making [18]. Ease of use and rapid accessibility facilitates mHealth app use among clinicians [18].

However, poor-quality mHealth apps can spread misinformation [4] and create mistrust in clinical relationships. Furthermore, it is difficult to assess the quality of endometriosis mHealth apps in app stores. There is a need to systematically evaluate endometriosis mHealth apps to inform the endometriosis community and clinicians about the advantages and disadvantages of those currently available using validated and standardized tools [9,19]. Therefore, the aim of this study was to conduct a systematic search of mHealth apps that support endometriosis care to evaluate the quality and recommend those apps that meet specific quality metrics to the endometriosis community and clinicians.

Methods

Search Strategy

This systematic search was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines [20]. (Multimedia Appendix 1). Before undertaking this study, a systematic search protocol was developed and registered with the International Prospective Register of Systematic Reviews (PROSPERO; registration CRD42020185475). There was no patient or public involvement in this study.

"Endometriosis," "adenomyosis," and "pelvic pain" were used as search terms in the 2 largest app stores (Google Play and Apple) on July 24, 2020. Only the first 30 listed mHealth apps were screened, as there is evidence that most people do not investigate beyond this number [21]. Each term was separately searched in the Apple app and Google Play store. The search was later updated on July 22, 2024, to include new mHealth apps and remove redundant ones. Duplicate results were removed, and the remaining mHealth apps were screened for eligibility.

Inclusion and Exclusion Criteria

mHealth apps were included if they related to endometriosis, adenomyosis, or pelvic pain, were in the English language, and were available free of cost. mHealth apps that did not meet the inclusion criteria were excluded (Textbox 1). There were no geographical limitations. For those mHealth apps with free and

XSL•FO
RenderX

paid membership sections, only the free components were assessed. In-app purchases were not made.

Textbox 1. Inclusion and exclusion criteria for including mobile health (mHealth) apps for endometriosis care.

Inclusion criteria:

- Relevance to the subject: mHealth apps that relate to endometriosis, adenomyosis, or pelvic pain in women.
- Cost: Free mHealth apps (no associated cost) or free components of mHealth apps.
- Language: mHealth apps written in the English language.

Exclusion criteria:

- Relevance to the subject: mHealth apps that did not relate to endometriosis, adenomyosis, or pelvic pain in women.
- Cost: mHealth apps that require a payment or subscription to access them.
- Language: mHealth apps written in a language other than English.

Data Extraction

Descriptive data was manually extracted by 1 researcher (DS) after reading an explanation of each mHealth app's purpose. This data was collated in a Microsoft Excel spreadsheet under the following categories: (1) mHealth app name, (2) hyperlink, (3) developer, (4) version, (5) stated purpose, (6) target audience, (7) category, (8) country of origin, (9) last updated, and (10) user rating (Multimedia Appendix 2). The target audience was classified into 2 categories: (1) the endometriosis community (eg, laypeople in the community who have endometriosis or pelvic pain) and (2) clinicians. mHealth apps were classified into 5 types: (1) symptom trackers, which allowed users to record and analyze their symptoms; (2) endometriosis screening tools, which assessed the probability of having endometriosis; (3) pelvic pain symptom assessment tools, which analyzed users pelvic pain symptoms to suggest self-management strategies; (4) a fertility coaching program for those affected with endometriosis; and (5) endometriosis classification tools, which assisted clinicians with endometriosis classification based on radiological and/or surgical findings.

Quality Assessment

The ENLIGHT quality assessment tool was used to evaluate all included mHealth apps [22]. The ENLIGHT tool assesses 7 criteria: (1) usability, (2) visual design, (3) user engagement, (4) content, (5) therapeutic persuasiveness, (6) therapeutic alliance, and (7) general subjective evaluation (Table 1).

XSL•FO
RenderX

Table 1. Description of the ENLIGHT quality assessment criteria [22], objectives, and factors assessed.

Domains of quality assessment	Objective	Criteria assessed
Usability	Assesses the ease of learning how to use a mHealth app and the ease of using it appropriately.	• Navigation • Learnability • Ease of use
Visual design	Assesses the look and feel of the mHealth app and the visual quality of the Graphical User Interface (GUI).	• Aesthetics • Layout • Size
User engagement	Assesses the extent to which the mHealth app design attracts users to use it.	• Content presentation • Interactive • Not irritating • Targeted/tailored/personalized reports • Captivating
Content	Assesses the content provided or learned while using the mHealth app.	• Evidence-based content • Quality of information provided • Complete and concise • Clarity about the program's purpose
Therapeutic persuasiveness	Assesses the extent to which the mHealth app is designed to encourage users to make positive behavior changes or to maintain positive aspects of their lives.	• Call to action • Load reduction of activities • Therapeutic rationale and pathway • Rewards • Real data-driven/adaptive content • On-going feedback • Expectations and relevance
Therapeutic alliance	Assesses the ability of the mHealth app to create an alliance with the user to effect a beneficial change.	• Basic acceptance and support • Positive therapeutic expectations • Relatability
General subjective evaluation of program's potential	Examines the mHealth app's general potential to benefit its target audience based on the rater's subjective evaluation	• Appropriate features to meet the clinical aim • Right mix of ability and motivation • I like the program

The mHealth apps were reviewed in 2 stages. Initially, one researcher (DS) reviewed all included mHealth apps. Then, the mHealth apps were divided and reviewed by a team of six independent researchers (RO, MLH, NB, HS, MP, and CHMN). Hence, each app was reviewed by 2 researchers (DS and 1 of the 6 researchers).

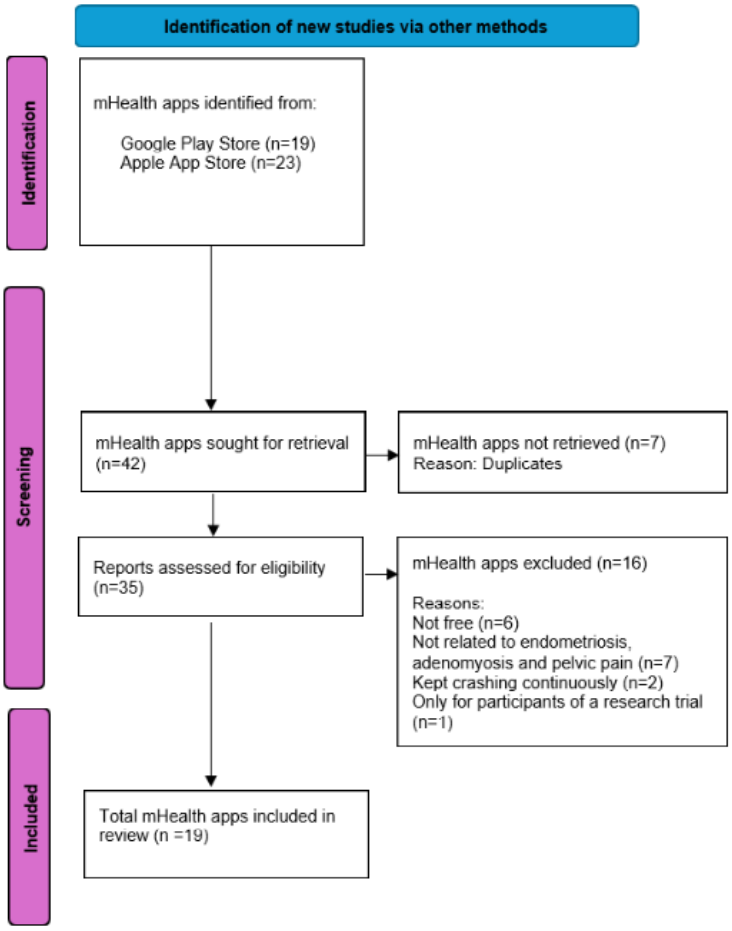
All reviewers were required to download the mHealth app to their smartphone devices (mobile phone or tablet). The ENLIGHT scores of each mHealth app were collated in an Excel spreadsheet. Each ENLIGHT quality assessment criteria was scored using a rating scale of 1-5 (Very Poor to Very Good) using the ENLIGHT checklist [22]

Discrepancies in ratings (any deviation greater than 1 rating unit) were resolved by discussion between the two reviewers. If evaluation differences were not resolved, a third independent assessor was consulted. After a detailed assessment, the average of the 2 reviewer's ratings was used to calculate a score for each of the 7 domains.

Good-Quality mHealth Apps

A total score for each mHealth app was calculated according to the ENLIGHT formula (Multimedia Appendix 3). mHealth apps with a total score of ≥3.5 were classified as "good" according to the ENLIGHT scoring system [23] and were recommended as good-quality mHealth apps for endometriosis care.

Ethical Considerations



An ethics approval was not required for this study, because this was a systematic search of mHealth apps and did not involve the recruitment of participants.

Results

The mHealth app search identified 42 apps, 23 from the Apple App Store and 19 from the Google Play store. A total of 7 mHealth apps were duplicates, leaving 35 apps, of which 13 were excluded as they did not meet the inclusion criteria (Figure 1). A further 3 mHealth apps were excluded; of these, 2 were excluded due to technical difficulties with the app (eg, it kept crashing), and one was excluded as it was specifically for participants enrolled in a research study. A total of 19 mHealth apps were included in the final analysis (Multimedia Appendix 2). There were discrepancies between the first and second reviewers in 6% of the ratings. All discrepancies were resolved without needing a third reviewer through consensus meetings.

XSL•FO
RenderX

Figure 1. Flow chart showing the selection of mobile health (mHealth) apps from Apple App and Google Play stores. Adapted from PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram.

Out of the 19 included mHealth apps, the majority (n=16) were designed for use by laypeople in the community. In addition, 2 mHealth apps were designed for health care providers. The majority of apps mainly provided symptom tracking functions (73.7%, n=14), 2 apps provided digital endometriosis classification tools (10.5%), 1 app offered an endometriosis fertility-related coaching program (5.3%), 1 app provided an endometriosis screening tool (5.3%), and 1 app offered a pelvic pain assessment tool (5.3%).

Quality of mHealth Apps

A total of 6 mHealth apps met the cutoff criteria for classification as “good” (ie, final score >3.5 to 5) according to the ENLIGHT quality assessment criteria. (Table 2). These mHealth apps are recommended as “good quality” apps for endometriosis care for community use.

Table 2. “Good” scoring (≥3.5 to 5) mHealth apps using the ENLIGHT Quality Assessment criteria (based on the final score).

Name	Usability	Visual design	User engagement	Content	TP[a]	TA[b]	GSE[c]	Final score
QENDO [24]	4.67	4.50	4.80	4.38	4.21	4.33	4.00	4.36
Bearable [25]	4.50	4.50	4.40	4.00	4.29	4.00	4.50	4.23
Luna for Health [26]	4.17	4.67	4.10	3.88	4.14	3.50	3.50	4.03
Matilda Health [27]	5.00	4.83	4.60	4.00	3.64	4.50	4.17	3.96
Branch Health: Pain Management [28]	4.00	4.17	3.70	3.50	3.71	3.67	2.83	3.67
CHARLI Health [29]	4.00	3.33	3.40	4.13	3.36	3.50	2.83	3.52

[a]TP: therapeutic persuasiveness.

[b]TA: therapeutic alliance.

[c]GSE: general subjective evaluation.

XSL•FO
RenderX

Usability

Approximately 84.2% (16/19) of the mHealth apps scored "good" (≥3.5) on usability (Multimedia Appendix 3). The highest-ranking mHealth apps were characterized by smooth, nearly frictionless, and easy navigation. These apps also had an intuitive interface that facilitated ease of learning and straightforward use of the app. Their structure was self-explanatory, and the user required minimum effort to obtain the desired output. Some examples of mHealth apps that scored "good" under this domain include QENDO [24], Bearable [25], Matilda Health [26], #Enzian [30], and the American Association of Gynecologic Laparoscopists (AAGL) Endo Classification app (Medicinia Atividades de Internet Ltda) [31]. While the first 3 mHealth apps are designed for community use, the last 2 can be used as resources in clinical practice.

Visual Design

The majority of mHealth apps (73.7%, 14/19) scored "good" (>3.5) on visual design. These mHealth apps (1) had an overall attractive visual design and an appealing color scheme (eg, QENDO [24]), (2) were well structured with a consistent layout (eg, Branch Health Pain Management (Upside Health) [28]), (3) clearly presented content that was easy to read (eg, Luna for Health; HDSI) [26]), and (4) displayed appropriately sized fonts, buttons, and menus (eg, Frendo [32]).

User Engagement

More than half of the mHealth apps scored ≥3.5 on user engagement (57.9%, 11/19). These were characterized by a good mix of text, images, and videos. The content was presented in an interactive and engaging manner. User engagement was further enhanced by avoiding features like pop-up ads, notifications, alerts, and sounds. Some mHealth apps in this domain provided tailored, targeted, and personalized user-specific health reports (eg, QENDO [24] and Matilda Health [27]) and/or charts (eg, Bearable [25]) that users could take to their health appointments. Users of the Luna for Health app [26], in addition to symptom tracking, could also undertake a menstrual well-being test that suggested the need for further medical evaluation.

Content

The majority of mHealth apps scored ≥3.5 under content (78.9%, 15/19). These mHealth apps contained appropriate, complete, and concise information with good clarity about the app's purpose. Some examples include QENDO [24], #Enzian [30], and Flutter [33]. Amongst the 15 apps that scored well in this domain, only 1 app was designed to assist clinicians (#Enzian [30]) in the classification of endometriosis based on radiological and/or surgical findings.

Therapeutic Persuasiveness

A low number of mHealth apps (31.6%, 6/19) scored ≥3.5 under the therapeutic persuasiveness. These apps had a clear call to action and engaged the user by developing health plans or health reports with an actionable outcome. For example, the Bearable app [25] allowed users to set goals like exercising, limiting caffeine intake, or avoiding screen time 1 hour before bedtime. Straightforward and easy-to-complete activities in these apps included completing a health assessment questionnaire, data entry for symptom tracking, and documenting daily challenges. For example, QENDO [24] provided users with a report to take to (or email) their doctor. Matilda Health [27] allowed users to schedule webinars of interest or ask questions to clinicians. The aim of these activities was clear to users. The "good" scoring apps also provided ongoing feedback about the user's health or recommendations regarding testing and likely diagnosis based on symptoms.

Therapeutic Alliance

Less than half (47.4%, 9/19) of the mHealth apps scored "good"(≥3.5) under the therapeutic alliance. These mHealth apps demonstrated basic acceptance, support, and relatability in creative ways. Features included (1) the use of supportive language (for example, the Luna for Health app [26] used phrases like "you are not alone in this journey"), (2) positive therapeutic support (eg, CHARLI Health; Lucid Labs Pty Ltd) [29] provided an option to chat with doctors and endometriosis specialists) and (3) an online community that fosters a sense of connectedness (eg, Flutter [33]).

General Evaluation of the mHealth Apps

This criterion evaluates the reviewers' subjective global score. A low number of mHealth apps (31.6%, 6/19) scored "good" (≥3.5) in this domain. The reviewers felt that they displayed features appropriate to their aims, had the elements to motivate the use of the app, and were generally likable. Some examples include QENDO [24] and Matilda Health [27].

Discussion

Principal Findings

We conducted a comprehensive, multidimensional quality assessment of endometriosis mHealth apps using the ENLIGHT tool [22]. This tool captures quality constructs like therapeutic persuasive design and therapeutic alliance, which are considered central to the successful uptake of mHealth apps among end users. Our study identified six "good" quality endometriosis mHealth apps that can be recommended for consideration in supporting the community in endometriosis care. Additionally, two mHealth apps can be recommended for consideration in assisting healthcare providers in the classification of endometriosis. To our knowledge, this is the first systematic search and assessment to use the ENLIGHT tool to comprehensively assess endometriosis and pelvic pain mHealth apps.

Comparison With Previous Work

mHealth Apps for the Endometriosis Community

In total, 17 out of the 19 mHealth apps in this study could be used by people in the community. mHealth apps are widely used for symptom tracking and self-management of menstrual pain [9]. We found that most mHealth apps were designed for community use, facilitated symptom tracking, and provided users with symptoms and/or activity reports that could be shared with health care providers. Such tracking and activity reporting appear to be desirable features of mHealth apps [34]. A study reported that 77.7% of people affected with endometriosis were

XSL•FO
RenderX

comfortable sharing data tracked on mHealth apps with clinicians, indicating the acceptability of data sharing for health care management [34]. The Bearable app [25] provides users with a correlations grid, demonstrating the impact of certain activities like meditation, exercise, or diet on symptoms, mood, sleep, and/or energy levels. Similarly, the Phendo app (Citizen Endo) [35] provided tailored insights on self-management strategies. In addition, Phendo [35] is a research app, which has used direct self-reported data to study the heterogeneity of endometriosis symptoms [36]. This can help analyze symptom variability among people with endometriosis [36,37], demonstrating the usefulness of digitally generated data in endometriosis research. Self-tracked data from mHealth apps can be used to analyze the association between symptoms and periodicity as potential health indicators for endometriosis assessment [37]. Furthermore, such data can be used as an additional data source that complements patient electronic health records to accurately and comprehensively evaluate patient health history [36].

Apps like Luna for Health [26], Matilda Health [27], and CHARLI Health [29] offer virtual consultations with clinicians specialized in endometriosis and with allied health professionals like physiotherapists and dietitians providing the community with comprehensive alternate pathways for endometriosis care through digital technology. These digital advancements build capacity to meet the gap in the health workforce and improve accessibility for endometriosis management. Data tracking, real-time visual representation of symptoms, the effectiveness of treatments, and self-management strategies can assist clinicians in planning more personalized endometriosis treatments in the future [34].

The effectiveness of mHealth apps for other chronic diseases has previously been evaluated. For example, a Canadian mHealth app, “bant” (University Health Network, Toronto, Ontario), developed for adolescents to manage type 1 diabetes, increased the daily average monitoring of blood glucose levels and demonstrated high user satisfaction [38]. Kollmann et al [39] found a significant decrease in hemoglobin A_{1c} levels using the Diab-Memory App in patients with type 1 diabetes. A mobile phone–based technology called NICHE [12] achieved similar results in patients with type 2 diabetes. There appears to be limited evidence on the evaluation of endometriosis mHealth apps. The Endo-App (Endo Health GmBH) [40] evaluated the impact of the app on disease-related quality of life and symptoms of endometriosis in 122 participants using a randomized controlled pilot trial [41]. Participants in the intervention group reported clinically relevant and statistically significant improvements in pain-specific self-efficacy, fatigue, depression, and quality of life after 12 weeks of use as compared with controls [41], demonstrating the scope of mHealth apps to improve the well-being of those affected by endometriosis. Given this potential, mHealth apps should ideally evaluate their effectiveness on users’ quality of life, impact on endometriosis knowledge, the effectiveness of recommended self-management strategies, and user satisfaction or outcomes of virtual consultations (such as reduced delay in diagnosis or impact on consultation wait times).

Endometriosis mHealth Apps as a Resource in Clinical Practice

This study found only 2 mHealth apps designed specifically for health care providers, both of which offered digital tools to classify endometriosis based on radiological and/or surgical findings. We did not find any mHealth app that provided education to clinicians, yet the need to improve endometriosis awareness among clinicians is expressed by both, the community [2,42] and clinicians [43]. A Dutch study reported that 87% (76/87) of general practitioners (GPs) reported the need to improve endometriosis education with the same study reporting that GPs scored 40% on endometriosis factual knowledge (ie, questions regarding pathophysiology) and 49.4% on clinical knowledge (ie, questions regarding endometriosis symptoms and treatment) [43].

Furthermore, mHealth apps are increasingly being used by clinicians for medical education, training, and clinical decision-making [44]. A study showed that 98.4% of doctors own a smartphone and 92% agree that mHealth apps positively impact clinical practice [45]. In this context, a meta-analysis reported that the pooled effect of 15 studies with 962 participants showed significant improvement in knowledge scores among health care providers who used mHealth apps compared with those who did not use them [17]. Previously, the Endo App by the European Society for Human Reproduction and Embryology (ESHRE) [46] provided a clinical decision-making tool to clinicians in busy clinical settings. Through the decision tool, clinicians could also conveniently access the ESHRE endometriosis clinical practice guidelines [47], which were time-saving in their daily practice. However, this app is no longer available through the app store and appears to have been discontinued. Given the rising popularity and uptake of mHealth apps among clinicians and the need for endometriosis education, digital technology can be leveraged to provide endometriosis-related continuing medical education and clinical decision-making tools for clinicians.

The ENLIGHT Quality Assessment

The ENLIGHT criteria evaluated factors that are central to the long-term and successful uptake of the mHealth apps. The majority of the mHealth apps scored “good” (≥3.5) on usability (84.2%) and visual design (73.7%). However, only 31.6% and 47.4% of mHealth apps scored “good” on user therapeutic persuasiveness and therapeutic alliance respectively. Usability and visual design are important features that determine the success and user uptake of mHealth apps [48,49]. mHealth apps that provide personalized and tailored feedback have demonstrated better user engagement [50,51]. A mental health, microrandomized, clinical trial reported that using push notifications to send a tailored health message was an effective strategy to increase user engagement [50]. Therapeutic persuasiveness is positively correlated with real-world usage of mHealth apps and is an important predictor of user adherence [52]. The ENLIGHT criteria assess the use of rewards to increase therapeutic persuasiveness [21]. Rewards are effective at motivating people [53]. One mHealth app intervention successfully used tangible rewards such as redeeming reward points for purchasing iTunes in an adolescent population [38].

XSL•FO
RenderX

Another study found that participants preferred tangible rewards such as gift cards or monetary incentives as compared with intangible rewards like points or badges [15]. We found a few mHealth apps that provided rewards to users. Users of the Luna for Health app [26] earned "Luna Coins" by participating in quizzes; however, it was unclear how these coins could be used. The therapeutic alliance enhances positive user engagement by fostering relatability [21,52]. It may be that future apps can incorporate conversational agents such as smartphone-based chatbots portraying human involvement [52,54,55] or conversational agents such as Alexa (Amazon), which mimic human conversations [54]. Although mHealth apps are not human, the extent to which they build an alliance is integral to their quality [21].

Strengths

Our systematic search and assessment of the quality of mHealth apps for endometriosis has several strengths. First, it presents novel findings on "good" quality mHealth apps developed for endometriosis care and relevant to the community. We identified mHealth apps that could be considered as a potentially useful resource for use in clinical practice. Clinicians may use the findings of this study to consider recommendations on mHealth app use to support people and families affected by endometriosis. Finally, our study highlights features of therapeutic persuasiveness and therapeutic alliance and additional quality metrics that can be incorporated into future developments of mHealth apps for endometriosis.

Limitations

The ENLIGHT criteria [20] were challenging to uniformly apply. The evaluation of evidence-based content was challenging as most mHealth apps were symptom trackers and presented limited evidence-related content. The quality of content was assessed based on material available in the free version of the app. However, most apps contained endometriosis content and learning modules as part of their paid version. For example, with both, Luna for Health [26] and Matilda Health [27], we were unable to evaluate content completely as we were only able to assess freely available content. In the #Enzian [30] and AAGL Endo Classification app [31], "rewards" and "ongoing feedback," which form part of therapeutic persuasiveness were not features offered to users. Hence, therapeutic persuasiveness was difficult to evaluate, with limited formal guidance on how to navigate such scenarios. Furthermore, this study did not include non-English mHealth apps, due to limitations in funding for translation services. In addition, due to the search algorithm on both app stores that used geographical location, that is, Australia, which is predominantly an English-speaking country, we did not come across any app that was not developed in the English language.

Conclusions

Our systematic search presents novel findings on the quality assessment of mHealth apps that can be used for endometriosis care. Based on the use of a validated tool for rating app quality metrics, our findings are suggestive of "good quality" mHealth apps for community use. These quality ratings can be considered by clinicians as potential recommendations to patients to support their care. Clinicians can use 2 mHealth apps for endometriosis classification in clinical practice. To further strengthen app development for the endometriosis community, we recommend that (1) endometriosis-related mHealth apps incorporate the standardized experience and outcome measures to assess the effectiveness of programs offered. For example, user satisfaction, effectiveness of recommended self-management strategies, impact on user's endometriosis knowledge, pain self-efficacy, and overall quality of life, (2) digital technology is leveraged to develop clinical resources for endometriosis-related continued medical education and to support clinical decision-making, and (3) good design features are considered more carefully including therapeutic persuasiveness and therapeutic alliance for the successful uptake of endometriosis mHealth apps.

Authors' Expertise in Conducting the Search and Quality Assessment

The interprofessional team consisted of endometriosis researchers, clinical pain researchers, clinicians (gynecologist, specialist physiotherapist, and endometriosis nurse specialist), and digital health experts. The team has expertise in the clinical management of endometriosis, community engagement, co-design of digital health tools, endometriosis content, and evaluation research to support self-management and care. All authors were involved in the quality assessment.

Acknowledgments

We thank Ms Vikki Langton (Librarian – Adelaide Medical School, University of Adelaide) for rendering assistance in formulating the search strategy. DS is a PhD (Medicine) candidate and is supported by the Australian Government, Research Training Program Stipend.

Data Availability

All data generated or analyzed during this study are included in this published article and Multimedia Appendices 1-3.

Authors' Contributions

DS contributed to the study design, conducted a search of mHealth apps, data extraction, quality assessment, data collation, data analysis and drafting of the manuscript. RO contributed to the study design conducted the search of mHealth apps, contributed to quality assessment, and drafted the manuscript. CHMN contributed to the quality assessment and drafting of the manuscript.

XSL•FO
RenderX

NB, HS, MP, and MLH contributed to the study design, quality assessment, and reviewing the manuscript. All authors have read and approved the final manuscript.

Conflicts of Interest

Although this systematic assessment has not received separate funding, it is part of the EndoZone, a digital platform for endometriosis project funded by the Australian Government Department of Health and Aged Care and Jean Hailes for Women's Health. CHMN is an employee of The University of New South Wales and manages grant funding from the Australian Government Department of Health and Aged Care, and Medical Research Future Fund, and was a previous employee of Jean Hailes for Women's Health and CSL Vifor (formerly Vifor Pharma Pty Ltd). NB has shares in goAct Pty Ltd and received research funding support from Digital Health CRC, Medical Research Future Fund, and Barossa Fleurieu Local Health Network. Other authors declare no conflicts of interest.

Abstract

Background: A toothbrush device that telemonitors toothbrushing is a technologically advanced solution providing personalized feedback on toothbrushing habits and oral hygiene. These devices integrate smartphone apps to enhance oral health compliance through dental professional feedback.

Objective: This 6-month prospective randomized controlled trial aimed to compare the clinical effectiveness, defined as improved oral hygiene measured by plaque reduction and halitosis control, of an interactive telemonitoring toothbrush (ITT), an oscillating-rotating power toothbrush (ORT), and a manual toothbrush (MT).

Methods: Participants were recruited offline from the Department of Advanced General Dentistry at Yonsei University Dental Hospital, South Korea. A total of 150 participants were randomly assigned to 3 groups (50 participants each): (1) an ITT connected to a smartphone app providing real-time feedback and weekly dental professional reviews, (2) an ORT with smartphone-based guidance requiring participants to send weekly brushing records via screenshots, and (3) an MT with a brushing diary for review. Data collection occurred in clinical settings. Primary outcomes included plaque reduction measured using the Simple Hygiene Score (SHS), while secondary outcomes included plaque reduction measured using the Turesky modification of the Quigley-Hein plaque index (QHI), reductions in halitosis, and changes in oral microbiota. All outcomes were assessed at baseline and 1 month, 3 months, and 6 months.

Results: A total of 150 participants completed the study. Over 6 months, the SHS increased in the MT group (mean 3.16, SD 4.86 to mean 5.66, SD 5.20) but significantly decreased in the ITT group (mean 3.47, SD 5.50 to mean 2.27, SD 3.82; *P*=.004). Similarly, QHI decreased more in the ITT group (mean 1.79, SD 0.72 to mean 0.85, SD 0.63) than in the ORT (*P*<.001) and MT (*P*<.001) groups. Regarding microbiota, there were no significant differences in high-risk periodontal microbiota or the ratio of caries-risk to anticaries microbiota between the ITT and ORT groups. However, in the MT group, the ratio of caries-risk microbiota was significantly higher at the 3-month (*P*<.001) and 6-month (*P*=.005) recalls than at baseline and at the 3-month (*P*=.048) and 6-month (*P*=.03) recalls than at the 1-month recall. Poststudy questionnaires indicated that 45 of 50 ITT participants (92%) and 37 of 50 ORT participants (76%) reported improved brushing ability. The most effective feature in the ITT group was brushing training, while participants in the ORT group cited the brushing guide as most useful (*P*<.001). Satisfaction scores were higher in the ORT group (mean 7.90, SD 1.21) than in the ITT group (mean 7.15, SD 1.66; *P*=.004). The number of brushing events decreased significantly in the ORT group (*P*=.02), while brushing duration increased in the MT group (*P*=.01).

Conclusions: ITTs enable better oral hygiene management than MTs through dental professional feedback. However, further studies are needed to optimize feedback intervals and improve long-term adherence.

Introduction

Toothbrushing plays an important role in plaque removal and maintenance of optimal oral health [1]. It can also prevent oral diseases, particularly caries, gingivitis, and periodontitis [2,3]. Moreover, a prior study reported that regular toothbrushing, flossing, and dental visits are essential to prevent dental problems and maintain good oral hygiene [4].

With technological advances, the oral care industry has introduced smart toothbrushes. A smart toothbrush is a technologically advanced toothbrush that uses sensors, connectivity, and data analysis to provide personalized feedback on an individual's toothbrushing habits and oral hygiene. These toothbrushes have various features, such as a pressure sensor to prevent overbrushing, a timer to ensure that the tooth surfaces in the mouth are brushed for an appropriate amount of time, and a Bluetooth connection that sends data to a mobile app for analysis. Additionally, some smart toothbrushes can be used by professionals as telemonitoring devices for oral care advice.

Software that offers real-time visual feedback on an individual's brushing movements is being developed to improve brushing techniques. The real-time feedback provided by the toothbrush connected to the mobile app allows users to enhance their toothbrushing technique to improve oral hygiene and reduce the risk of dental problems, such as plaque and gingivitis [5]. In addition, these telemonitoring toothbrushes can help users maintain the right habits by monitoring their toothbrushing habits and providing notifications to signal the recommended brushing time [6]. However, relatively few studies have compared the efficacy of telemonitoring and manual toothbrushes; thus, more research on the impact of telemonitoring toothbrushes on oral health is needed [7-9].

We hypothesized that, among smart toothbrushes, toothbrushes with a telemonitoring function might improve users' oral hygiene compared with other toothbrushes. Therefore, this study aimed to report the results of a 6-month prospective randomized controlled trial to compare the clinical effectiveness of using an interactive telemonitoring toothbrush (ITT) or an oscillating-rotating electric toothbrush (ORT) among smart toothbrushes as well as a manual toothbrush (MT). Furthermore, we compared the overall oral hygiene results regarding plaque, halitosis, dental caries, and periodontal microbiota between the 3 groups using the 3 different types of toothbrushes. In addition, participants' toothbrushing habits, awareness of telemonitoring toothbrushes, and compliance were also investigated.

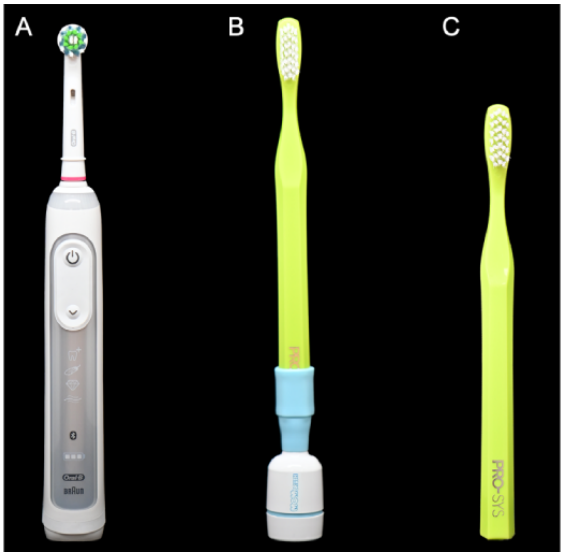
Methods

Study Design

This study was a parallel-group, randomized, controlled, single-blind clinical trial and was conducted in the Department of Advanced General Dentistry between January 2021 and May 2022. In this trial, the data analysts were blinded to the group assignments to ensure unbiased statistical analysis. This study was registered with the Clinical Research Information Service and is reported following the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (Multimedia Appendix 1) [10].

Participants

Participants were recruited via offline recruitment strategies. The study recruited participants through notices posted at Yonsei University Dental Hospital and within Yonsei University. Interested individuals underwent a screening process, including a review of medical records and an oral examination, to confirm eligibility based on the study criteria. The inclusion criteria were as follows: patients (1) with good general health and who were aged >19 years; (2) who had 24 or more teeth, including implants or bridges; and (3) who used a smartphone. The exclusion criteria were as follows: patients (1) with moderate to severe periodontitis [11]; (2) with orthodontic devices in the oral cavity; (3) with removable dentures; (4) with salivary gland–related diseases; (5) with halitosis caused by systemic diseases (eg, digestive system–related diseases, liver-related diseases, kidney-related diseases, medication-related osteonecrosis of the jaw); (6) who had received head and neck radiation therapy; (7) who were pregnant or lactating; (8) who lacked communication skills (including disabled individuals); and (9) whose work was related to dentistry or medicine



The sample size was 150 participants, divided into 3 groups of 50 each. The sample size was calculated using G-Power 3.1.9.2, with an effect size of 0.3, significance level of .05, and statistical power of 85%, considering a dropout rate of 15% [12]. The study participants were randomly divided into 3 groups (ORT, ITT, and MT) using block randomization (block size: 5) via software (Excel, Microsoft Corp) before the start of the study. Participants identified as eligible were randomized using a computerized randomization tool by 2 independent researchers who were not involved in the rest of the study. Before participating in the study, participants who met the inclusion criteria completed a self-reported questionnaire.

Procedures and Study Test Products

In this study, an MT and 2 types of smart toothbrushes were used: (1) ITT and (2) ORT (Figure 1).

XSL•FO
RenderX

Figure 1. Toothbrush types used in the study: (A) Oral-B Genius 8000 (Procter & Gamble), (B) Mombrush (XiuSolution), (C) manual toothbrush (PRO-SYS Sensitive Toothbrush).

The ITT (Mombrush; XiuSolution) was chosen as the primary intervention due to its advanced telemonitoring capabilities. This toothbrush connects to the Mombrush ProCare smartphone app via Bluetooth, allowing for real-time tracking of brushing behavior, including frequency, duration, and technique.

After installing the Mombrush ProCare app on the participants' smartphones, they brushed according to the video guide on how to brush with the rolling method (Multimedia Appendix 2). Participants in the ITT group were also registered in the Mombrush advisor application, which allowed the researcher to check the records of continuous brushing habits, regular brushing habits, brushing balance, and brushing areas in real time. These brushing records were stored on a cloud server and reviewed weekly by dental professionals, who provided personalized feedback on regular brushing habits, brushing balance, and brushing zones.

The ORT with a CrossAction brush head (Oral-B Genius 8000; Procter & Gamble), which was included as a comparator, features smartphone-guided brushing without telemonitoring capabilities. It represents an advanced electric toothbrush widely used in practice, enabling a direct comparison with the telemonitoring approach.

Selected participants were instructed to install the Oral-B app and connect the electric toothbrush to their smartphone via Bluetooth (Multimedia Appendix 3). Participants brushed in Clean mode using the coaching function provided by the app. Since this app was an on-device app, the researcher could not check the brushing records in real time, so the researcher received a screenshot of the brushing records once a week and provided feedback.

The American Dental Association reference MT (PRO-SYS Sensitive Toothbrush; Benco Dental) was selected for the control group and serves as the standard brushing method. This allowed for the evaluation of the added benefits provided by digital and telemonitoring interventions.

The MT group recorded the number of brushing strokes in a brushing diary after receiving brushing instruction. Participants in the MT group sent their brushing diaries to the researcher once a week. The diaries were reviewed, and a professional provided feedback.

All participants were instructed to brush their teeth with the products distributed at least twice daily during the study period and to abandon other oral hygiene aids, such as dental floss, interdental brushes, and mouthwashes. All groups were provided with standard sodium fluoride toothpaste (1450 ppm NaF) for use with their assigned toothbrush.

Clinical Measurement Outcomes

Primary Outcome: Simple Hygiene Score (SHS)

To evaluate dental plaque, the following 5 white-light and fluorescent images were captured using the quantitative light-induced fluorescence system (Qraycam; AIOBIO): (1) frontal photograph showing the labial surfaces of the anterior teeth, (2) right and (3) left lateral photographs showing the buccal surfaces of the posterior teeth, (4) maxillary dentition photograph showing the palatal and occlusal surfaces of the maxillary dentition, (5) mandibular dentition photograph showing lingual and occlusal surfaces of the mandibular dentition. The fluorescent plaque index scoring for the fluorescent images of the quantitative light-induced fluorescence system was performed automatically using the Simple Hygiene Score (SHS) with the analysis program Q-ray (version 1.38; Inspektor Research Systems BV). The SHS scores the plaque level from 0 to 5 based on the area of red fluorescent plaque attachment, with a larger plaque attachment area giving a higher score [13].

Secondary Outcomes

Plaque Reduction

The Turesky modification of the Quigley-Hein plaque index (QHI) was used to measure the presence of plaque [14,15]. The crown and cervical surfaces of the maxillary right first molar, left central incisor, left first premolar, mandibular left first molar, right central incisor, and right first premolar were stained with the disclosing solution (1% neutral red). Plaques were

XSL•FO
RenderX

evaluated at 2 sites (buccal and lingual) per tooth, and each site was scored on a scale of 0 to 5 (0=no plaque, 1=slight staining at the cervical margin, 2=plaque band up to 1 mm at the cervical margin, 3=plaque band wider than 1 mm but covering less than one-third of the crown of the tooth, 4=band covering at least one-third but less than two-thirds of the crown of the tooth, and 5=band covering more than two-thirds of the crown of the tooth).

Volatile Sulfur Compounds

To measure halitosis, H_2S, and CH_3SH concentrations were measured using the Twin Breasor II (iSenLab Inc) with a nanotech semiconductor sensor made by a plasma ion beam. The participants held a straw in their mouth, breathed through their nose for 50 seconds, and exhaled through their mouth for 10 seconds. Exhaled breath was collected by an automatic suction method using a straw, and the sampling gas volume was approximately 10 mL. Analysis was performed 150 seconds after exhalation, and the measurement units were ng/10 mL and ppb.

Collection of Saliva Samples

To examine caries-related and periodontal bacteria in the oral cavity, a T-SWAB TRANSPORT UTM (Noble Biosciences) was used to swab the gingiva, cervical region, and tooth area of the right maxillary and mandibular molars for more than 30 seconds. Afterward, the cotton swabs were stored in a collection container containing a preservative solution and frozen at –80 °C before DNA extraction. Bacterial genomic DNA was extracted using the MagNA Pure 96 DNA and Viral NA Small Volume Kit (Roche Diagnostics) according to the manufacturer's instructions. DNA concentration was determined fluorometrically on the Qubit 3.0 Fluorometer (Thermo Fisher Scientific) using the Qubit dsDNA HS Assay Kit. Real-time polymerase chain reaction (PCR) was performed using the PowerCheck Periodontitis Pathogens Multiplex Real-time PCR kit (KogeneBiotech) and PowerCheck Dental Caries Pathogens Multiplex Real-time PCR kit (KogeneBiotech). In this study, *Aggregatibacter actinomycetemcomitans*, *Porphyromonas gingivalis*, *Tannerella forsythia*, and *Treponema denticola* were classified as high-risk periodontal microbiota. *Streptococcus mutans*, *Streptococcus obrinus*, *Actinomyces gerencseriae*, *Scardovia wiggsiae*, *Veillonella parvula*, and *Candida albicans* were classified as caries-risk microbiota, whereas *Streptococcus sanguinis* was classified as anticaries microbiota [16].

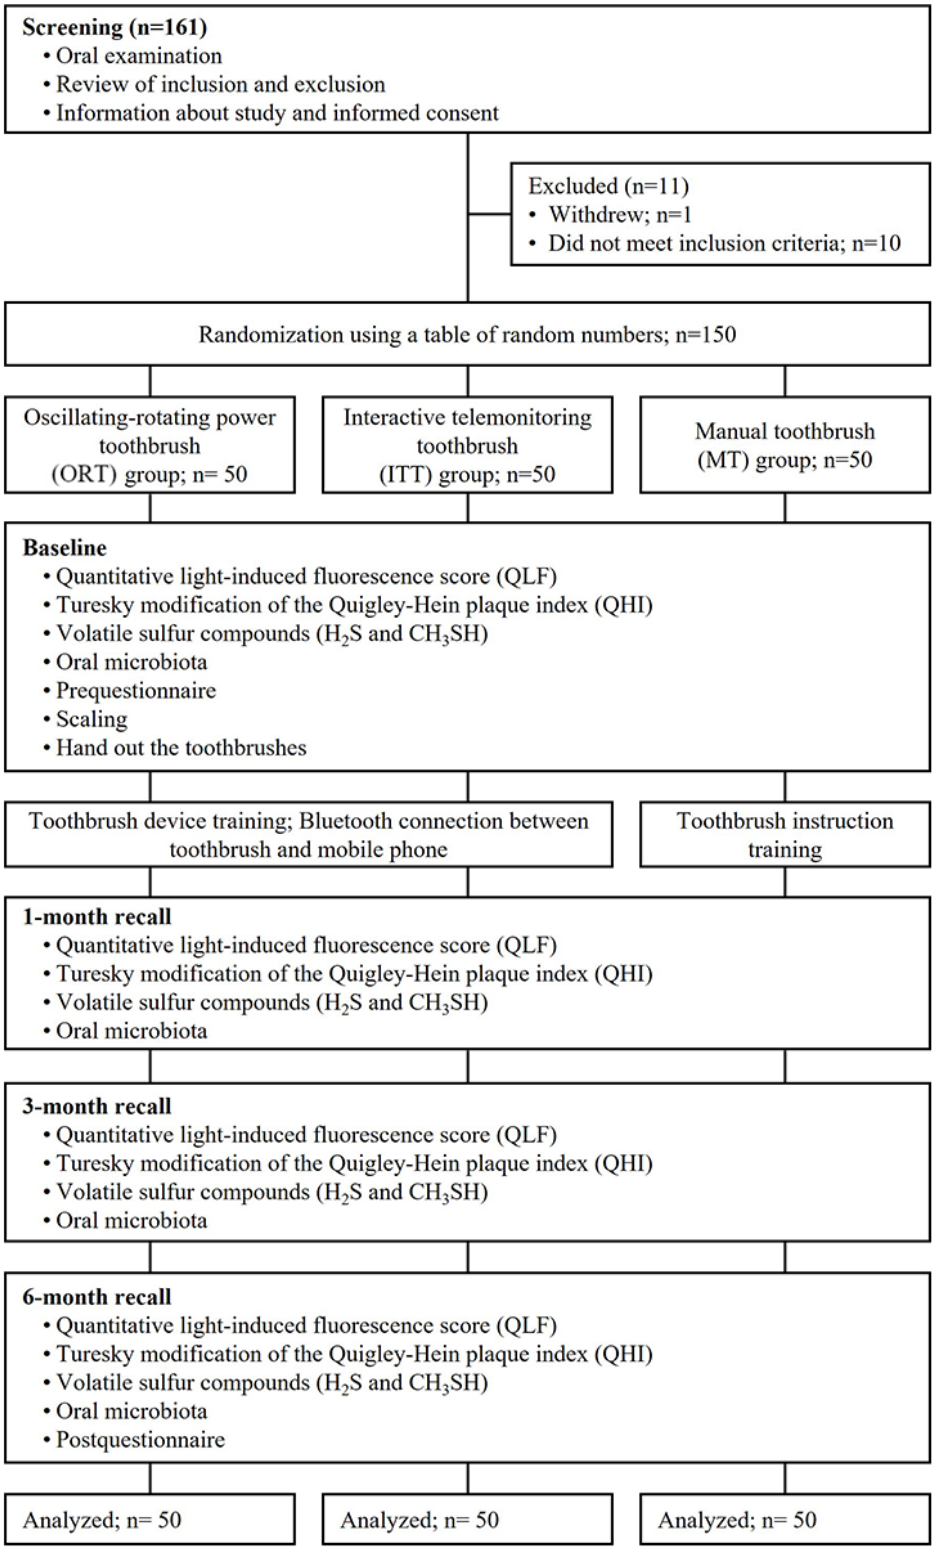
The clinical evaluations at baseline and follow-ups were completed by dental professionals in the same dedicated location within the Department of Advanced General Dentistry at Yonsei University Dental Hospital. To ensure consistency and minimize interexaminer variability, the same examiner performed all measurements and assessments for each participant throughout the study. After clinical evaluation at baseline, scaling was performed for all participants, and toothbrushes assigned in advance were distributed. After 1 month, 3 months, and 6 months from the beginning of the study, the participants underwent follow-up clinical evaluations in the same manner as at baseline. At the last visit, the participants completed a self-reported, paper-based questionnaire consisting of 8 questions on current oral care habits and awareness regarding telemonitoring toothbrushes. The dental professional abstracted the responses from the paper-based questionnaires and inputted the data into a database for subsequent analysis.

Statistical Analysis

All statistical analyses were performed using SPSS (version 25; IBM Corp). Data were tested for normality using the Kolmogorov Smirnov test. One-way ANOVA and chi-square tests were used to analyze the demographics and questionnaire responses of the study participants. Independent-sample *t* tests were used to compare changes in brushing habits by group. SHS, QHI, and volatile sulfur compounds were analyzed using repeated measures ANOVA with Bonferroni multiple comparison tests. Changes in microbiota within groups were analyzed using a paired-samples *t* test. All statistical analyses were 2-tailed, and the statistical significance level was set at $P<.05$.

Ethical Considerations

The Institutional Review Board (IRB) of the Dental Hospital at Yonsei University reviewed and approved the study protocol prior to the trial in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki and its later amendments (IRB number: 2-2020-0032). All participants completed a written consent form and were given information regarding the study. All data were anonymized to ensure participant confidentiality.



Results

Participant Characteristics

A total of 161 participants completed the screening; 11 of the screened participants did not meet the inclusion criteria, resulting in 150 participants who completed the study (Figure 2). The general characteristics of the participants are presented in Table 1. The average age of the participants was 31.90 (SD 7.34) years, and 61 (61/150, 40.7%) men and 89 (89/150, 59.3%) women were included. Regarding their academic qualifications, a bachelor’s degree was the most common academic qualification in all groups. There were no statistically significant differences in general characteristics among the 3 groups. Similarly, there were no statistically significant differences between the groups in the self-reported questionnaire on current oral care habits and awareness of telemonitoring toothbrushes at the beginning of the study.

Changes in SHS, QHI, and H2S and CH3SH Levels

The mean SHS increased over time in the MT group (3.16, SD 4.86 to 5.66, SD 5.20) and decreased at the 1-month recall in the ORT and ITT groups (1.53, SD 3.24 and 1.41, SD 3.49, respectively). Compared with the MT group, the SHS significantly decreased over time in the ITT group (*P*=.004; Figure 3A). Regarding QHI, the mean scores decreased from baseline at the 1-month recall in all 3 groups (ORT group: 2.2, SD 0.72 to 1.39, SD 0.53; ITT group: 1.79, SD 0.72 to 1.19, SD 0.69; MT group: 1.99, SD 0.84 to 1.74, SD 0.79). However, at the 6-month recall, the scores in the ORT and MT groups increased (ORT group: 1.68, SD 1.11; MT group: 1.86, SD 1.25), while that in the ITT group decreased (0.85, SD 0.63; *P*<.001; Figure 3B). However, there were no significant differences in H_2S and CH_3SH levels among the 3 groups during the entire study period (Figures 3C and 3D).

Figure 3. Comparison of the mean (SD) of the (A) Simple Hygiene Score (SHS), (B) Turesky modification of the Quigley-Hein plaque index (QHI), and halitosis in terms of (C) H2S and (D) CH3SH values between the oscillating-rotating power toothbrush (ORT), interactive telemonitoring toothbrush (ITT), and manual toothbrush (MT) groups uing 2-way, repeated-measures ANOVA with the Bonferroni multiple comparisons test.

	Baseline	1-month recall	3-month recall	6-month recall
ORT	3.15 (4.53)	1.53 (3.24)	2.98 (4.67)	3.63 (4.77)
ITT	3.47 (5.50)	1.41 (3.49)	1.98 (3.85)	2.27 (3.82)
MT	3.16 (4.86)	3.26 (3.34)	4.38 (3.97)	5.66 (5.20)

	Baseline	1-month recall	3-month recall	6-month recall
ORT	2.21 (0.72)	1.39 (0.53)	1.71 (0.94)	1.68 (1.11)
ITT	1.79 (0.72)	1.19 (0.69)	1.02 (0.70)	0.85 (0.63)
MT	1.99 (0.84)	1.74 (0.79)	1.81 (1.16)	1.86 (1.25)

	Baseline	1-month recall	3-month recall	6-month recall
ORT	0.30 (0.63)	0.16 (0.36)	0.28 (0.85)	0.62 (0.92)
ITT	0.29 (0.86)	0.17 (0.36)	0.45 (0.73)	0.54 (1.13)
MT	0.31 (0.52)	0.27 (0.53)	0.30 (0.53)	0.49 (1.08)

	Baseline	1-month recall	3-month recall	6-month recall
ORT	0.09 (0.24)	0.07 (0.24)	0.11 (0.37)	0.19 (0.34)
ITT	0.06 (0.09)	0.05 (0.98)	0.13 (0.23)	0.14 (0.25)
MT	0.06 (0.12)	0.11 (0.25)	0.14 (0.28)	0.17 (0.31)

Microbiota Changes

Regarding the microbiota, there were no significant differences in the high-risk periodontal microbiota over time among the 3 groups (Figures 4A-4C). Likewise, there was no significant difference in the ratio of caries-risk microbiota to anticaries microbiota between the ORT and ITT groups (Figures 4D and 4E). However, in the MT group, the ratio of caries-risk microbiota significantly increased at the 3-month (*P*<.001) and 6-month (*P*=.005) recalls compared with baseline and at the 3-month (*P*=.048) and 6-month (*P*=.03) recalls compared with the 1-month recall. Conversely, the ratio of anticaries microbiota significantly decreased at the 3-month and 6-month recalls (Figure 4F).

XSL•FO
RenderX

Figure 4. At each of the study time points, boxplots of the percentages of periodontal high-risk, caries-related microbiota in the (A) oscillating-rotating power toothbrush (ORT), (B) interactive telemonitoring toothbrush (ITT), and (C) manual toothbrush (MT) groups, with the boxes representing the 25th to 75th percentiles and the line representing the median, as well as the ratio of caries-risk to anticaries microbiota in the (D) ORT, (E) ITT, and (F) MT groups at the different time points, with changes in the ratios over time analyzed using paired-samples t tests.

Self-Reported Questionnaire and Toothbrushing Behavior Changes

The groups completed a self-reported questionnaire on current oral care habits and awareness of telemonitoring toothbrushes after finishing the study. On the questionnaire, the most common answers to the question regarding the most effective function of a telemonitoring toothbrush were the brushing guide function by the ORT and MT groups and the standard brushing training by the ITT group (P<.001; Table 2). The most inconvenient feature of the telemonitoring toothbrush was inaccurate toothbrush position recognition, according to participants in the ORT and ITT groups (P<.001). In the ORT and ITT groups, 88% (44/50) and 82% (41/50) of the participants, respectively, indicated that the smart toothbrush was helpful for oral health, and 76% (38/50) and 92% (46/50) of the participants, respectively, reported that their brushing ability had improved. Mean satisfaction with the smart toothbrush was 7.90 (SD 1.21) and 7.11 (SD 1.67) in the ORT and ITT groups, respectively; these were significantly lower in the ITT group than in the ORT group (P=.008). The need for a smart toothbrush was not significantly different between the ORT (mean 7.44, SD 1.64) and ITT (mean 7.71, SD 1.67) groups.

Discussion

Principal Findings

This study demonstrated that ITTs could improve oral hygiene management. The SHS and QHI, indicators of oral hygiene, improved significantly more for the ITT group than the ORT and MT groups when the values at baseline and the 6-month recall were compared between the groups. Along with these results, changes in the oral microbiota were also confirmed. We classified *Streptococcus sanguinis* as anticaries microbiota and compared its quantitative ratio against caries-risk microbiota, such as *Streptococcus mutans*, *Streptococcus sobrinus*, *Actinomyces gerencseriae*, *Scardovia wiggsiae*, *Veillonella parvula*, and *Candida albicans*. In the ITT group, the proportion of anticaries microbiota increased over time. In the ORT group, the proportion of anticaries microbiota increased until the 3-month recall; however, it decreased at the 6-month recall. In the MT group, the proportion of anticaries microbiota continued to decrease at all time points. Although reducing caries-risk microbiota is important, increasing anticaries microbiota is also an important part of oral hygiene [17,18]. These findings highlight the importance of compliance and sustained engagement in oral hygiene maintenance, which was facilitated by continuous feedback in the ITT group.

Comparison With Prior Work

The importance of compliance effects for smartphone-based digital health care devices has been reported in previous studies. For example, a telemonitoring application for blood glucose management by individuals with diabetes was effective at the beginning of use, but as satisfaction with the application decreased, the effectiveness also decreased [19]. Using telemonitoring to control asthma has also been reported to be effective. However, a higher level of outpatient care was received compared with national averages [20]; therefore, we cannot rule out the possibility that this may have had an impact on compliance with continued application use.

Based on the questionnaire administered before and after the study, 83% of the participants in the ORT and ITT groups who used smart toothbrushes responded that their brushing abilities improved. Among the 2 groups using smart toothbrushes, the SHS and QHI improved more in the ITT group, whereas satisfaction with the smart toothbrush was higher in the ORT group. This might be due to Oral-B's fancy hardware and application appearance and easy-to-use charging method compared with the ITT.

In the 2000s, an interactive toothbrush equipped with a monitoring function using toothbrushing and grip axis recognition was introduced [21]. With the advancement in modern technology, it has become possible to provide instructional brushing videos on smartphones and app-based brushing monitoring using real-time motion recognition via Bluetooth [22]. In addition, messages and chat apps are known to help improve brushing, and recently released smart toothbrushes are equipped with various functions, such as messages and motion recognition. An interactive toothbrush with a smartphone app has the advantage of recording toothbrushing data, enabling dental specialists to provide personalized feedback and improve habits through toothbrushing

XSL•FO
RenderX

notifications [23,24]. In particular, these findings suggest that children and adolescents who use an interactive toothbrush will benefit from plaque removal and improved gingival health [25-27]. We believe that our study is meaningful in that we have suggested an optimal oral hygiene management method for patients, by comparing clinical efficacy not only between interactive and manual toothbrushes but also between 2 different smart toothbrushes.

The medical paradigm has recently changed to include quick information use and interactive communication using smartphones, which are gradually being used for telemedicine, remote monitoring, and health intervention provision [28-30]. In dentistry, apps to improve oral hygiene are used in various ways, and many studies have verified their effectiveness [31,32]. These innovative smartphone-based mobile apps are also being used as digital therapeutics. Digital therapeutics and software medical devices that provide evidence-based therapeutic interventions to prevent, manage, and treat medical disorders or diseases have been launched in various countries [33]. Moreover, the results of this study showed that smart toothbrushing is not limited to hardware only. An interactive app that encourages the correction of toothbrushing habits has the potential to be used as a digital treatment. In addition, although the duration of and scores for toothbrushing temporarily improved immediately after recall in this study, it was confirmed that interest in brushing had decreased at the 3-month and 6-month recalls, which was probably a long recall period. This suggests that, when using a smart toothbrush, the recall interval with a dental professional should not be too long to promote effective teledentistry treatments, such as a digital therapeutic, and that patient compliance with the smart toothbrush is important.

Strengths and Limitations

Strengths

This study is one of few to comprehensively compare an ITT and ORT with an MT, evaluating their effectiveness in clinical, microbiological, and user experience dimensions. A robust randomized controlled trial design with clearly defined interventions and outcomes ensured the reliability of the findings.

Limitations

The limitations of this study are as follows. First, we restricted the use of auxiliary oral hygiene devices, such as dental floss and interdental brushes, during the study period. Although the use of auxiliary oral hygiene devices was restricted to compare the efficacy of the smart toothbrush itself, the use of auxiliary oral hygiene devices plays an important role in oral hygiene management in interdental areas [34]. Since auxiliary oral hygiene devices are highly recommended in clinical practice, it is necessary to evaluate plaque removal and gingival health improvement when using auxiliary oral hygiene devices together with a smart toothbrush. Second, the nutrition practices of the participants were not recorded. Nutrition practices could affect the oral environment in addition to brushing, but this was not considered in the result analysis. Third, right-handedness and left-handedness were not considered. Since the app showed a video guide on how to brush based on right-handedness, it could have been confusing for left-handed participants. Finally, participants were recruited from specific higher education institutions, resulting in a younger demographic. Additionally, as participants responded to a recruitment posting, they may have been more motivated or interested in oral health than the general population, potentially limiting the generalizability of the findings.

Conclusions

The ITT group had significant improvements on the SHS and QHI, demonstrating that telemonitoring toothbrushes enable proper oral hygiene management compared with manual and oscillating-rotating toothbrushes. This highlights the importance of expert feedback through the transmission of users' toothbrushing data. However, it was confirmed that interest in toothbrushing declined at the 3-month and 6-month recalls, which were long recall periods. In the future, additional research will be needed on the appropriate feedback cycle and compliance with the app by participants.

Acknowledgments

This research was supported by a grant from the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HI20C1055).

All authors concur that neither ChatGPT nor any generative AI was used during writing the manuscript.

Data Availability

Data that support the findings of this study are available from the corresponding authors upon request and following institutional review board rules and privacy regulations.

Authors' Contributions

JK, YC, YS, and WP jointly designed and conducted the research. JK and YC contributed to drafting the manuscript, creating the figures, data analysis, and data interpretation. WP reviewed the final manuscript. All authors read and approved the final manuscript.

Abstract

Background: With the climbing incidence of type 2 diabetes, the health care system is under pressure to manage patients with this condition properly. Particularly, pharmacological therapy constitutes the most fundamental means of controlling blood glucose levels and preventing the progression of complications. However, its effectiveness is often hindered by factors such as treatment complexity, polypharmacy, and poor patient adherence. As new technologies, artificial intelligence and digital technologies are covering all aspects of the medical and health care field, but their application and evaluation in the domain of diabetes research remain limited.

Objective: This study aims to develop and establish a stand-alone diabetes management service system designed to enhance self-management support for patients, as well as to assess its performance with experienced health care professionals.

Methods: Diabetes Universal Medication Schedule (DUMS) system is grounded in official medicine instructions and evidence-based data to establish medication constraints and drug-drug interaction profiles. Individualized medication schedules and self-management programs were generated based on patient-specific conditions and needs, using an app framework to build patient-side contact pathways. The system's ability to provide medication guidance and health management was assessed by senior health care professionals using a 5-point Likert scale across 3 groups: outputs generated by the system (DUMS group), outputs refined by pharmacists (intervention group), and outputs generated by ChatGPT-4 (GPT-4 group).

Results: We constructed a cloud-based drug information management system loaded with 475 diabetes treatment–related medications; 684 medication constraints; and 12,351 drug-drug interactions and theoretical supports. The generated personalized medication plan and self-management program included recommended dosing times, disease education, dietary considerations, and lifestyle recommendations to help patients with diabetes achieve correct medication use and active disease management. Reliability analysis demonstrated that the DUMS group outperformed the GPT-4 group in medication schedule accuracy and safety, as well as comprehensiveness and richness of the self-management program (P<.001). The intervention group outperformed the DUMS and GPT-4 groups on all indicator scores.

XSL•FO
RenderX

Conclusions: DUMS's treatment monitoring service can provide reliable self-management support for patients with diabetes. ChatGPT-4, powered by artificial intelligence, can act as a collaborative assistant to health care professionals in clinical contexts, although its performance still requires further training and optimization.

KEYWORDS

pharmaceutical services; diabetes; self-management; intelligent medication scheduling system; drug database; GPT-4

Introduction

Chronic diseases are prevalent among the older adult population [1]. Diabetes, a common chronic disease, imposes a significant self-management burden on individuals and their families. Individuals with type 2 diabetes are increasingly being treated with multiple-medication regimens, including oral medications and/or exogenous insulin. Long-term medication and lifestyle changes are necessary for the successful management of both type 1 and type 2 diabetes [2]. However, the low success rate of diabetes self-management reflects some of the burdensome drug regimens and side effects [3]. A study pointed out that approximately 43.4% of patients with diabetes in low- and middle-income countries fail to adhere to their prescribed treatments, resulting in adverse health outcomes [4,5]. National survey data from the United States report basic knowledge gaps for many adults with diabetes, wherein only less than 50% are aware of their glycemic control levels. Guidelines emphasize that all patients should receive diabetes self-management education and support (DSMES), including regular medication taking, self-monitoring their blood glucose, changes in diet and physical exercise, foot self-care, and routine check-ups [2,6,7].

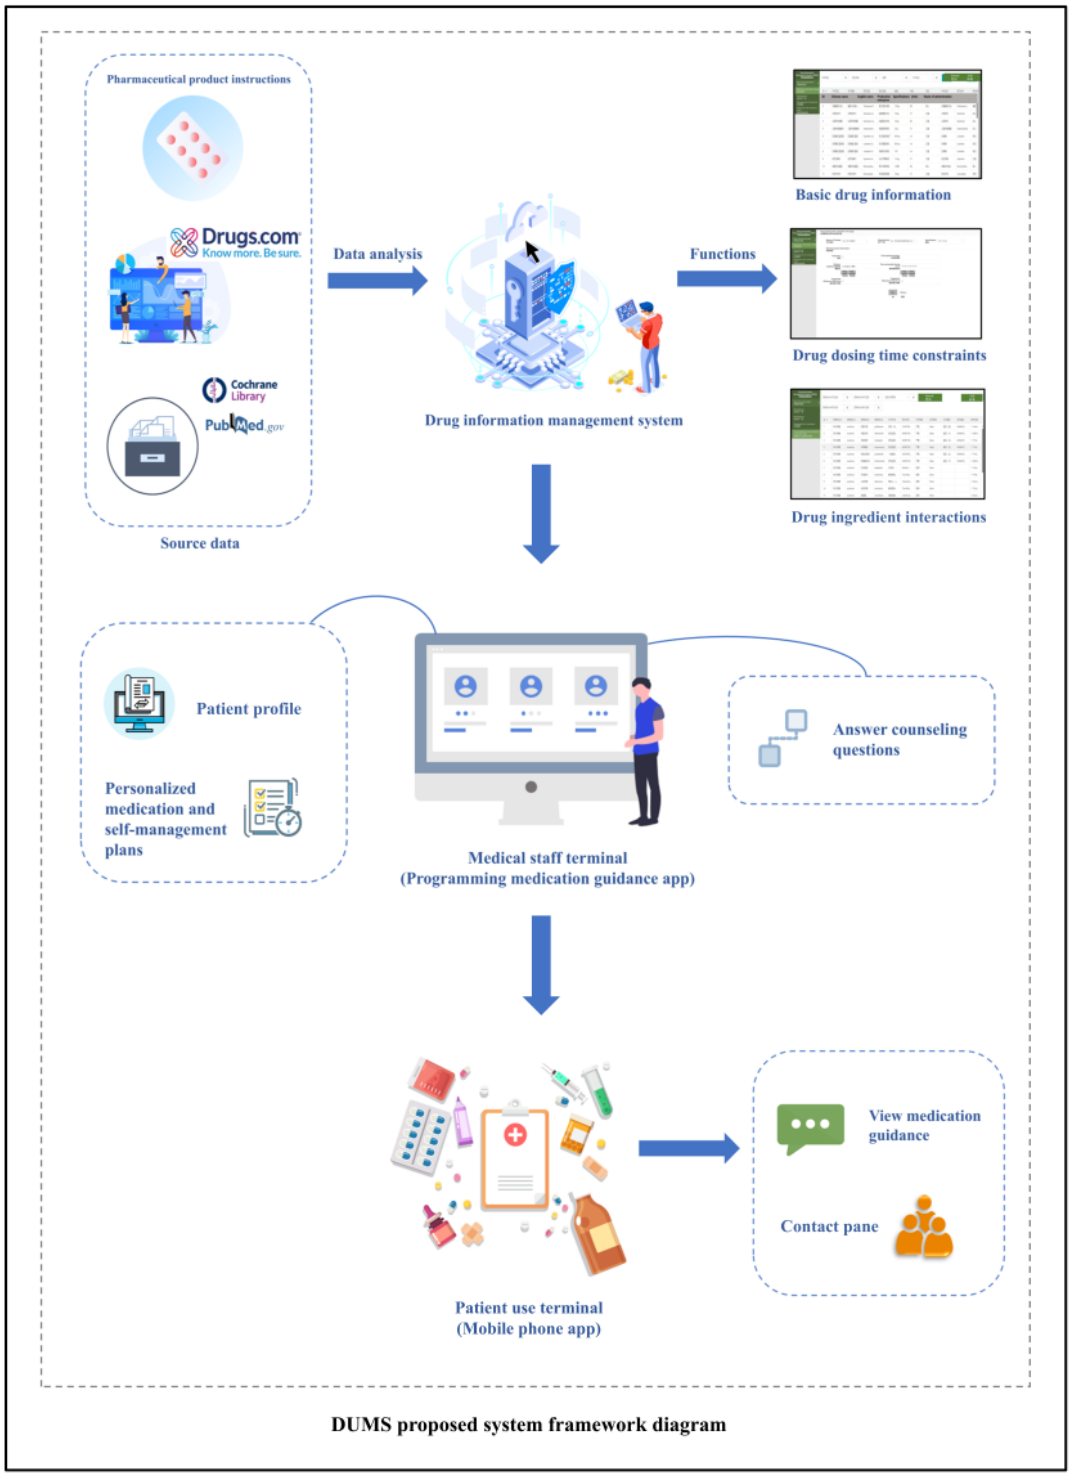
Nowadays, many apps and smart devices are being developed to enable patients to take their medications correctly and on time [8-13]. Some types of medicine boxes have also been proposed, but due to the complexity of filling, large volume, and lack of portability, most are not suitable for older adults [8,11,14]. In addition, producing the medicine box incurs certain costs, and many devices lack personalized medication guidance. Gupta et al [15] integrated drug names and doctor-prescribed schedules into a hardware device to provide reminders, but it lacked a friendly interface for interaction with health care professionals. Similarly, Wachira et al [16] designed and developed a guideline-encoding and execution engine using the JSON format and an optimization algorithm for medication plans through computer-aided output, yet their approach did not account for potential drug-drug interactions (DDIs) or real-world clinical data validation. In a report on the treatment plans and health status of individuals with diabetes, possible interactions were identified in 413 cases, and 53.1%, 7.8%, and 7.2% of the participants presented with moderate, minor, and serious risk of DDIs, respectively. Older adult patients are the primary users of multiple medications and consequently are more susceptible to inappropriate use, polypharmacy, and DDIs [17].

It is worth noting that generative artificial intelligence (AI)—based large language models (LLMs) have demonstrated significant potential innovation in health care in recent years. One such advanced model is ChatGPT [18], developed by OpenAI, which is currently among the largest publicly available language models [19]. ChatGPT-4 excels in a variety of medical evaluation benchmarks such as the United States Medical Licensing Examination (USMLE) [20,21] owing to its strong logical self-consistency and data analysis capabilities [22]. These LLMs leverage chat-based interfaces to respond to complex queries and solve problems [23]. Incorporating AI into the health care systems has the potential to significantly reduce task completion times and optimize workflows, thereby improving overall industry efficiency. As the availability and accessibility of these models increase, understanding their potential and limitations in real-world applications is essential. Song et al [24] evaluated ChatGPT-4' s ability to provide health education to patients with urolithiasis across two clinical scenarios involving 21 questions. While the model had high accuracy, its responses lacked contextual relevance in some cases. However, the performance of generative AI in DSMES remains an area that requires further exploration and evaluation.

The study aims to develop a medication reminder system tailored for older patients with diabetes. Additionally, to explore the real-world application of this system, we compared its capabilities in providing patient medication plans and self-management programs with those of the latest publicly available version of ChatGPT. It provides reference for the auxiliary decision-making function and the ability to empower the pharmaceutical field of generative AI in medicine.

Methods

Infrastructure Work



Pharmaceutical Constraint Management

Building upon the findings from our team's earlier work [25], we developed the Diabetes Universal Medication Schedule (DUMS) system as a more comprehensive solution for diabetes management. The system was built using the Python web framework, Flask, and the Flutter framework, written in Dart and Visual Studio Code. Data management and storage were implemented using a MySQL database and a Redis cache database.

Medication data were sourced from official medicine instructions and open-source medical professional websites, including information on ingredients, specifications, dosages, indications, and others. These data formed the foundational feature modules of the system. Dietary effects, interaction data, and physiologically based pharmacokinetic analysis were performed to establish pharmacological constraint information (Figure 1).

XSL•FO
RenderX

Figure 1. The architectural diagram and functional explanation of the Diabetes Universal Medication Schedule (DUMS) system.

Interaction information was organized by drug active ingredient. Key data were extracted from official medicine description; the Drugs.com website; and scientific databases such as PubMed, Web of Science, and the Cochrane Library. A combination of subject-specific search terms (individual drug ingredients) and free-text queries was used to identify relevant studies on drug-dose relationships. Source data, including ingredient-ingredient expression of action, interaction severity, and treatment recommendations, were reviewed by 3 independent 5-member panels composing of physicians and pharmacists. The panels collaboratively assessed the data, ultimately confirming that the credibility of the data source and the logic of the interpretation.

Self-Management Program

Self-management is a dynamic process involving the identification of disease needs, activation of available resources, and adaptation to living with a chronic condition. Guidance and

XSL•FO
RenderX

resolution from health care providers contribute to effective self-management. In addition to the regulating diet and exercise, a comprehensive management plan is developed based on the patient's medication history, allergy history, adverse drug reaction history, and treatment adherence. Unstructured information is usually provided temporarily by health care professionals.

Reception and Interaction

The patient interface was built using the WeChat app framework featuring a responsive data binding system that synchronizes data with the user interface. This framework includes a view layer description language, a style language, and a JavaScript logic layer programming language. A mobile phone number serves as the user log-in ID to locate the medication data of the target patient.

Dependability Tests

To evaluate the DUMS system's real-world application performance, the prescription details of older patients with diabetes were extracted. After inputting the prescription details, the DUMS system extracts the established drug characteristics and constraints from the cloud-based drug database and does not adjust the output results (referred to as the "DUMS group"). Pharmacists then refined these preliminary results to create active output schemes that are better suited to clinical practice (hereinafter referred to as the "intervention group"). For comparison, the same prescription details were entered into ChatGPT-4, prompting it to generate medication schedules and self-management programs based on the drug label and relevant literature guidelines, where appropriate (hereafter referred to as the "GPT-4 group"; refer to Table S1 in Multimedia Appendix 1 for details).

Health care experts with professional titles at the associate senior level or above were invited to participate in the evaluation. They rated the results from the DUMS, intervention, and GPT-4 groups using a 5-point Likert scale following a horizontal comparison approach. Table 1 outlines the assessment indicators and their corresponding scoring criteria.

Table 1. Evaluation indicators and definitions.

Classification and indicators	Definitions
Medication schedule	
Accuracy	Ensures that the use of medications aligns with mealtimes, drug-drug interactions, pharmacological timing, and daily routines
Safety	When scheduling medication times, fully consider potential drug-drug interactions
Adherence	Takes into account the convenience, rationality, and feasibility of medication
Usefulness	It can effectively reduce the workload of health care workers and improve work efficiency
Self-management program	
Accuracy	The content is accurate and error-free
Comprehensiveness	Provides all necessary information for patients regarding medication, including usage precautions, identification and prevention of adverse reactions, and dietary therapy
Richness	Provides information resources that exceed expectations
Redundancy	Evaluates whether the content contains excessive, repetitive, or useless information; a score of 5 can be given if there is no excess or useless content
Usefulness	Effectively reduces the burden on health care workers in education and public awareness efforts

Statistical Analysis

SPSS (version 27.0; IBM Corp) was used to statistically analyze the data. Measurement information was expressed as mean (SD). Independent-sample ANOVA was used, followed by the least significant difference test for multiple comparison. The expert opinion harmonization coefficient (w) was calculated using Kendall W, with differences assessed through the chi-square (χ^2) test. A $P<.05$ difference was considered statistically significant. Furthermore, the Bland-Altman method was used to generate scatter plots for pairwise comparisons of the 3 methods and to assess the degree of consistency.

Ethical Considerations

This study was reviewed and approved by the Hospital Ethics Committee of Xiangya Hospital, Central South University (approval 2023030556). This study exclusively used prescribing information for test evaluation. There was no direct interaction with patients, in line with the principles of ethical conduct in the study. All data were deidentified to protect privacy and ensure confidentiality, with access restricted to authorized members of the research team.

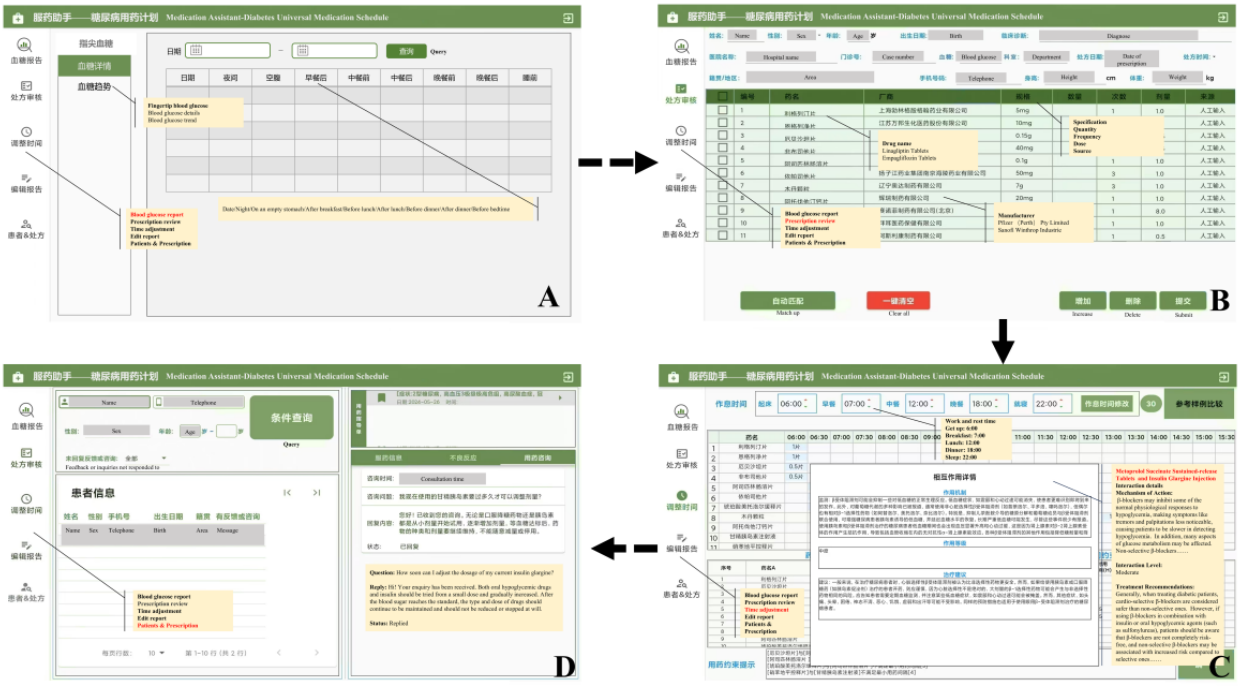
Results

Construction of an Intelligent Medication Scheduling System

Enhancement of the DUMS System's Cloud Database

From the endocrinology medication catalog, 475 commonly used medicines for patients with diabetes, including 146 imported medicines, were loaded. Each medicine's information was summarized and organized into concise, comprehensive, and user-friendly entries based on the official instructions. Further, a total of 684 drug constraints were established for

XSL•FO
RenderX



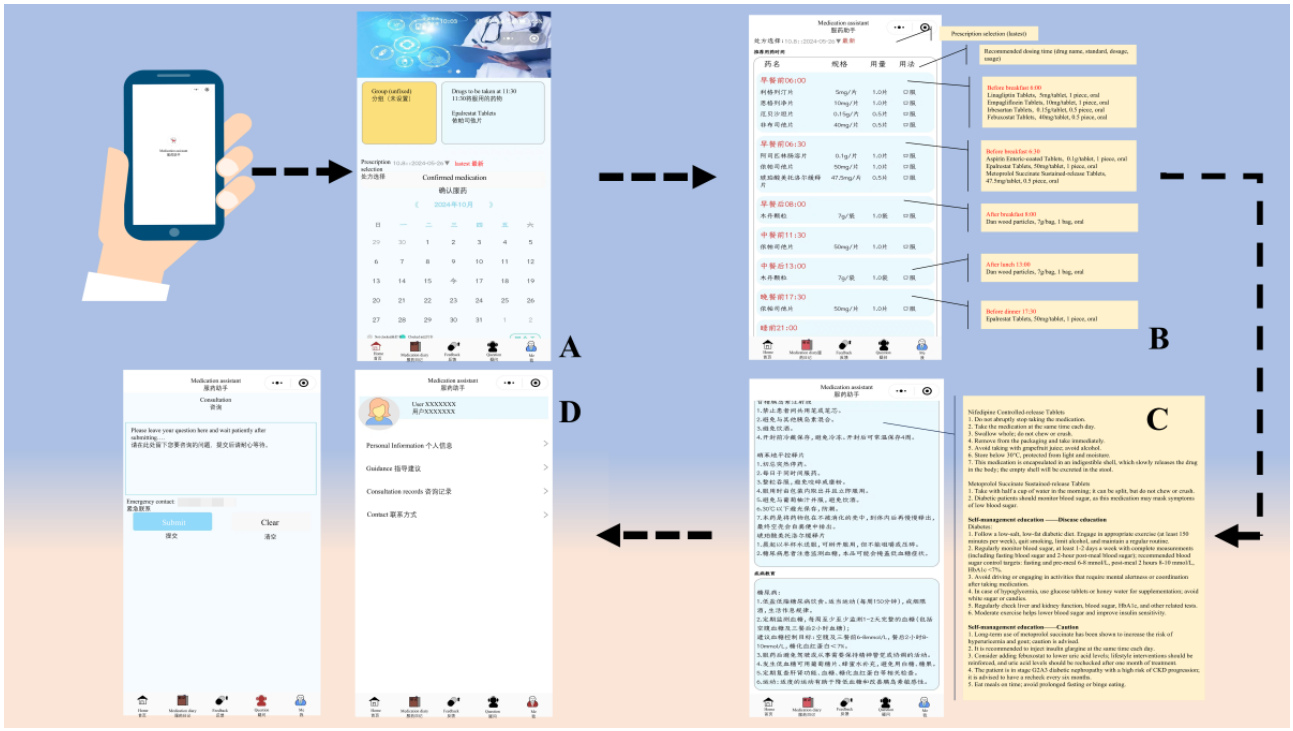
drugs, according to clinical recommendations related to chronopharmacology and diet-drug interactions.

After eliminating duplicate data, 8921 drug components were identified, and 12,351 drug interaction records were generated. Each interaction record included triple theoretical support: mechanism of action, interaction severity, and treatment recommendations. DDIs were classified into four categories based on severity: mild (n=6564, 53.15%), moderate (n=3392, 27.46%), severe (n=1876, 15.19%), and contraindicated (n=519, 4.2%). This classification helps medical professionals make quick and informed clinical decisions (refer to Table S2 in Multimedia Appendix 1 for details).

Individualized Medication Schedules and Self-Management Programs

To facilitate timely management and personalized patient care, each patient's profile was independently loaded with essential clinical information such as blood glucose status, medical diagnoses, and basic prescription. Default mealtimes were set at 7 AM, 12 PM, and 6 PM, with bedtime set at 10 PM, although health care providers can adjust these based on patient-specific needs and system-generated suggestions. Based on in-depth analysis of patients, providing more precise drug treatment plans and enhancing patient adherence can help improve long-term disease outcomes (Figure 2).

Figure 2. Diabetes Universal Medication Schedule (DUMS) interface: (A) blood glucose report; (B) prescription review; (C) time adjustment; (D) patients and prescription.



Once the medication plan is arranged, patient can access detailed schedules given by the medical staff through the user terminal. For patients with diabetes, self-management programs cover exogenous insulin use (eg, insulin pens), awareness of drug side effects, dietary guidance, and prevention and control education.

In addition, a communication module enables patients to submit inquiries regarding their current treatment status. Health care workers actively responded, reducing the likelihood of acute events while enhancing patients with diabetes' understanding of and adherence to treatment plans (Figure 3).

XSL•FO
RenderX

Figure 3. User terminal (medication assistant app): (A) time hint; (B) medication schedule; (C) self-management program; (D) consultation and settings.

System Testing and Evaluation

A total of 12 specialists, comprising 8 general clinicians and 4 pharmacists, participated in this study, with a mean clinical experience of 3.08 (SD 0.99) years. The evaluation involved prescriptions for 20 older patients with diabetes, through 60 medication plans presented in 3 different output modes. Among the patients, more than half (n=14, 70%) were female, with an average medication frequency of 12.65 (SD 4.10) doses per day. The basic information about the patient cases is shown in Table 2.

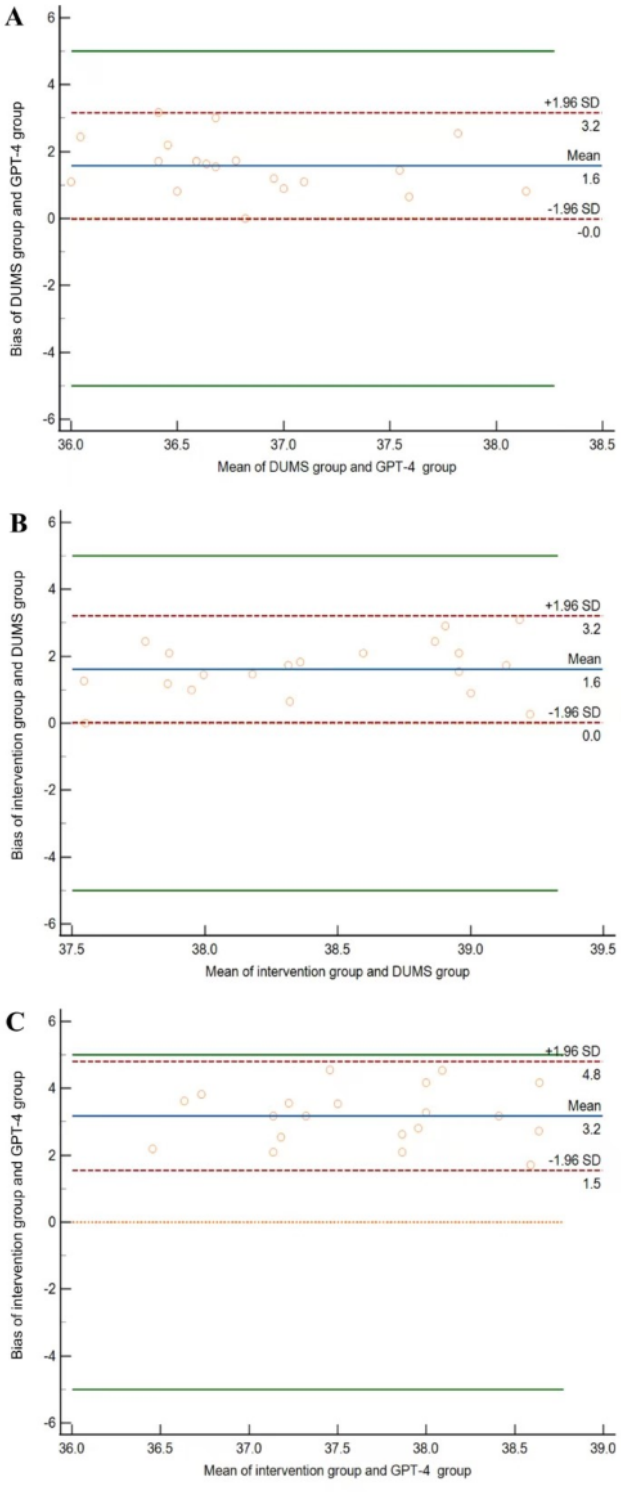


Table 2. Patient and prescription information for the system test.

Characteristics	Value (N=20)
Sex, n (%)	
Male	6 (30)
Female	14 (70)
Age (years), mean (SD)	69.65 (4.17)
Number of medications, n (%)	
<9	15 (75)
≥9	5 (25)
Number of chronic disease comorbidities, mean (SD)	4.05 (2.04)
Medication frequency (doses per day), mean (SD)	12.65 (4.10)

The Kendall W coordination coefficient was used to calculate the agreement between raters (Kendall W for overall mark=0.21; *P*<.001), suggesting that the different scoring systems are reliable in producing reproducible results. Then, we supplemented the comparison between the two groups using the Bland-Altman method (Figure 4), revealing a mean bias between the DUMS group and the GPT-4 group as 1.57. The 95% CI for the lower limit of agreement (LoA) was –0.66 to 0.65, and the 95% CI of the upper LoA was 2.50-3.81. The mean bias between the intervention group and the DUMS group was 1.60, with 95% CI –0.65 to 0.67 for the lower LoA and 95% CI 2.54-3.86 for the upper LoA. No points of difference exceeded 95% LoAs. Comparing the intervention group to the GPT-4 group, the mean bias was 3.18. Most of the data points fell within the LoA, indicating no significant systematic bias or trend. Although some bias existed, the overall consistency was good.

XSL•FO
RenderX

Figure 4. Bland-Altman plot for agreement analysis among the DUMS, intervention, and GPT-4 groups: (A) DUMS group vs GPT-4 group; (B) intervention group vs DUMS group; (C) intervention group vs GPT-4 group. Limits of agreement are shown as dashed, purplish red lines; bias is shown as solid blue lines; equivalence (difference=0) is shown as orange dashed lines; and maximum allowed difference between the groups is shown as solid green lines. DUMS: Diabetes Universal Medication Schedule.

The evaluation results revealed that the DUMS group achieved significantly higher accuracy and safety scores than the GPT-4 group (P<.001), with full consideration of multiple aspects of DDI, pharmacokinetics, and dietary restrictions. However, in order to reduce the occurrence of adverse events, the medication frequency was increased, which may reduce adherence to the medication plan. Regarding medication schedule usefulness, the DUMS group scored slightly higher than the GPT-4 group, and both DUMS and ChatGPT-4 were able to provide valuable information for pharmacists to assist patients in taking effective medication, but the difference was not statistically significant (P=.23). The self-management programs provided by DUMS not only deliver easy-to-understand instructions on medications but also offer multifaceted guidance on disease education,

XSL•FO
RenderX

lifestyle, and dietary management, with positive feedback on accuracy, comprehensiveness, and richness (*P*<.001).

The total evaluation scores showed that the mean values of the DUMS group, intervention group, and GPT-4 group were 37.96 (SD 0.56), 39.52 (SD 0.80), and 36.35 (SD 0.89), respectively. The "adjusted" DUMS results (ie, the intervention group) were better than those of the other groups, with statistically significant differences (*P*<.001), as shown in Table 3.

Table 3. Results of the system testing and evaluation.

Classification and indicators	DUMS[a] group, mean (SD)	Intervention group, mean (SD)	GPT-4 group, mean (SD)	*P* value (DUMS vs intervention)	*P* value (DUMS vs GPT-4)	*P* value (intervention vs GPT-4)
Medication schedule						
Accuracy	4.43 (0.16)	4.49 (0.19)	3.84 (0.25)	.35	<.001	<.001
Safety	4.44 (0.11)	4.44 (0.16)	3.91 (0.21)	.94	<.001	<.001
Adherence	3.81 (0.34)	4.24 (0.24)	4.02 (0.25)	<.001	.03	.02
Usefulness	4.11 (0.18)	4.30 (0.16)	4.04 (0.17)	.002	.23	<.001
Self-management program						
Accuracy	4.56 (0.09)	4.64 (0.17)	4.34 (0.21)	.16	<.001	<.001
Comprehensiveness	4.08 (0.21)	4.35 (0.15)	3.86 (0.18)	.04	<.001	<.001
Richness	3.95 (0.26)	4.30 (0.24)	3.73 (0.19)	.03	<.001	<.001
Redundancy	4.34 (0.17)	4.45 (0.19)	4.42 (0.19)	.07	.55	.61
Usefulness	4.24 (0.12)	4.31 (0.13)	4.18 (0.13)	.16	.54	.04
Total	37.96 (0.56)	39.52 (0.80)	36.35 (0.89)	<.001	<.001	<.001

[a]DUMS: Diabetes Universal Medication Schedule.

Discussion

Principal Findings

Faced with the challenge of ensuring that patients with diabetes take the correct medication at the right time, the emergence of telemedicine and AI has provided researchers with new directions. In this study, we established constraint management of essential pharmaceutical products by summarizing the relationship between drugs and evidence-based arguments and created an individualized medication reminder platform.

Our system extends beyond traditional auxiliary models by offering a visually interactive personalized medication plan and a user-friendly interface. Through secondary data analysis, we establish a robust medicine constraint management and DDI risk assessment framework to guide health care providers in precision medication timing. A variety of complications in patients with diabetes often leads to complex medication management and puts patients at an increased risk of moderate to severe DDIs, which may threaten their lives or may deteriorate their quality of life [26,27]. To mitigate the above risks, a triple rationale for DDI is provided in our system, allowing health care providers to balance multiple drug demands with the possibility of harmful drug poisonings. Additionally, the system promotes DSMES by strengthening blood glucose management, ensuring patient take drugs correctly and on time, and developing exclusive planning [28].

ChatGPT is an evolving model in natural language processing, as Microsoft and OpenAI continue to develop it, and its potential applications in medical education have garnered a great deal of attention [29]. Previous studies indicate that ChatGPT-4 performs well in providing descriptive and objective content, often generating largely accurate information for a variety of medical queries [30-32]. In this study, to ensure consistency, the commands entered into ChatGPT-4 were manipulated by a single researcher, who entered the following instruction:

> *Patients (basic situation) and the prescription of the following drugs: (including drug name, dosage, frequency of use). It is assumed that the patient gets up at 6:00 every day, takes three meals at 7:00, 12:00 and 18:00 respectively, and goes to bed at 22:00. Please make a specific medication schedule and self-management plan for the patient according to the medicine instructions and relevant guidelines, and taking into account the patient's medication compliance.*

However, the accuracy, comprehensiveness, and richness of the health education component of self-management provided by ChatGPT-4 could not replace that in the DUMS group and the "experienced" intervention group. A conceivable explanation is that, within the medical field, examinations often prioritize testing theoretical knowledge, frequently deviating from genuine patient-focused clinical environments. Such deviations might be more pronounced for LLMs, which are well versed in rapidly integrating available information. Another notable limitation is ChatGPT-4's reliance on English-language training data, which affects its performance in other languages. The lack of culturally specific knowledge and the latest medical literature and data in other languages is a significant limitation of ChatGPT, which may lead to irrelevant or incorrect answers and conclusions [33,34]. Moreover, many scientific experts have pointed out that ChatGPT presents information redundantly and irrationally in most cases, offering repeated content and references, which

XSL•FO
RenderX

may not be of obvious practical utility [35,36]. Although the development of machine learning and AI methods represents a significant technological advancement, and the output of ChatGPT-4 has a certain level of practicality, achieving reliable performance in various data scenarios still requires proper training of the model algorithms to maximize efficiency.

Limitations

However, there are some limitations with the DUMS system. Its accuracy and usability rely heavily on the integrity of the drug information management database. Failure to update or expand the database promptly can result in suboptimal administration suggestions. Therefore, to continue expanding the number of drugs in the database and promptly improve the information resources, it is essential to develop a more efficient input mechanism for maintaining and managing the database, thus minimizing the risk of human errors or omissions. Additionally, comparing the performance of DUMS solely against that of ChatGPT-4 limits the generalizability of the findings to other intelligent systems or devices. Further validation is required to determine whether DUMS can perform consistently within its intended domain. Future iterations of DUMS will aim to enhance output quality by leveraging the imitative learning capabilities of LLMs, thereby improving the scientific and systematic nature of the output.

Conclusion

The DUMS system represents an innovative and cost-effective mobile health solution. Without making any changes to the existing health care system, health care institutions can deploy our proposed system to provide safer and more rational medication services for patients with diabetes. The drug information and constraint management database, combined with the user-friendly interface developed in this study, supports health care professionals in creating accurate, personalized medication schedules and self-management programs. In addition to serving as a reminder, the inquiry component allows older individuals living independently to receive timely solutions when treatment issues arise. However, it remains unclear whether mobile health can help health care workers improve patient health literacy. Significant further research will be required from managers and end users to ensure the safety, reliability, and effectiveness of this technology.

Acknowledgments

We sincerely thank the 12 medical practitioners from Xiangya Hospital of Central South University who participated in this evaluation activity at our invitation. No generative artificial intelligence was used in this manuscript.

Data Availability

The datasets analyzed during this study are not publicly available to protect the privacy of individuals who participated in the study. Data are available from the corresponding author upon reasonable request.

Abstract

Background: Up to 75% of patients with Parkinson disease (PD) experience voice and speech impairments, such as breathy phonation and low speech volume, which worsen over time and negatively impact the quality of life. However, given their increasingly limited mobility, face-to-face speech therapy is often inaccessible. Mobile health (mHealth) apps offer accessible and cost-effective alternatives; yet, their application in PD-specific, self-delivered voice therapy remains underexplored.

Objective: This study aimed to evaluate the feasibility, adherence, and satisfaction of a self-delivered smartphone app for voice therapy in patients with PD, designed to minimize speech-language pathologist involvement while promoting patient independence. In addition, it seeks to assess the preliminary therapeutic effectiveness of the app in addressing voice and speech problems in this population.

Methods: A single-arm, rater-blinded, and pretest and posttest study was conducted between September to November 2023. Patients with PD with voice and speech problems who have no problem with using Android (Google) smartphones were recruited. Participants downloaded the researcher-developed mHealth app on their smartphone and participated in a patient-tailored 5-week home-based speech training program. Each session included 5 stages: breathing, oral motor exercises, loudness, prosody, and functional speaking. The training program consisted of 20 sessions, with participants completing 1 session per day, 4 days per week. Each session lasted approximately 20-30 minutes. Adherence was monitored through app logs, satisfaction was assessed through a phone survey, and therapeutic effectiveness was evaluated using acoustic analysis and auditory-perceptual assessments.

Results: Out of 30 patients were initially recruited, but 2 of them withdrew. Out of 25 participants completed all the training sessions while 3 dropped out. The adherence was above 90% in 20 participants (80%, 20/25), 70% to 90% in 4 (16%, 4/25), and below 70% in 4 (16%, 4/25). Satisfaction was 75% (18/24) among the 24 people who participated in the survey. Significant improvements were observed in all acoustic measures: the maximum phonation time increased from 11.15 (SD 5.38) seconds to 14.01 (SD 5.64) seconds (P=.003), and vocal intensity increased from 71.59 (SD 4.39) dB to 73.81 (SD 3.48) dB (P<.001) across both sustained phonation and reading tasks. Voice quality scores on the GRBAS (grade, roughness, breathiness, asthenia, and strain) scale improved significantly (all components P<.001). Furthermore, 58.3% (14/24) of participants reported subjective improvements in their voice.

Conclusions: This study demonstrates that home-based, self-training speech therapy delivered through a mHealth app is a feasible solution for patients with PD, suggesting that mHealth apps can serve as a convenient and effective alternative to face-to-face therapy by enhancing accessibility and empowering patients to actively manage their condition.

Introduction

During the progression of patients with Parkinson disease (PD), around 75% of patients experience difficulties with their voice and speech functions at some stage [1]. The main characteristics of speech include breathy phonation, hoarseness, low speech volume, inaccurate articulation, and monotonous speech. These symptoms worsen over time. Consequently, these symptoms can significantly impact the quality of life, affecting physical, emotional, functional, and social well-being [2]. They also hinder communication, daily activities, and social participation. Therefore, rehabilitation is essential for individuals with PD, with speech therapy being particularly important as it helps patients maintain and improve their communication abilities in everyday life [3]. Traditionally, speech therapy involves in-person sessions with a speech-language pathologist (SLP). However, the global COVID-19 pandemic disrupted traditional service delivery models, leading to increased interest in remote rehabilitation and mobile health care technologies as viable alternatives. In addition, the rising demand for rehabilitation due to an aging population, coupled with limited health care resources, further highlights the need to adopt and expand information and communication technology [4].

A review of previous studies has confirmed the feasibility of remote speech-language therapy (SLT) across various disability groups. According to Weidner and Lowman [5], remote SLT is primarily conducted in real-time using commercial software such as Skype (Skype Technologies) and Zoom (Zoom Video Communications), or through custom-developed software installed on computers or tablets. While most remote SLT initiatives have focused on patients with chronic aphasia, some have targeted individuals with PD. Many existing studies have concentrated on delivering the Lee Silverman Voice Treatment LOUD or its extended versions, which are proven to be effective for addressing speech and voice issues in patients with PD, through remote platforms [6-9]. Research on remote SLT for patients with PD has shown that it is just as effective as in-person therapy, with no significant reduction in efficacy [6-10]. Meanwhile, mobile health (mHealth) apps, developed to support users in managing their health independently, have advanced considerably. According to the World Health Organization, mHealth is a broad term encompassing activities that involve the use of smartphones, sensors, personal digital assistants, wireless monitoring devices, or other wireless technologies to deliver public health and health care services [11]. These technologies hold promises for promoting autonomous patient participation in treatment, thus maintaining continuity of care while offering benefits in terms of accessibility and cost [12,13].

To date, most mHealth have been designed and studied with a focus on health outcomes such as nutrition and physical activity, mental health management, and diabetes care, primarily targeting populations with chronic conditions, mental health issues, or obesity [14]. Recently, some evidence has emerged supporting the use of mHealth for home-based SLT across various patient groups with speech and language disorders including children with articulation disorders, poststroke aphasia, presbyphonia, and voice disorders associated with PD [15-19].

mHealth apps designed for patients with PD have mostly focused on symptom monitoring and providing information or education [20]. Research in this area has mainly addressed specific aspects of care, such as symptom management, medication adherence, physical activity, and exercise interventions [20-22].

However, very few studies have explored the use of mHealth apps for delivering speech therapy to patients with PD. Maas et al [23] proposed a study protocol for a single-blind randomized controlled trial using the Voice Trainer app and an online platform that provides real-time feedback, enabling patients to practice at home alongside remote therapy. The study aimed to evaluate the effectiveness of personalized, home-based speech therapy on quality of life, speech intelligibility, and social participation in individuals with PD who have reduced speech intelligibility. However, no follow-up research has been published to date. Lo et al [18] developed a speech rehabilitation app specifically for patients with PD and validated its usability with 2 participants, reporting improvements in articulation and volume after short-term use. Horin et al [19] investigated the utility of a mHealth app designed for the comprehensive treatment of PD symptoms, including gait, dexterity, and speech, and concluded that the application alone was insufficient to effectively address gait, speech, or dexterity symptoms in PD.

While the use of mHealth apps for speech therapy in patients with PD is still in its early stages, there is potential for significant advancement through ongoing research and technological development. mHealth offers great benefits in terms of accessibility and cost, especially for patients with PD who gradually experience reduced mobility, as it allows them to access therapy from anywhere with a mobile device [24-26]. Furthermore, it provides patients with the opportunity to practice independently without time constraints, and it can automatically measure, collect, and store data, thereby reducing the workload for clinicians.

This study aims to evaluate the feasibility of using a smartphone app to provide self-delivered voice therapy for patients with PD with minimal involvement from SLPs. It also seeks to explore patient satisfaction with the app and its potential effectiveness as a therapeutic tool.

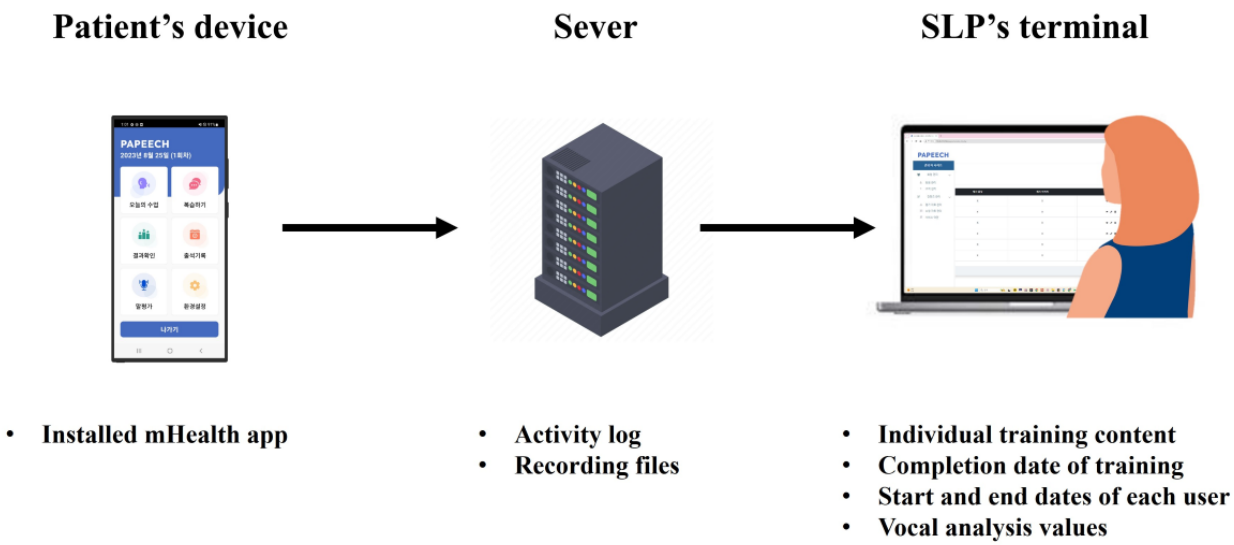
Methods

Participants and Recruitment Procedures

Participants were recruited from the Movement Disorders Clinic of the Department of Neurology at Seoul National University Hospital, Seoul, South Korea from September to November 2023. Recruitment was conducted through clinical referrals by neurologists during routine outpatient visits. When neurologists identified patients who presented with speech or voice problems, they referred them to the SLPs for further evaluation. The referrals were based on the neurologists' clinical judgment at the clinic. Once referred, SLPs independently conducted auditory-perceptual evaluations to confirm the presence of speech and voice issues. The inclusion criteria which were (1) patients with PD reporting voice problems and speech difficulties with these issues confirmed by both SLPs through auditory-perceptual evaluation; each SLP having over 5 years of clinical experience, independently verified the presence of voice problems in all patients; (2) Android smartphone users without visual or auditory difficulties in using apps; and (3) not having laryngeal dysfunctions caused by other diseases. Exclusion criteria which were (1) being illiterate, (2) having a recent (<6 months) history of speech therapy, (3) difficulty in operating a smartphone due to cognitive and motor dysfunction, and (4) having limited access to the internet at home.



Study Design

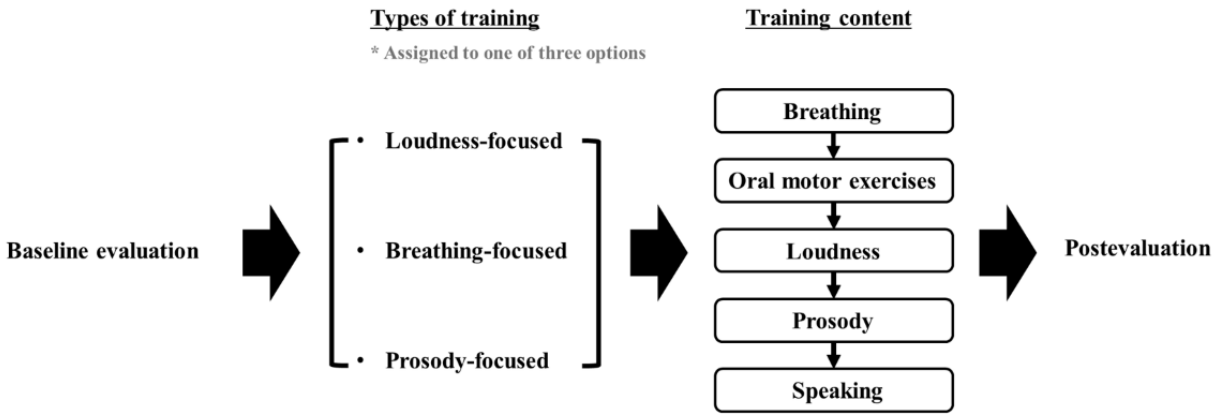
This study is a single-arm, rater-blinded, and pretest and posttest design to evaluate the feasibility and, satisfaction of an mHealth program among individuals with PD. The preliminary effectiveness of the app was also assessed.

mHealth App and Training Program

We developed an Android-based smartphone app for voice and speech training (Figure 1). The app consists of a patient's device (patient's own smartphone), a server, and a SLP's terminal (laptop or desktop computer). All the content for patient evaluation and training, which was developed by the SLPs, is stored on the server.

Figure 1. A simplified overview of the composition of the mobile health (mHealth) app used for voice and speech training in Parkinson disease patients. The app comprises 3 main components. SLP: speech-language pathologist.

Participants downloaded the mHealth app onto their smartphones at the hospital. Afterward, they were invited to complete a 5-week home-based training program following the registration and user approval process for participation. The SLPs ensured that the installed app was functioning correctly and educated the participants on how to use it. The server transmitted the content to the devices of approved participants. This content was designed with a user-friendly interface and experience. A sufficiently large font size was used to accommodate older users, and the size and spacing of the buttons were appropriately adjusted to consider motor symptoms such as hand tremors. In addition, if the participants have used a smartphone before, the design was made simple and intuitive enough for them to operate without difficulty. This is because the goal was for patients to use the app independently for evaluation and training during the study, without assistance from clinicians, including SLPs, or caregivers.



All speeches practiced in the session were recorded. The recorded files and the associated activity logs are all stored on the server. The SLP's terminal is designed for monitoring the entire process, allowing the SLP to check each participant's start and end dates of training, their individual training content, and the analysis of the recorded speeches within the training. SLPs did not interact with the patient or server in real time during evaluation or training.

Based on the results of the self-administered baseline evaluation (refer below), each participant was assigned to one of 3 different types of training: loudness-focused, breathing-focused, and prosody-focused training. Each training type is designed to include a variety of tasks that target the specific focused area more effectively. The training content comprised 5 stages: breathing, oral motor exercises, loudness, prosody, and speaking (Figure 2). The breathing stage addresses the energy source for speech. PD patients often experience weak or shallow breathing, which can reduce speech volume and stamina. Strengthening

XSL•FO
RenderX

respiratory muscles improves airflow, enabling clearer and more sustained speech [27]. Oral motor exercises target the strength and agility of oral muscles, which are often reduced in PD, leading to unclear speech and difficulty swallowing. Strengthening these muscles enhances articulation and supports swallowing function [28]. Loudness training focuses on hypophonia, or reduced speech volume, which is common in PD. Loudness exercises retrain patients to use stronger vocal effort, helping them communicate more effectively in daily conversations [29]. Prosody training helps address the monotone voice often seen in PD, which can make speech sound flat and less engaging. Prosody exercises enhance speech expressiveness, allowing patients to convey meaning more effectively [30].

Figure 2. Contents and structure of the 5-week speech training program for participants with Parkinson disease patients using the mHealth app.

	Examples of tasks in the training content
Breathing	Practice slow inhaling and exhaling
Oral motor exercises	Neck stretching, Gentle laryngeal massage, Smiling
Loudness	Producing a loud, sustained /a/ sound, Producing a loud, short /a/ sound
Prosody	Singing, Gliding /a/ phonation
Speaking	Reading functional phrases or short sentences commonly used in daily life

Finally, functional speaking practice supports patients in initiating and maintaining fluid conversations. This stage builds confidence, improves speech flow, and integrates the skills learned in breathing, loudness, and prosody exercises [31].

This 5-week home-based training program consists of a total of 20 sessions, each lasting approximately 20 minutes to 30 minutes. Participants were instructed to use the app at least 4 days a week, one session a day. To minimize attrition, SLPs monitored the participant's daily use of the app using the dashboard equipped in the SLPs' terminal. If necessary, SLPs called the patients to encourage training. The app also includes a pop-up alarm to remind users of each day's training.

Measuring Adherence, Satisfaction, and Effectiveness

To verify adherence, we created a webpage for SLPs to monitor the participants' completion of app training sessions in real-time. The overall adherence was calculated by dividing the number of training sessions completed by the total number of sessions prescribed [8]. The number of participants who withdrew from the study was also identified.

The Satisfaction survey was conducted by phone within a week of either completing or discontinuing the app's use. Their satisfaction levels were gauged using a 5-point Likert scale anchored by "very satisfied" (5) to "very dissatisfied" (1), aiming to derive the Customer Satisfaction (CSAT) score. The CSAT score is calculated by dividing the number of positive responses (those who are rated 4 or 5) by the total number of responses.

To assess the effectiveness, we conducted both acoustic analysis and auditory perceptual assessments at baseline and at the completion of app use. The tasks included sustained phonation of the vowel /a/, reading 3 short sentences, and reading a 28-word passage from a Korean standardized "Ga-eul" passage. All tasks were recorded using the built-in microphone of each participant's smartphone and were stored on the server. During the recording, participants were instructed to sit upright and remain still, maintaining a distance of approximately 30 cm between their mouths and the smartphone microphone.

The acoustic analysis was conducted using Praat (University of Amsterdam) software (version 6.4.04) embedded in the app. The analysis included the maximum phonation time of the vowel /a/ and the mean vocal intensity (including pauses) for each task, measured in sound pressure level decibel.

The auditory perceptual assessment was performed on all tasks using the GRBAS scale, which is widely used to assess the

XSL•FO
RenderX

severity of voice quality. It contains grade (G), which is the overall degree of hoarseness, roughness (R), breathiness (B), asthenia (A), and strain (S). Out of 2 experienced SLPs, each with over 10 years of clinical experience, conducted the ratings on a 4-point Likert scale from 0 (normal) to 3 (severe). The baseline and posttraining evaluation voice files pair were provided in random order in WAV (Waveform audio format) without any identifying information about the order. Furthermore, participants who completed all app usage were asked, during a phone survey, to self-report any changes in their overall voice quality after the training.

Statistical Analysis

Data were analyzed using SPSS (version 29.0; IBM Corp) for Windows. Frequency analysis was conducted to examine adherence, satisfaction, and self-reported voice quality changes. Paired sample *t* tests were conducted to determine if there were significant changes in the maximum phonation time during sustained phonation of the vowel /a/ before and after app usage, as well as to assess for significant changes in vocal intensity in all tasks. These tests were chosen to compare pre- and postintervention measures for the same participants. The normality of the data was tested using the Shapiro-Wilk test. The results indicated that intensity scores were normally distributed with a *P* value of *P*=.34. Based on this, we chose parametric tests for subsequent analysis. To analyze the reliability of the average agreement rate between evaluators for the auditory perceptual assessment of GRBAS scores, intraclass correlation coefficients (ICCs) were calculated.

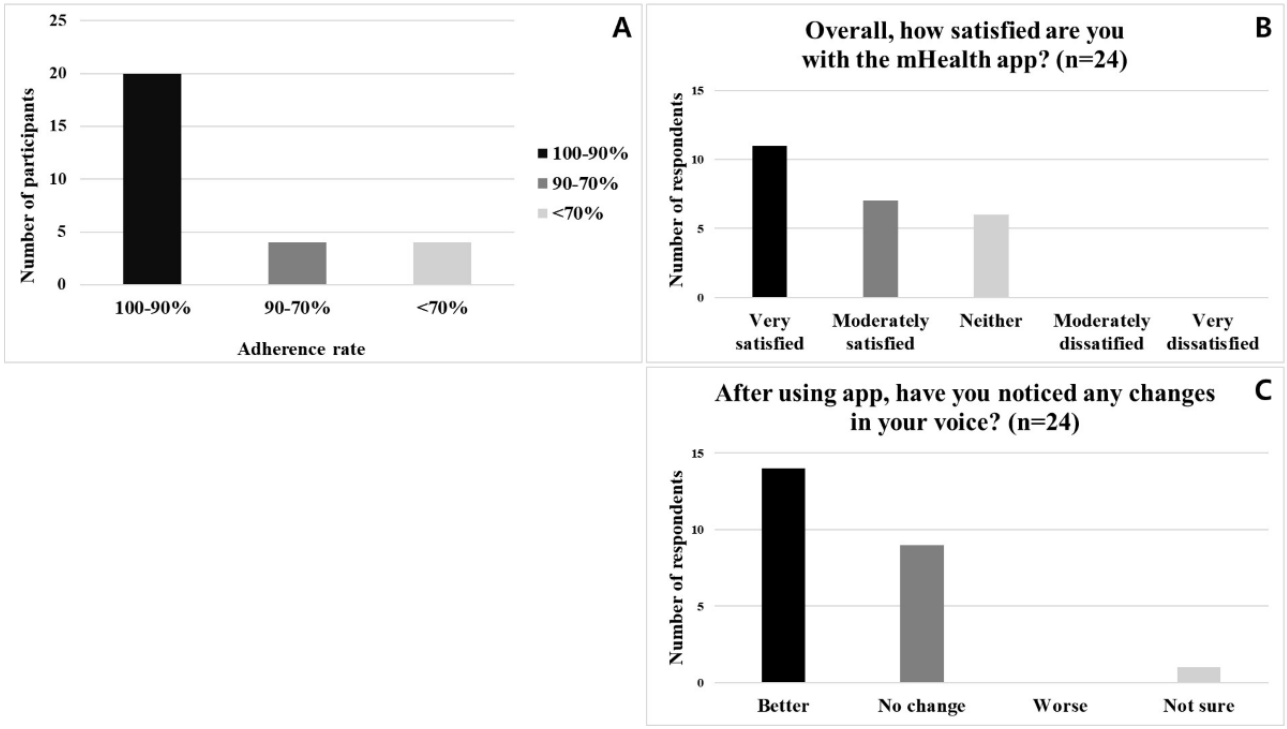
Ethical Considerations

This study was approved by the Seoul National University Hospital Ethics Committee (H-2308-040-1456 and H-2401-010-1499). The research adhered to the principles outlined in the Declaration of Helsinki, and all procedures were conducted in compliance with ethical standards for research involving human participants. All participants provided informed written consent before their participation. They were informed about the study's purpose, procedures, voluntary nature, and their right to withdraw at any time without consequences. The consent process ensured participants understood that their data would be used for research purposes and protected under the approved ethical guidelines. Data were securely stored on an encrypted server accessible only to authorized research personnel. Participants were not monetarily compensated for their participation.

Results

Participants' Characteristics and Adherence

Thirty patients with PD were initially recruited, but 2 withdrew due to health problems not related to PD. A total of 28 patients with PD participated in the study and used the app. Participant characteristics are summarized in Table 1. Details regarding participant recruitment are provided in Multimedia Appendix 1. Based on the results of baseline evaluation, 20 were assigned to the loudness-focused training program and the remaining 8 participated in the breathing-focused training program. None were assigned to the prosody-focused training program. Out of 25 participants (15 male, 10 female; mean age 68.04, SD 7.81 years; mean disease duration 7.32, SD 4.78 years; H and Y scale ranged from 1 to 4, mean 2.39, SD 0.88) completed all the training sessions while 3 dropped out. One participant could not be reached and the other 2 dropped out due to (1) problems with the internet connection and (2) being too busy, respectively. They completed only 12, 3, and 4 sessions respectively.



The adherence was above 90% of 20 participants, 70-90% in 4, and below 70% in 4 (Figure 3A).

Table 1. Demographic and clinical characteristics of the participants with Parkinson disease (N=28), recruited from the Movement Disorders Clinic, Seoul National University Hospital, Seoul, South Korea, between September and November 2023.

Subgroup	Value
Age (years), mean (SD; range)	67.5 (8.16; 51-81)
Sex, n (%)	
Male	17 (60.7)
Female	11 (39.3)
Disease duration (years), mean (SD; range)	7.54 (4.73; 1-19)
H and Y scale score (mean 2.39, SD 0.88, median 2, IQR 2–3), n (%)	
1	3 (10.7)
2	15 (53.6)
3	6 (21.4)
4	4 (14.3)
Type of training program, n (%)	
Loudness-focused	20 (71.4)
Breathing-focused	8 (28.6)
Prosody-focused	0 (0)

XSL•FO
RenderX

Figure 3. Adherence, satisfaction, and self-reported voice changes among participants using the mobile health (mHealth) app for voice and speech training. (A) Adherence: The percentage of participants who completed the 5-week training program (20 sessions) using the mHealth app. (B) Participant satisfaction: Using a 5-point Likert scale. (C) The self-report of changing voice: Participants' subjective assessments of whether their voice improved, stayed the same, worsened, or if they were not sure after completing the training program.

Satisfaction

After using the app, 24 participants took part in the survey on satisfaction (Figure 3B). Out of 11 (45.83%) responded "very satisfied," 7 (29.17%) "moderately satisfied," 6 (25%) "neither" and none answered, "moderately dissatisfied" or "very dissatisfied." The CSAT score was 75%. Most were satisfied with the convenience of being able to practice at their own home, citing it as the primary reason. None reported any technical difficulties.

Effectiveness

Acoustic analysis and perceptual assessment results are presented in Table 2. Significant differences were observed in all acoustic measurements (P<.05). Significant differences in voice quality in all components of the GRBAS scale were observed before and after using the app. The inter-rater reliability between the 2 raters was fair too good (ICC=0.440). Among the 24 who took part in the survey (Figure 3C), 14 (58.33%) reported their voice "getting better," 9 (37.50%) reported "no change," 1 (4.17%) reported being "unsure," and none reported "getting worse."

Table 2. Pre- and postintervention changes in maximum phonation time (MPT), vocal intensity, and GRBAS[a] scale scores in participants with Parkinson disease (N=25).

Variable	Before	After	*t* test (*df*) or *z* score	*P* value
MPT (seconds)	11.15 (5.38)	14.01 (5.64)	–3.273 (24)	.003
Vocal intensity, mean (SD)				
Sustained phonation (dB)	72.32 (5.04)	75.67 (3.75)	–4.761 (24)	<.001
Reading short sentences (dB)	72.59 (4.09)	74.04 (4.08)	–3.164 (24)	.004
Reading “Ga-eul” passage (dB)	69.64 (4.55)	71.59 (3.61)	–3.546 (23)	.002
All tasks (dB)	71.59 (4.39)	73.81 (3.48)	–4.462 (24)	<.001
Variable (GRBAS scale score)				
Grade	1 (2)	1 (1)	–4.601	<.001
Roughness	0 (2)	0 (1)	–3.804	<.001
Breathiness	1 (2)	0 (1)	–5.959	<.001
Asthenia	0 (1)	0 (0)	–6.130	<.001
Strain	0 (1)	0 (1)	–3.930	<.001

[a]GRBAS: grade, roughness, breathiness, asthenia, and strain.

Discussion

Principal Findings

The aim of this study was to investigate the feasibility of patients with PD independently performing voice and speech training at home using a smartphone app as an alternative to traditional face-to-face therapy. The study involved SLPs in developing a mHealth app based on speech training content commonly used on patients with PD, and evaluated patients’ adherence to treatment schedules, satisfaction with app-based therapy, and treatment effectiveness.

Our study indicates that speech therapy delivered through an mHealth app is a feasible solution for patients with PD. A total of 20 out of 25 participants who completed the app showed an adherence rate of over 90%. Given that dropout rates in fields requiring various health behavior changes reach 30%-60%, an adherence rate of over 90% can be considered sufficiently high and indicative of successful adherence [32]. It is typically stated that an adherence rate of over 80% is necessary for optimal therapeutic efficacy, and our study has achieved this.

About 75% of participants were satisfied with the app use and improvements in voice and speech were observed both in objective and subjective evaluations. This is similar to the satisfaction rate (70%) of an internet-based telerehabilitation application for speech therapy [33] and is also comparable to a study reporting satisfaction rate of 82.6% with the smartphone app for people with aphasia [34].

Another notable point is that positive results were obtained for both objective and subjective ratings for voice. It is generally known that acoustic assessments highly correlate with SLP’s auditory perceptual ratings but have a low correlation with patient subjective assessments [35,36]. This indicates that there is a discrepancy between the degree of voice impairment assessed by the assessor and by the patients. The consistency in our results among 3 methods of evaluation indicates the robustness of effectiveness.

The advancement of mobile and electronic technologies has increased interest in non–face-to-face therapy, which has been further accelerated by the COVID-19 pandemic. This can help address medical accessibility issues. If non–face-to-face methods are proven to be as usable and effective as face-to-face therapy, they will be a more convenient way to receive medical services. Previous studies have confirmed its feasibility and effectiveness in various rehabilitation fields, such as speech, motor, and cognition [10,37,38]. In addition, the benefits of online treatment reported include time and cost savings and reduced caregiver burden. Along with these benefits, a key advantage of mHealth apps is that they enable patients to take an active role in managing their condition. Previous studies indicate that the integration of mHealth technology into therapy is an optimized clinical pathway for patients [6]. Although the number of studies is limited compared to real-time teletherapy provided by therapists, there are a few that have confirmed the usefulness and effectiveness of app-based therapies [15,17,18,39]. These include reports of significant improvements in pronunciation and speech volume in people with PD who received speech therapy using homegrown software [18]. This finding is in line with our results and illustrates the potential of the mHealth app as a feasible approach to speech rehabilitation.

In contrast to the high adherence in our study, a previous study investigating the usability of an mHealth app developed to address walking, speech, and dexterity symptoms in patients with PD reported low adherence and effectiveness [19]. The adherence to speech exercises was 66.8% (SD 26.5%). In the study, participants in the intervention group were instructed to independently complete exercises using the provided mHealth app on their personal smartphones once a day for approximately 90 days. This app required practicing various areas such as mobility exercises in addition to speech, and it took about 30

XSL•FO
RenderX

minutes to complete all sessions. This may have placed a physical and mental burden on the users.

In addition, considering that appropriate feedback and interaction with therapists generally impact the adherence and effectiveness of therapy, the extent to which sufficient feedback was automatically provided within the app may have also influenced these outcomes. In our app, not only does it provide reminder functions through pop-up alarms, but it also provides different feedback each time whenever the patient performs a task (eg, "Good job! Squeeze your abdomen and speak louder!"). Such feedback may have positively influenced the patient's continued use. Furthermore, over 50% of the participants in the previous study experienced technological issues with the app, which may have interfered with the outcomes. In our app, we tried to create a user interface older adults friendly as much as possible and to ensure the seamless operation of the app. As a result, there were no reports of technical issues, and this also could have affected adherence, effectiveness, and satisfaction.

Limitations and Future Directions

However, our study has several limitations. Because the primary aim of this study was to evaluate the feasibility and it was an uncontrolled study, the effectiveness observed in our study should be interpreted with caution. Larger randomized controlled trials are needed to provide more robust results on effectiveness. In addition, consideration of factors that may affect the usability of the mHealth app, such as disease severity and digital literacy [40] of patients from the recruitment stage, would be useful to evaluate the potential for introducing this app to a broader population of individuals with PD.

Second, we were unable to conduct functional assessments to determine whether participants' voice issues improved in real-life communication situations. While the Voice-Related Quality of Life tool does not directly measure improvements in voice use during real-life situations, it provides valuable insights into how patients perceive the impact of their voice disorder on their quality of life. Studies have demonstrated that after face-to-face speech therapy, such as the Lee Silverman Voice Treatment or the Speak Out Voice program, patients exhibit improved Voice-Related Quality of Life scores [41,42].

Using the Dysarthria Impact Questionnaire to evaluate the psychosocial effects of dysarthria could also provide meaningful insights [43]. In addition, assessing effectiveness using data collected from naturalistic environments, such as real-life conversational settings, could yield more reliable results. Including evaluations from primary caregivers to determine whether patients' speech problems have improved would provide a more objective perspective. Patients with PD often face challenges with self-monitoring due to the nature of the disease, making patient-reported improvements insufficient [44]. Therefore, evaluations should integrate diverse perspectives and methodologies.

Third, our study encountered difficulties in achieving consistent calibration across all participants' devices. The variations in smartphone models and built-in microphone sensitivities presented challenges in standardizing intensity calibration. According to Park and Lee [45], differences in microphone characteristics among smartphone models can lead to discrepancies in recording and analysis, with omnidirectional microphones, in particular, being more susceptible to ambient noise. They suggested that using a unidirectional wired lapel microphone could offer more consistent recording quality. Consequently, we recommended that participants maintain a specific distance from the microphone and minimize background noise, providing tutorial videos within the app to facilitate consistent recording practices. However, hardware differences among devices may still impact the consistency of intensity measurements. This suggests that future research may benefit from implementing additional calibration methods to improve measurement reliability.

Fourth, while this app was designed as a tool to substitute face-to-face therapy, it currently faces limitations due to its inability to fully replicate the real-time feedback and personalized adjustments provided during in-person therapy. To overcome these challenges, future research should focus on improving the app's functionality and design.

Specifically, integrating customized feedback mechanisms and improved monitoring systems is crucial. Without these features, participants may risk developing vocal abuse by overcompensating with improper techniques. Continuous monitoring can help identify and resolve any discomfort or tension early, ensuring the app's safety and effectiveness. These improvements could help bridge the gap between app-based therapy and face-to-face therapy. In this process, it is also important to investigate the app's impact on the overall quality of life of patients with PD compared to traditional in-person therapy. Widely used tools such as the World Health Organization Quality of Life Questionnaire or Parkinson Disease Questionnaire-39 can be used for this purpose [46].

In addition, understanding the impact of self-managed mHealth apps on caregiver burden, particularly from the perspective of primary caregivers, is an important research topic. If such apps enable patients to manage themselves more effectively, they could reduce the caregiving burden, alleviating stress and fatigue for caregivers. This would not only enhance the quality of life for caregivers but could also have a positive impact on the patient-caregiver relationship. Therefore, such analyses are crucial for evaluating whether the app provides meaningful benefits for both patients and their caregivers.

Finally, future research could consider longitudinal studies to evaluate the long-term effects and sustainability of mHealth apps. Patient adherence is crucial for treatment effectiveness and improvement in their health status. Nevertheless, most existing studies have short durations, limiting research on factors affecting mHealth app adherence [47]. Tracking changes in user adherence over extended periods could help develop user retention strategies. Furthermore, the accumulated data could be used to analyze user behavior patterns and develop predictive models.

Conclusions

Despite the small sample size of this study, this study supports the feasibility of self-delivered speech therapy at home for patients with PD. Especially considering the age of the

XSL•FO
RenderX

participants, the mHealth app we developed is not only suitable for older users but also proves to be satisfying for them.

Acknowledgments

This research was supported by a grant of the Korea Health Technology R and D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health and Welfare, Republic of Korea (grant number: RS-2023-00265517). We sincerely thank all the participants for their involvement in this study. We also extend our gratitude to the 2 SLPs, Professor Seung Jin Lee and Professor Jung Wan Kim, for their assistance with the auditory perceptual assessment.

Data Availability

The datasets generated during this study are not publicly available due to the small sample size, which requires protecting the privacy of participants, but are available from the corresponding author on reasonable request.

Authors' Contributions

Study concept and design were performed by Han-Joon Kim, Jiae Kim, and Sol-Hee Lee. Acquisition, analysis, or interpretation of data were conducted by Han-Joon Kim, Jiae Kim, and Sol-Hee Lee. Drafting of the paper was handled by Han-Joon Kim and Sol-Hee Lee. Critical revision of the paper for important intellectual content were performed by Han-Joon Kim, Jiae Kim, and Sol-Hee Lee. All authors have approved the submitted version and have agreed both to be personally accountable and to ensure that questions are appropriately investigated, resolved, and the resolution documented in the literature.

Abstract

Background: Tinnitus is the perception of sound without an external auditive stimulus and can be a severe burden for affected patients. Medical guidelines recommend cognitive behavioral therapy (CBT) for tinnitus treatment, which effectively improves tinnitus-related distress and anxiety.

Objective: This study investigates the outcome of a 9-month smartphone-based CBT for patients with tinnitus.

Methods: The randomized controlled clinical trial in this study investigates the efficacy of a smartphone-based CBT for 187 patients with chronic tinnitus over a 9-month treatment period. In the initial 3 months, a waiting list design was applied, and in the subsequent study phase, the data of both treatment groups were collectively analyzed. The scores on the Tinnitus Questionnaire (TQ); 9-item Patient Health Questionnaire (PHQ-9); 9-item Self-Efficacy, Optimism, Pessimism (SWOP-K9) questionnaire; and 20-item Perceived Stress Questionnaire (PSQ-20) were assessed as endpoints after 3 and 9 months of treatment.

Results: We observed a statistically significant reduction in the tinnitus burden in patients who received the smartphone-based CBT intervention. Although no changes were observed initially in the TQ sum scores in the waiting control group (baseline mean, 37.8, SD 4.7; 3 months mean 37.5, SD 4.8; analysis of covariance [ANCOVA] P=.52), the scores significantly decreased once the app-based CBT had commenced. Data pooled from both groups revealed significant reduction in the TQ sum score by 12.49 (SD 1.44) (ANCOVA, P<.001) and 18.48 (SD 1.85) (ANCOVA, P<.001) points after 3 and 9 months, respectively, which was also clinically important. The calculated Cohen d was 1.38. Similarly, the scores on PSQ-20 (–9.14 points; ANCOVA, P<.001), PHQ-9 (–2.47 points; ANCOVA, P<.001), and SWOP-K9 (0.17 points; ANCOVA, P<.001) were significantly improved at the end of the therapy, with corresponding intermediate effect sizes after 9 months.

Conclusions: The data in our study provide evidence of statistically significant, clinically relevant, and continuous benefits of an app-based CBT intervention in patients with chronic tinnitus.

Introduction

Subjective tinnitus is the perception of sound without an external stimulus and is considered chronic if it is present for more than 3 months. The total prevalence of tinnitus among adults is about 14%, which is independent of sex but increases with age and is considered severe in about 2.3% of the affected patients [1]. How the burden is perceived differs substantially depending on the characteristics and severity of tinnitus or accompanying comorbidities and may affect the quality of life substantially. The multifaceted nature of tinnitus, risk factors, and the purely subjective evaluation and accompanying comorbidities make the treatment challenging [2,3]. Highly diverse treatment options have been developed, which may, however, be effective only in a certain subset of patients [4-7]. Treatment may also target not tinnitus itself but comorbidities (eg, hearing loss, depression) with secondary beneficial effects on the patients' tinnitus [8,9].

In patients with tinnitus resulting from hearing impairment, cochlear implants and hearing aids can significantly improve tinnitus, although variable methodologies applied in clinical trials complicate comparisons between the studies [5,10]. Despite short-term benefits from the intravenous application of lidocaine in some patients, no superiority compared to placebo was observed for commonly prescribed drugs such as betahistine or dexamethasone [8,11]. A study comparing the efficacy of ginkgo extracts and pentoxifylline to reduce tinnitus burden reported comparable decrease in the tinnitus burden for both products. However, reduction in the score of the mini Tinnitus Questionnaire (TQ) was below 10% for both study arms and thus most likely did not reach clinical relevance [12]. Currently, no medicinal products are approved for the treatment of chronic tinnitus. In contrast, pharmacological treatment may be required for comorbidities such as depression or anxiety. A number of therapeutic options have been developed for symptomatic treatment in patients without causative organic dysfunction or unsuccessful treatment. However, clinical evidence for treatments such as transcranial electric or vagus nerve stimulation, hyperbaric oxygen therapy, sound therapy, or tinnitus retraining therapy is scarce, and the evaluation of their efficacy in the clinical guidelines is ambiguous [10].

Among current symptomatic treatment options, cognitive behavioral therapy (CBT) has the highest clinical evidence compared to other treatment approaches. Its validity has been confirmed in several studies, and clinical guidelines recommend CBT for symptomatic treatment [13,14]. Although CBT does not target the tinnitus characteristics (eg, loudness), it focuses on perception and acceptance by the patients and thereby improves their quality of life and comorbidities. In recent years, app- or internet-based telemedicine has become a promising treatment alternative to conventional therapies. The application of CBT, both guided or nonguided by a psychologist or audiologist, is predestinated for remote therapy, and its efficacy to reduce the distress resulting from tinnitus has been proven over the years [15-17]. Nevertheless, more clinical trials are needed to strengthen the clinical evidence, and the research continues [16].

The randomized controlled clinical trial in this study investigates the long-term efficacy of an app-based CBT for tinnitus treatment. The primary endpoint was the difference in the TQ scores between patients who started CBT without delay (group 1) and a waiting list control group (group 2) who started CBT after 3 months, and the results have been previously published [18]. The baseline score of the patients in group 1 using the app improved from 39.7 by 13.4 points but remained largely unchanged (0.6 score points) in group 2. Following the 3 months waiting period, patients of group 2 received the CBT app as well, and patients of both groups continued treatment for a total duration of 9 months, after which final assessments of tinnitus severity (TQ score) as well as stress perception (20-item Perceived Stress Questionnaire [PSQ-20]), depression (9-item Patient Health Questionnaire [PHQ-9]), and self-efficacy (9-item Self-Efficacy, Optimism, Pessimism [SWOP-K9] questionnaire) were performed. This paper presents the long-term results of the full 9-month app-based treatment period in patients with tinnitus of both groups.

Methods

Our longitudinal analysis represents the outcome of the full 9-month treatment period with a CBT app, marketed under the name Kalmeda. The outcome of the initial 3-month period has been previously published [18].

Ethics Approval

The clinical investigation plan was prospectively approved by the Ethics Committee of North Rhine, Germany, on May 20, 2020 (case 2020026), following the ISO 14155 norm (Clinical Investigation of Medical Devices For Human Participants: Good Clinical Practice). This study was registered in the German Clinical Trials Register (DRKS-ID DRKS00022973) and conducted in 2 ENT (ear, nose, and throat) centers in North Rhine, Westphalia, Germany.

Patient Recruitment

Recruitment lasted from August 2020 to March 2021. The follow-up of the last patient ended in March 2022. The eligibility of the patients was assessed during a web-based visit. All patients fulfilled the inclusion criteria age ≥18 years and chronic subjective tinnitus of more than 3 months duration and not the exclusion criterium of an already diagnosed acute or chronic mental illness, whereby tinnitus-related anxiety or depression was no exclusion criterium. All patients signed an informed consent form prior to randomization to one of the treatment arms. The intervention group started using the app immediately after inclusion for a total of 9 months, while the control group commenced treatment after a 3-month waiting period.

Kalmeda Tinnitus App, Associated Regulations, and Study Design

This study investigates the efficacy of the Kalmeda app in the treatment of chronic tinnitus (Figure S1 in Multimedia Appendix 1). This app follows the principles of CBT, a self-help format following the Zürcher Ressourcen Modell (motivational psychology) and acceptance and commitment therapy for tinnitus [19]. The Kalmeda app was developed by mynoise GmbH and is a CE-marketed medical device since 2019 (DIMDI registration: DE/CA20/mynoise_01/18). During our study, software version 1.5.1 was used. The app was downloaded by users from commonly used app stores and activated by activation codes provided to the patients without a fee. The app has 5 levels with 9 steps each. The first 2 levels of behavioral therapy are typically accomplished within 3 months and the subsequent levels in not less than 7 months.

The efficacy of this intervention was assessed using a randomized controlled clinical trial by applying a waiting group design. The CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist was used for reporting of this randomized controlled trial (Multimedia Appendix 2). Patients were randomized to the 2 trial arms in blocks of 6 in the order of their appearance. Although the patients in group 1 started CBT immediately following randomization at T0 (baseline), patients in group 2 postponed treatment and began after the 3-month waiting period (Figure 1). In both groups, the efficacy of CBT was assessed after 3 and 9 months of treatment in comparison to baseline by using paper-based questionnaires sent to the patients by mail. Thus, the total study duration of the patients in group 1 and 2 was 9 and 12 months, respectively. The efficacy endpoints were the changes in tinnitus severity (TQ sum score) [20], depression scores (PHQ-9) [21], stress perception (PSQ-20) [22], and self-efficacy (SWOP-K9) [23] by using validated questionnaires. Published minimal clinically important difference (MCID) values of the TQ score depend on the baseline severity and can vary considerably between 12 for severe baseline values and <5 for lower baseline severity; this study considered the published MCID value of 6.65 [24-27]. The MCID of PHQ-9 varies with severity as well. In mild cases of depression characterized by PHQ-9 scores <10, corresponding to values reported in this study, the MCID is 1-2 points or 14%-22% of the baseline value [28,29]. No MCIDs are published for PSQ-20 and SWOP-K9; thus, generic improvements by 15% of the total scale range were considered as clinical important changes [27]. The severity of tinnitus was assessed according to 4 categories (<30, 31-46, 47-59, and 60-84) from mild to very severe, whereby it is considered as decompensated for TQ scores ≥47 [20]. Once the 3-month waiting period of the control group ended and app-based CBT was initiated, TQ sum scores significantly improved both statistically and clinically in individuals of the control group to a similar extent as in the intervention group. As data from baseline and after 3 and 9 months of treatment did not differ significantly between the groups, the data for all the patients using the app were pooled for our further analysis and evaluated collectively, independent from the initial randomization into group 1 or 2.

Figure 1. Scheme of the study design. Timepoints of assessments in group 1 and 2 (initial waiting group) are indicated by arrows. CBT: cognitive behavioral therapy.

Statistical Analysis

Sample size calculations were based on an effect size of 0.5 and a power of 0.8 by using a 2-sided *t* test with an α level of .05. The assumed intermediate effect size is based on the range of efficacy of CBT reported in tinnitus studies [30-33]. This agreed to a sample size of 64 per group or 128 patients in total. Considering a dropout rate of 15%, a total of at least 150 patients needed to be enrolled. All statistical analyses were performed with SAS 9.4 (SAS Institute Inc).

The primary statistical analysis was performed by applying analysis of covariance (ANCOVA). Missing data were imputed using reference-based multiple imputations. Robustness was verified with a sensitivity analysis by using a completer data set, which encompassed only individuals without any missing answers in particular questionnaires over the whole period. Thus, the numbers of completers vary between the different endpoints (TQ: n=88, PHQ-9: n=86, PSQ-20: n=86, and SWOP-K9: n=91). The outcomes were analyzed in comparison to baseline by using the paired 2-sided *t* test. Furthermore, Pearson correlations were performed for changes of TQ and the

XSL•FO
RenderX

3 secondary scores. The distribution of the demographic and clinical characteristics of both groups at baseline were tested for normality by using Shapiro-Wilk test and for variance homogeneity by using Levene test. Depending on the outcome of the tests, group comparisons were performed using nonparametric (Mann-Whitney *U* test, chi-square) or parametric analyses (*t* test). Frequency changes in tinnitus severity categories were analyzed using chi-square tests. Values in the text are represented as mean (SD).

Results

Patient Demographics and Disposition

A total of 187 patients were randomized in blocks of 6 to group 1 or 2 (Table 1). Group 1 started using the app immediately after randomization, whereas patients in group 2 were assigned to a 3-month waiting period before treatment commenced. In group 1, 53 patients completed the treatment. In group 2, 42 patients completed the treatment. Thus, a total of 95 patients completed the study after 9 treatment months (Figure 2). At baseline, groups 1 and 2 did not differ with regard to mean age (48.2 years, SD 12.5 years), sex ratio (males, 97/187, 51.9%; females, 90/187, 48.1%), and duration of tinnitus (mean 6.57 years, SD 6.93 years). The mean duration of the app-based therapy was comparable in both study arms and was 99.3 (SD 14.4) and 288.1 (SD 29.0) days for the 3- and 9-month treatment period, respectively. Tinnitus distress was measured with TQ scores as the primary outcome. Secondary outcomes were measured with PSQ-20, PHQ-9, and SWOP-K9 questionnaires (Table 1).

Table 1. Demographic and clinical characteristics of the participants at baseline (N=187).

	Group 1 (n=94)	Group 2 (n=93)	*P* value

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram. Disposition of the patients in this trial. The term "completers" encompasses all patients with complete entries without any missing data in the Tinnitus Questionnaire. TQ: Tinnitus Questionnaire.

Primary Outcome

The app-based CBT significantly improved the subjective tinnitus burden, as assessed by the TQ sum scores in patients of both study arms after 3 and 9 months of treatment, whereas the TQ scores of patients of group 2 did not improve during the waiting period (Table 2, Figure 3). During treatment, the TQ sum scores of the completers declined significantly from 37.27 (SD 13.49) at baseline to 23.99 (SD 13.50) (paired t_{87}=10.75; P<.001) and 18.73 (SD 11.48) (paired t_{87}=13.0; P<.001) after 3 and 9 months of treatment, respectively.

Figure 3. Tinnitus questionnaire sum score of completers in group 1 (blue) and 2 (orange) during the waiting (group 2 only) and the app-based treatment period. For improved clarity of the treatment effect, the improvement during the app-based treatment period is shown in parallel for both groups. Significant improvements compared to baseline are indicated by stars. TQ: Tinnitus Questionnaire.

In agreement, the imputation of missing data by using multiple imputations resulted in initial TQ sum scores of 38.46 (SD 15.49), which improved to 25.97 (SD 14.03) after 3 months and to 19.98 (SD 9.32) after 9 months of CBT in the analysis of the completed courses corresponding to a total improvement of 12.49 (SD 9.65) after 3 months (*P*<.001) and 18.48 (SD 12.43) after 9 months (*P*<.001) during therapy for all the patients (Table 3). Thus, the prolonged treatment period of another 6 months resulted in a further and significant decrease of TQ scores.

Table 3. Analysis of covariance of treatment difference compared to baseline of Tinnitus Questionnaire sum scores after multiple imputations at 3 and 9 months after the beginning of the treatment.

Parameter	Estimate	SE	*P* value	95% confidence limits	
				Lower limit	Upper limit

[a]Score difference after 3 months of treatment compared to baseline.

[b]Score difference after 9 months of treatment compared to baseline.

The calculated effect size Cohen *d* was 1.15 and 1.38 after 3 and 9 months of therapy, respectively, corresponding to a strong effect, whereby improvement correlated with severity at baseline (*r*=–0.48) and after the first 3 months (*r*=–0.53) being much more pronounced in patients severely affected by tinnitus. The improvement of the mean TQ sum score was accompanied by significant reductions in the incidence of decompensated tinnitus (TQ sum score≥47). Among completers, the number of patients with decompensated tinnitus was reduced from the initial 22 to 7 after 3 months (χ^2_1=9.3; *P*=.002) and to only 1 patient after

XSL•FO
RenderX

9 months of treatment (χ^2_1=22.1; *P*<.001). Not very severe cases were remaining, but patients had improved to lower severity categories. In agreement, the number of patients characterized by mild tinnitus severity (TQ≤30) increased from 25 at baseline to 63 and 73 after 3 and 9 months, respectively (χ^2_1=32.8 and 53.1, respectively; *P*<.001; Figure S2 in Multimedia Appendix 1). After 3 months, 68% (60/88) responded to the treatment, and after 9 months of therapy, 80% (70/88) responded to the treatment, as their TQ sum score improved by more than the MCID value of 6.65. The baseline TQ score and its improvement during the first 3 months of therapy and its impact on completion or premature discontinuation of therapy was assessed. An initial worsening of symptoms does not seem to result in premature termination, as this was more often observed in completers (7 patients) than in dropouts (3 patients).

Individuals with mild and intermediate tinnitus (<46 points) at baseline documented average improvements by about 10 points (or 35% of baseline severity) within the first 3 months of treatment and thereby reached TQ scores of about 20 (Figure S3 in Multimedia Appendix 1). Approximately equal numbers of patients either terminated participation prematurely (55 patients) or completed treatment (66 patients). In contrast, patients with severe tinnitus (≥47) either experienced strong improvements of 18 points in the TQ score (35% of baseline severity) and completed treatment (22 patients) or small improvements of 10 points in the TQ score (equivalent to 18% improvement when compared to baseline severity), and treatment was terminated prematurely (13 patients).

Secondary Outcomes

Aside from the TQ sum score, the secondary outcomes, that is, stress, depression, and self-efficacy were assessed. The beneficial effects of our app-based CBT were observed in PSQ-20 scores over the whole treatment period. Significant reductions became evident already after 3 months (–4.62 points), and the score improved even further by –9.14 after 9 months of treatment (ANCOVA, *P*<.001). Similar significant changes (–5.66 and –9.55) were present in the completer data after 3 and 9 months as well (paired *t* test, *P*<.001), respectively, without reaching the clinically important difference. The effect sizes were 0.45 after 3 months and 0.60 after 9 months of CBT. Thus, the initially small effect became intermediate in the second treatment phase. Individual changes in PSQ-20 scores were well-correlated with TQ improvement after 3 (*r*=0.57) and 9 (*r*=0.58) months, respectively (Tables S1 and S2 in Multimedia Appendix 1).

The PHQ-9 score, as a measure of depression severity, decreased significantly by 1.40 and 2.47 points (ANCOVA, *P*<.001) after 3 and 9 months, respectively, as evaluated using multiple imputation. The sensitivity analysis using the completer data set yielded comparable significant results starting with 7.77 (SD 4.00) at baseline and lower values of 6.29 (SD 3.48) and 5.42 (SD 3.07) following treatment (paired *t* test, *P*<.001). Based on the published MCID, PHQ-9 changes were considered clinically relevant. The corresponding effect sizes were 0.52 and 0.68 after 3 months and 9 months, respectively, representing intermediate effects (Tables S1 and S2 in Multimedia Appendix 1). Changes in TQ and PHQ-9 were correlated after 3 (*r*=0.57) and 9 (*r*=0.58) months of therapy.

Self-efficacy was assessed using SWOP-K9. Imputed data revealed no significant improvement after 3 months (0.04, ANCOVA, *P*=.16) but after 9 months of treatment (0.17, ANCOVA, *P*<.001). Completers were characterized by mean baseline values of 2.77 (SD 0.51). Although no significant improvement was evident after 3 months (2.78, SD 0.54; paired *t* test *P*=.75), statistically significantly higher values of 2.95 (SD 0.47) were obtained after 9 months (paired *t* test, *P*<.001); however, the improvement did not reach the generic MCID of 15%. The 9-month effect size was 0.5 corresponding to an intermediate effect (Tables S1 and S2 in Multimedia Appendix 1). Only low correlations between individual changes of TQ score and SWOP-K9 were obtained after 3 months (*r*=–0.22), which increased after 9 months (*r*=0.54). No adverse events were reported during this clinical study.

Discussion

Principal Results

This study reports the outcome of a 9-month treatment with an app-based CBT for chronic tinnitus. This study is a follow-up to the previously published data of the initial 3-month treatment period [18]. The 9-month data confirm highly beneficial improvements in the tinnitus burden by CBT with the Kalmeda app. Within 3 months of treatment, the TQ sum scores improved significantly. There are currently 3 studies on the MCID of the TQ scores available. Adamchic and colleagues [24] reported an MCID of 6.65 (SD 7.99) points (mean follow-up time, 44 days) [24]. Hall and colleagues [25] reported an MCID of 12 (SD 9.8) points (follow-up time, 5 days) [25] and 7.5 points for the Mandarin version (follow up time, 6 months) [26]. After 3 months of web-based CBT, the average improvement in the tinnitus burden surpassed the average thresholds, and during the long-term treatment, tinnitus symptoms continued to improve even further, leading to an additional decrease by 5.99 points in the TQ score. Importantly, as perceived improvement of tinnitus is independent of the duration of treatment but depends on the baseline value, it is smaller in patients with lower initial burden [24]. The MCID for mild tinnitus (TQ≤30) corresponds to 3.17 (SD 7.15); this is much lower than the mean value of both MCID criteria [24,25]. After the first 3-month treatment period, patients were characterized by mean TQ scores of 23.99; thus, it is likely that further amelioration of their tinnitus symptoms experienced during the complete 9-month treatment is considered clinically relevant. Our study data reveal that the efficacy of the app-based CBT in the reduction of the tinnitus burden is comparable to that of treatments such as neuromodulation or transcranial direct current stimulation [6,34].

The comparison of active treatment to a waiting list control group is a common study design; yet, the assessment of the long-term outcome is difficult once the control group receives the same treatment. In this trial, the efficacy of CBT was compared to the waiting list control group, which remained largely unchanged during the initial 3-month period, but no control group was present during the full 9-month treatment period [18].

XSL•FO
RenderX

In order to compensate for the lack of an internal control, treatment efficacy in this study was compared to the outcomes of untreated control groups in randomized clinical trials with comparable durations. Few studies [35-39] have reported TQ sum scores in patients not receiving adequate treatment over several months. In a randomized trial testing the efficacy of tinnitus retraining therapy, no improvement was observed for patients in the waiting list control group after 12 months [35]. No improvement but a tendency of worsened symptoms was observed in patients in the waiting list control over a period of 6 months [36]. In patients receiving no treatment, the Tinnitus Severity Index was largely unchanged after 6 and 12 months, corresponding to an effect size of 0.0 and 0.1 [37]. In patients in the waiting list group during a 24-week trial, improvement in the TQ sum score corresponded to an estimated effect size below 0.4 [38]. Evidence from literature suggests only minor changes in tinnitus severity in untreated controls and a maximum effect size up to 0.4 corresponding to at most a small effect according to the definition by Cohen [39]. In comparison, the effect size of the app-based CBT group was 1.15 after 3 months and increased even further to 1.38 after 9 months of therapy. Thus, long-term app-based CBT in this trial resulted in pronounced improvement, which exceeded the expected outcome in the absence of any treatment in studies of comparable length by far. In addition, a waiting control group design does not allow to evaluate a potential placebo effect. In trials investigating medicinal products or medical devices, the efficacy of placebo treatment can be of relevance but at the same time is smaller by a factor of 3 than the improvement observed in the recent studies [40,41].

Dropouts can be a problem for the outcome of clinical trials. In this trial, 12.8% (24/187) of the patients stopped participation during the initial 3-month period until the primary endpoint was reached. In the following study period from 3 to 9 months, the dropout rates increased, resulting in a total loss of follow-up of 52.9% (99/187). A comparable rate of 51% was reported in a previous study applying internet-based CBT for tinnitus [15]. In general, dropout rates in studies using app-based treatments (~43%) often exceed rates common for studies applying in-person treatment [42]. However, despite the risk of therapy attrition, treatment apps are advantageous, for example, they are readily available without extended waiting periods, can be used 24/7, and are available even in remote areas.

Improvement of tinnitus-related distress within the first 3 months of app-based CBT did not differ significantly between dropouts and completers, suggesting that the patient's decision to prematurely end treatment was based on either treatment success (an individual had either reached an acceptable level of tinnitus severity or experienced considerable relief of its burden) or treatment failure (as defined by unsatisfying improvement or the burden for the treatment was too high). As in most cases, no further information on the reasons for dropouts were given; therefore, we cannot be sure about the reason with absolute certainty, but an analysis of the data after 3 months of treatment supports this hypothesis. Interestingly, in patients with mild and intermediate tinnitus (<46 points) who reached an average TQ score of about 20 within the first 3 months, subsequently, it was merely a 50/50 chance if they dropped out or completed treatment. Patients may have continued therapy even longer and thus reach even lower scores before prematurely dropping out; unfortunately, detailed information is not available. In contrast, patients with more severe burden at baseline did not reach such low TQ levels within 3 months. However, the majority of them experienced a pronounced and clinically relevant reduction of 18.9 points, which seemed to motivate continuation of therapy. Indeed, these patients finally reached TQ scores of 25.8 points after 9 months. A smaller number of 13 patients had improved to a lesser extent by 10 points (18% of baseline), thus still reaching the MCID and discontinued later. For the latter, it seems likely that unsatisfactory treatment was the major reason for the dropout. Thus, the data suggest that premature termination can result from subjective evaluation of success or failure of therapy depending on the relative improvement. The same may apply during the second study phase; however, the pronounced increase in dropouts suggests that the long study duration might have contributed to premature terminations as well. This is supported by the higher dropout rate of patients from the waiting list control group (51/93, 55%) whose involvement in the trial lasted for a full year when compared with the intervention group (41/94, 44%) who finished treatment 3 months earlier.

Patients with tinnitus are often characterized by elevated depression and stress perception, which was measured with PHQ-9 as well as PSQ-20, respectively [43,44]. Following the 3-month treatment, PHQ-9 and PSQ-20 measures had significantly improved. Both parameters decreased even further during the prolonged treatment, and improvements became clinically relevant. As suggested by Wallhauser-Franke and colleagues [45], the measures of tinnitus loudness and tinnitus distress need to be distinguished. The app-based CBT in our study did not improve perception of tinnitus loudness but significantly reduced tinnitus distress. Improvement of PHQ-9 and PSQ-20 scores after CBT therefore are in parallel to the observed reduction of the TQ sum score observed after 3 and 9 months of treatment.

In contrast to the 2 previous secondary endpoints, self-efficacy assessed by SWOP-K9 was almost unchanged following 3 months of CBT, but a statistically significant improvement was evident after 9 months, albeit clinically relevant levels were not reached. This highlights the importance of prolonged treatment beyond the initial 3 months period, leading to significant improvements of tinnitus burden on all tested scales.

Limitations

This study has limitations. The waiting list design allows an accurate quantification of treatment effects of CBT in comparison with the untreated control but lacks an internal control for the whole 9-month treatment period. Thus, the superiority of the treatment had to be verified by comparison to studies in this indication with comparable duration. Furthermore, a potential placebo effect was not assessed and therefore cannot be ruled out, but is likely to be relatively small [40,41]. The tinnitus distress of the included study participants was assessed with an average TQ sum score of 39.6 in group 1 and 38.3 in group 2. Patients with this amount of tinnitus distress are considered as grade 2 patients (out of 4 grades). This study

XSL•FO
RenderX

shows that patients with chronic tinnitus of this grade of severity can significantly benefit from the app-based treatment. At the current state of research, the results cannot be generalized to patients with very severe amount of tinnitus distress (grade 4).

Conclusions

This study reveals the pronounced effect of an app-based CBT on tinnitus distress, and in the course of treatment, the number of patients affected by decompensated tinnitus decreased significantly. In addition, the majority were characterized by mild tinnitus severity during the final assessment.

Abstract

Background: Depression affects 32% of older adults. Loneliness and social isolation are common risk factors for depression in older adults. Mobile apps can connect users and are also effective in depression management in the general population. However, older adults have specific needs in terms of the content of depression self-care interventions and their accessibility. It remains unknown whether existing apps for depression self-care are applicable to older adults.

Objective: The initial aim of this assessment was to systematically identify interactive depression self-care apps specifically designed for older adults. As we did not find any, we assessed the applicability of existing depression self-care apps to the needs of older adult users.

Methods: Using an established app assessment methodology, we searched for Android and iOS interactive mental health apps providing self-care for depression in English and Chinese in the 42Matters database, Chinese Android app stores, and the first 10 pages of Google and Baidu. We developed an assessment rubric based on extensive revision of the literature. The rubric consisted of the following sections: general characteristics of the apps (eg, developer, platform, and category), app content (eg, epidemiology and risk factors of depression in older adults, techniques to improve mood and well-being), and technical aspects (eg, accessibility, privacy and confidentiality, and engagement).

Results: We identified 23 apps (n=19, 82.6%, English and n=4, 17.4%, Chinese apps), with 5 (21.7%) iOS-only apps, 3 (13%) Android-only apps, and 15 (65.2%) apps on both platforms. None specifically targeted older adults with depression. All apps were designed by commercial companies and were free to download. Most of the apps incorporated cognitive behavior therapy, mood monitoring, or journaling. All but 3 (13%) apps had a privacy and confidentiality policy. In addition, 14 (60.9%) apps covered depression risk factors in older adults, and 3 (13%) apps delivered information about depression epidemiology in older adults via a chatbot. Furthermore, 17 (73.9%) apps mentioned other topics relevant to older adults, such as pain management, grief, loneliness, and social isolation. Around 30% (n=7) of the apps were supported by an online forum. Common accessibility issues included a lack of adaptations for users with visual or hearing impairments and incompatibility with larger font sizes in the phone settings.

Conclusions: There are no depression apps developed specifically for older adults. Available mobile apps have limited applicability to older adults in terms of their clinical and technical features. Depression self-care apps should aim to incorporate content relevant

XSL•FO
RenderX

to older adults, such as grief and loss; include online communities; and improve accessibility to adapt to potential health impairments in older adults.

(J Med Internet Res 2025;27:e56418) doi:10.2196/56418

Introduction

The population is aging worldwide, and this demographic shift is coupled with higher depression incidence rates in older adults compared to younger populations [1]. China, for example, had 254 million adults over 60 years old in 2019 [2], with a growing incidence of mental disorders and a high risk of suicide [3-5]. In 2020, the number of older adults in the United States was 55.8 million, representing 16.8% of the total population [6]. It was estimated that 8 million older adults in the United States aged 65 years and above had depression, and depression affects 32% of older adults worldwide [7,8]. Older adults with depression are more likely to have comorbidities, worse sleep, decreased quality of life, and poorer self-perceived health compared to those without depression [9,10]. There are many barriers to older adults seeking mental health treatment, including low awareness, which may lead to a poor prognosis [11]. There is a need for effective, scalable, accessible, and affordable mental health interventions that are tailored to the needs of older adults. Digital health interventions, particularly those delivered via mobile phones, have the potential to address this burden of mental illness in older adults.

Older adults are increasingly using mobile phones, which facilitates using mobile apps to improve their mental health. In the United States, the ownership of smartphones between 2017 and 2022 in adults aged 65 years and above increased from 40% to 65% [12]. In China, over a third of the internet users in 2021 were adults aged 50 years or older [13]. The need to minimize in-person contact during the COVID-19 pandemic also boosted the use of digital technology in older adults. For example, in Singapore, more than half of 55-75-year-olds used social media platforms or the internet to search for news of the pandemic [14]. Mobile apps also provide users with an opportunity to stay connected and may potentially mitigate loneliness and social isolation [15], which are common risk factors for depression in older adults [16].

Contrary to some common beliefs, older adults are becoming increasingly tech-savvy, with some preferring to use digital health tools for mental health treatment over face-to-face treatment [17-21]. Furthermore, digital mental health interventions can help reduce the long waiting times for counseling and avoid the time and financial costs of travel from rural areas [22]. In addition, the privacy provided by digital mental health tools may reduce the potential stigma and shame, which is common among older adults [22-26]. Mental health mobile apps have been shown to be effective in the treatment of depression in the general population [27,28]. Although there were mental health apps specifically targeting the youth [29], it remains unknown whether there are apps that cater for older adults' specific needs in terms of mental health content and digital accessibility [30,31]. For example, worldwide, around 51% of older adults aged 60 years and above have multimorbidity [32] and would benefit from content on physical health, cognitive decline, stress, aging, and isolation [33,34]. They may also need bigger fonts, and louder and clearer audio to address potential visual or hearing impairments [35].

Therefore, the initial aim of this assessment was to systematically identify interactive depression self-care apps specifically designed for older adults. As we did not find any, we assessed the applicability of existing depression self-care apps to the needs of older adult users. We focused on English and Chinese app markets as they represent 31% of the world population [36].

Methods

Study Design

We used an app assessment methodology that has been extensively used in previous papers aiming to systematically assess other types of apps [37-40]. The assessment methodology derives from systematic review methodology as it includes a systematic search for apps with a clear mention of the search strategy and databases searched, clear inclusion/exclusion criteria, 2-step screening for eligible apps, and systematic data extraction using a predefined data extraction form. Our method was mostly aligned with a guide on the systematic review and evaluation of mobile health apps [41].

Search Strategy

We searched for apps in English and Chinese in the 2 leading app markets, Android and iOS, in November-December 2022. We searched Apple's App Store for English and Chinese apps and Android apps in English using 42Matters, a comprehensive proprietary app database. As Google Play is unavailable in mainland China, we searched the most popular Android Chinese app stores, used by more than 81% of mobile phone users, including Tencent App Store, Huawei App Market, MIUI App Store, Oppo Software Store, VIVO App Store, 360 Mobile Assistant, Baidu Mobile Assistant, MM App Store, PP Assistant, and the Wandoujia platform [42]. In addition, we screened the first 10 pages on popular English and Chinese search engines (Google and Baidu) for any other potentially relevant depression self-care–focused mobile apps [43]. Search terms for apps in English included "mental health," "mindfulness," "cognitive behavioral therapy," "CBT," "psychotherapy," "online therapy," "mood," "depress," "anxiety," "sadness," "melancholia," "worry," and "counseling." When we combined the

XSL•FO
RenderX

aforementioned search terms with “older adults,” “elderly,” “ageing,” or “geriatric” using the AND Boolean operator, no results were returned on 42Matters. Therefore, we decided to broaden the search strategy and manually capture aging-related content in the apps’ descriptions, if any. The search terms for Chinese apps included 抑郁 OR 焦虑 OR 心理健康 OR 心理咨询 OR 行为疗法 OR 精神健康 OR 正念 OR 自杀 OR 悲伤.

Eligibility Criteria

Textbox 1 shows the inclusion and exclusion criteria of the apps. We included interactive mental health apps that explicitly mentioned depression, were free or required one-time payment to download, and targeted older adults or the general population. Popular apps were included because users are more likely to encounter and use them [44]. As there was no consensus on the criteria related to popularity, previous studies have adopted the strategy of excluding apps with less than 10 [45] or 5 [43,46] reviews. Meanwhile, highly downloaded apps were defined as those with 100,000 or more downloads in Android markets [47]. Therefore, Android apps with ≥100,000 downloads on Google Play or Chinese Android app markets and iOS apps with ≥10 reviews on Apple’s App Store were included. Apps available on both platforms were included if their number of downloads was ≥100,000 in Android markets and they had ≥10 reviews on Apple App Store. Apps that (1) targeted children, adolescents, or young adults; (2) focused exclusively on meditation or mindfulness, positivity, affirmations, or well-being; (3) had technical issues; (4) only allowed consultations with health care providers; or (5) had <100,000 downloads on Google Play or Chinese Android app markets or <10 reviews on Apple’s App Store were excluded.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Targeted older adults or the general population
- Explicitly provided depression self-care
- Included interactive features (ie, “allowing information to be passed continuously and in both directions between a computer or other device and the person who uses it” [47,48])
- Were in English or Chinese
- Were available on Google Play, Chinese Android stores, or Apple’s App Store
- Were found in the following app store categories: health and fitness, lifestyle, and medical
- Were released or updated from May 2021 onwards
- Were free or paid to download
- Had ≥100,000 downloads on Google Play or Chinese Android app markets and ≥10 reviews on Apple’s App Store

Exclusion criteria:

- Targeted children, adolescents, or young adults
- Focused exclusively on meditation or mindfulness, positivity, affirmations, or well-being in general
- Had technical issues and could not be used after 2 attempts, required an access code provided by a health care institution or insurance company, or had been removed from the app store at the time of the assessment
- Only allowed online consultations with health care providers
- Had <100,000 downloads on Google Play or Chinese Android app markets or <10 reviews on Apple’s App Store

App Screening

In the first round of screening, 1 reviewer (author RY) followed the inclusion and exclusion criteria in Textbox 1 to manually screen the apps on ASReview, a screening tool using machine learning algorithms [49] that has been increasingly used in systematic reviews [50-53]. After each decision (include/exclude) by the reviewer, ASReview applied machine learning models (term frequency–inverse document frequency method as the feature extractor and logistic regression as the classifier) and actively sorted the rest of the apps according to their relevance, from the most relevant to the least relevant. As such, ASReview facilitated screening by allowing the reviewer to screen a subset of the total apps. As shown in prior simulation studies, ASReview was able to identify 95% of all relevant records while screening between 8% and 33% of the total records [49]. Since there is no consensus on the stopping rule [54], the reviewer in this study predefined the stopping criteria as screening one-third (33.3%) of the total apps [49]. The apps were then downloaded to an iPhone 13 (iOS 16.1.1), a Samsung A52s (Android 13, One UI 5.1), and 2 of 3 reviewers (authors RY, DR, and FC) independently and in parallel evaluated eligibility. Apps available on both iOS and Android platforms were counted as one app in the assessment.

Assessment Rubric Development, Data Extraction, and Analysis

To develop an assessment rubric for content relating to older adults, we searched the following keywords on Google Scholar and PubMed: aging, depression clinical practice guidelines, geriatric depression, psychoeducation or psychotherapy for older adults, and accessibility guidelines. We also conducted a

XSL•FO
RenderX

qualitative systematic review of older adults' views and experiences with using digital mental health interventions [55] and a scoping review of experts' opinions on digital mental health interventions for older adults [56]. Our scoping review confirmed the essential content and features for older adults, including therapeutic approaches, relevant topics, personalization, and accessibility.

Table 1 shows the sources of evidence used in the development of the assessment rubric. The sources included established clinical practice guidelines [57-60], systematic and scoping reviews [61-64], academic books [65-69], a systematic assessment of mental health apps [70], and guidelines and checklists of technical features [71-73], including the Mobile Application Rating Scale (MARS), the mobile Health On the Net Code (mHONcode), and the World Wide Web Consortium (W3C) guidelines for accessibility of content on mobile phones.

Both MARS and mHONcode were designed to evaluate apps' technical features, while neither of them was specifically designed to assess apps' applicability to older adults. Furthermore, most of the included apps have been evaluated using these scales elsewhere [45,75-77]. However, existing app assessments have seldom evaluated accessibility in detail. Thus, in this study, we focused on assessing app accessibility using the W3C guidelines, and we used a few items from MARS and mHONcode that do not overlap with the W3C guidelines and are directly relevant to older adults, as indicated in a systematic review on the views and experiences of older adults with digital mental health interventions [55]. According to our review, engagement with the target group (older adults), the quality/resolution of graphics with regard to aesthetics, information credibility, and the evidence base from MARS are relevant and important to older adults [78-80]. In addition, older adults often have concerns about privacy and confidentiality when using digital mental health tools [23,33,78,80-84]. Therefore, we supplemented the W3C guidelines with 3 groups of items from MARS (target group, aesthetics, and information) and 2 items from mHONcode (privacy and confidentiality).

The following information about each app was recorded using a data extraction form (Multimedia Appendix 1) with 3 sections:

- General features of apps, including their description and category in the app store, developers, ratings, target user group, regions, languages, privacy policy, total downloads in Android markets, and cost of download and subscription. Ratings of apps ranged from 1 to 5, with higher scores indicating users' positive perceptions.
- Content relevant to older adults, which consisted of the following 6 sections: symptoms and natural history of depression in older adults (11 binary questions with yes/no answers and 3 open-ended questions), screening of depression (7 binary questions and 5 open-ended questions), self-care techniques (2 binary questions and 4 open-ended questions), personalization (5 binary questions and 1 open-ended question), human involvement (3 binary questions and 1 open-ended question), and other functions (6 binary questions and 2 open-ended questions).
- Technical features, including the W3C guidelines for accessibility of content on mobile phones [35,73], supplemented by 5 items covering engagement, aesthetics, and information from MARS [71,85] and 2 items on privacy and confidentiality from mHONcode [72]. The W3C guidelines consisted of 4 principles: perceivable (6 binary items), operable (6 items), understandable (7 items), and robust (4 items).

For every item except MARS, a "yes" was assigned 1 point. Each app was independently evaluated by 2 of the 3 reviewers working in parallel (RY, DR, and FC). Assessments were then compared from September to October 2023, and disagreements were discussed until consensus was reached. We used each app for at least 15 minutes to ensure interaction with all app features. Data were recorded in a Microsoft Excel worksheet and summarized. We calculated the percentage of each app's score over its total score. Narrative data synthesis was used to present our findings.

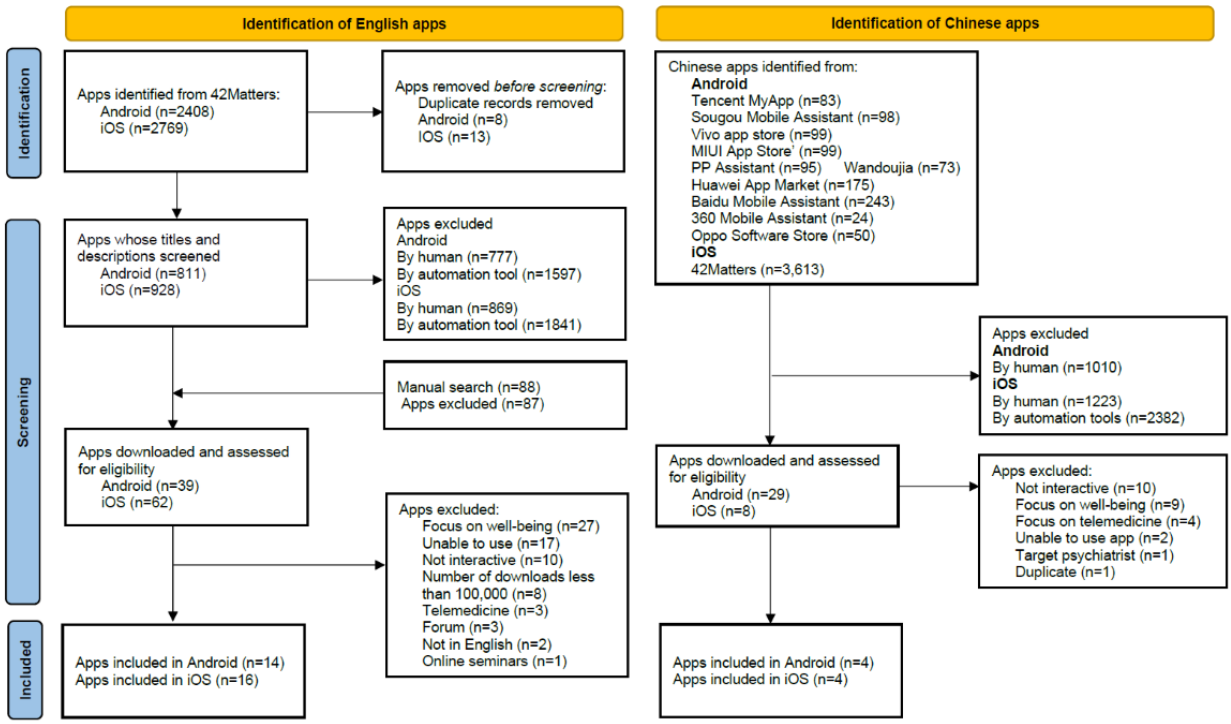
[c]W3C: World Wide Web Consortium.

[d]mHONcode: mobile Health On the Net Code.

Ethical Considerations

Ethical approval was not required for this systematic assessment of mobile apps as no human participants or personal data were involved.



Results

Identification of Apps for Depression Self-Care

We identified 5177 English apps (n=2408, 46.5%, on Android and n=2769, 53.5%, on iOS) in 42Matters and 4652 Chinese apps (n=1039, 22.3%, on Android and n=3613, 77.7%, on iOS) in 42Matters and Chinese app stores. One additional English app, Happify, was identified on Google and none from the Baidu search engine. After title and description screening, 101 (2%) English apps (n=39, 38.6%, on Android and n=62, 61.4%, on iOS) and 37 (0.8%) Chinese apps (n=29, 78.4%, on Android and n=8, 21.6%, on iOS) were downloaded to examine eligibility. We included 23 (16.8%) apps for systematic assessment (n=19, 82.6%, English apps and n=4, 17.4%, Chinese apps. In addition, 15 (65.2%) apps were available on both iOS and Android platforms, 5 (21.7%) on the iOS platform, and 3 (13%) on Android platforms (Figure 1).

XSL•FO
RenderX

Figure 1. Flowchart of app screening.

Basic Characteristics of the Included Apps

Table 2 shows the basic characteristics of the included apps. All 23 apps were developed by commercial companies and were free to download. Most of the apps (n=20, 87%) were in the health and fitness category in the app stores, and 3 (13%) were in the medical category. Of the 18 (78.3%) apps available on Android platforms, 8 (44.4%) had been downloaded more than 1 million times; unfortunately, Apple does not provide iOS download data. In addition, 16 (69.6%) apps had in-app purchases for subscriptions or courses or counseling services. Of the 19 (82.6%) English apps, 4 (21.1%) were available in other languages (Chinese, German, French, Italian, Japanese, Portuguese, Spanish, Japanese, and Korean). One of the four Chinese apps supported English and Arabic.

Table 3 shows the ratings of the apps on each platform. Most of the apps available on iOS (n=19, 95%) had a rating of 4-5, indicating good user experience in general, while 1 (5%) app had a rating of 3-4. Similarly, 2 (11.1%) of the 18 apps available on Android had a rating of 3-4, 13 (72.2%) had a rating of 4-5, while ratings were unavailable for 3 (16.7%) apps.

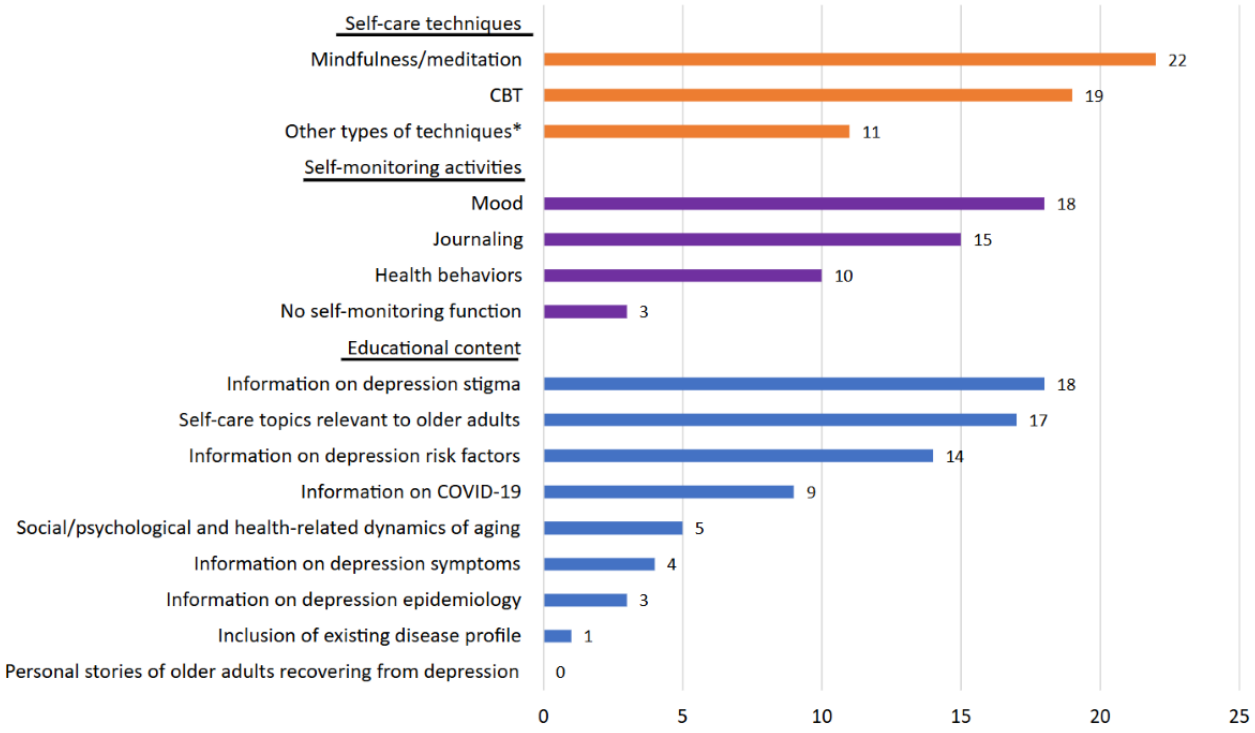
>1000	9 (45.0)	13 (72.2)
No ratings	0	3 (16.7)

Applicability of the Content of the Included Apps on Older Adults' Depression Self-Care Needs

Figure 2 presents a summary of app content related to older adults. All apps mainly targeted the general population instead of older adults. The most common self-care technique was mindfulness or meditation (n=22, 95.7%), while 19 (82.6%) apps used CBT. Other types of techniques included acceptance and commitment therapy (n=4, 17.4%), behavioral activation (n=2, 8.7%), positive psychology (n=2, 8.7%), interpersonal therapy (n=2, 8.7%), problem-solving therapy (n=1, 8.7%), music therapy (n=1, 4.3%), and dialectical behavior therapy (n=1, 4.3%). In addition, 2 (8.7%) apps offered 2 types of techniques other than mindfulness/meditation and CBT. More than half (n=17, 73.9%) of the included apps mentioned topics relevant to older adults, such as pain management, grief, loneliness, and social isolation. Most of the apps (n=20, 87%) provided self-monitoring of mood or allowed users to keep journals, while 10 (43.5%) apps asked users to track other behaviors, such as exercise, diet, sleep, and medication, in addition to mood and journaling. Each app's self-care techniques and self-monitoring activities are shown in Multimedia Appendix 2.

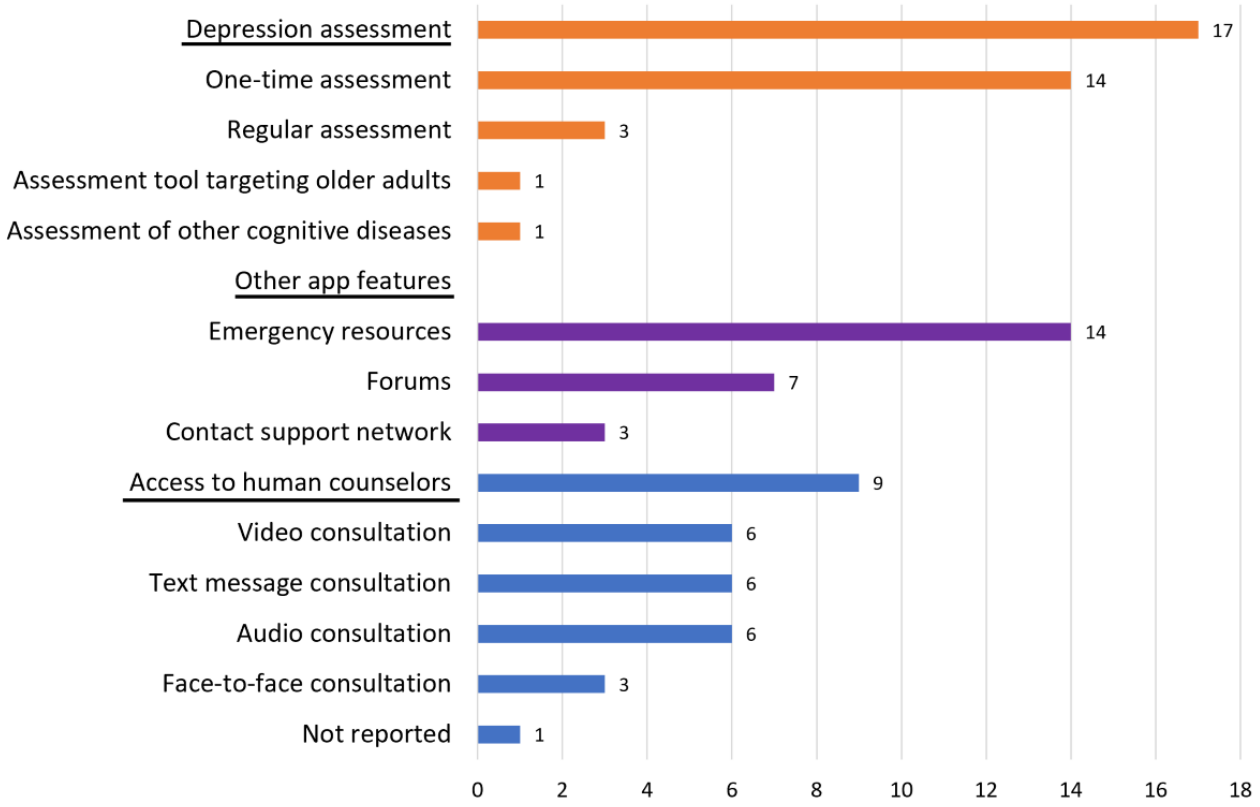
Furthermore, 3 (13%) apps described depression epidemiology in older adults, 2 (66.7%) of which provided this information in conversations with generative artificial intelligence (AI) chatbots. In addition, 14 (60.9%) of the apps reported common risk factors of depression in older adults, such as chronic diseases, loss of family members, and loneliness, and 4 (17.4%) apps described depressive symptoms in older adults. Regarding the psychosocial and health-related dynamics of aging, 5 (21.7%) apps discussed how aging impacts life. When creating a new account in 1 (4.3%) app, there was a question about what



XSL•FO
RenderX

diseases users have. More than two-thirds of the apps (n=18, 78.3%) addressed the stigma of depression by normalizing mental disorders, providing affirmations to users, and encouraging them to acknowledge and accept the illness. However, none of the apps shared a personal story of an older adult recovering from depression. Multimedia Appendix 3 shows the total score of each app on the 9 items of educational content. The mean score was 2.7 (range 1-5), indicating the scarcity of content relevant to older adults.

Figure 3 presents the main features of the included apps, such as the assessment of depression, comorbid diseases, etc. Of the 23 apps, 17 (73.9%) provided depression assessment using validated tools, such as the Patient Health Questionnaire-9 (n=7, 41.2%). One Chinese app used the Geriatric Depression Scale, an assessment scale targeted at older adults, and also provided assessment tools for dementia, cognitive impairment, and functional ability (activities of daily living). Of the 17 (73.9%) apps with depression assessment tools, 14 (82.4%) administered the assessment once, while the other 3 (17.6%) offered regular assessment.



Furthermore, 7 (30.4%) apps had forums that allowed users to communicate with each other, and 9 (39.1%) apps provided access to counselors using video or audio calls, text messages, or emails. On 3 (75%) of the 4 (17.4%) Chinese apps, users could book face-to-face appointments with a counselor. The process for accessing counselors could not be evaluated on 1 (5.3%) English app because the feature was limited to India and we were Singapore based. In addition, 3 (13%) of the 23 apps allowed users to contact or seek help from their social network directly through the apps by entering the contact details of those people, while 14 (60.9%) apps included emergency resources, such as suicide prevention helplines, and users could be redirected to these services from the apps. Multimedia Appendix 4 shows each app's main features.

Figure 2. Content related to older adults. *Other types of techniques included acceptance and commitment therapy (n=4, 17.4%), behavioral activation (n=2, 8.7%), positive psychology (n=2, 8.7%), interpersonal therapy (n=2, 8.7%), problem-solving therapy (n=1, 4.3%), music therapy (n=1, 4.3%), and dialectical behavior therapy (n=1, 4.3%). In addition, 2 (8.7%) apps offered 2 types of techniques other than mindfulness/meditation and CBT, respectively; CBT: cognitive behavioral therapy.

XSL•FO
RenderX

Figure 3. Main features of the apps included in this study.

Comparison of Chinese and English Apps Based on Content

There were similarities and differences between the 4 (17.4%) Chinese and 19 (82.6%) English apps. The similarities were the inclusion of self-care techniques (eg, CBT and mindfulness, mood tracking, and journaling functions) and the reporting of depression risk factors in older adults. All English apps targeted users with mental health needs, but 3 (75%) of the 4 (17.4%) Chinese apps also included educational content for mental health providers. Perhaps for this reason, the Chinese apps contained more information (eg, mental disorder encyclopedia) and functions (eg, cognitive function assessment) than the English apps. Although all the included apps were free to download, 12 (63.2%) English apps had a paid version, where users could access all content in the apps with monthly or yearly subscriptions, while 1 (5.3%) English app and 3 (75%) Chinese apps adopted a different commercial mode by offering specific courses or assessments addressing various mental health issues with separate purchases.

Applicability of the Technical Features of the Included Apps to Older Adults' Needs

All apps offered some degree of personalization, including addressing the user by name, recording their preferences for dark mode and haptic feedback, and providing tailored suggestions and individualized responses from AI-assisted chatbots. Of the 23 apps, 15 (65.2%) had notifications to remind users to use the apps. In addition, 21 (91.3%) apps included information about contacting customer support in the case of technical issues, questions, or suggestions. Multimedia Appendix 5 shows detailed information about these technical features of each app.

Table 4 shows the selected items of MARS and mHONcode. Detailed information about these items of each app can be found in Multimedia Appendix 6. Using MARS, both involvement and aesthetics had a mean score of 3.8 (SD 0.4) out of 5.0. The average score for information credibility was 2.9 (SD 0.5) out of 5. Furthermore, 6 (26.1%) apps were evaluated in feasibility studies [86-88] or randomized controlled trials (RCTs) [89-91] and had positive outcomes related to participants' mental health. None of the Chinese apps has yet been evaluated. However, the study participants mainly targeted the general adult population aged 18 years and above [86,87,89,91,92]. With regard to mHONcode, all but 3 (13%) apps had a privacy and confidentiality policy. Of the 20 (87%) apps with a privacy and confidentiality policy, 2 (10%) had inaccessible policies.

XSL•FO

Table 4. Selected items of MARS[a] and mHONcode[b].

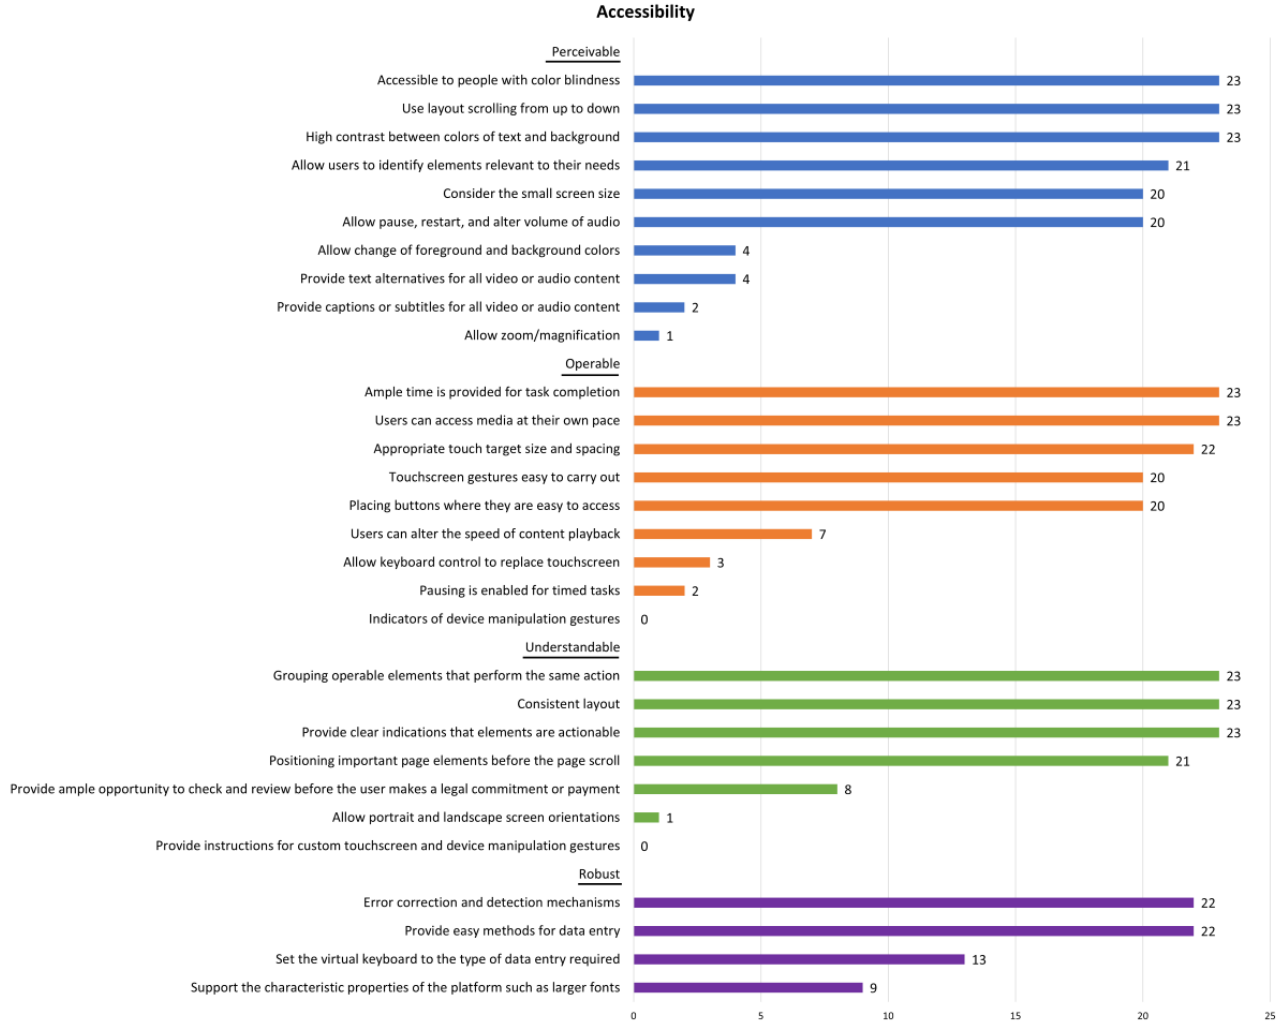
Technical features	Score (out of 5)
MARS, mean (SD)	
Engagement	3.8 (0.4)
Aesthetics	3.9 (0.6)
Information credibility	2.9 (0.5)
Evidence base of information	3.2 (1.0)
mHONcode, n (%)	
Privacy and confidentiality policy	20 (87.0)
Privacy policy accessible within the app	18 (78.3)

[a]MARS: Mobile Application Rating Scale.

[b]mHONcode: mobile Health On the Net Code.

Accessibility Features

Multimedia Appendix 7 shows each app's accessibility feature and the total score. The mean percentage of each app's score over its total score was 65.5% (range 58.6%-77.8%), suggesting moderate accessibility and areas for improvement. Figure 4 shows the accessibility of the included apps. Most of the apps (n=20, 87%) considered the smartphone's small screen size and avoided delivering too much information on 1 page. The contrast between the text and the background color was visible in all apps (n=23, 100%), and 4 (17.4%) apps allowed users to change the foreground and background colors. All apps could be viewed by scrolling from top to bottom. Users would be able to identify elements relevant to their needs, and the content was accessible to people with color blindness. However, only 1 (4.3%) app allowed zooming or magnification. Of the 20 apps with video or audio content, a small proportion (n=4, 20%) provided text alternatives, while 2 (10%) provided captions or subtitles for all video and audio content. In addition, only 1 AI chatbot, Hector, could read out responses and provided users with the option to call rather than type.



The apps were generally easy to operate (ie, with an appropriate touch target size and spacing and easy touchscreen gestures). When connected to a Bluetooth keyboard, 3 (13%) of the 23 apps could be fully controlled by the keyboard, while 20 (87%) apps were partially or totally unresponsive to keyboard commands. Most of the apps did not restrict the time for completing a task, and 2 (50%) of 4 (17.4%) apps with a timed task allowed users to pause. Users could change the content playback speed in embedded videos in 7 (30.4%) apps, including YouTube videos in 4 (57.1%) apps.

All apps had a consistent layout and easy-to-recognize actionable buttons. Most of the apps (n=21, 91.3%) showed important elements regardless of page scroll. Although none of the apps provided instructions for custom touchscreen or device manipulation gestures, 3 (13%) apps from one company (Excel At Life) included a detailed tutorial explaining the meaning of each icon. Only 1 (4.3%) app allowed both portrait and landscape screen orientations, and 8 (34.8%) apps provided ample opportunity for users to check the terms and conditions and review them before making a payment.

Data entry on the apps was easy, supported by the error correction feature of the system's default keyboard, and 13 (56.5%) apps provided user-friendly data entry methods by adjusting the keyboard according to the type of data. For example, a keyboard with "@" and ".com" was provided for entering email addresses. Lastly, although the phone's operating system allows for fonts to be adjusted, only 9 (39.1%) apps supported this feature, with an additional app having adjustable font sizes within itself.

Figure 4. Accessibility of the apps included in this study.

Discussion

Principal Findings

This systematic assessment of mental health apps is the first to have evaluated the applicability of existing mental health apps for depression self-care in older adults. We identified a total of 23 apps on Chinese and English app markets, but none of them specifically targets older adults with depression. A few apps provide information about depression specific to older adults or incorporated assessment tools for cognitive disorders or functional capacity. The level of accessibility, such as adaptations for users with visual or hearing impairments and adjustable font sizes, remains low, potentially limiting older adults' use of the apps.

There is a lack of mental health apps to assist depression self-care in older adults. This gap in the current app market is somewhat at odds with other health care areas, as there are mobile health apps with medication reminders, apps for chronic disease management, apps promoting physical activity, and apps providing cognitive training activities [93]. Research has shown that a lack of consideration for older adults' needs may reduce their perceived relevance and motivation to use such mobile apps [33]. However, a systematic review in 2023 showed that chatbots were promising in improving older adults' depression and insomnia symptoms [94]. Although the use of generative AI chatbots in health care is still at an early stage, and its safety remains untested [95], the development of specific content for older adults must not be neglected.

We found fewer interactive Chinese depression self-care apps than English apps. Two recent systematic assessments of mental health apps in China identified 67 apps [76] and 172 apps [96]. These apps connected users with health care providers or provided noninteractive mental health education, but they frequently lacked self-care techniques [96] and thus were excluded from our study. Furthermore, despite the management of severe mental disorders being included in basic public health services in China, there are persisting challenges due to the lack of psychiatric professionals [97] and the traditional stigma associated with mental disorders [98]. Therefore, more interactive Chinese applications with self-care techniques are needed to support Chinese older adults' mental health care demands.

We documented potential accessibility issues for older adults in the apps identified. According to qualitative studies on older adults' experience with digital mental health interventions, the lack of detailed instructions is a barrier to their use [78,83]. Older adults have less experience with digital technology and are, at times, anxious about how to use it [99]. Therefore, clear

XSL•FO
RenderX

instructions and guidance on how to use mobile apps are essential for many older adults, but we found only 3 of the 23 apps included a detailed tutorial for app navigation, suggesting a widespread lack of consideration for users with less technology literacy. Worldwide, around 1 in 10 adults over 50 years had a visual impairment in 2019 [100]. Hearing loss is also common in older adults, affecting over 50% of older males and 30% of older females aged 65 years and above [99]. Therefore, digital health interventions need to cater to their needs. We found that few apps with video or audio content provide text substitutes or captions or offer adjustable font sizes or are compatible with the accessibility features of larger text in the phone settings.

Around 30% of the depression self-care apps had an online forum, which may help reduce loneliness and increase social connections. A recent editorial highlighted the impact of loneliness and social isolation on adverse mental health outcomes, such as depression and anxiety [101]. Due to physical impairments, older adults are at a higher risk of loneliness and social isolation [102]. Online communities or forums could bring people with similar interests or circumstances together and provide them with a convenient opportunity to communicate from the comfort of their homes. A scoping review in 2022 found that online social networking improves older adults' mental health and well-being by enhancing communication with their existing social network, increasing life satisfaction, and reducing depressive symptoms [103]. These communities may address the absence of interpersonal interactions in digital interventions by allowing older adults to provide each other emotional support, such as affirmation and encouragement, and technical advice to use developing technology [103-105].

Strengths and Limitations

We used a consistent and reliable approach to app identification and assessment. We performed the search in Apple's App Store, Google Play, and various Chinese Android app markets and adopted an AI screening tool that helped increase the efficiency by screening one-third of the names and descriptions of apps. The AI tool's ability to retrieve 95% of the eligible records by screening 8%-33% of the total records was validated in simulation studies [49]. To capture all eligible apps, we further supplemented the search using Google and Baidu search engines. Two reviewers independently performed an in-depth assessment of apps by downloading and testing them on research phones. Second, there was no validated scale for the assessment of mobile apps for depression self-care in older adults. We developed an assessment rubric by synthesizing evidence from the extensive literature, including established clinical practice guidelines, systematic reviews, scoping reviews, academic books, and widely used guidelines or checklists of technical features.

However, this study also has some limitations. First, older adults with lived experience were not involved in the assessment, which calls for public and patient involvement in future studies targeting older adults. Another potential weakness is the exclusion of apps focused on well-being without explicitly addressing depression: we acknowledge that they might still be useful for older adults with mental disorders. However, the provision of information about depression is perhaps superior as it helps older adults gain awareness and knowledge [34] and reduces mental health stigma [106]. Third, we did not include apps in other languages due to the limited capacity of research manpower and resources.

The study has limited implications for clinical application in older adults because we did not identify any existing apps with high applicability to older adults. However, there are many implications for app developers and researchers in the field of digital mental health. As some older adults were skeptical of the credibility of apps [84], it is crucial for apps to clearly demonstrate their validity, reliability, and accuracy of information to enhance older adults' trust. Three of the apps reviewed were clearly evaluated in the form of an RCT [89-91], and others may have been, but there was no mention of authors and sources, weakening the trust, real or perceived, in the evidence base of the existing apps. Although apps cannot replace clinical diagnosis and treatment, and users need to seek professional advice when necessary, self-care apps may still serve as an interim solution for older adults when they are waiting for clinical appointments [107], thereby providing them with early access to mental health resources and promoting their mental health. Future studies should aim to evaluate the clinical effectiveness of apps and their potential to lessen the strain on health care professionals.

Conclusion

Although there are many depression self-care apps available in English and Chinese markets, our study suggests that they have limited applicability to older adults. The apps integrating generative AI chatbots have higher applicability because of tailored feedback and the provision of a text-to-speech option. In the future, new and updated depression self-care apps should consider incorporating content relevant to older adults, including online communities to reduce their social isolation, and improving accessibility for older adults with physical and sensory impairments.

Acknowledgments

We would like to thank Ms Lin Xiaowen for helping with screening Chinese iOS apps.

This study received funding from the Singapore Ministry of Education (MOE) Tier 1 Grant RT05/21. The funder played no role in the design or conduct of the study.

Abstract

Background: In addition to standard older adult care services, mobile medical devices have proved to be an effective tool for controlling the health of older adults. However, little is known about the variables driving the acceptance of these gadgets and the willingness of older adults in China to use them.

Objective: This study aims to explore the factors that affect the use of mobile health (mHealth) devices by older adults in China, focusing on individual, social, and family influences.

Methods: The Psychology and Behavior Investigation of Chinese Residents survey database provided the data for this study. The survey was conducted in 148 Chinese cities between June 20 and August 31, 2022. The parameters linked to older persons' desire to use mobile medical devices were determined by this study using a combination model of multiple stepwise linear regression and a classification and regression tree decision tree.

Results: In total, 4085 older adults took part in the poll. On a scale of 0 to 100, the average score for willingness to adopt mHealth devices was 63.70 (SD 25.11). The results of the multiple stepwise linear regression showed that having a postgraduate degree and higher (β=.040; *P*=.007), being unemployed (β=.037; *P*=.02), having a high social status (β=.085; *P*<.001), possessing high health literacy (β=.089; *P*<.001), demonstrating high self-efficacy (β=.043; *P*=.02), not living with children (β=.0340; *P*=.02), having a household per capita monthly income of >Y4000 (US $550) (β=.048; *P*=.002), experiencing high perceived social support (β=.096; *P*<.001), reporting a high quality of life (β=.149; *P*<.001), having higher levels of family communication (β=–.071; *P*<.001), having an identity bubble (β=.085; *P*<.001), not having chronic diseases (β=.049; *P*=.001), and experiencing mild depression (β=–.035; *P*=.02) were associated with older adults' willingness to use mHealth devices. The classification and regression tree decision tree model's findings demonstrated that the primary determinants of older adults' desire to use mHealth devices are quality of life, identity bubble, social status, health literacy, family health, and perceived social support.

Conclusions: This study uses the Andersen Healthcare Utilization Model to investigate the effects of demand variables, enabling resources, and predisposing traits on older persons' propensity to use mHealth devices. These results offer reference data for the marketing and use of mHealth devices for older individuals in the future. The ultimate goal of this strategy is to create a balanced and harmonious integration of technology and humanistic care.

Introduction

Background

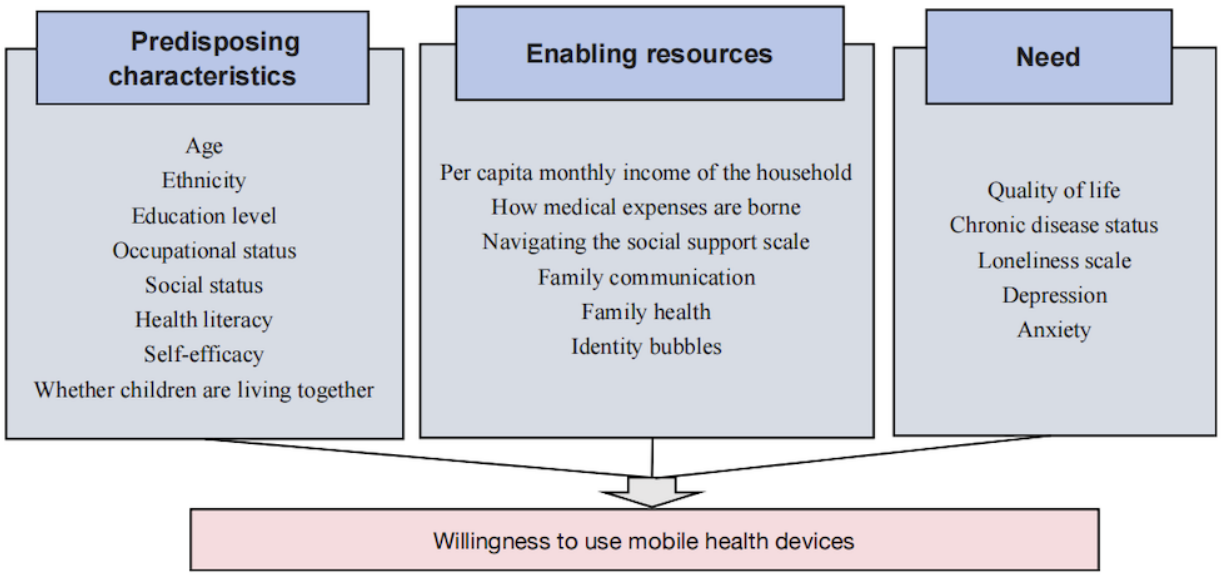
In the context of the rapidly advancing global demographic shift toward aging and the exponential growth of mobile health (mHealth) technology, mHealth devices have emerged as pivotal instruments for augmenting the quality of life of older adults, fostering proactive health self-management, and mitigating the effects of aging. As the nation harbors the world's largest older adult population, China confronts the imperative of effectively harnessing mHealth technology to cater to the extensive needs of its aging populace. According to statistics from the National Bureau of Statistics of China from December 2023 [1], China was home to 296.97 million individuals aged ≥60 years, constituting 21.1% of the national population, with 216.76 million of these being aged ≥65 years, representing 15.4%. This pervasive aging trend is concurrent with a surge in the incidence of chronic diseases [2], as more than two-thirds of Chinese older adults aged ≥65 years contend with multiple comorbidities. However, in 2022, China recorded a physician-to-population ratio of 3.15 practicing (assistant) physicians per 1000 individuals, alongside a ratio of 3.71 registered nurses per 1000 population—figures that, while placing the country in the middle tier internationally [3], nonetheless present a formidable challenge to the effective management of chronic conditions and the provision of comprehensive public health services. These circumstances significantly strain the nation's capacity to manage chronic illnesses and deliver robust public health services.

The World Health Organization's Draft Global Strategy on digital health 2020 to 2025 underscores the strategic importance of digital health within global health care systems. The Chinese government actively promotes an "internet+medical service" development model, vigorously driving forward initiatives for intelligent health and older adult care services. The clinical practice of the 2023 hypertension guidelines update has been released, for the first time incorporating wearable devices into its recommendations, presenting them as a novel modality for blood pressure measurement, working in conjunction with traditional methods, such as home blood pressure monitoring, to fortify the health defense against hypertension. mHealth, as a novel paradigm facilitating the exchange and management of health care information via mobile devices, assumes a crucial role in health management, demonstrating immense potential in domains such as chronic disease management, fall prevention [4], activity monitoring [5], and individual health behavior tracking [6]. It offers personalized and precision health care services [7], enabling the creation of individualized health profiles through integration with hospital systems. In turn, it assists in alleviating issues related to the unequal distribution of medical resources and health care services [8]. An example is the HUAWEI Watch D, which, having secured class II medical device registration certification from national authorities and undergone international standard validations, garners endorsement.

Moreover, against the backdrop of increasing empty-nest syndrome among the older adult population and the integration of medical and older adult care services in China, mHealth devices can be synergistically combined with health care services to enhance the quality and efficiency of older adult care provision. Data from the 2022 National Report on the development of national undertakings for the older adults by the National Bureau of Statistics of China reveal that, as of the end of 2022, China boasted 387,000 older adult care institutions and facilities nationwide, housing 8.294 million beds dedicated to older adult care services. Even with a conservative estimate adhering to the national standard ratio of 1 caregiver per 4 older adults, there is a pressing need for at least 2.075 million caregivers. However, the current workforce comprises only approximately 300,000 caregivers, leaving a substantial shortfall [9]. mHealth devices can, to a certain extent, mitigate this shortage of personnel. For instance, Apple's iOS 16 and watchOS 9 now come bundled with a medication reminder app within their native "Health" software, assisting older adults with medication adherence. In Beijing's Xicheng district, authorities have installed smart caregiving mattresses in older adult homes, continuously monitoring vital signs, such as heart rate and respiratory patterns, as well as bed entry and exit times, thereby augmenting care provision without direct human intervention.

In the field of commercial layout, the market size of smart wearable devices is expanding and will still maintain rapid growth in the next few years. International Data Corporation's latest quarterly tracking report on China's wearable devices market shows that China's wearable devices market shipped 34.7 million units in the third quarter of 2023, a year-on-year increase of 7.5%, and the overall market continues to grow. International Data Corporation expects that in 2024, the number of adult smartwatches will increase by 11%, driven by diversified product offerings [10].

Despite the multitude of benefits associated with mHealth, several critical challenges persist in its practical implementation. Previous studies have examined the willingness of the general Chinese population to use mHealth devices [11]; however, given the differences in digital divide, health literacy, technology acceptance, social support network, and concept of life among the older adults, the application of mHealth devices in the older adults has not reached an ideal state. Particularly in China, studies have shown that the older adults and the groups that are chronically ill, who are the potential main users, are not very receptive to mHealth services [8]. Furthermore, concerns over data security and accuracy [12], affordability of devices and associated services, equitable access [13], insufficient age-appropriateness of the products, anxiety induced by data-driven insights, and marginalization of certain functionalities, such as fall detection, all contribute to a less-than-ideal adoption scenario. Therefore, the willingness of the older adult population to use mHealth devices remains a larger issue.



XSL•FO
RenderX

In summary, while mHealth devices are being developed for a wider range of functions and see significant growth on the supply side, demand-side research primarily focuses on factors influencing the willingness to use these devices. These factors include perceived usefulness, product innovation, privacy protection, self-efficacy, self-perceived aging, and health awareness among users [14-17], and there is a significant lack of a large-scale sample of the older adult population. Therefore, in this dissertation, a large-scale cross-sectional survey was conducted nationwide with the aim of revealing the current status of Chinese older adults' willingness to use mHealth devices and the key influencing factors behind it. This is of great significance for the global understanding of the characteristics of the acceptance of new technologies among the older adult population, enhancing the effectiveness of digital health interventions and promoting the development of the smart aging industry, as well as providing a valuable empirical basis for international health equity and policy making for an aging society.

Theories and Hypotheses

The Anderson Behavioral Model of Health Services Use is the model of choice in the field of health services to explain and predict health care behaviors as well as to analyze the factors influencing health services use behaviors of different households. The model identifies predisposing characteristics, enabling resources, and need as key factors affecting the use of health services [18]. This contributes to the systematic analysis of factors influencing individual health service use behavior and the evaluation of the accessibility of health service use [19]. From the viewpoint of the population to which the study applies, the Anderson model is applicable to the study of the health care service use behavior of the general population as well as the study of the health care service use behavior of special populations, such as older adults, women, low-income earners, children, and people with the HIV infection. In terms of the scope of application, the model is applicable to the study of the entire process of individual health service use behavior, including the study of factors influencing the choice of individual health care modality, medical costs, disease screening, drug use, and so on [20,21]. This study views mHealth device use as a form of health service delivery and therefore uses the Anderson Health Service Utilization Model to explore the impact of different factors on mHealth device use. The specific model is shown in Figure 1.

Figure 1. A model of factors influencing the willingness of older adults to use mobile health devices.

On the basis of this hypothesis, the following propositions are made, informed by theory and existing research:

- Hypothesis 1: older adults will be more likely to be willing to use mHealth devices than non–older adults.
- Hypothesis 2: older adults' willingness to use mobile devices is positive overall.

Methods

Participants

The data for this study came from the Psychology and Behavior Investigation of Chinese Residents database. This study was carried out across an extensive geographical expanse within China, encompassing 148 cities; 202 districts; 390 townships, towns, and streets; as well as 780 communities and villages, between June 20 and August 31, 2022. The sampling strategy used for this survey was multistage, meticulously informed by quota attributes derived from China's seventh national census data at the city level. These attributes included sex, age, and urban-rural distribution, ensuring a representative and stratified selection of participants. The detailed application of the quota method has been thoroughly documented in a preceding investigation by Wang et al [22]. This study was registered in the China Clinical Trial Registry (ChiCTR2200061046).

The study used the web-based Questionnaire Star platform for questionnaire distribution. Participants were eligible if they

XSL•FO
RenderX

were Chinese nationals aged ≥12 years, voluntarily participating, comprehending each questionnaire item, and completing the questionnaire independently. For those with limited mobility but intact cognitive function, investigators conducted one-on-one interviews, offering necessary assistance without influencing responses, thereby ensuring inclusivity and data integrity.

Ethical Considerations

This study was approved by the Ethics Research Committee of the Health Culture Research Center of Shaanxi (JKWH-2022-02). Informed consent was obtained from all participants. All data were collected anonymously and kept confidential. Participants did not receive any material or monetary rewards for participation. We ensure that all the images in the written materials published by this study do not contain the identity information of individual participants.

Self-Administered Questionnaires

The self-administered portion of the questionnaire investigated the demographic characteristics of the participants. The demographic characteristics included sex (male and female), age (60-74 years and ≥75 years), income (≤Y 4000 and ≥Y 4000 [US $550]), place of residence (eastern region, central region, and western region), education level (senior high school and below, junior college and bachelor degree, and postgraduate degree and above), occupational status (employed, retired, and unemployed: unemployed, jobless, and no regular occupation), and health care cost-bearing method (purely health insurance, purely commercial insurance, mixed insurance, and no health insurance), and chronic disease status (no chronic disease and chronic disease). The dependent variable measured was willingness to use mHealth devices (rated on a scale from a score of 0=not accepted to 100=very accepted).

Standard Scale

Health Literacy Questionnaire

In 2013, Sørensen et al [23] developed the 47-item European Health Literacy Survey Questionnaire, and in 2019, Duong et al [24] simplified the European Health Literacy Survey Questionnaire, creating a 12-item scale known as the Health Literacy Scale–short form (HLS-SF; HLS-SF12), designed to assess public health literacy in Asian countries. In 2023, Sun et al [25] sinicized HLS-SF12 using translation, reverse translation, and cultural debugging procedures. In 2023, Sun et al [26] applied the Mokken model in item response theory, classical test theory, to simplify HLS-SF12 (simplified to HLS-SF9). In this study, namely, the HLS-SF9 was used to measure the respondents' health literacy. The scale consists of 3 dimensions—health care, disease prevention, and health promotion—with 9 entries, each of which is rated on a 4-point scale (1=very difficult, 2=difficult, 3=easy, and 4=very easy), and the standardized health literacy index (ie, the total score of the scale) was calculated using a formula, which ranges from 0 to 50, with the higher the index representing the higher level of health literacy. The formula was calculated as index = (mean – 1) × (50/3), where mean is the average of the scores of all the entries for each individual, 1 is the smallest possible value of the mean (at which point the minimum value of the index is 0), 3 is the range of the mean, and 50 is the maximum value of the index. The higher the index, the higher the level of health literacy of the respondent. The Cronbach α coefficient of the scale was 0.923.

The New General Self-Efficacy Scale

The New General Self-Efficacy Scale (NGSES) was developed by Chen et al [27] on the basis of the General Self-Efficacy Scale, developed in 2001. The members of the project team of the "2022 Survey of Psychology and Behavior of the Chinese Population" applied the Mokken model of item response theory and classical test theory to simplify the NGSES-8, reducing the original 8 items to 3 items, and forming a new general self-efficacy scale. The NGSES-8 was simplified from the original 8 items to 3 items to form the NGSES (Wu et al [28]). In this study, respondents' self-efficacy was measured by the NGSES-3, which contains 3 entries on a 5-point Likert scale (1=strongly disagree and 5=strongly agree; the total scale score is the sum of the 3 entries, and the range of scale scores is from 3 to 15, with higher scores indicating higher levels of self-efficacy among respondents). It includes 3 entries on whether they can accomplish difficult tasks, whether they can successfully overcome many challenges, and whether they have the confidence to accomplish many different tasks effectively. The Cronbach α coefficient of the scale was 0.912.

The Perceived Social Support Scale

The Perceived Social Support Scale (PSSS) is used to assess participants' perceptions of social support (Li et al [29]). The PSSS consisted of 3 parsimonious items in this study, assessing perceived emotional support from friends, family, and significant others. It has been validated to be well correlated with the original items' scale, and the factor structure, reliability, and validity have also been well established (Wu et al [28]). Each item is scored on a 7-point scale of 1 to 7 (1="strongly disagree" and 7="strongly agree"). The summed scores on the PSSS range from 3 to 21 points, with higher scores representing greater perceived social support. The Cronbach α coefficient of the scale was 0.902.

The Family Communication Scale

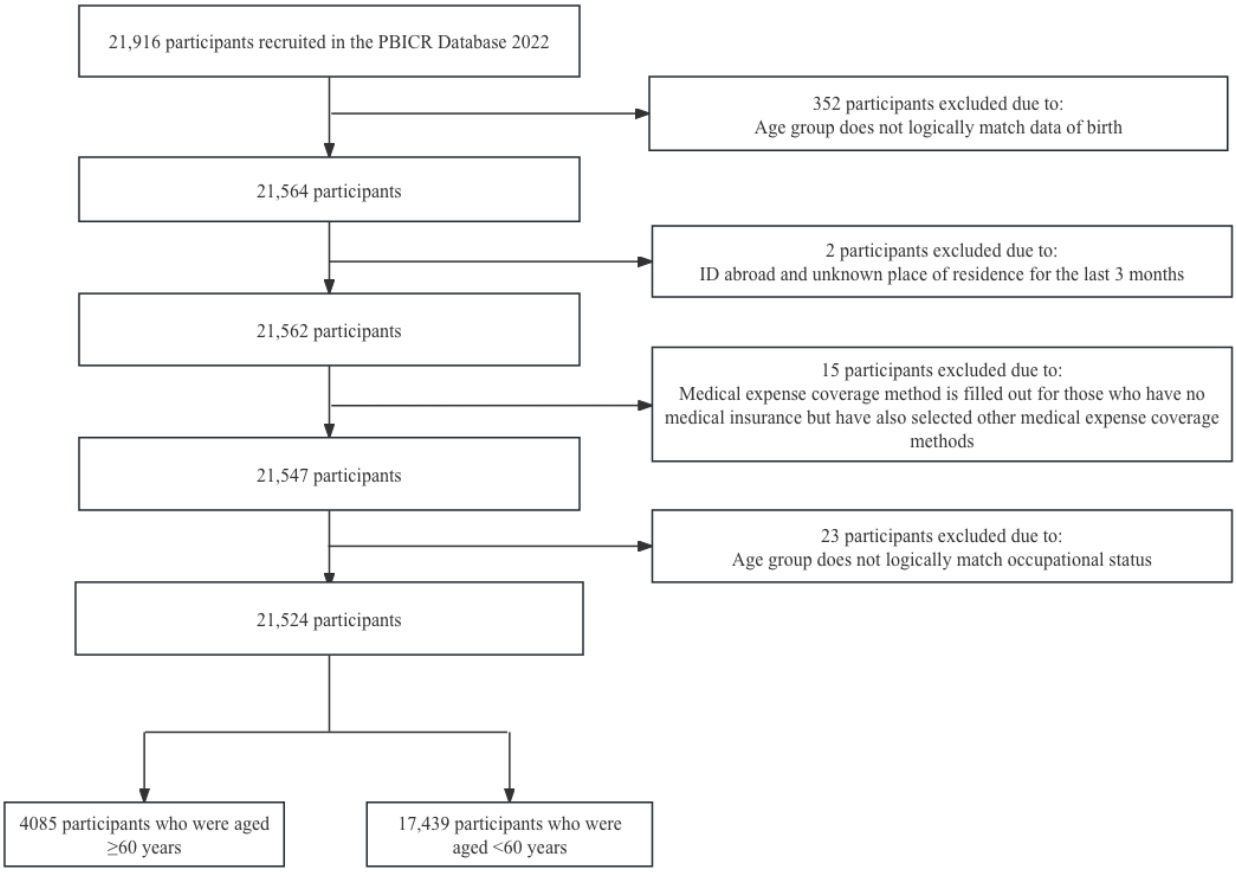
The Family Communication Scale-10 (FCS-10) was used to evaluate the respondents' family communication. The scale was developed by Olson and Barnes and was sinicized by Guo N et al (Kwon et al [30] and Guo et al [31]). The FCS-10 consists of 10 entries on a 5-point Likert scale (1=strongly disagree and 5=strongly agree; the total scale score is the sum of the 10 entries, and the scale score ranges from 10 to 50, with higher scores indicating that the respondent's family communication is better). The purpose of the scale is to measure the quality of communication among family members with regard to the exchange of ideas, information, level of concern, openness, confidence, and emotions among family members. The Cronbach α coefficient of the scale was 0.957.

The Health Effect Values Visual Analog Score

The Health Effect Values Visual Analog Score (EQ-5D-VAS) is part of the European Five-Dimensional Health Scale. In this study, respondents rated the goodness of their health using the EQ-5D-VAS. The scale is a numerical range from 0 to 100, where 100 represents the respondent's perceived best possible

XSL•FO
RenderX

health condition and 0 represents the worst. Respondents are asked to indicate their self-assessed health status by selecting a whole number between 0 and 100.



The Identity Bubble Reinforcement Scale

The Identity Bubble Reinforcement Scale focuses on the social and information homogenization tendency brought about by identity-driven social media use from a psychosocial point of view. It is mainly used to measure the tendency of social media users to get involved in identity-driven online bubbles (bubble refers to homogenized information environments) and to emphasize the impact of identity-driven social activities on individual behavior within social media. The scale consists of 9 entries divided into 3 dimensions—social identity (3 entries), homogenization (3 entries), and information bias (3 entries)—and is based on a 10-point scale ranging from 1 (not at all like me) to 10 (not at all like me), with higher scores representing a more significant tendency to homogenize an individual's identity-driven social media activities (Kaakinen et al [32]). The Cronbach α coefficient of the scale was 0.948.

Data Exclusion

The specific data selection process is shown in Figure 2. The total sample size of the Psychology and Behavior Investigation of Chinese Residents database in 2022 was 21,916, of which 2 participants' ID abroad and unknown place of residence for the last 3 months, and 390 participants filled in information that was illogical. Thus, 392 participants were excluded, and 21,524 participants were retained. Among these 21,524 participants, 17,439 (81.02%) were aged <60 years and 4085 (18.97%) were aged ≥60 years.

Figure 2. Flowchart of sample selection of older adults' willingness to use mobile health devices. PBICR: Psychology and Behavior Investigation of Chinese Residents.

Statistical Analysis

Data analysis was conducted using SPSS (version 26.0; IBM Corp) and RStudio (RStudio, Inc), and all comparisons were 2-tailed, with *P* values <.05 considered statistically significant. The basic information of participants, along with their scores on the quality of life scale, family communication scale, health literacy scale, and willingness to use mHealth devices, were first analyzed descriptively. This was followed by univariate analysis of each potential explanatory variable: binary independent variables were analyzed using a 2-tailed *t* test, multicategorical independent variables with an *F* test, and continuous independent variables with correlation analysis. On the basis of these results, a model combining multiple stepwise linear regression and classification and regression tree (CART) decision tree models was developed to explore the factors influencing older adults' willingness to use mHealth devices.

Results

Characteristics of the Participants

A total of 21,916 samples were collected in this study, and 392 (1.78%) sets of abnormal data were excluded by logical

XSL•FO
RenderX

checking, while 21,524 (98.21%) sets of valid data were retained. The overall sample consisted of 18.98% (n=4085) older adult respondents (aged ≥60 years) and 81.02% (n=17,439) non–older adult respondents (aged <60 years). The mean score of all respondents' willingness to use mHealth devices was 68.14 (SD 25.30), with non–older adult respondents (69.18, SD 25.23) having a higher mean score of willingness to use mHealth devices than older adult respondents (63.70, SD 25.11).

There were 49.91% (n=2039) male participants and 90.8% (n=3709) Han Chinese in the sample of 4085 older adults, with a preponderance of younger older adults aged <75 years and >60 years (n=3383, 82.82%); most respondents' per capita monthly income of the household were ≤Y 4000 (US $550; n=2560, 62.67%); most respondents had a senior high school and below education (n=3523, 86.24%); 55.25% (n=2257) of the respondents are retired; 41.42% (n=1692) of the respondents are unemployed; and only 3.33% (n=136) of the respondents are still employed. Some (n=1471, 36.01%) respondents have lived in the eastern region for the last 3 months, 47.69% (n=1948) of the respondents have lived in the western region for the last 3 months, and 16.3% (n=666) of the respondents have lived in the central region for the last 3 months.

Each Scale Score of Participants

In total, 4085 respondents had a mean score of 69.86 (SD 18.55) for quality of life (EuroQol Visual Analog Scale), 29.74 (SD 9.85) for health literacy (HLS-SF9 scale), 35.40 (SD 12.05) for identity bubble (Identity Bubble Reinforcement Scale), 14.79 (SD 3.63) for perceived social support (PSSS), 10.51 (SD 2.42) for self-efficacy (NGSES), 4.44 (SD 1.54) for loneliness (T-ILS scale), and 36.92 (SD 7.63) for family communication (FCS-10 scale).

Willingness to Use mHealth Devices Among Chinese Older Adults

The mean score of the older adult population's willingness to use mHealth devices in this study was 63.70 (SD 25.11; median 65.00). To explore the distribution of older adult populations' willingness to use mHealth devices, the continuous variable of willingness to use mHealth devices was divided into 10 groups (0-10, 11-20, ... 91-100), and the number of respondents in each willingness to use subgroup was counted and presented in the form of a frequency distribution histogram. The specific results are shown in Multimedia Appendix 1.

As shown in Multimedia Appendix 1, older adults' willingness to use mHealth devices is roughly based on a clear dividing line of 40 points, with 17.36% (n=709) of the 4085 older adults having a willingness to use mHealth devices with scores <40 and 82.64% (n=3376) of older adults having a willingness to use mHealth devices with scores >40, with the largest number of older adults (n=664, 16.25%) having a willingness to use mHealth devices located in the range of 91 to 100. Subsequently, we observed 3 specific attitudinal older adult populations with respect to their willingness to use mHealth devices, namely, the strong nonwillingness to use mHealth devices population (scored 0) and the strong willingness to use mHealth devices population (scored 100). Some (n=51, 1.25%) older adults had no willingness to use mHealth devices at all, and 11.43% (n=467) of the older adults had a strong willingness to use mHealth devices.

Univariate Analysis of the Willingness of Older Adult Population to Use mHealth Devices

Because the dependent variable in this study is a continuous variable, a *t* test was used for binary independent variables, an *F* test was used for multicategorical independent variables, and correlation analysis was used for continuous independent variables. Most of the study variables were associated with willingness to use mHealth devices ($P<.001$; Table 1).

What Are the Factors Influencing the Willingness to Use mHealth Devices Among Chinese Older Adults?

Factors Influencing the Willingness to Use mHealth Devices Among Chinese Older Adults Based on Multiple Stepwise Linear Regression

This study used multiple stepwise linear regression to explore the factors affecting the willingness of older adults to use mHealth devices, and the specific results of multiple stepwise linear regression are shown in Table 2. The 13 main factors influencing older adults' willingness to use mHealth devices were education level, occupational status, social status, health literacy, self-efficacy, whether children were living together, per capita monthly income of the household, perceived social support, quality of life, family communication, identity bubbles, chronic disease conditions, and depression. In terms of predisposing characteristics, older adults who lived with their children (P=.02; β=.034), had high health literacy (P<.001; β=.089), had high self-efficacy (P=.02; β=.043), had high social status (P<.001; β=.085), were unemployed (P=.02; β=.037), and had the highest education level of postgraduate degree and above (P=.007; β=.040) were willing to use mHealth devices. In terms of enabling resources, older adults with a household per capita monthly income of ≥Y 4000 (P=.002; β=.048), a high quality of life (P<.001; β=.149), high perceived social support (P<.001; β=.096), and a lower family communication level (P<.001; β=–.071) were more willing to use mHealth devices. In terms of need, older adults who did not have a chronic disease (P=.001; β=.049) and had mild depression (P=.007; β=.040) were less willing to use mHealth devices.

Table 2. Multiple stepwise linear regression results of the older adults' willingness to use mobile health devices.

Factors Influencing the Willingness to Use mHealth Devices Among Chinese Older Adults Based on CART Decision Tree Model

Multiple stepwise linear regression can explore the main influencing factors of the use of mHealth devices for the older adults, but it is not possible to intuitively understand the relative importance of the influencing factors and the interaction between the influencing factors; therefore, this study uses the CART decision tree model to visualize the influencing factors (with a training set:test set ratio of 70%:30%) to explore the interaction between the influencing factors. The specific results are shown in Figure 3. Figure 3 shows that quality of life is the most important factor influencing the willingness to use mHealth devices among older adults, and the willingness to use mHealth devices among older adults with high quality of life (73 points) is significantly higher than that of older adults with low quality of life (60 points). For the older adult group with low quality of life, identity bubbles is the main influencing factor on their willingness to use mHealth devices. When the identity bubbles score is ≥43, the mean value of the older adults' willingness to use mHealth devices is 68 points, and when the identity bubbles score is <43, the mean value of the older adults' willingness to use mHealth devices is 58 points. And then if the identity bubbles score is <27, the mean value of willingness to use mHealth devices for such older adults is 51 points, and if the identity bubbles score is ≥27, family health becomes the main factor influencing older adults' willingness to use mHealth devices, with the mean value of willingness to use mHealth devices for the older adults with moderate family health being 54 points and the mean value of willingness to use mHealth devices for the older adults with poor family health or excellent family health being 62 points. For older adults with high quality of life, social status is the main factor influencing older adults' willingness to use mHealth devices, with the mean value of mHealth devices for older adults with high social status being 81 points, while older adults with medium and low social status need to further judge their health literacy, with the mean value of mHealth devices for older adults with low health literacy being 63 points, and older adults with high health literacy needed to be further judged in terms of their sense of perceived social support, with older adults with high perceived social support (79 points) having a significantly higher willingness to use mHealth devices than older adults with low perceived social support (65 points). This shows that older adults with high quality of life and high social status have the highest willingness to use mHealth devices (81 points), while older adults with low quality of life and low status bubbles (<27 points) have the lowest willingness to use mHealth devices (51 points).

Figure 3. Classification and regression tree (CART) decision tree results of older adults' mobile health device use willingness.

RenderX

Discussion

Overview

This study found that Chinese older adults have positive attitudes toward using mHealth devices, with significant positive effects of education, quality of life, self-efficacy, and health literacy on the use of mHealth devices at the individual level; a positive effect of perceived family social status at the social level; and a negative effect of family communication on their willingness to use the devices. Social-level perceived social support and identity bubble had a significant positive effect on using mHealth devices.

Principal Findings

The study finds that the gap in willingness to use mHealth devices between older adults and non–older adults is relatively small. The average willingness score for older adults is 63.70, compared to 69.18 for non–older adult respondents. This differs from the conclusions of existing studies, which indicate that older adults have a significantly lower proportion of using electronic health devices to access information compared to non–older adult groups [33,34]. A Canadian-based study also showed significant differences in the use of smart devices between older and younger adults, with nearly half of them using smartphones but not downloading health-related apps [35]. This may be partly because older adults have greater health needs [36]. Meanwhile, it may also be attributed to the fact that today's digital technologies have increasingly prioritized age-friendly design, making older adult–friendly devices more accessible and ensuring that older adults are no longer left on the periphery of digitalization [37]. Studies have shown that, most of the time, older and younger adults share similar preferences for using electronic health devices. When the devices are impractical or lack inclusive design, people across different groups tend to reduce their use [38].

In terms of research methodology, this study uses a combined model of logistic regression and decision tree analysis to comprehensively and rigorously examine the factors influencing older adults' willingness to use mHealth devices. Both methods identify key determinants, such as quality of life, identity bubble, perceived social support, self-efficacy, family communication, per capita monthly household income, and health literacy. The logistic regression model further highlights additional demographic factors, including region of residence, education level, and chronic disease status. In contrast, the decision tree model emphasizes the stronger impact of subjective psychological factors.

Factors Influencing Older Adults' Willingness to Use Health Devices

This study focuses extensively on the adaptability of the older adult population in the context of digital health and smart health care. Using older adults' use of mHealth devices as a starting point, it explores their willingness to use such devices and the influencing factors. Using a comprehensive systematic framework of predisposing characteristics, enabling resources, and needs, this study conducts a thorough analysis of variables and fits the data using binary logistic regression. The findings indicate that educational level, perceived family social status, perceived social support, self-efficacy, quality of life, health literacy, identity bubble, and intrafamily communication significantly influence the older adults' willingness to use mHealth devices. This not only validates the Behavioral Model of Health Services Use in explaining the use of health care services among the older adults but also demonstrates its applicability in the digital age.

In terms of predisposing factors, this study reveals that perceived family social status, educational level, and health literacy are positively correlated with older adults' willingness to use mHealth devices. This conclusion complements existing research, which often focuses on the relationship between objective social class and status and the use of digital devices. For example, some studies suggest that individuals with higher social class are better equipped to use digital devices in the field of education [39]. However, there has been relatively little research on the relationship between subjective class perception and the use of digital devices. This study creatively establishes a link between the 2 and focuses specifically on the health domain. In terms of health literacy, research shows that the application of digital health technologies is highly correlated with users' health literacy [40]. In terms of education and health literacy, this study aligns with the conclusions of existing research. Research showed that digital health education can enhance people's understanding of diseases and is more effective than traditional education methods in improving overall health [41]. Therefore, older adults who have received digital health education and possess higher health literacy are more motivated to use digital health devices.

This finding can be elucidated through the lens of the digital divide. Concerning perceived family social status, on one hand, the formation of the digital divide often relates to the objective social strata within families, encompassing dimensions such as income [42] and sociocultural factors. Individuals with higher incomes are more likely to have greater access to the internet and IT [43]. Moreover, formal and informal rules regarding inequality within social cultures also influence the digital divide experienced by different groups [44]. On the other hand, as a subjective variable, perceived social class is influenced by objective social strata and often correlates more closely with individuals' life and psychological states [45]. Therefore, individuals who perceive themselves as belonging to a higher social class often possess the capability to access digital devices, use digital technologies effectively and reasonably, and fulfill their personal needs through these technologies. They also exhibit higher levels of acceptance and inclusiveness toward digital technologies, resulting in a greater willingness to use mHealth devices. It is important to note that existing research typically describes the phenomenon of the digital divide among the older adults from the perspective of objective social strata or social capital, without extensively exploring the impact of subjective social class perceptions on older adults' preferences for using mHealth devices. Thus, this study contributes by supplementing existing research from a subjective psychological perspective.

Research on the digital divide and digital engagement among older adults often presents 2 perspectives concerning the

XSL•FO
RenderX

variables of education level and health literacy. One perspective considers the integration or participation of older adults in digital life because of the 3-level digital divide. It suggests that individuals with higher education levels and greater technological understanding are generally more active in using digital devices. Accordingly, older adults benefit from mastering digital technologies and actively engaging in digital life [46]. The second perspective views "digital disengagement" among older adults as a fourth type of digital divide [47]. It contends that even as older adults enhance their digital literacy and acquire basic knowledge and skills in IT while integrating into the digital society, they may become unwilling to use digital technologies due to discriminatory content and other factors present in digital applications aimed at older demographics [48]. The results of this study support the first perspective, indicating that overall, individuals on the periphery of the digital society within the older adult population exhibit relatively lower willingness to use digital devices. This finding aligns with some existing research in this field. A survey of the Polish population reveals that the educational level of older adults and their motivation to use digital devices are significant variables influencing their level of digital participation [49]. There is also evidence suggesting that through professional training or digital literacy education, older adults' digital skills and literacy can significantly improve [50]. These digital skills form the foundation for older adults to use digital devices [22]. Therefore, reducing the digital divide and increasing familiarity with digital devices among older adults may be a way to enhance their willingness to use such devices.

Furthermore, this study found that self-efficacy significantly influences older adults' use of mHealth devices, consistent with previous research findings. The research indicates a correlation between willingness to use digital technology and self-efficacy among retired older adult populations [51]. On one hand, learning to use digital technology can enhance self-efficacy among older adults [52]; on the other hand, lower self-efficacy can diminish their ability to use smart devices [53]. These findings provide a basis for the conclusions drawn in this study.

In terms of facilitating resources, first, this study found a significant positive correlation between perceived social support, identity bubbles, and the willingness of older adults to use mHealth devices. This aligns with previous research findings. Scholars argue that perceived social support is among the crucial factors influencing tablet device use among older adults [54]. This can be explained using social identity theory. Research indicates that there are often stereotypes about older adults within society, and younger individuals who have more contact with older adults tend to possess greater knowledge about aging-related issues. They also show more understanding and fewer biases toward older adults [55]. Due to their greater proficiency and flexibility in using mHealth devices, younger individuals often serve as exemplary models for older adults when they experience higher levels of social acceptance and reduced stereotyping. Consequently, older adults are more likely to learn from younger generations in using mHealth devices and receive greater encouragement in digital device use. Therefore, increased social support and a sense of belonging on social media platforms among older adults enhance their willingness to engage with mHealth devices. Furthermore, the findings of this study validate hypotheses derived from social capital theory, which posits that objective resources and subjective identities and trust within social relationships positively influence internet use [56]. Therefore, older adults' identification with internet communities and their level of digital identity bubbles also positively influence their willingness to use digital devices.

Second, this study found that family communication significantly negatively impacts the willingness of older adults to use mHealth devices, indicating that greater family communication correlates with a reduced inclination among older adults to use such devices. This finding contrasts with existing research conclusions. Existing studies suggest that intergenerational family networks are crucial in enhancing older adults' digital literacy and can increase their willingness to use relevant digital devices [57]. This could be due to several factors. On one hand, there are distinctions between health devices and typical digital social devices. On the other hand, older adults experience significant social isolation, particularly those living alone and lacking care from their children, thereby increasing their willingness to use digital devices [58]. The application of digital devices by older adults often serves as a substitute or supplement to real-world social and health needs. When these needs are adequately met in reality, there is a decrease in both the willingness and use rates of relevant digital devices among older adults [59], which could serve as an explanatory mechanism for the conclusions drawn in this study.

In terms of demand, this study found that quality of life has a significantly positive impact on older adults' willingness to use mHealth devices. Existing research has laid the groundwork for this conclusion. Studies, such as those involving telephone interviews with older adults in Hungary during COVID-19, have identified substantial demand for digital health solutions among older adult populations, highlighting its importance as a critical application area [37]. This suggests that older adults' subjective perception of health and their objective life circumstances both influence their demand for and willingness to use digital health devices. This supports the conclusions drawn in this study.

It is noteworthy that explanations of these 3 dimensions are not entirely distinct; in fact, these variables collectively exert a systematic and comprehensive influence on older adults' willingness to use mHealth devices.

Future Prospects

This study has the following strengths: regarding the research topic, it explores the psychological foundation of the digital divide among older adults from the perspective of subjective willingness, enriching the structural discussion as corroborated by existing research. In terms of data, the study uses scientifically sampled large-scale samples of older adults, encompassing rich variables and comprehensive discussions, thereby supplementing existing research with empirical analysis from China. Theoretically, the study systematically categorizes variables and discusses the theoretical relationship between subjective class perception and the digital divide, while

XSL•FO
RenderX

validating social identity and social capital theories, contributing to theoretical significance.

However, the limitations of this study primarily stem from its cross-sectional design, which offers only a preliminary exploration of influencing factors without addressing potential mechanisms or causal effects. In addition, the lack of comprehensive external databases for triangulating results in the decision tree analysis is another limitation. Furthermore, the study lacks subgroup explanations. In reality, older adults with different characteristics may not score similarly on various influencing factors, and their motivations for using mHealth devices can vary in terms of initiative, passivity, and purpose. In addition, the study relies on a single-item measure for the dependent variable—older adults' willingness to use mHealth devices. While a single-item measure offers simplicity and ease of administration, it may lack the depth and reliability of multiitem scales, which could better capture the complexity and nuances of willingness and actual behaviors. This limitation might lead to measurement bias and restrict the robustness of the findings.

To further delve into this topic in the future, we propose the following questions for in-depth discussion: Do older adults use medical devices differently than the general population? first, this study found that there was no significant difference in the willingness of older adults to use health devices compared to the general population, which contrasts with previous researches. Existing studies indicate that younger age groups prefer generative artificial intelligence that enhances productivity compared to generative artificial intelligence primarily used in health settings. In addition, research suggests that the internet has a greater impact on younger individuals than on older adults. However, individuals aged ≥60 years tend to approach the use of IT devices with caution, shyness, and deliberation [60]. It suggests a need for further exploration into the underlying reasons for this distinction.

Second, do the influencing factors on older adults' willingness to use health devices similarly apply to different age groups? Research indicates that for children and adolescents, family factors and parent-child relationships often have a significant positive impact on their use of digital devices [61], yet there remains a lack of research on their use of health devices. Therefore, this could serve as a direction for further exploration in the future.

Conclusions

The results of this study showed that Chinese older adults' willingness to use mHealth devices was positive overall. The positive state of family communication, on the contrary, reduced their willingness to use. This suggests that particular attention should be paid to the singleton and widowed older adult groups, where the lack of family communication may translate into higher acceptance and dependence on mHealth devices. Therefore, policy development should focus on providing free or subsidized health devices for these groups, and in addition, when designing promotional strategies, attention should be paid to balancing the relationship between family communication and technology acceptance, and at the same time, strengthening family digital health education to promote the incorporation of technology in ways that can enhance rather than weaken family health management and emotional connection, help fill the gaps in older adult care services and improve health management, and realize the harmonious coexistence of technology and humanistic care.

Acknowledgments

This work was supported by the Chinese Academy of Medical Sciences Innovation Fund for Medical Sciences—A Strategic Study on Healthy China Development and Health System Reform (2021-I2M-1-046). The authors are very grateful to the staff and participants of the Psychology and Behavior Investigation of Chinese Residents. Abstract

Background: Smartphone mobile health (mHealth) apps have the potential to enhance access to health care services and address health care disparities, especially in low-resource settings. However, when developed without attention to equity and inclusivity, mHealth apps can also exacerbate health disparities. Understanding and creating solutions for the disparities caused by mHealth apps is crucial for achieving health equity. There is a noticeable gap in research that comprehensively assesses the entire spectrum of existing health apps and extensively explores apps for specific health priorities from a health care and public health perspective. In this context, with its vast and diverse population, India presents a unique context for studying the landscape of mHealth apps.

Objective: This study aimed to create a comprehensive dataset of mHealth apps available in India with an initial focus on heart disease (HD)–related apps.

Methods: We collected individual app data from apps in the "medical" and "health and fitness" categories from the Google Play Store and the Apple App Store in December 2022 and July 2023, respectively. Using natural language processing techniques, we selected HD apps, performed statistical analysis, and applied latent Dirichlet allocation for clustering and topic modeling to categorize the resulting HD apps.

Results: We collected 118,555 health apps from the Apple App Store and 108,945 health apps from the Google Play Store. Within these datasets, we found that approximately 1.7% (1990/118,555) of apps on the Apple App Store and 0.5% (548/108,945) on the Google Play Store included support for Indian languages. Using monograms and bigrams related to HD, we identified 1681 HD apps from the Apple App Store and 588 HD apps from the Google Play Store. HD apps make up only a small fraction of the total number of health apps available in India. About 90% (1496/1681 on Apple App Store and 548/588 on Google Play Store) of the HD apps were free of cost. However, more than 70% (1329/1681, 79.1% on Apple App Store and 423/588, 71.9% on Google Play Store) of HD apps had no reviews and rating-scores, indicating low overall use.

Conclusions: Our study proposed a robust method for collecting and analyzing metadata from a wide array of mHealth apps available in India through the Apple App Store and Google Play Store. We revealed the limited representation of India's linguistic diversity within the health and medical app landscape, evident from the negligible presence of Indian-language apps. We observed a scarcity of mHealth apps dedicated to HD, along with a lower level of user engagement, as indicated by reviews and app ratings. While most HD apps are financially accessible, uptake remains a challenge. Further research should focus on app quality assessment and factors influencing user adoption.

Introduction

Background

Mobile health (mHealth) apps are prominent among the recommended interventions for addressing health disparities and improving health care accessibility. mHealth, as defined by the World Health Organization, encompasses the use of mobile devices like phones and wireless tools to enhance health care practices, boost health information access, and encourage positive behavioral changes [1,2]. In low-resource settings like India, mHealth offers a cost-effective means to bridge health care gaps [2-8].

India has experienced a substantial surge in mobile phone technology adoption, with more than 70% of urban and 50% of rural households using smartphones [9]. The number of smartphones in India has been estimated to reach 1 billion by the end of 2023 [10]. This widespread use presents a valuable opportunity for leveraging smartphone health apps (mHealth apps) to enhance health care delivery [11-14]. mHealth apps are also being used by community health workers, making them accessible to people without smartphones [15]. During the COVID-19 pandemic, mHealth apps proved particularly valuable by enabling teleconsultations, contact tracing, and web-based prescription services, effectively overcoming barriers to traditional health care access [16-19].

However, mHealth apps can also contribute to increasing systemic inequities. They may risk widening health disparities through a lack of inclusivity and by addressing the health needs of already advantaged groups [20]. Language options in the mHealth apps, or the lack of them, have been highlighted in previous studies [21-25]. In addition to social determinants of health, digital determinants like technology access and community infrastructure (eg, broadband internet) can have a crucial impact on mHealth outcomes and health [25-30]. The COVID-19 pandemic has highlighted how limited access to digital technologies or supporting infrastructures, apps unsuited for target groups, and lack of high-quality data for tailoring interventions to the needs of marginalized groups might undermine the very potential of digital technologies for mitigating health disparities [31]. Therefore, understanding health disparities caused by mHealth apps and creating solutions for working toward health equity is crucial and requires several research efforts.

Although there is limited research on mHealth apps in India, there are many studies on mHealth apps in general. Many are systematic reviews looking at previous literature on individual or small groups of apps [25-30,32]. There are also reviews [4,33] and policy proposals [34] on mHealth apps. Many of these studies focused on the quality, privacy, and security concerns of mHealth apps [35-40]. There are also studies that focused on rating the quality of mHealth apps, such as the one using the MARS (Mobile Application Rating Scale) tool [41,42]. While assessing the quality of apps is essential, this is still manual, time-consuming, and does not give an overall picture of the mHealth apps available. There is a noticeable gap in research that comprehensively assesses the entire spectrum of existing health apps or extensively explores apps for specific health priorities from a health and health care perspective. This gap is even more evident in the context of mHealth apps available in India.

While some studies have investigated the landscape of mHealth apps in app stores, they have used methodologies based primarily on manual searching and screening of apps. Among those, Siddiqui et al [43] focused on orthodontic-related apps, Bassi et al [16] on COVID-19–related apps, and Coulon et al [27] on stress management–related apps. From their search processes, they gathered 952, 4600, and 902 apps, respectively, which were then manually screened and reviewed. However, searching app stores and screening apps manually is a time- and labor-intensive process [27], especially when exploring a large number of apps. Moreover, app store search functions tend to prioritize popular or highly rated apps, which, while useful for analyzing the most widely used apps, limits the ability to gain a comprehensive view of the app landscape. This approach may overlook lesser-used apps that could provide insights into why some apps fail to gain traction.

A significant obstacle in carrying out more extensive studies focusing on a diverse and larger set of mHealth apps is the difficulty of acquiring such a comprehensive dataset. There are some publicly available datasets [35] obtained using large-scale web crawling methods, with information about many apps available on such app stores. However, such datasets do not record all available information for each app and are not usually updated with the latest information. Furthermore, since the data on these datasets are not collected with a specific intention, they may not be entirely suitable for a particular research question. While Danahiswari et al [44] and Fu [45] have used such datasets and additional scraping methods in the context of mHealth apps, their focus was app development and market analysis. Other researchers also used similar scraping methods. In 2015, using web scraping methods, Xu and Liu [46] and Dehling et al [47] made datasets of 24,405 and 60,000 mHealth apps, respectively. More recently, in 2020, Tsinaraki et al [48] analyzed COVID-19–related apps from the 2 app stores using updated scraping methods. However, accessing these app stores, especially Google Play Store, by similar methods has become significantly more challenging due to more restrictive database designs, throttling limits, and IP blocking [48]. Stach et al [35] looked at mHealth apps and proposed a pipeline to search for specific types of apps from the app stores in their crawling techniques, overcoming the restrictions posed by these app stores.

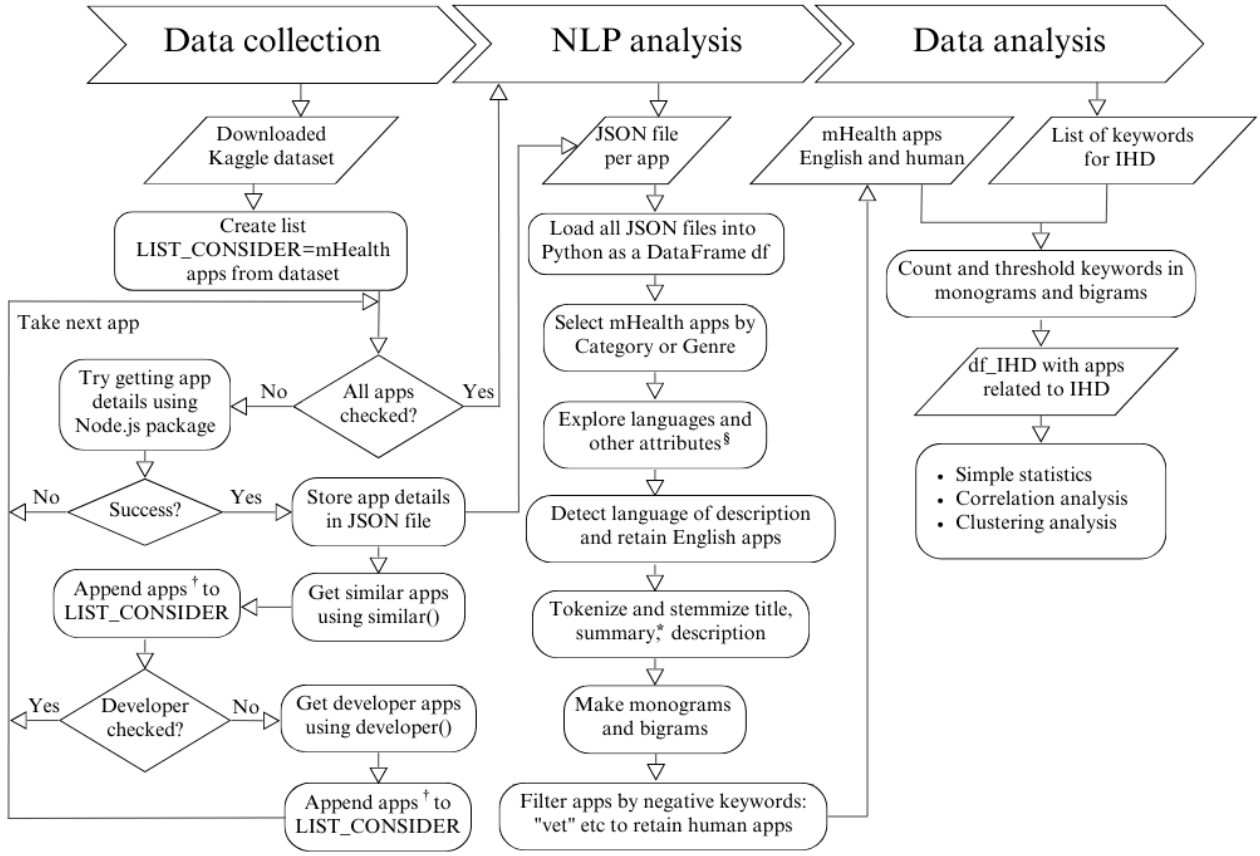
Objective

Building on the above methods, we aimed to create a comprehensive dataset of mHealth apps using an automated and replicable method for collecting and analyzing metadata

XSL•FO
RenderX

from mHealth apps. We present an updated web crawling method for obtaining information about mHealth apps in a particular country. This method can help map the landscape and enable the analysis of mHealth apps. We used these methods to prepare a dataset of mHealth apps available in India from 2022 to 2023 on the Apple App Store and the Google Play Store. As a country with a large and diverse population, India faces unique health care challenges that can be effectively addressed through innovative technological solutions [4,49]. By exploring the landscape of mHealth apps, we can gain insights into their effectiveness and relevance and identify gaps and potential for improvement.

As a crucial first step in mapping these apps, we concentrated on apps relevant to heart disease (HD) using natural language processing (NLP) and clustering techniques. HD cause the most significant number of deaths in India and, therefore, are a crucial health priority to focus on [49]. This evidence can serve as a foundation for shaping health care policies, improving access, and promoting positive health outcomes.



Methods

Overview

The methodology in this study was developed to address the need for a comprehensive and updated dataset of apps available in India, with a focus on HD apps. Our approach builds on previous studies that have used automated methods for collection of metadata from mHealth apps [27,42-46] and aimed to overcome the challenges posed by restrictive database designs, throttling limits, and IP blocking by using a replicable web crawling method. We used analysis techniques, such as NLP and clustering, which have been used in health care research for various applications [50-54]. These techniques enabled us to identify apps related to HD and group these apps further on the basis of their focus and utility. Our methodology facilitates the effective gathering of a comprehensive dataset and allows for the process to be scaled and adapted for future research.

In this section, we will first discuss our data collection methodology. Then, we will discuss the NLP methods we used for identifying HD apps, followed by statistical analysis and clustering of selected apps. Figure 1 illustrates all the steps included in this methodology.

Figure 1. Methodology for extracting mobile health (mHealth) apps and selecting and analyzing apps for heart diseases. †While for Apple App Store, at this stage we already retain only mHealth apps; §Other attributes include installs, app sizes, ratings, reviews, rating scores; *Apple App Store apps do not have summary included. IHD: ischemic heart disease; NLP: natural language processing.

XSL•FO
RenderX

Data Collection

The 2 final datasets used for analysis contained app metadata from the "medical" and "health and fitness" categories on the Google Play Store in December 2022 and on the Apple App Store in July 2023, providing a snapshot of the app stores in these 2 months. This metadata includes app attributes, such as a unique app ID, the app's title, the provided description, the number of installs, and the price of the app, among other such details. A complete list of attributes is included in Table 1.

Table 1. Attributes of the apps in the datasets.

Attribute description	Attribute of the apps from the Apple App Store	Attribute of the apps from the Google Play Store	Attribute used for
Unique identification	ID	ID	Identifying individual apps and preventing duplicates during data collection.
App name	Title	Title	Tokens, monograms, and bigrams
App summary	N/A[a]	Summary	Tokens, monograms, and bigrams
App description	Description	Description	Tokens, monograms, bigrams, and number of characters (description length)
Release date	Released	Released	Tracking number of apps released over the years
App size	Size	Size	Average size of apps on each platform
Required operating system	Required_os	Android_2022	Most used versions of operating systems
Price of the app	Price	Price	Price of apps in INR[b]
Rating-score (ie, star-rating)	Score	Score	Average rating-scores
Number of reviews	Reviews	Reviews	Average number of reviews
App's category	Category	Category	To select health and medical apps
Presence of in-app purchases	N/A	IAP[c]	Number of apps with in-app purchases
Number of ratings	N/A	Ratings	Average number of ratings
Number of installs (ie, downloads)	N/A	installs_2022	Average number of installs
All the languages the app is available in	Languages[d]	—[e]	Distribution of languages in apps
Updated date	Updated	✓[f]	Tracking the number of apps updated over the years

[a]N/A: not available.

[b]INR: Indian national rupee.

[c]IAP: in-app purchases.

[d]Apple App Store lists many languages (ie, those in which the app can be used) in the languages attribute of a given app.

[e]Google Play Store does not have an attribute called languages. In both cases, for filtering apps based on language, we detected the language of the app description. This is illustrated in detail in Multimedia Appendix 1.

[f]Google Play Store does not have the attribute for updated year at the time of data collection.

We obtained the initial datasets from (1) a Kaggle dataset [55] containing >2.3 million apps scraped from the Google Play Store in June 2021 and (2) a Kaggle dataset [56] containing >1.2 million apps scraped from the Apple App Store in October 2021.

As Google Play Store has changed its internal data structure, it has become extremely challenging to use crawling tools to scrape its whole database. In such a context, the publicly available Kaggle datasets from recent years offer a great starting point to expand and compile the latest dataset. As these datasets are publicly available, researchers can obtain them as starting points for future efforts to expand such datasets or already perform analysis on them. An important note is that the Kaggle datasets do not have all the necessary information like app descriptions, which we therefore obtained through our scraping methods as follows.

For each of the app stores, we extracted app-specific unique identifiers (ie, *app_id*s) to create 2 separate lists called LIST_CONSIDER, comprising apps from the "medical" and "health and fitness" categories.

We then used the *Node.js* modules *google-play-scraper* [57] and *app-store-scraper* [58] to access updated app details from the Google Play Store and the Apple App Store in December 2022 and July 2023, respectively, and to expand our dataset of "medical" and "health and fitness" apps. For each *app_id* in LIST_CONSIDER, we performed the following three steps:

(1) We queried the app's metadata and stored the returned metadata in a JSON file named after its *app_id*. If the app was

XSL•FO
RenderX

not available on the queried date, we skipped the next 2 steps and considered the next app in LIST_CONSIDER.

(2) We obtained a list of other apps deemed as "similar" to the app using the "similar()" function. This function uses an internal algorithm to suggest similar apps given an input app. From this list of apps, we filtered to retain only "medical" and "health and fitness" apps and added their corresponding *app_id*s to the end of LIST_CONSIDER.

(3) We obtained a list of other apps developed by the same developer of the app using the "developer()" function. We again filtered this list of apps to retain only "medical" and "health and fitness" apps and added their corresponding *app_id*s to the end of LIST_CONSIDER.

As we kept adding more apps to LIST_CONSIDER, as described above, our dataset grew. We repeated this process until LIST_CONSIDER was exhausted, and no new *app_id*s could be added. In the end, we had 2 sets of JSON files—one for the Google Play Store and the other for the Apple App Store.

Filtering Medical and Health and Fitness Apps

We analyzed these 2 sets of JSON files as separate datasets (ie, Google dataset and Apple dataset). The 2 datasets were never added together into a single analysis but only compared against each other. To start with, we used 2 steps of filtering as follows: (1) the main language used in the description should be English, and (2) the app should be concerned with human health and not with animal health. To achieve the first filtering step, we detected the main language of the description using the *langdetect* package in Python and selected only those with descriptions in English language. This step was important to use NLP techniques later. Then, from the resulting English language apps, we removed veterinary and animal health apps using NLP techniques. To identify apps related to animal health topics, we looked for the presence of a preselected set of veterinary and animal health keywords in the app title, summary (ie, present only in the Google dataset), or description. We discuss these techniques in detail in the section for selecting apps for HD.

Selecting Apps Related to HD

NLP applies computational techniques to analyze natural language and speech [59]. NLP treats textual content as data and offers a variety of methods for efficiently processing substantial amounts of text [60]. In this study, we used the app titles, app summaries (ie, present only in the Google dataset), and app descriptions as our text data. We used tokenization, lemmatization, stop-word removal, and n-grams as part of our NLP methodology [60]. Tokenization identifies individual words or tokens within a given text. Lemmatization transforms each word into its root form by removing suffixes. For instance, lemmatization consolidates word forms like "diagnose," "diagnosis," "diagnosed," and "diagnosing" into the common root word "diagnose." By treating different word forms as a single entity, lemmatization enables accurate analysis in further steps. After eliminating stop-words like "and," "or," "also," and "then" as well as special characters, we made monograms and bigrams from the text. Monograms are single words, while bigrams consist of pairs of consecutive words. These allow for the analysis of not only individual words by themselves but also in the context of their use. For example, the words "heart" and "disease" each have some meaning in the health context, whereas "heart disease" as a pair conveys a specific meaning. Using monograms and bigrams allows us to capture and use both contexts in our analysis.

We made a "dictionary" of terms relevant to HD using Medical Subject Headings terms from PubMed database [61] and added more terms from Google searches. This dictionary is listed in Table 2.

Table 2. Heart diseases—keyword dictionary.

Categories	Keywords
Diseases	heart disease, cardiovascular disease, coronary artery disease, myocardial infarction, ischemic heart disease, angina, atherosclerosis, hypertensive heart disease, valvular heart disease, congenital heart disease, rheumatic heart disease, heart failure, cardiomyopathy, arrhythmia, atrial fibrillation, ventricular fibrillation, supraventricular tachycardia, bradycardia, heart murmur, pericarditis, endocarditis, myocarditis, Kawasaki disease, systemic lupus erythematosus, rheumatoid arthritis, giant cell myocarditis, viral myocarditis, dilated cardiomyopathy, hypertrophic cardiomyopathy, restrictive cardiomyopathy, blocked arteries, clogged arteries, heart blockage, heart attack, and cardiac arrest
Symptoms	chest pain, shortness of breath, fatigue, edema, high blood pressure, hypertension, palpitations, chest discomfort, chest tightness, heartache, breathlessness, labored breathing, heavy breathing, racing heart, rapid heartbeat, irregular heartbeat, skipped beats, swelling, and fluid retention
Treatments or procedures	coronary artery bypass graft, percutaneous coronary intervention, stent, echocardiogram, electrocardiogram, cardiac catheterization, cardiac magnetic resonance imaging, cardiac rehabilitation, bypass surgery, heart surgery, open-heart surgery, coronary bypass, bypass surgery, stent surgery, stent placement, balloon procedure, valve surgery, heart valve repair, valve replacement, cardiac rehabilitation, heart transplant, new heart, and artificial heart
Medications	beta-blockers, calcium channel blockers, angiotensin-converting enzyme inhibitors, diuretics, statins, antiplatelet medications, anticoagulants, angiotensin receptor blockers, blood thinners, clot-busting drugs, clot-preventing medication, blood pressure medicines, and cholesterol-lowering drugs
Medical devices	pacemaker, defibrillator, shock device, and electrical device
Medical specialties	cardiology, cardiologist, and cardiothoracic

XSL•FO
RenderX

We made monograms and bigrams from this HD keyword dictionary (ie, HD monograms and bigrams). We also made monograms and bigrams for each app's title, summary, and description (ie, app monograms and bigrams). Then, for each app, we counted the frequency of HD monograms and bigrams in the app monograms and bigrams, which we used to select apps relevant to HD. We tried different iterations and found that selecting apps with (1) at least 1 *relevant* HD monogram or (2) at least 1 HD bigram is an optimal method. We eliminated apps with only one monogram if the monogram was not exclusive to HD—for example, "pain." However, apps with single and HD-relevant monograms, such as "ECG" (electrocardiogram), were selected. Apps without any HD monograms or bigrams in their app monograms and bigrams were not selected.

Simple Statistics and Correlation Analysis of HD Apps

We explored the HD apps using various app attributes like app sizes, app prices, number of ratings, rating-scores, number of reviews, presence of in-app purchases, the release year of each app, and the length of description. We used descriptive statistics like arithmetic mean to understand the distribution of the apps along the mentioned attributes. We also performed correlation analysis to understand the relationships among these attributes.

Clustering and Topic Modeling of HD Apps

To understand the different types of apps present in the selected HD apps, we performed cluster analyses. We used the latent Dirichlet allocation (LDA) algorithm for clustering and topic modeling using app descriptions as input. This technique allows us to uncover underlying topics within the dataset. We used the *CountVectorizer* function from the *scikit-learn* package to convert the description text into a matrix of token counts. The matrix consists of the counts of the frequency of individual words (ie, tokens) across all the app descriptions. This matrix was then subjected to LDA using the *LatentDirichletAllocation* function from *scikit-learn*. After several iterations using different parameters, we configured the LDA model to identify 3 topics (ie, clusters) using the following parameters: *n_components*=3, max_iter=5, *learning_method='online'*, and learning_offset=50. Each app's cluster assignment was determined based on the topic with the highest probability in its distribution.

We explored the resulting clusters, but we did not find any further meaningful subclusters. To address specific research inquiries, alternative supervised topic modeling methods could be explored to extract more nuanced subclusters. We also experimented with k-means clustering [44], but our results indicated that LDA clustering yielded superior outcomes with this dataset. Clouds from k-means clustering are attached in Multimedia Appendix 2.

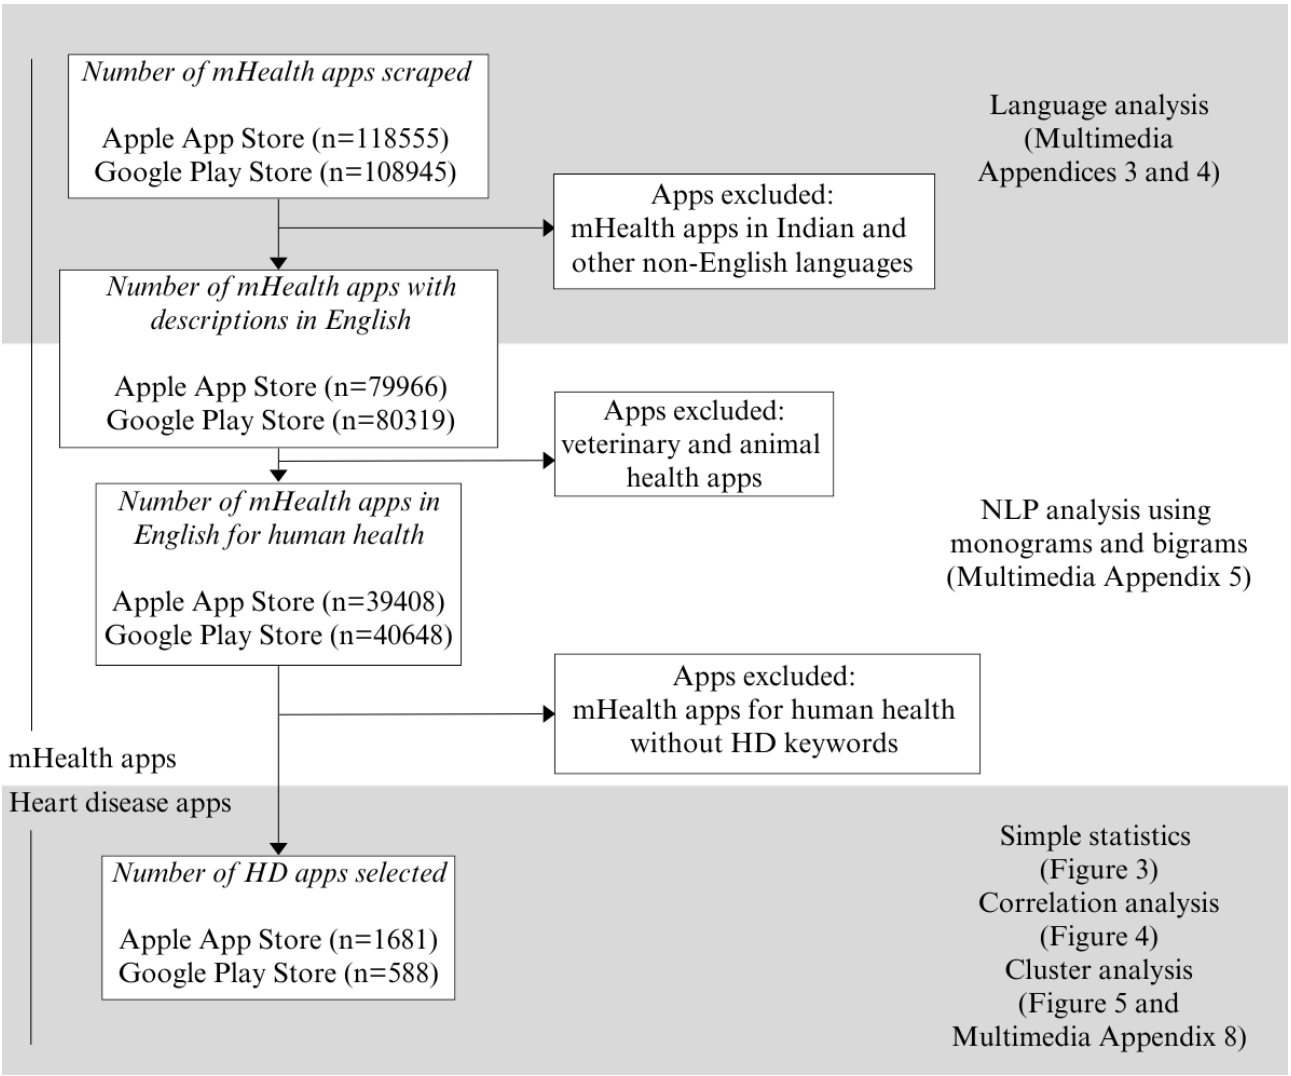
Tools Used

In general, we used *Python* as the main scripting language, the *pandas* [62] package for data analysis, and *matplotlib* [63] for data visualization. To expand the list of apps by crawling and scraping the app stores, we used *Node.js*—modules "*google-play-scraper*" [57] and "*app-store-scraper*" [58] for the Google Play Store and the Apple App Store, respectively. We wrapped the *Node.js* scripts inside a *Python* script that iteratively looped over the Kaggle dataset and expanded the list of apps with their details. Next, for NLP tasks like tokenization and stemmization, we used the *nltk* [64] package. For language detection, we used the *langdetect* [65] package and for word cloud visualizations, we used the *wordcloud* [66] package. For further NLP analysis, we used vectorizers and methods from the *scikit-learn* package, and for LDA visualization, we used the *pyLDAvis* [67] package.

The code written and used for data collection and analysis in this study is available in our GitHub repository [68].

Ethical Considerations

No ethics board review was needed as our study does not use patient data or involve human participants.



Results

Overview

Using the data collection methods described in the previous section, we scraped 118,555 apps from the Apple App Store and 108,945 apps from the Google Play Store categorized as "health and fitness" or "medical" (ie, health and medical apps). Figure 2 illustrates a summary of the results discussed below.

XSL•FO
RenderX

Figure 2. Summary of results. HD: heart disease; NLP: natural language processing.

App Language

An important consideration here is the presence of the app attribute *language* in the Apple App Store dataset, and its absence in the Google Play Store dataset. Apple App Store's *language* attribute lists all the languages an app supports and is exactly the information needed to evaluate the language support of an app. However, the Google Play Store dataset lacks this attribute, so it is not possible to know which languages it supports. Hence, as an indirect indication, we used the main language of the app description detected by the *langdetect* package as Google Play Store's stand-in attribute for languages.

In the resulting health and medical apps, Apple App Store has more than 90% (109,425/118,555, 92.3%) apps that support English whereas Google Play Store has 73.72% (80,319/108,945) apps in English (ie, descriptions in English). We found that approximately 1.7% (1990/118,555) of apps on the Apple App Store included support for Indian languages and 0.5% (548/108,945) of apps (ie, descriptions) on the Google Play Store were in Indian languages. Among Indian languages, apps supporting Hindi makes up the majority on Apple App Store whereas apps in Bengali are the majority on Google Play Store followed by Hindi. Although there were only a few health and medical apps on Google Play Store in Indian languages, these apps had higher average rating-scores, installs, and higher average number of reviews compared to others. The distribution of apps in different languages and the average rating scores and number of installs and reviews of apps in Indian languages are presented in Multimedia Appendices 3 and 4, respectively.

As most of the apps were in English language, we continued with these apps for further analysis, excluding apps in Indian and other non-English languages. After screening for apps with descriptions in the English language, and removing veterinary and animal health apps, we had 39,408 apps from the Apple App Store and 40,648 apps from the Google Play Store.

HD Apps

Using HD monograms and bigrams, we selected 1681 HD apps from the Apple App Store and 588 HD apps from the Google Play Store. These HD apps had elevated frequencies of various HD monograms and bigrams as expected. A list of frequently occurring keyword monograms and bigrams in selected HD apps are shown in Table 3 and the corresponding word clouds are presented in Multimedia Appendix 5.

XSL•FO
RenderX

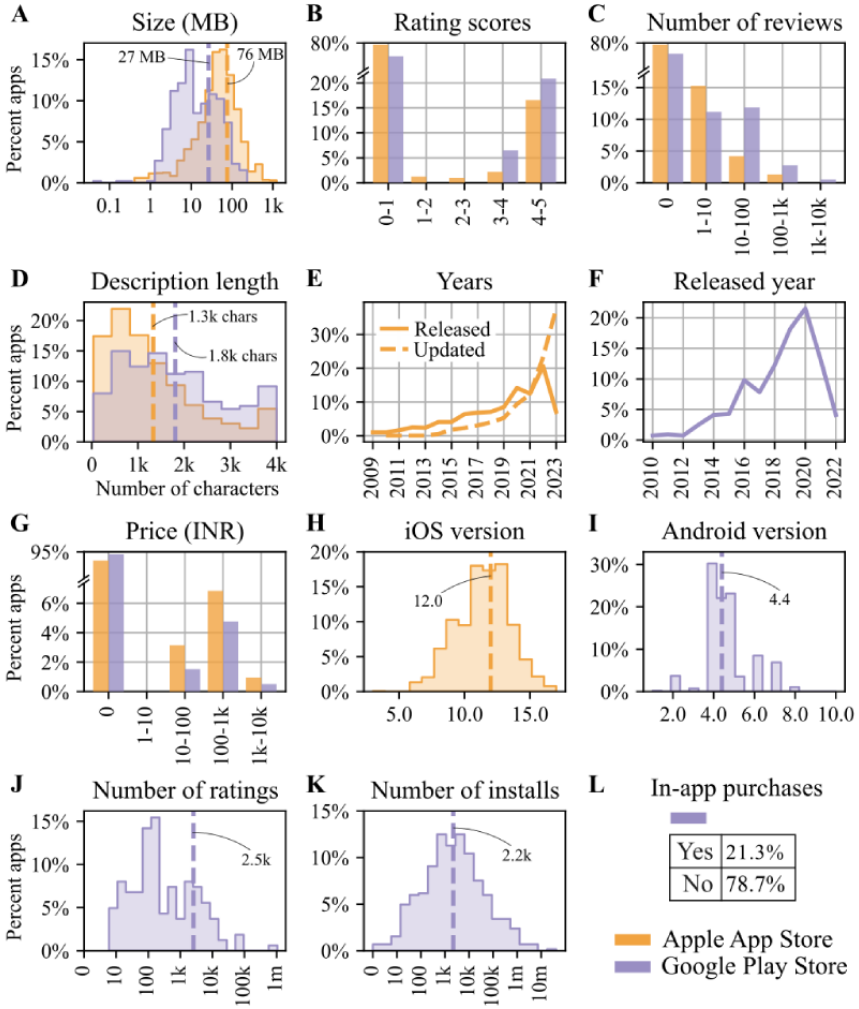


Table 3. Keyword monograms and bigrams found in (selected) heart disease apps.

Store	Keywords
Apple App Store	
Monograms	drug, beat, race, heart, cardiovascular, block, rapid, cardiac
Bigrams	chest pain, cardiac arrest, heart attack, short breath, supraventricular tachycardia, valvular heart, skip beat, irregular heartbeat
Google Play Store	
Monograms	heart, blood, pain, cardiovascular attack, chest, short, cardiac
Bigrams	heart attack, chest pain, cardiac arrest, irregular heartbeat, chest discomfort, valvular heart, supraventricular tachycardia, rapid heartbeat

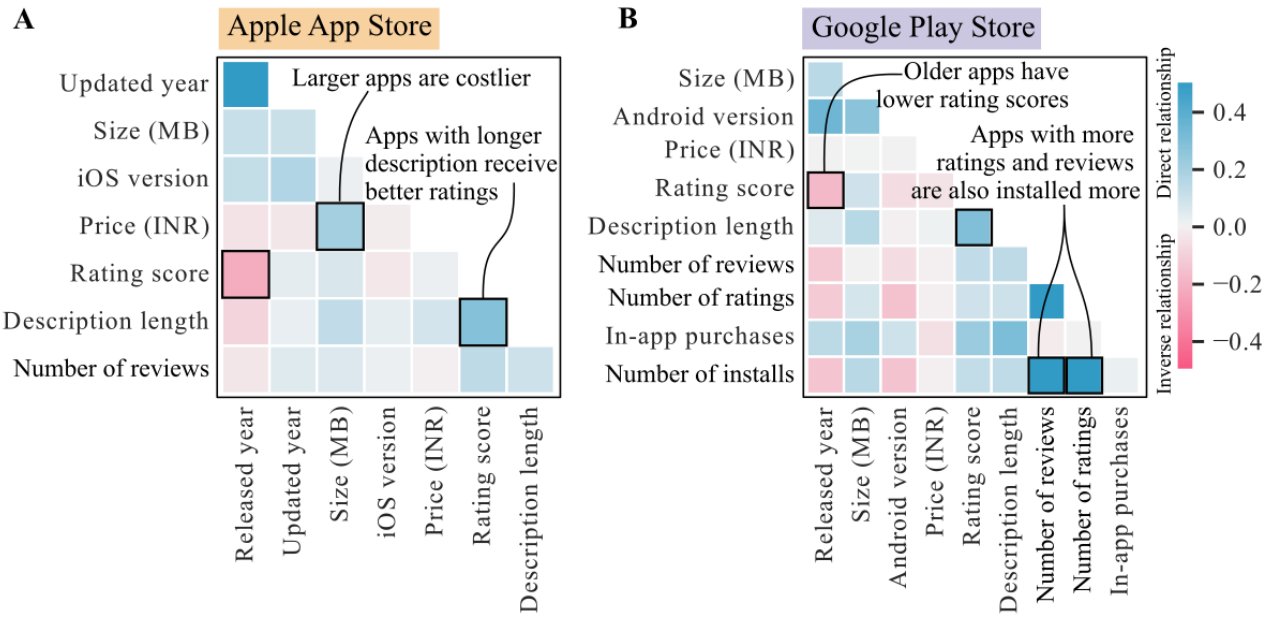
Exploring HD Apps

The distributions of various app attributes for HD apps from the Apple App Store and the Google Play Store are shown in Figure 3. There had been an increase in the number of HD apps released over the years on both the Apple App Store and the Google Play Store. Many of the Apple App Store HD apps had been updated in the last year (Figures 3E and 3F). The average size of HD apps was 76 MB on the Apple App Store and 27 MB on the Google Play Store (Figure 3A). Very few apps had rating-scores, and when they did, they mostly had scores>3 (Figure 3B). Similar to rating-scores, very few apps had reviews (Figure 3C). Among those apps with reviews, there were rarely >1000 reviews. Data for the number of ratings and installs were available only for Google Play Store apps. Many apps did not have any ratings or installs. Among the apps with number of ratings and installs, the average was around 2000 (Figures 3J and 3K).

Figure 3. Analysis of attributes for heart disease apps on Apple App Store (N=1681) and Google Play Store (N=588).

About 90% (1496/1681 on Apple App Store and 548/588 on Google Play Store) of the HD apps were free on both platforms. Among those apps that were not free, prices were mostly between 100 and 1000 INR (Indian national rupee; US $1.2 and US $12; Figure 3G). About 20% (125/588, 21.3%) of the HD apps on the Google Play Store had in-app purchases (Figure

XSL•FO
RenderX



3L). In-app purchase data was not available for Apple App Store HD apps.

Google Play Store HD apps had an average of 1800 characters and Apple App Store HD apps had 1300 characters in their descriptions (Figure 3D). Many HD apps did not need the latest operating systems (OS) and were functional with earlier OS versions (Figures 3H and 3I).

Correlation Analysis

Figure 4 shows the correlations between pairs of attributes for Apple App Store and Google Play Store HD apps as heatmaps. Correlation matrices are included in Multimedia Appendices 6 and 7. The number of installs for HD apps on Google Play Store was positively correlated with the number of ratings and the number of reviews. On both Apple App Store and Google Play Store, we found a positive correlation between the length of description and rating-scores, and a negative correlation between app release year and rating-score. For HD apps on the Apple App Store, there was a positive correlation between the size and price of the apps.

Figure 4. Explorative correlation analysis between the pairs of app attributes.

Cluster Analysis of HD Apps

Using the LDA topic modeling methods, we identified 3 distinct clusters in both Apple App Store and Google Play Store HD apps. After investigating the topics they dealt with, we assigned them the following names: clinical cluster, fitness and lifestyle cluster, and sleep and wellness cluster. Table 4 shows the number of apps in each cluster and its most relevant terms in app descriptions. An expanded set of top 20 relevant terms in each cluster, their frequency within clusters and their overall frequency in all apps are presented in Figure 5. LDA modeling results using the *pyLDAvis* package and the resulting word clouds for each cluster are included in Multimedia Appendix 8.

Because these clusters were made from apps in 2 categories (ie, “medical” and “health and fitness”), we also checked the distribution of the categories within the clusters (Multimedia Appendix 9). We found that the clinical cluster had many apps from “medical” category. However, it was not exclusive to “medical” category apps. Likewise, apps categorized as “medical” were also found in the other 2 clusters, albeit significantly less in number.

We explored the distribution of app attributes for each of these clusters separately (Figure 6), similar to the analysis above on all HD apps. We found that clinical apps were comparatively smaller in size and had shorter descriptions. Price was higher for apps in the fitness and lifestyle cluster.

Table 4. Number of apps in the various clusters from latent Dirichlet allocation cluster analysis.

Cluster name	Number of Apple App Store HD[a] apps (N=1681), n (%)	Number of Google Play Store HD apps (N=588), n (%)	Most relevant terms for each topic
Clinical	817 (48.6)	286 (48.63)	Disease, medical, cardiac, risk, pain, treatment, and doctor
Fitness and lifestyle	594 (35.33)	136 (23.12)	Diet, workout, training, and fitness
Sleep and wellness	270 (16.06)	166 (28.23)	Sleep, yoga, meditation, and stress

[a]HD: heart disease.

Discussion

Languages in Health and Medical Apps

The language diversity within health and medical apps is a notable concern based on our findings. In India, the availability of health and medical apps in Indian languages remains limited, representing only a small fraction of the total. Around 64% of internet users from rural India and 25% of urban India access the internet in their regional language [21]. This shows that most of the mHealth apps that are available in India are not accessible to those who do not understand English, or prefer a regional language.

Previous research has identified the lack of available health apps in native languages in India as a major access barrier. In a study conducted to understand the acceptability of app-based interventions in India, Sinha et al [21] found that language was a significant barrier to adopting health apps, as most of them are available in English. The study by Singh et al [22] focused on privacy policies and directly assessed app descriptions of mental health apps in app stores. Their findings suggest that the lack of native language translation of app description negatively affects the ability of users to understand and evaluate privacy policies.

Outside of India, Huang et al [23] performed a screening of diabetes self-management apps on the Google and Apple app store platforms. They found that most diabetes self-management apps only had English-language descriptions, thereby making them inaccessible to non–English speakers. Haggag et al [24] looked at the mHealth app user reviews on Apple and Google app stores in Australia, the United States, and the United Kingdom. They found that the users faced considerable challenges when they were not able to use the apps in their native language. In a systematic review conducted to study the health equity considerations in mHealth interventions for caregivers of older adults, Garnett et al [25] found that only 11% of app providers considered the provision of alternate language options. These numbers are much worse in Indian mHealth apps. However, despite being fewer in number, apps in Indian languages seem to have better user engagement, as indicated [47] by their higher installs, average ratings, and number of reviews compared to others. This highlights a strong case for developing more health apps in Indian languages.

Health Priorities: Number of HD Apps

A crucial requirement for mHealth apps is to address existing health issues [69]. Our findings indicate that this is only partly the case in India. Compared to the thousands of apps available in India in the “medical” and “health and fitness” categories, the number of relevant apps for HD, which is number one in the top 10 causes of death in India [49], is exceedingly low. In a scoping study on mHealth initiatives in India in 2016, Bassi [70] searched the Google Play Store and the Apple App Store and found 81 and 107 apps, respectively for HD. Although the numbers have multiplied over the years, the fraction of apps for HD is still small.

While the selection method could be improved to find more apps, if the apps do not have some of the basic keywords, it would be just as difficult for a typical smartphone user to find them as it was for us. Moreover, if the app is not easy to find, it can add to the accessibility barrier from a technological perspective.

We found that the Apple App Store had more HD health and medical apps compared to the Google Play Store, in line with previous research. Dehling et al [47] found that the ratio of Apple mHealth apps to Google mHealth apps was about 9 to 1. However, the numbers for overall mHealth apps in our study (ie, after screening for apps in English language and eliminating animal health-related apps) were comparable on both platforms.

App Size

We found that the average size of HD apps on the Apple App Store and on the Google Play Store in this study was higher compared to previous studies on mHealth apps. Coulon et al [27] reported that the average size of apps for stress management on the Apple App Store was 60.5 MB. Siddiqui et al [43] found that most of the orthodontic mHealth apps on the Apple and Google app stores were <40 MB in size.

Considerations of app size are important due to their impact on the ease of downloading and using these apps. Research has consistently demonstrated that larger apps tend to prolong the downloading process and increase user burden during their use [71]. In addition, Haggag et al [24] underscored that those individuals with older smartphones or limited storage capacity reported significant challenges when engaging with mHealth apps.

The implication of this issue is particularly pronounced in low-resource settings, where access to more advanced smartphones and reliable internet connectivity for downloading and using these large apps is a persistent concern [46,72]. Addressing these logistical challenges and developing easily usable apps is essential in ensuring equitable access to mHealth apps, especially in Indian settings where resources are constrained.

Price of Apps and In-App Purchases

We found that most of the HD apps were offered free of charge, aligning with observations made in prior studies [34]. For the minority of apps that did entail a cost, we identified that prices of apps were relatively higher on the Apple App Store compared to the Google Play Store. Furthermore, about 20% (125/588, 21.3%) of these apps featured in-app purchases on the Google Play Store. While it was noted that some paid health apps had shown increased user engagement [73], in general, both price and in-app purchases have been identified as potential barriers to the adoption and use of mHealth apps [40,74].

In low-resource settings, the appeal of mHealth apps often revolves around their potential to mitigate barriers to health care access, including the financial burdens of health care [75]. In this context, it is encouraging to observe that most HD apps are accessible to smartphone users free of cost. However, it is crucial to highlight that free apps may come with limited access to a wide range of interventions, comprehensive programs, and qualified health care professionals [75].

XSL•FO
RenderX

Ratings and Installs: Google Play Store

The absence or scarcity of ratings has been linked to limited widespread use [47]. Dehling et al [47] found that apps with fewer ratings were less likely to be downloaded and used, possibly due to their diminished visibility in app stores relative to the number of ratings. Moreover, users tend to view apps with a greater number of ratings as more credible and trustworthy.

HD app installs on the Google Play Store vary widely, ranging from 1 to 1 million, with an average of approximately 2000 installs. It is important to note that while the number of installs provides an indication of app use, it does not necessarily reflect the number of active users.

Rating-Scores and Reviews

Prior research indicates that app rating-scores do not strongly correlate with the clinical utility and validity of health apps [76]. In fact, rating-scores from app stores often diverge significantly from ratings provided by health care professionals and patients [77]. Despite this, rating-scores positively impact app downloads [76]. When users choose apps, rating-scores and reviews are frequently the sole available measures [77] that influence their decision to download the app [78]. Rating-scores and reviews also offer valuable user feedback, enabling app developers to enhance their apps [79].

In our study, most HD apps on both the Apple and Google app stores lacked rating-scores and reviews. However, among those apps with rating-scores, the majority received ratings >3 stars. Reviews, when present, typically ranged in number from 1 to 1000, with very few apps accumulating more than 1000 reviews. These findings suggest that active use and user engagement with HD apps in India are confined to only a fraction of the available apps.

Length of Description

In our study, the average length of description for HD apps was around 1300 characters on the Apple App Store and around 1800 characters on the Google Play Store. The length of description in mHealth apps has been studied in previous research. In their study about psychiatric apps on Google Play Store, Pinheiro et al [74] reported that the app descriptions ranged from 75 to 3456 characters with an average of 1253 characters. Previous studies have indicated that the length of app descriptions in mHealth apps can influence their demand and install rates [71,79]. Typically, a more comprehensive and explanatory description tends to correlate positively with a higher number of installs. We discuss the correlation between the length of the description and other attributes further in the correlation analysis section below.

OS Versions and Update Years

In our analysis, we observed that most HD apps available on both the Apple App Store and Google Play Store in India did not require the latest OS versions. This is significant because apps that demand newer OS versions may become inaccessible to users with older smartphones [24].

Furthermore, we found that most of the HD apps on the Apple App Store have received updates within the last few years. It is worth noting that the timing of the latest update has been linked to the quality of mHealth apps [76]. Specifically, apps updated within the previous 6 months tend to exhibit higher quality [76]. However, it is essential to highlight that app updates can sometimes lead to compatibility issues, impacting users' ability to use these apps effectively. Such issues have been reported to hinder the use of certain mHealth apps [24].

Release Years of Apps

The distribution of apps according to their release years (Figures 3E and 3F) reveals interesting observations. While Apple App Store HD apps peaked in 2021, Google Play Store HD apps reached their peak in 2020. However, it is essential to interpret this data cautiously, as it may not accurately reflect the actual number of HD apps released in the last 2 years. Several factors contribute to this disparity. First, our study builds upon Kaggle datasets acquired in October 2021 and June 2021, which might inherently carry a bias in terms of app release years due to variations in total app store coverage and the timing of data collection. Second, newer apps introduced to these platforms since June and October 2021 may have varying degrees of linkage to apps in our initial Kaggle datasets. This linkage relies on app similarity, defined by internal algorithms of the Google Play Store and the Apple App Store, and the presence of common developers, both of which are beyond our control.

Despite these potential limitations, it is important to note that our dataset remains extensive, encompassing >200,000 mHealth apps and >2000 HD apps across both platforms. While acknowledging these considerations, our study's primary findings and insights into the landscape of mHealth apps, especially those related to HD, remain valid and valuable for researchers and stakeholders in the field.

Correlation Analysis

This analysis sheds light on various aspects of HD apps, offering insights into factors influencing their downloads, user ratings, and overall dynamics.

We found that for HD apps on Google Play Store, the number of installs positively correlated with the number of ratings and reviews. Pinheiro et al [74] noted a similar strong correlation between the number of installs and ratings in psychiatry apps on the Google Play Store. Notably, they reported no significant correlation between installs and reviews [74]. Pinheiro et al [74] also reported a strong association between installs and low app prices, as well as installs and the presence of in-app purchases. Interestingly, these associations were not found in the context of HD apps in this study.

On both Apple App Store and Google Play Store, we found that app rating-score and description length were positively correlated. This suggests that longer descriptions tend to correspond to higher app rating-scores. We found that the release year of the apps was negatively associated with the number of reviews and rating-scores on both Apple App Store and Google Play Store, suggesting that newly released apps had a lower number of reviews and lower rating-scores, and older apps tended to have slightly higher rating-scores and reviews.

XSL•FO
RenderX

In addition, our analysis revealed a positive correlation between the size and price of HD apps on the Apple App Store, contrary to findings from the study by Fu [45]. Fu studied apps from all categories in Apple App Store, not only mHealth apps, and found that larger apps tend to be cheaper. In our analysis of HD apps, we found that larger apps, in general, were more expensive. The large size of such apps could be due to additional features offered.

Clustering

We used LDA clustering techniques to identify and classify the different types of HD apps available in India. We found that about half of the apps were classified into the clinical cluster. This cluster had terms like doctor, disease, treatment, cardiac, and pain. This cluster can be used to conduct in-depth analysis and identify the numbers and characteristics of various clinical HD apps like those meant for teleconsultations, ordering medication, and health education.

Previous studies have used clustering techniques while studying apps from app stores. However, those apps were very different from our study. Fu [45] used numerical clustering methods on apps from the Apple App Store to group apps according to the number of ratings and user rating-score. Danahiswari et al [44] studied the Google Play Store apps and used k-means clustering to identify the differences in characteristics between apps that were attractive to users and those that were not. Both these studies were aimed toward app developers and making better apps.

Dehling et al [47] studied the security and privacy of mHealth apps on the Apple App Store and Google Play Store using clustering techniques. To the best of our knowledge, ours is the first study to use app descriptions to cluster and classify HD apps.

These clusters can be used in further research depending on one's research focus. For example, researchers interested in preventive and public health aspects of HD apps may incorporate apps from the lifestyle and fitness clusters, whereas those seeking more clinical apps can concentrate solely on the clinical cluster.

Further analysis of app attributes within individual clusters showed that clinical apps were smaller in size. Among the largest (ie, >100 MB app size) apps, there were a few clinical apps. However, these were outliers, and most apps from the clinical cluster were much smaller. They also had shorter descriptions. Clinical cluster apps on the Google Play Store had a lower number of installs and rating-scores, and the lowest percentage of apps with in-app purchases. More detailed descriptions can perhaps help increase the installs of these apps.

Our analysis revealed key insights into the current landscape of health and medical apps in India. Language accessibility remains a significant barrier, with most apps not supporting regional languages. Despite the high prevalence of HD, there is a notable scarcity of relevant mHealth apps. The existing HD apps are generally large, creating challenges for users with limited storage or slow internet. While most HD apps are free, paid apps (ie, especially on the Apple App Store), and in-app purchases (ie, on the Google Play Store) can hinder accessibility. User engagement (ie, from the number of ratings and reviews, and rating) is in general low, possibly due to issues with app discoverability and perceived credibility. We found that longer app descriptions tend to correlate with higher ratings, enhancing user trust. Many apps support older OS versions, reducing technological barriers. However, frequent updates, while improving quality, can lead to compatibility issues. In recent years, there has been a peak in app releases. Correlation analysis showed that the year of release for the apps was closely linked to ratings and reviews. Apps that have been around for a while had more ratings and reviews, which can add to their perceived credibility. Clustering revealed that "clinical apps," which focus on teleconsultation and health education, were prominent in number but had lower engagement. They had a lower number of installs, rating-scores, and shorter descriptions. Each of the clusters can be studied further in future research to obtain deeper insights.

Limitations

We used a comprehensive approach and a thorough methodology in this study; however, it is important to acknowledge the limitations for a balanced interpretation of the findings.

A downside to using the Kaggle datasets is that any biases or inaccuracies in the original scraping process could have extended into our study. While we made diligent efforts to compile a comprehensive dataset of mHealth and HD apps, it is important to acknowledge the absence of a definitive list encompassing all available apps on both app stores to compare against. To enhance the reliability of future research based on this dataset, we propose a validation approach wherein our dataset can be cross-referenced with a carefully selected subset of apps that are unequivocally expected to be part of such a list.

While the keyword dictionaries cover an extensive list of relevant terms, they are not exhaustive as we may have missed some terms, leading to some missed HD apps. Furthermore, we used the tokenized text from the title, summary, and description of the apps as text data for NLP analysis, and we did not appraise the quality of the texts. Our method can be used as a first step to gather all these apps that claim to address specific health issues (eg, HD), which can then be scrutinized under a quality lens using the already existing tools, such as MARS (Mobile Application Rating Scale) [41,42].

Our analysis of HD apps exclusively focused on apps with English descriptions, excluding those with descriptions in an Indian language. However, it is important to note that apps with descriptions in an Indian language represent a minor fraction, 0.5% (548/108,945) in Google apps and 1.68% (1990/118,555) in Apple apps. Our aim was to offer a comprehensive overview of HD apps accessible in India. We highlight the scarcity of apps with descriptions in Indian languages and emphasize the importance of exploring these apps in future research.

The LDA model parameters were selected based on iterative testing; however, they might not be optimal for all types of health apps. They may need to be adjusted when these methods are replicated for other mHealth apps.

XSL•FO
RenderX

In our analysis, we used simple descriptive statistics and unsupervised clustering methods. More detailed statistical techniques and supervised topic modeling could yield deeper insights into the data. However, with this study, we aimed to establish our methods to create a database for health apps and analyze data to provide an overview of the HD apps available in India. We believe that these initial findings set the stage for more in-depth research, offering a baseline for future studies to build upon.

The results and models of this study are not validated with external datasets, limiting the robustness of the conclusions. However, we aimed to lay a strong foundation for future research by providing a comprehensive and replicable methodology. The code is available on GitHub, allowing other researchers to easily validate and extend our work with additional datasets, enhancing the credibility and broader applicability in future studies.

Our Methods Versus Previous Methods

Studies on mHealth apps so far either looked at existing literature on specific apps or explored and analyzed a handful of apps by searching app stores manually. Manual scraping cannot help while mapping a vast number of apps. It only works for collecting data about a very specific health condition, and even then, it is time-taking.

Studies, such as the one by Dehling et al [47] have previously used similar scraping methods, but the regulations and designs of app stores have changed since then. Moreover, there is a limitation on the number of results one can obtain in both the app stores by searching with specific keywords. Our methods help increase the search range by using the “similar to” and “from the same developer” features on app stores and automate the process of collecting and screening metadata from a large number of apps.

Future Research

In the future, this method can be used to compile a dynamic dataset of mHealth apps available in India at any given time, allowing for regular updates and enabling trend analysis over time. Expanding the analysis on the HD apps, one could look at apps concerning the major health priorities in India, such as the top 10 causes of death. Furthermore, an analysis of the users’ reviews using NLP techniques and sentiment analysis could help to understand the users’ views and challenges while adopting mHealth apps. Our study and methodology facilitate the selection of apps with particular characteristics for further qualitative evaluation with tools, such as MARS [41,42]. This enables a systematized understanding of the app quality, instead of depending on the blackbox methods used by the app stores for manual searching.

Our methods hold particular significance in mapping the landscape of mHealth apps, particularly in low-resource settings like India, where evidence on the rapidly evolving mHealth ecosystem is scarce. This study addresses a significant gap in the academic literature by offering a relatively user-friendly approach to access and analyze valuable metadata from mHealth apps. Importantly, our method is designed to be accessible to health researchers without extensive coding expertise, serving as an effective means to overcome this potential barrier. Researchers can readily adapt and replicate our approach to explore mHealth apps in various low-resource settings, leveraging geolocation and condition-specific keyword dictionaries to analyze apps tailored to address diverse health issues with targeted research inquiries.

Conclusions

Our study introduced a robust method for collecting and analyzing metadata from a wide array of mHealth apps available in India through the Apple App Store and the Google Play Store. We revealed the limited representation of India’s linguistic diversity within the health and medical app landscape, evident from the negligible presence of Indian language apps. Despite the high prevalence and number of deaths caused by HD in India, we observed a disproportionate scarcity of mHealth apps dedicated to this crucial health issue, along with a lower level of user engagement, as indicated by reviews and app ratings. While most HD apps are financially accessible, uptake remains a challenge. Further research should focus on app quality assessment and factors influencing user adoption.

Abstract

Background: Malaria remains a significant cause of maternal and neonate morbidity and mortality in sub-Saharan Africa. Long-lasting insecticidal nets (LLINs) represent an important component of malaria prevention and can decrease the adverse health outcomes associated with malaria infection during pregnancy. Voucher programs have been successfully implemented for a variety of initiatives across sub-Saharan Africa, including the distribution of subsidized LLINs in Tanzania. However, mobile messaging for behavior change communication (BCC), in combination with an e-voucher program, has not been explored for malaria prevention.

Objective: This study aimed to assess the efficacy of mobile messaging in increasing the redemption of e-vouchers for LLINs for pregnant women and adolescents in Tanzania.

Methods: This study was a blinded, 2-arm, cluster randomized controlled trial implemented in 100 antenatal health facilities in Tanzania (both urban and rural settings), with 50 clusters in both intervention and control groups. Clusters were antenatal clinics with e-voucher capabilities, with randomization stratified such that 25 urban and 25 rural clinics were randomized to each arm. Participants were pregnant females aged 13 years or older. Participants in both intervention and control groups were issued e-vouchers on their mobile phones that could be redeemed for LLINs at registered retailers within a 14-day redemption period. Participants in the intervention group received targeted BCC messages about the importance of malaria prevention and LLIN use during pregnancy, while participants in the control group did not receive BCC messages. Analyses were by intention to treat. The primary outcome was the redemption rate of e-vouchers for LLINs from retailers. Outcome measures pertain to clinic sites and individual participant-level data.

Results: The study enrolled 5449 participants; the analysis included 2708 participants in the intervention arm and 2740 participants in the control arm (49 clusters in each group analyzed). There was no significant difference in the raw redemption rate of e-vouchers between pregnant participants in the intervention group (70%) and the control group (67%). Younger participants were less likely to redeem e-vouchers.

Conclusions: The use of a BCC mobile messaging intervention did not result in a significant increase in LLIN uptake for pregnant individuals. However, the study shows that e-voucher distribution through nurses in antenatal clinics in partnership with

XSL•FO
RenderX

local retailers is feasible on a large scale. Consideration of women and adolescents who are low-income and live in rural areas is needed for future interventions leveraging e-vouchers or mHealth technology in low-resource settings.

Trial Registration: ClinicalTrials.gov NCT02561624; https://clinicaltrials.gov/ct2/show/NCT02561624

KEYWORDS

malaria prevention; pregnant; mHealth; mobile health; short message service; behaviour change communication; long-lasting insecticidal nets; protozoan infections; parasitic diseases; vector borne diseases; randomized controlled trial; morbidity; mortality; intervention

Introduction

Malaria, a parasitic infectious disease spread by mosquitoes, was responsible for an estimated 56 million cases and 132,500 deaths in the East and Southern Africa subregion in 2020 [1]. The United Republic of Tanzania accounted for 12.8% of these total cases [1]. Pregnant women and adolescents are at heightened risk of morbidity and mortality by malaria, with 22% of pregnant women exposed to malaria in East and Southern Africa in 2020 [1]. Malaria infection during pregnancy can result in miscarriage, premature delivery, low birth weight, or death in neonates, as well as maternal anemia and maternal death [2]. Insecticide-treated nets (ITN) are recognized as a mainstay of malaria prevention, whereby trials of pregnant women in sub-Saharan Africa using ITNs during pregnancy compared with no nets reported decreased malarial infection, fewer neonate deaths before delivery, and fewer low birthweight babies [3]. Long-lasting insecticidal nets (LLINs) are a subset of ITN that retain their effective biological activity for approximately 3 years of recommended use without retreatment [4]. While malaria chemoprevention is being more widely implemented in endemic areas, especially for children and pregnant women, this is not a stand-alone strategy; LLINs remain an important component of the malaria prevention toolbox, in combination with medication [5,6].

The Tanzania National Voucher Scheme (TNVS) was a public-private partnership active between 2004 and 2014 that provided pregnant women and children with vouchers at antenatal clinics to be redeemed for ITNs and LLINs at a subsidized price [7]. The TNVS, widely known as Hati Punguzo (Swahili for “discount voucher”), contributed to an increased usage of LLINs among pregnant women, distributing 1.2 to 1.8 million LLINs per year [7]. Initially using paper vouchers, in 2011, the TNVS transitioned to electronic “e-vouchers,” allowing for enhanced tracking, real-time redemption data, and improved workflow efficiency [7]. Voucher programs have been successfully implemented in sub-Saharan Africa for a variety of initiatives, including reproductive and sexual health services, as well as agricultural interventions [8-10].

The transition of the TNVS to e-vouchers presented an opportunity for research assessing the impact of mobile health (mHealth) technology. With 495 million people subscribed to mobile phone services in sub-Saharan Africa in 2020, accounting for 46% of the region’s population, mobile phones provide a platform for widespread health interventions in low-resource settings [11].

Behavior communication change (BCC) strategies, which use targeted messaging to promote and maintain healthy behaviors, have been implemented in Africa for malaria prevention and control. In Benin, BCC messages delivered by social mobilization, radio, and flyers increased LLIN use in pregnant women [12]. Similarly, in Uganda, BCC messages spread by interpersonal communication, community mobilization, radio, and flyers increased the usage of LLIN in pregnant women [13]. However, the delivery of BCC messages through mHealth technology to increase malaria prevention efforts remains an under-researched area.

Data from 2006-2013 suggests that only 47% of women who attended an antenatal clinic accessed a net through the TNVS [7]. While the Under Five Catch Up Campaign, which distributed over 9 million free LLINs to children under 5 between 2008-2010, as well as the Universal Catch Up Campaign, which distributed over 17 million LLINs to households in 2010-2011, may have caused bed-net saturation, it remains unclear why many women were not redeeming vouchers to access LLINs before these mass campaigns [7,14]. Furthermore, LLINs typically only last up to 3 years, meaning that the protection against malaria afforded by these mass LLIN distribution campaigns is not permanent.

Despite pregnant women being at high risk of malaria morbidity and mortality, the ability of BCC messages on a mHealth platform to increase LLIN uptake for pregnant women remains uninvestigated. The Hati Salama (HASA) (Swahili for “secure voucher”) cluster randomized controlled trial aimed to test the hypothesis that BCC mobile messages targeted at pregnant women would increase redemption of e-vouchers for LLINs in regions of Tanzania with high malaria prevalence and a history of low LLIN uptake; the cluster design allowed for assessment in a real-life setting, to evaluate redemption of e-vouchers at antenatal clinic clusters. This study also aimed to determine perceived barriers to e-voucher redemption.

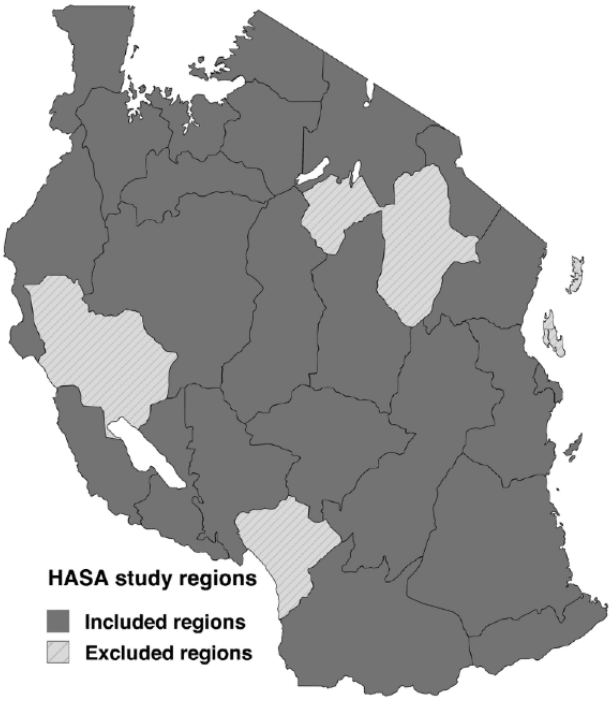
Methods

Study Design and Participants

The HASA study was a cluster randomized controlled, blinded 2-arm study implemented in 100 antenatal health facilities across Tanzania, with 50 clusters randomly allocated to the intervention group and 50 clusters to the control group, as shown in Figure 1. The study was registered on ClinicalTrials.gov (NCT02561624). The clinics selected for participation in the study were drawn from a pool of former TNVS health facilities. Study clusters were defined as clinics from both urban and rural

XSL•FO
RenderX

settings with e-voucher capabilities, with an issuance of more than 175 e-vouchers per quarter but less than 70% voucher redemption of LLINs during the TNVS program.



In Figure 1, the regions highlighted in dark grey are regions of Tanzania included in the HASA study. Regions highlighted in light grey are regions excluded from the HASA study.

Participants included in the study were pregnant women and adolescents aged 13 years and older attending one of the selected antenatal health facilities. To be eligible, participants were either literate or living with someone who could assist them with reading SMS text messages. While lack of phone ownership was not a reason for exclusion, participants needed to at least have access to a proxy phone, which was recommended to be the phone of a family member, throughout the entirety of the trial.

Eligible participants who consented to participate were enrolled by trained nurses. Consent was obtained by each participant verbally and in written form by the nurses, and a signature or fingerprint of all participants was obtained. We had ethical approval to enroll participants aged 13 years and older. While most publications discuss teenage pregnancy in Tanzania for females aged 15-19, there are a number of reports that highlight teenage pregnancy for primary school-aged adolescents under and up to the age of 15 [15]. The minimum enrollment age of 13 was used as local stakeholders informed the research team of the presence of adolescents under the age of 15 attending antenatal clinics. The TNVS, the main bed net program in Tanzania, did not have a specific age limit for pregnant women, but data from that participant group informed our decision to use a low minimum enrollment age of 13 to ensure more pregnant individuals were provided the opportunity to receive an e-voucher and mHealth messaging.

Participants were ensured of the confidentiality and anonymity of the trial with regard to the information collected from them. Ethical approval was obtained from the National Institute of Medical Research Tanzania and Queen's University Health Sciences and Affiliated Teaching Hospitals Research Ethics Board.

Figure 1. Map of the regions of Tanzania included in the Hati Salama (HASA) study.

Randomization and Masking

The study enrolled 50 urban and 50 rural clinics with redemption rates below 70% in the previous year. Each site was asked to enroll at least 50 participants. Randomization was stratified such that 25 urban and 25 rural clinics were randomized to each arm. The statistician prepared the randomization list before the start of the trial using clinic codes of the 50 urban and 50 rural participating sites without knowing which clinic the codes referred to. Randomization was performed by randomly sorting 25 intervention and 25 control assignments within each of the 50 rural and 50 urban clinics by a computer-generated sequence. All health care workers and relevant stakeholders, including nurses, were blinded to their group assignment, as were participants and investigators, although participants would presumably become aware of their assignment after receiving their first BCC SMS message. Intervention group nurses and control group nurses were trained separately, and the control and intervention clinics were located large distances from each other to minimize contamination.

Procedures and Interventions

Participants in both the intervention and control groups were issued LLIN e-vouchers on their mobile phones by nurses upon enrollment into the study. E-vouchers could be redeemed for a high-quality LLIN at registered retailers for a discounted price; while the original cost of LLINs was approximately US $8, participants with an e-voucher were only required to pay a co-payment of 500 Tanzanian shillings (at the time of the study, equivalent to approximately US $0.25). All women attending

XSL•FO
RenderX

antenatal clinics enrolled in the study were offered an e-voucher through the HASA program, regardless of whether they provided informed consent to participate in the trial and receive BCC messages. Women who accepted e-vouchers but did not participate in the study were not included in the analyses, but all women enrolled in the study were included.

The study undertook a phased approach with rolling enrolment during the period from July to December 2015, whereby each site had 12 weeks to complete recruitment, and each individual participant had 14 days for e-voucher redemption, starting from when they were enrolled. Participants attending one of the 50 clinics allocated to the intervention group received targeted BCC messages on their registered mobile phones at programmed intervals during the 14-day period in which the e-voucher was active. Messages contained health promotion and sensitization information on the importance of malaria prevention and LLIN use during pregnancy, in addition to reminders to redeem the e-voucher for an LLIN at a registered retailer (Textbox 1). Participants attending one of the 50 clinics randomized into the control group did not receive any targeted BCC messages on their phones during the 14 days following e-voucher issuance. As the allocation of clinics to intervention and control groups was random and blinded, all participants were told by study nurses that they may or may not be receiving SMS messages during the 14 days following issuance. Each participant also had a case report form completed by a nurse, collecting information including the participant's age, marital status, number of pregnancies, number of children, previous LLIN ownership, and education level.

Following voucher expiration (14-day period), all participants who did not redeem their e-vouchers in both the intervention and control groups received a follow-up phone survey asking them to indicate the reason why they did not redeem the voucher for an LLIN. All participants were analyzed through intention to treat in the arm their cluster was randomized to, regardless of whether they redeemed their e-voucher or not.

Textbox 1. Content of SMS behavior communication change (BCC) messages sent to participants (translated from Swahili to English).

- Insecticide-treated bed nets are proven to prevent malaria when used correctly when sleeping in your home.
- Insecticide-treated bed nets should always be used when you or your children sleep.
- Malaria can make young children very sick and can cause death.
- Malaria is a very serious illness among pregnant women. It can have dangerous consequences for the woman and her unborn child, including death.
- Your small children should always sleep under a bed net, and bed nets should be replaced every 5-7 years or as soon as they are in poor condition.
- You have recently received a voucher that can be redeemed for a bed net, but you have not yet redeemed this voucher.
- The net voucher you received at the clinic can be redeemed at any participating shop (Duka or Duka la Dawa) that provides bed nets for Hati Punguzo.
- This is a reminder that you received a bed net voucher 1 week ago, and you have not yet redeemed it to receive your bed net.
- This is a reminder that you received a bed net voucher 10 days ago, and you have not yet redeemed it to receive your bed net.

Outcomes

The prespecified primary outcome was the redemption rate of e-vouchers for LLINs from retailers in regions with high malaria prevalence and a history of low uptake. Outcomes were measured using participant-level redemption data available through the electronic platform. The data displayed how many participants (with appropriate code and phone numbers) redeemed their e-vouchers for an LLIN within the 14-day period from each clinic and the exact times the transactions took place; outcome measures pertain to cluster sites and individual participants. A subsequent manuscript will examine perceived causes and barriers to nonredemption by a structured phone survey of participants who did not redeem their e-vouchers within the allotted 14-day period [16]. In addition, with regard to longer-term outcomes, the trial serves as a pilot study to test the overall effectiveness, security, and sustainability of a mobile platform design and its potential for delivering other private-sector health solutions in the region.

Statistical Analysis

When calculating the sample size, a baseline voucher redemption rate of 50% was estimated, with a 10% increase to 60% considered minimally clinically important. Furthermore, it was assumed that the intracluster correlation would be 0.1 and that each site would enroll 50 participants. Under these assumptions, 47 sites per arm would provide over 80% power at a 2-sided α=.05. To allow for potential loss of sites or underrecruitment at some sites, 50 sites per arm were enrolled. This calculation did not account for our analysis adjusting for reach (urban vs rural) and baseline site redemption rates, which could increase power slightly.

The redemption rates were compared between arms using a generalized estimating equation with a compound symmetric (ie, exchangeable) working correlation structure. A binomial distribution and an identity link were used so that adjusted risk differences could be estimated. However, it was confirmed that all *P* values remained nearly identical if the logit link was used. Adjusted risk differences were based on the estimate of an intervention indicator variable. The model also included the site level baseline (baseline referring to the previous year) redemption rate as a linear covariate and the site reach (urban vs rural) indicator variable. *P* values and confidence intervals were based on the Wald method using empirical standard errors. Since the primary analysis only adjusted for site-level factors, nearly identical results were obtained in a sensitivity analysis performed at the site level using a regression model with arm,

XSL•FO
RenderX

baseline redemption rate, and reach as independent variables and the observed site redemption rates as the dependent variable. Sensitivity analyses were also performed, excluding one outlier site and including only participants who were known to have had their own mobile phones.

The ANOVA estimator was used to estimate the intracluster correlation coefficient of e-voucher redemption separately by the arm with 95% CIs estimated by the nonparametric percentile bootstrap based on 1000 bootstraps for each arm. Our bootstrap selected entire clinics rather than individual participants [17].

The research team attempted to identify predictors of e-voucher redemption based on our preselected list of site and participant characteristics. First, the redemption rate was compared by characteristic. Subsequently, the aforementioned generalized estimating equation approach was used to identify significant predictors of e-voucher redemption. A multivariable model was selected, including predictors of e-voucher redemption based on a backward selection with an exit criterion of $P<.15$.

All analysis was performed using SAS (version 9.4; SAS Institute).

Role of the Funding Source

This Project is supported by Grand Challenges Canada. Grand Challenges Canada is funded by the Government of Canada and is dedicated to supporting Bold Ideas with Big Impact.

Ethical Considerations

This study was conducted in accordance with ethical standards for human subject research (Declaration of Helsinki). Before initiation, the study protocol and study forms were reviewed and given approval by the National Institute for Medical Research in Tanzania approval (certificate number NIMR/HQ/R.8a/VOL./IX/1750) and Queen's University Health Sciences and Affiliated Teaching Hospitals Research Ethics Board institutional review board in Canada (approval number 6013000).

Participants were informed that their participation and responses would be completely confidential and no identifying information about them would be recorded and stored. Each participant was given a copy of the informed consent document. Consent was allowed in both verbal and written formats after the participant was given enough time to review the document and ask questions or discuss any concerns in a private setting with a research team member. Participants were informed throughout the consent process and the duration of the study that participation was voluntary, they may withdraw from the study at any time without consequence, and that they would still receive an e-voucher for redeeming a long-lasting insecticidal net (LLIN) even if they decided not to participate and withdrew. No compensation was given for participation in this study.

Results

The trial took place between July and December 2015. A total of 25 rural and 25 urban clinics were randomized to each study arm. During the study timeline, each clinic had a 12-week period to complete the recruitment of at least 50 participants. Each participant had 14 days for e-voucher redemption starting from when they were enrolled. One rural clinic in the control arm and 1 rural clinic in the intervention arm dropped out of the study for administrative reasons after randomization but before enrolling any participants. This left a total of 49 clinics in each arm, as shown in Figure 2. In total, 5449 participants from the randomized sites consented to participate in the trial. One of the consented participants was excluded from the analysis because their e-voucher redemption status was uncertain, leaving 2708 participants in the intervention arm and 2740 participants in the control arm. Site and participant characteristics were well-balanced between arms (Table 1). In the year before the study, the average (SD) redemption rate at the participating sites was 54% (SD 12%) in control groups and 54% (SD 13%) in intervention groups. (range 3%-68%). In the control groups, the average age of participants was 26.4 (6.2) years old (range 13-49), the median parity was 2, 87% (2372/2740) were married, and 62% (1693/2740) were known to have their own phones (no proxy phone). In the intervention groups, the average of participants was 26.4 (6.2), the median parity was 2 (IQR 1-4), 85% (2311/2708) were married, and 62% (1687/2708) were known to have their own phones. Where data for marital status, education, or proxy phone status is missing, this indicates that this data was not collected by antenatal nurses, or participants declined to provide this information (Table 1).

Figure 3 displays the within-site-specific change in redemption rates from the previous year compared with the rate during the study. Generally, the rates increased. The actual site-specific counts are presented in Table 2. The one notable outlier was the 24th rural site in the control group (Table 2). This site had a baseline redemption rate of 62% yet had only a 6% (1/18) redemption rate during the study. This site had substantially fewer participants than the next lowest accruing site, which had 33 participants (all other sites accrued at least 50 participants as planned) and had a much lower redemption rate than the next lowest site, which had a rate of 21%. After querying this site, it was found that they had administrative problems, which hindered accrual and redemption. Our primary analysis includes all sites as randomized, but a sensitivity analysis excluding this one outlying site was performed.

In Figure 3, the black lines depict site-specific rates, and the bold red line shows the overall mean rate.

Overall, the raw redemption rate in the intervention arm was 70% compared with 67% in the control arm. The difference after controlling for the sites' reach (urban vs rural) and the sites' baseline redemption rates was 4% (95% CI –2% to 10%; *P*=.19). After excluding the one outlying site, the raw rates were 70% and 68% in the intervention and control arms, respectively, and the adjusted difference was 3% (95% CI –3% to 9%; *P*=.31). The intracluster correlation of e-voucher redemption status (without adjusting for covariates) was 0·12 (95% CI 0.05 to 0.15) in the intervention arm and 0·13 (95% CI 0.7 to 0.16) in the control arm. In a prespecified subgroup analysis, the 3380 (62%) participants who were known to have their own phones were included. In this subgroup, the raw redemption rates in the intervention and control arm were 71% and 69%, respectively, with an adjusted risk difference of 3% (95% CI –3% to 9%; *P*=.27).

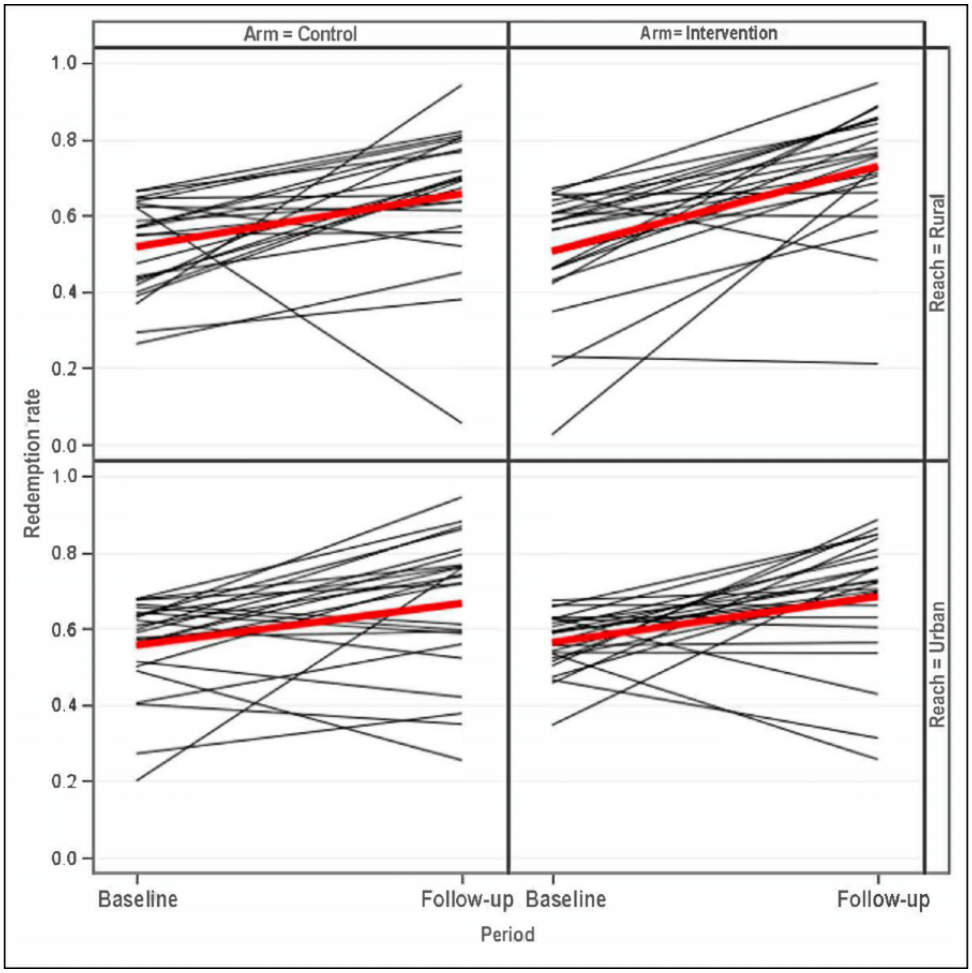

Table 3 compares the site and participant characteristics between participants who did and did not redeem their e-vouchers. Of note, people who redeemed their vouchers were 0.7 years older than those who did not. E-voucher redemption status was lower among participants where marital status, education, or proxy status was missing; however, there was no difference in e-voucher redemption rates among known education levels, marital status, or proxy status. Where proxy status was missing, this indicates that this data was not collected by antenatal nurses or participants declined to provide this information (Table 3). On average, participants who redeemed their e-vouchers came from sites with a baseline rate of 2% (*P*=.04) higher than participants who did not redeem their e-vouchers. In fact, aggregated to the site level, the correlation between the previous redemption rate compared with the study redemption rate was *r*=0.23 (*P*=.03), and after excluding the one outlier site (with only 18 participants and 1 redemption), the correlation became *r*=0.27 (*P*=.007). Parity, number of children, number of LLINs owned, number of LLINs accessed through TNVS, and clinic reach were not significantly different between participants who did and did not redeem their e-vouchers.

All participant characteristics were missing for 186 participants, an additional 55 were missing parity, an additional 108 were missing education, and an additional 950 were missing proxy. For categorical variables, the total number of missing values is displayed, but for continuous variables, the missing values have been excluded.

Table 4 provides the single predictor and multiple predictor regression results. The multiple predictor regression included all predictors that were significant at *P*<.15 by backward selection. From the multiple predictor model, it was determined that for every 10% increase in the sites' baseline redemption rate, the study redemption rate increased by 3% (95% CI 0%-6%, *P*=.03), and for every decade of age, the redemption rate increased by 4% (95% CI 2%-5%, *P*<.001).

Discussion

Principal Findings

This cluster randomized trial aimed to assess the effectiveness of mHealth technology in the uptake of LLINs for pregnant women in Tanzania. It was anticipated that targeted BCC mobile messages would increase the redemption of e-vouchers for LLINs in regions of Tanzania with high malaria prevalence and a history of low LLIN uptake. However, our results demonstrate no significant difference in the redemption of e-vouchers between pregnant women in the intervention group that received BCC mobile messages and those in the control group that did not receive mobile messages.

Comparison With Previous Work

The existing literature using mHealth messaging as a tool for malaria prevention and control in sub-Saharan Africa shows a combination of both successful and unsuccessful interventions. There are several studies investigating the feasibility of mHealth technology as a malaria surveillance tool in sub-Saharan Africa that have shown encouraging results [18-20]. Evidence also suggests that mobile messaging improved antimalarial drug supply management in Tanzania, improved Kenyan health care workers' adherence to malaria treatment guidelines, increased adherence to malaria rapid diagnostic test results in Nigeria, and increased adherence to artemisinin-based combination therapy regiments in Ghana [21-24]. There are also several mHealth studies with conflicting results. A cluster randomized trial sending mobile messages about artemether-lumefantrine treatment to retail staff in Tanzania drug shops found some improvement in dispenser knowledge but no difference in participant adherence, suggesting that increased knowledge of retail staff did not translate to increased adherence in participants [25]. Furthermore, a randomized controlled trial in Ghana sending mobile messages to caregivers of children with malaria under 5 years of age found increased posttreatment return to the health facility but no impact on treatment adherence [26]. It was suggested that this could be due to adherence levels already being high in both groups, meaning that mobile

XSL•FO
RenderX

messages were unnecessary. Similarly, it is possible that pregnant women in Tanzania have significant baseline knowledge that LLIN use in pregnancy is important, regardless of educational mobile messaging.

In the HASA study, site and participant characteristics were well-balanced between intervention and control groups, and characteristics including parity, number of children, education levels, and marital status did not impact redemption. Notably, younger participants were less likely to redeem their e-vouchers, and for every decade of age, the redemption rate increased by 4%. Previous literature from Tanzania suggests that individuals in the age group 30-49 had the greatest knowledge of malaria, potentially explained by having more life experience than younger individuals [27]. Together, this may suggest a need for interventions directly targeting pregnant women below the age of 30 years.

Despite a null result, both groups experienced an increase in LLIN uptake from baseline during the trial. As such, one possible explanation for the null result is that nurses at participating antenatal clinics contributed to the increased uptake of LLINs in both groups. Despite nurses being blinded to their intervention group, antenatal nurses likely played a role in encouraging LLIN uptake. Antenatal clinic nurses were involved in orientation and extensive training for the HASA trial (nurse training described in subsequent manuscript), which may have prompted them to provide additional information about malaria and motivate pregnant women in both groups to follow through on e-voucher redemption upon enrollment into the study [16]. This would be consistent with previous findings in Tanzania that for pregnant women, knowledge of malaria correlates with ITN uptake [28]. While this represents an overall positive health outcome resulting from the trial implementation, it is a type of contamination bias from a clinical trial perspective, whereby the effects of the intervention were received by members of the control group and possibly shifted the outcome of the control group in the same direction as the intervention group [29]. Contamination bias is a potential problem for clinical trials of educational and behavioral interventions due to the ease of transferring intervention knowledge; in this case, information about the importance of LLINs and malaria prevention could be inadvertently shared with participants in the control group by nurses, thereby changing the behavior of the control group participants and impacting the results of the trial [29].

The current prevailing practices for increasing ITN uptake in pregnant women focus on a multipronged approach. This includes integrating ITN provision and counseling into antenatal care visits, engaging and educating the community about the importance of ITNs, strengthening health care systems by ensuring the availability and distribution of ITNs to health care facilities, and training health care workers on ITN promotion and counseling techniques [30,31]. Due to the importance of increasing widespread LLIN use in pregnancy to prevent malaria and its morbidity and mortality, and given the significant body of evidence for the use of mobile messaging to promote healthy behavior change in low- and middle-income country contexts, the authors feel that there is still significant equipoise in this area of research.

Strengths and Limitations

A major strength of the HASA study was the distribution of e-vouchers from antenatal clinics. Antenatal care coverage in Tanzania has been above 90% of pregnant women for over 2 decades, with 98% receiving care from a skilled provider in 2015-2016 [32]. Over half of pregnant women in Tanzania had 4 or more antenatal facility visits during the year of the trial, providing ample opportunity for nurses to provide them with LLIN e-vouchers at visits [32].

An additional strength of the study was that it was a large, robust study. A total of 5448 women were enrolled in the study, and 3746 e-vouchers were redeemed. One can assume that 5.5 lives per year are saved for every 1000 children with an LLIN in the household [33]. With 3746 e-vouchers redeemed by pregnant women with an average of 2 children each already and a new baby (assuming all pregnancies resulted in a live birth), the HASA study protected 11,238 children and saved approximately 62 lives, which is a success in terms of trial implementation.

A major challenge encountered in this study was the low penetration of mobile phone ownership in women at numerous study facility sites, with only 62% (1687/2708) of participants possessing their own phones. This represents a barrier for researchers and health program implementers considering using a mHealth strategy to improve access to health care and health education for rural-dwelling low-income women. Participants whose phone proxy status was missing or not available were less likely to redeem their e-vouchers. This low penetration reflects the gap in gender equity in mobile phone ownership. In sub-Saharan Africa, women are 13% less likely than men to own a mobile phone; literacy, digital skills, and affordability are the largest barriers to phone access [34]. Women in rural areas, particularly Maasai women, may have been disadvantaged in terms of the trial as they are less likely to own a phone; cell coverage in these rural areas can also be particularly poor.

Unexpected outages of cellular network services in many parts of Tanzania during the study represented another challenge. Clinic nurses reported network outages and the resulting inability to activate e-vouchers while a participating woman was at the clinic. The investigators are aware that some women who sought to participate were unable to either receive or redeem their e-vouchers due to connectivity issues. Given that cellular coverage is increasing in rural areas and network reliability is consistently improving, perhaps in a few years, these issues will be less prevalent for mHealth studies.

Previous findings suggest that in Tanzania, women of low socioeconomic status have a lower uptake of ITN vouchers than women of higher socioeconomic status since there is still some expense required to obtain a net [35]. The voucher redemption rate for ITNs in Tanzania is influenced by socioeconomic status and co-payment cost [36]. This disparity for women of lower socioeconomic status may be amplified using e-vouchers, as these women may be less likely to have their own mobile phones or live in an area with reliable connectivity. Despite the co-payment cost being relatively low, this finding suggests the need for interventions targeted at low-income women.

XSL•FO
RenderX

In Tanzania, the literature has indicated past challenges with the misuse of ITN vouchers. A study investigating a paper discount voucher scheme in Tanzania in 1999 suggested that some vouchers were not being used for the intended population (pregnant women and young children), likely resulting in increased usage of nets in men and older children [35]. As the HASA study measured e-voucher redemption, a limitation is an inability to determine whether the LLINs were used by the intended population following e-voucher redemption. Furthermore, in 2013, there was evidence of fraudulent e-voucher activities by some clinic and retail staff, whereby staff could create vouchers for fake beneficiaries so that LLINs could be subsequently sold on the commercial market [7]. For the HASA study, the potential of e-voucher fraud was addressed by a redesign of the e-voucher to create a more secure system. Components of the redesign included a unique identifier for all pregnant women, random barcode usage activated once at retailers, periodic reports to the clinic in charge to verify the numbers issued, the ability of participants to provide SMS feedback to confirm whether a voucher code was received, and a log indicating SMS delivery confirmation or errors causing delivery failure.

Conclusions

The HASA study has demonstrated that the use of a mHealth intervention for BCC mobile messaging does not result in a significant increase in LLIN uptake for pregnant women. However, the use of an e-voucher distributed by nurses in antenatal clinics in partnership with local retailers is feasible on a large scale and holds promise for other health interventions. Future studies evaluating e-vouchers or mHealth initiatives should take into consideration the barriers to phone ownership experienced by those who are most vulnerable, especially among women who are low-income and live in rural areas.

Abstract

Background: The use of geosocial networking apps is linked to increased risky sexual behaviors among men who have sex with men, but their relationship with HIV and other sexually transmitted infections remains inconclusive. Since 2015, the prevalence of app use among men who have sex with men in Shenzhen has surged, highlighting the need for research on their spatiotemporal and behavioral patterns to inform targeted prevention and intervention strategies.

Objective: This study aims to investigate the population size, spatiotemporal and behavioral patterns, and mobility of app-using men who have sex with men in Shenzhen using mobile big data. The goal is to inform enhanced and innovative intervention strategies and guide health resource allocation.

Methods: By leveraging mobile big data application technology, we collected demographic and geographic location data from 3 target apps—Blued (Blued Inc), Jack'd (Online Buddies Inc), and Zank (Zank Group)—over continuous time periods. Spatial autocorrelation (Global Moran I) and hot spot analysis (Getis-Ord Gi) were used to identify the geographic clusters. The Geodetector tool (Chinese Academy of Sciences) was adopted to measure spatially stratified heterogeneity features.

Results: From September 2017 to August 2018, a total of 158,387 males aged 15-69 years in Shenzhen used one of the 3 apps, with the majority (71,318, 45.03%) aged 25-34 years. The app user-to-male ratio was approximately 2.6% among all males aged 15-69 years. The estimated population of app-using men who have sex with men in Shenzhen during this period was 268,817. The geographic distribution of app-using men who have sex with men in Shenzhen was clustered, with hot spots primarily located in central and western Shenzhen, while the distribution of HIV testing and counseling was more concentrated in central-eastern Shenzhen. Approximately 60,202 (38%) app-using men who have sex with men left Shenzhen during the Spring Festival, and 37,756 (62.7%) of them returned after the holiday. The destination distribution showed a relatively centralized flow throughout the country, with the largest mobility within Guangdong province (67.7%), followed by lower mobility to Hunan province (7.9%) and other neighboring provinces (3%-5%), such as Jiangxi, Guangxi, and Hubei Provinces.

Conclusions: Shenzhen has a large population of men who have sex with men. The variation and inconsistent spatiotemporal distribution of app use and HIV testing and counseling emphasize the need to adapt traditional venue-based prevention and intervention to identified hot spots and to launch outreach initiatives that extend beyond traditional healthcare settings. Given the relatively high internal and interprovincial mobility of app-using men who have sex with men, further smartphone-based behavioral monitoring could provide valuable insights for developing enhanced and innovative HIV prevention and intervention strategies. Moreover, our study demonstrates the potential of mobile big data to address critical research gaps often overlooked by traditional methods.

men who have sex with men; geosocial networking apps; distribution; heterogeneity; mobility; HIV testing; risk behavior; big data

Introduction

Since the first case of AIDS was reported among men who have sex with men in the United States in 1981, AIDS has remained a major global public health issue. As of the end of 2023, it is estimated there are 39.9 million people living with HIV, with 1.3 million newly infected [1]. According to the Chinese Center for Disease Control and Prevention (CDC), there were 1.22 million people living with HIV in China by the end of 2022, with 107,000 new cases reported that year. The proportion of newly reported HIV or AIDS cases transmitted through men who have sex with men has grown rapidly in the past decades, rising from 9.1% in 2009 to 25.6% in 2022 [2,3]. Men who have sex with men have emerged as a significant high-risk group globally, with a likelihood of acquiring HIV that is 28 times greater than that of the general population [4]. In China, the HIV prevalence among this population has risen from 1.4% in 2005 to 6% in 2021 [5,6], raising concerns about the sustained effectiveness of current public health initiatives and underscoring the need for targeted interventions.

With the rapid development of the internet and social media, men who have sex with men can connect with others through various web-based platforms, including smartphone-based geosocial networking (GSN) apps. Unlike traditional fixed-location social networking, GSN apps effectively bridge online and offline dating functions, facilitating the process of seeking relationships or casual encounters. This convenience and privacy have led to the rising popularity of these apps, particularly in countries or regions with low levels of social acceptance of homosexuality. GSN apps designed for men who have sex with men, such as Grindr and Jack'd, have rapidly gained popularity in Western countries since 2009 [7]. Subsequently, several other apps including Blued and Aloha, emerged and have become increasingly popular among Chinese men who have sex with men since 2013 [8]. Blued is the first and most popular gay dating app of its kind in China. Its global users have increased from 27 million in 2015 to 49 million in 2020, with approximately 70% of users being Chinese [9].

Prior research found about 66-67% of the men who have sex with men in China used GSN apps to seek sexual partners within the past 6 months [10,11]. Our previous cross-sectional study revealed a sharp increase in app use among men who have sex with men in Shenzhen, with the rate surging from 12.5% in 2015 to 52.6% in 2017 [12]. The rapid growth of gay dating apps suggests that they have become one of the primary means for seeking sexual partners in the Chinese men who have sex with men community. Literature has documented that the use of GSN dating apps is associated with both increased risky sexual behaviors (eg, multiple sexual partners, condomless anal intercourse, drug use) and risk-reduction behaviors (eg, HIV testing and consistent condom use), although their impact on the risk of HIV and other sexually transmitted infections remains inconclusive [12-14].

Currently, the HIV testing rate in China remains below UNAID's first 95% target, with only 78.7% of men who have sex with men having been tested for HIV, despite concerted efforts of the government, community organizations, and nongovernmental organizations [3]. Recent economic development in China has accelerated population mobility, which is recognized as an important driver for HIV transmission and a potential barrier to HIV care and treatment [15-17]. Prior research reported that the HIV epidemics in Shenzhen were predominantly driven by the migrant population [18]. Most previous studies and intervention programs relied on sentinel surveillance or venue-based populations, resulting in limited coverage of young and mobile populations. Therefore, there is a pressing need for further research into the crucial HIV-related behaviors of these marginalized groups, particularly concerning mobility patterns and access to HIV testing.

With the growing accessibility of the internet and rapid advancements in technology, mobile big data—encompassing aggregated demographics, social behavior, and geographic location information of users—has become a valuable tool for research, particularly in understanding HIV prevention, behavioral patterns, spatial dynamics, and migration trends among men who have sex with men. Earlier studies have used GSN apps to explore various aspects of the men who have sex with men including demographic characteristics, sexual practices, HIV testing, Pre-exposure prophylaxis (PrEP) use, and geospatial distribution, however, most of them were from developed countries or regions [19-23]. In China, domestic research on men who have sex with men and GSN app use primarily focused on risky sexual behavior, HIV infection, and sexually transmitted infections relying on self-reported data [24-27], which may introduce biases due to underreporting or overreporting of sensitive behaviors. Some recent studies explored spatial distribution, migration, and PrEP adherence among men who have sex with men through GSN apps [28,29]. However, most of these studies did not directly use mobile big data.

Shenzhen, designated as China's first special economic zone in 1979, has transformed from a small village into a metropolis with a population of over 15 million. With a massive influx of internal migrant workers from across the country, Shenzhen now has the largest proportion of immigrants in China, with 66% of its population comprised of internal migrants [30]. The relatively open and inclusive cultural environment of Shenzhen attracted many men who have sex with men from across the country. Surveillance data from 2020 revealed that 62.6% of newly diagnosed HIV or AIDS cases in Shenzhen were attributed to male-to-male sexual transmission, exceeding the national average [31]. A previous cross-sectional study estimated that the active population of men who have sex with men in Shenzhen reached approximately 150,000 in 2014 [31]. Our venue-based survey showed the proportion of men who have sex with men using gay dating apps in Shenzhen has rapidly increased since 2015 [12]. The demographic context of

XSL•FO
RenderX

Shenzhen, with its significant migrant population and a high proportion of men who have sex with men using gay dating apps, presents unique challenges for effective HIV prevention and interventions within this group. By leveraging large-scale mobile big data, this study aimed to investigate the actual population size, spatiotemporal and behavioral patterns, and mobility of GSN app-using men who have sex with men in Shenzhen, to gain deeper insights into this key population and inform the development of enhanced and innovative strategies for HIV prevention and interventions.

Methods

Setting

Mobile big data possesses characteristics such as wide coverage, real-time processing, and continuity, allowing for continuous capture of mobility information from the target population. In this study, we used a longitudinal observational design and used mobile big data app technology, specifically structured query language, to gather information on gay dating app users in Shenzhen through the platform as a service (PaaS) and further analyzed the app use patterns, the geographic distribution of app use and HIV testing and counseling (HTC) of the population over a continuous time: from September 2017 to August 2018, leveraging mobile signaling data.

In addition, as the most important traditional festival in China, the Spring Festival (Chinese New Year) is a time for family reunions, cultural celebrations, and various customs. The unique cultural significance makes it an ideal period for examining population mobility as most people travel to their hometowns. Therefore, to better understand the mobility patterns of the app-using men who have sex with men, we analyzed the geographic location changes of the population in Shenzhen before (January 1-31), during (February 1-28), and after (March 1-31) the Spring Festival, and the destination cities where these men who have sex with men traveled during the Spring Festival in 2018.

Participants

According to guidelines for HIV prevention interventions among men who have sex with men from the China CDC, the three most frequently used apps among men who have sex with men are Blued (Blued Inc), Jack'd (Online Buddies Inc), and Zank (Zank Group) [32]. Our preliminary survey also found that approximately 97.2% of men who have sex with men in Shenzhen used Blued [12]. Therefore, all users of the target 3 apps (Blued, Jack'd, or Zank) in Shenzhen were recruited as participants, while only those males aged 15 to 69 years were included for further analysis in this study.

Assessments

The mobile big data collected and the outcomes in this study are included as follows.

- User demographics: Information such as age, sex, and possibly other relevant characteristics of users of Blued, Jack'd, and Zank.
- Geographic location data: Information on the geographic distribution of app users, including district and subdistrict where the apps are accessed during the three defined time periods on weekdays (Monday to Friday): work time (9 AM-6 PM), social time (8 PM-2 AM), and home time (2 AM-6 AM). Additionally, data on the geographic distribution of users' visits to free the HTC sites was collected, including users' visits to city- or district-level (CDC) during the same 3 time periods on weekdays (Monday to Friday), and their visit to Shenzhen 258-Rainbow Working Group (258-RWG) during work time (9 AM-6 PM) on Wednesday and Sunday. 258-RWG is a nongovernmental organization composed of men who have sex with men volunteers, with technical support from Shenzhen CDC. Its initiatives such as outreach, behavioral interventions, peer education, and voluntary counseling and testing to promote prevention and mitigate high-risk behaviors. Both 258-RWG and Shenzhen CDC are the key health service providers for men who have sex with men in Shenzhen, offering free HTC, which is crucial for understanding men who have sex with men's engagement with HIV-related services.
- Mobile signaling data: Information on the distribution of app-using men who have sex with men at the subdistrict level in Shenzhen before the Spring Festival (January 1-31, 2018), the destination cities of those who left Shenzhen during the Spring Festival (February 1- 28, 2018), and the distribution of app-using men who have sex with men after the Spring Festival (March 1- 31, 2018).

Data Sources

The collection and preliminary statistics of the mobile big data were carried out by China Mobile Communications Corporation (CMCC) according to a signed cooperation agreement. The mobile big data on app user, geographic location, and mobile signaling were obtained from the PaaS platform and stored and analyzed using the Hadoop computing framework in the cloud computing environment of CMCC. Preliminary aggregated statistics, such as app user numbers, the geographical distribution of app use and HTC at subdistrict scale across different time periods, and the distribution of destination cities during the Spring Festival in 2018 were exported from the PaaS platform for further statistical analysis. The male population data at the subdistrict level were obtained from the Shenzhen Bureau of Statistics.

The GIS data (GeoJSON format, Geospatial Standard GS {2024} 0650) for the map of China were downloaded from the National Platform for Common Geospatial Information Services. Areas with extremely sparse populations, such as Guangming Farmland and Inner Lingding Island, were excluded from this study and were not displayed on the Map of Shenzhen, as they have minimal impact on the overall distribution and population mobility patterns.

Study Size

Given that mobile big data can potentially obtain information of all target app users, this study encompassed the entire target population, assuming all gay dating app users are generally men who have sex with men. CMCC counted all users of the 3 target apps (Blued, Jack'd, or Zank) in Shenzhen using unique phone numbers, allowing effective deduplication. Although dual SIM

XSL•FO
RenderX

cards enable 2 phone numbers to be used on a single phone, such instances are relatively rare and unlikely to significantly impact the results given the large population size.

Data Analysis

Population Estimates

The total population of men who have sex with men was estimated by combining the percentage (P1) of the target 3 apps among all apps of this kind based on surveillance data, the market share (P2) of CMCC, and the known number of the men who have sex with men users (S) of the target 3 apps (Blued, Jack'd, or Zank) from the survey. The total population of men who have sex with men (N) was then estimated using the formula.

where S is the number of users of Blued, Jack'd, and Zank in this survey; P_1 is the percentage of users of Blued, Jack'd, and Zank among all similar apps based on surveillance data; and P_2 is the market share of CMCC, representing the proportion of users in Shenzhen who are served by this telecom provider.

Spatial Analysis

Based on the acquired geographic location data at the subdistrict scale, ArcGIS (version 10.7; Esri), a professional mapping software for spatial geographic information systems, was used to create choropleth thematic maps of the spatial distribution of the population of men who have sex with men during different time periods. Spatiotemporal autocorrelation analysis was conducted, along with the identification of spatial hot spots in the distribution of app-using men who have sex with men across these time periods. In addition, the distribution of their visits to CDCs and the 258-RWG during different time periods was compared with the distribution of app-using at the subdistrict level.

As one of the most widely used spatial autocorrelation measures, Global Moran I was used to identify spatial autocorrelation. The Global Moran I index was used to assess the spatial autocorrelation of the app use and HTC of the app-using men who have sex with men, with value ranges from –1 to 1, where approximately 0-1 indicates clustering; 0=randomness; and approximately –1 to 0=dispersion. Meanwhile, the High/Low Clustering (Getis-Ord General G) tool was applied to measure the clustering of high or low values of the app using population. The Getis Ord Gi statistic, an index of local spatial autocorrelation, was also used to identify statistically significant spatial clusters of high values (hot spots) and low values (cold spots).

In addition, we used Geodetector software (Chinese Academy of Sciences) to measure and attribute the spatially stratified heterogeneity (SSH) feature of gay dating app use in Shenzhen, characterizing the differences both within and between geographic strata. Geodetector uses the *q*-statistic index to quantify SSH and to assess the interaction outcomes between one or more independent factors. A q value of 0 represents an absence of SSH, while a q value of 1 represents perfect SSH between strata.

Statistical Analysis

Pearson chi-square test and Kruskal-Wallis rank sum test were used to assess the differences in age distribution and median age among users of the 3 apps. The post hoc Dunn test was further applied to perform pairwise comparisons across the 3 apps. All statistical analyses were performed using R software (version 4.4.1; R Foundation for Statistical Computing).

Ethical Considerations

Given that only aggregated data was exported from the PaaS platform for further spatial and statistical analysis, no private information was collected, and no informed consent was required. Privacy protection was fully guaranteed. In addition, this research was reviewed and approved by the Medical Ethics Committee of the Shenzhen Center for Disease Control and Prevention (review number R2017010).

Result

Population of App-Using Men Who Have Sex With Men

From September 2017 to August 2018, a total of 158,387 people used one of the 3 apps: Blued, Jack'd, and Zank, with the majority using Blued (n=117,595, 74.25%) and Jack'd (n=39,040, 24.65%; Table 1). According to our surveillance data, 98.2% of men who have sex with men who reported using a GSN app used one of the 3 target apps, suggesting the population of users collected from these three apps is relatively representative of the entire app-using population of men who have sex with men. Considering that China Mobile Limited held a 60% share of the personal mobile market in 2018 [33], the population of app-using men who have sex with men in Shenzhen was estimated to be 268,817 during 2017-2018, using the formula outlined in the Methods section.

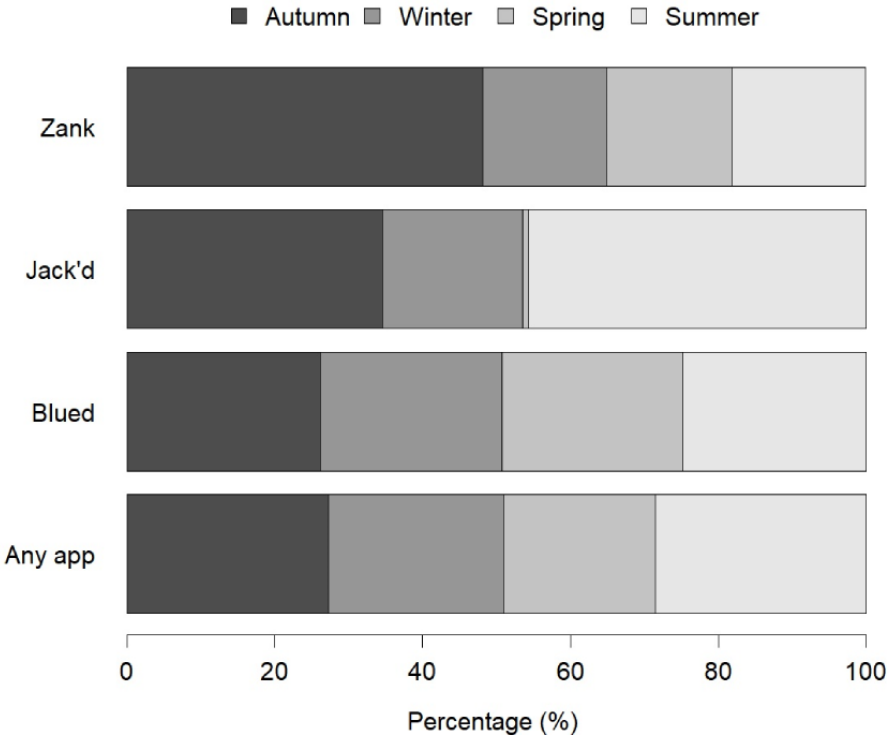
Table 1. Population of app users in Shenzhen from September 2017 to August 2018 (N=158,387).

Gay dating app use	Users, n (%)
Blued	117,595 (74.25)
Jack'd	39,040 (24.65)
Zank	79 (0.05)
Blued + Jack'd	1468 (0.93)
Blued + Zank	197 (0.12)
Jack'd + Zank	1 (0.00)
Blued + Jack'd + Zank	7 (0.004)

XSL•FO
RenderX

Characteristics of App Use

Of the 67,050 app-using men who have sex with men with age information available, the median age was 30 (IQR 25-38) years (Table 2). There was a significant difference in the median age of users across the 3 apps (χ^2_2=4.97; *P*<.001). The post hoc Dunn test revealed a significant difference in median age between Blued and Jackd (*P*<.001), but no significant differences were observed between Blued and Zank (*P*=.41), Zank and Jackd (*P*=.07). Additionally, the age distribution among users of the 3 apps was significantly different (χ^2_6=534.4; *P*<.001). Among the male population aged 15-69 years, the overall app user-to-male ratio was approximately 2.58%, with the highest ratio (3.31%) observed among those aged 25-34 years, and the lowest ratio (1.55%) observed among older adults aged 50-69 years.



The seasonal distribution of app use among men who have sex with men in Shenzhen within the study period (Figure 1) showed a slightly higher percentage of app use during summer and autumn compared to other seasons. For the specific app use, no significant seasonal trend was observed for Blued. However, a seasonal trend was observed for Jack'd and Zank. Specifically, Jack'd use was higher in the summer than in other seasons, whereas Zank use peaked in the autumn relative to other seasons.

Table 2. Age distribution of app-using men who have sex with men in Shenzhen from September 2017 to August 2018.

Age	Blued	Jack'd	Zank	Any app	Estimated users	Male population, n (%)	App user (male), %
All	46,969	20,738	181	67,050	158,387	6,129,495	2.58
15-24 years, n (%)	8971 (19.10)	5228 (25.21)	19 (10.50)	14088 (21.01)	33,279 (21.01)	1,715,435 (27.99)	1.94
25-34 years, n (%)	22,388 (47.67)	8180 (39.44)	92 (50.83)	30,191 (45.03)	71,318 (45.03)	2,157,632 (35.20)	3.31

RenderX

Distribution and Hot Spots of App Use

The geographic distribution of the gay dating app–using population during the 3 time periods was mapped at a subdistrict scale (Figure 2A). The population was relatively greater during work time (n=152,972) and social time (n=152,521) compared to home time (n=142,719). For work time, the largest population of app use was observed in the Futian, Yuehai, and Nanhu subdistricts (more than 7000), followed by Minzhi, Longhua, and Xixiang (n=5000-7000). During the social time, the highest population was observed again in the Futian subdistrict (more than 7000), followed by Minzhi, Nanhu, Xixiang, Longhua, and Buji subdistricts (n=5000-7000). For home time, the highest population was located in Xixiang, Minzhi, Futian, Longhua, Buji, and Nanhu subdistricts (n=5000-7000).

The Moran indexes derived from spatial autocorrelation analysis were all above 0 and statistically significant for the 3 time periods, suggesting the geographic distribution of app-using men who have sex with men in Shenzhen exhibited a clustered pattern (Table 3). Furthermore, the High/Low Clustering (Getis-Ord General G) statistics demonstrated significant high-high clustering for all 3 time periods (before: *z* score=3.426; *P*=.001; during *z* score=3.072; *P*=.002; after: *z* score=2.717; *P*=.007), indicating areas with high values of app-using population were spatially clustered.

Hot spot analysis identified Yuehai and Futian as the primary hot spots for app-using populations during work time, each with a Gi_Bin Score of 3 (*P*=.004 and *P*=.002). Meanwhile, Nanhu and Minzhi were also recognized as hot spots with a Gi_Bin Score of 2 (*P*=.01 and *P*=.04; Figure 2B; Multimedia Appendix 1). During social time, Futian, Minzhi, Nanhu, and Xixiang were identified as hot spots, each with a Gi_Bin Score of 2 (*P*=.01, *P*=.02, *P*=.02, and *P*=.02). Subsequently, for home time, Xixiang, Minzhi, Futian, and Longhua were recognized as hot spots, each with a Gi_Bin Score of 2 (*P*=.01, *P*=.02, *P*=.02, and *P*=.03) for home time.

Distribution and Hot Spots of HTC

The overall prevalence of HTC among app-using men who have sex with men aged 15-69 years in Shenzhen was 17.1%, with higher rates observed during home time (18.9%) compared to social time (17.8%) and work time (17.7%). The geographic distribution of HTC prevalence was uneven at the subdistrict scale in Shenzhen (Figure 3A), with higher prevalence reported in Cuizhu, Xiangmihu, Haishan, Nanshan, and Huangbei

XSL•FO
RenderX

subdistricts (>36%) during work time. For social time, a higher prevalence was observed in Cuizhu subdistrict (>48%), followed by Haishan, Shatoujiao, Liantang, Dongxiao, Huangbei, and Xiangmihu subdistricts (>36%). A similar distribution was noted for home time with the addition of Kuicheng subdistrict (>36%). The Moran indexes were statistically significant across all 3 time periods (Table 4). The High/Low Clustering (Getis-Ord General G) statistics indicated the distribution of high values of HTC prevalence was spatially clustered for both home time and social time, but not significant for work time. Hot spot analysis of the HTC prevalence revealed most of the hot spots were concentrated in the Cuizhu subdistrict with a Gi_Bin Score of 3 (P=.001), as well as in Xiangmihu and Haishan subdistricts, with Gi_Bin Score of 2 (P=.02 and P=.03) during the work time (Figure 3B; Multimedia Appendix 2). Similarly, the hot spots of the HTC prevalence during social time and home time were predominantly clustered in the Cuizhu subdistrict with a Gi_Bin Score of 3 (P=.002 and P=.002), and in the Haishan subdistrict with a Gi_Bin Score of 2 (P=.04 and P=.04; Figure 3B).

SSH of App Use and HTC

The Geodetector index of *q* statistics was also used to measure the stratified heterogeneity of app use and HTC across different strata (time period, district, subdistrict, and the proportion of non-Hukou population; Table 5). For both the prevalence of app use and HTC, the *q* statistics and *P* values indicated significant heterogeneity in administrative districts (*P*=.006 and *P*<.001), subdistricts (*P*<.001 and *P*<.001), and the percentage of non-Hukou migrants (*P*<.001 and *P*<.001). However, no significant heterogeneity was observed across different time periods. Luohu district demonstrated the highest risk for both app use and HTC. Nanhu subdistrict, along with subdistricts with 50%-60% non-Hukou migrants, exhibited a higher risk for app use than other areas. Meanwhile, the Cuizhu subdistrict and those subdistricts with 40%-50% non-Hukou migrants reported the highest rates for HTC.

Table 5. Stratified heterogeneity of app use and HTCa in Shenzhen (from September 2017 to August 2018).

Factors	*q* statistic	*P* value	Highest risk detector
App use			
Time period	0.004	.71	—[b]

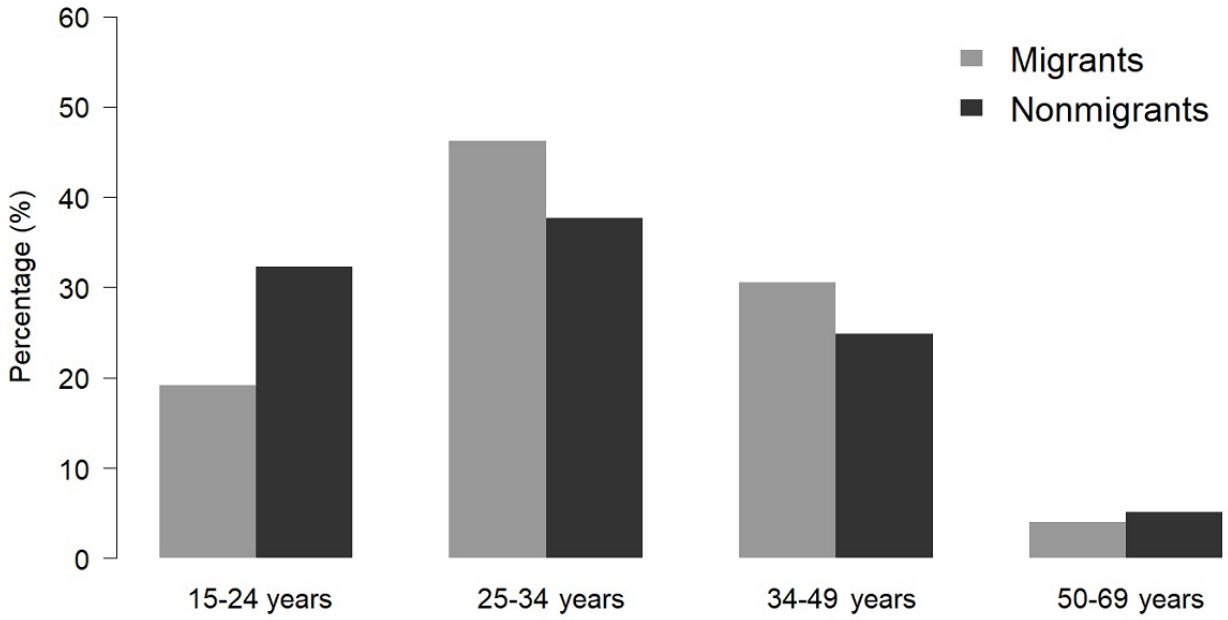
Population Mobility

The geographical distribution of app-using men who have sex with men in Shenzhen before, during, and after the Spring Festival of 2018 was mapped (Multimedia Appendix 3). The results showed that prior to the Spring Festival, app-using men who have sex with men were mostly located in Xixiang, Yuehai, and Longhua subdistricts. During the Spring Festival, those who stayed in Shenzhen were relatively concentrated in Xixiang, Longhua, and Minzhi subdistricts. After the Spring Festival, app-using men who have sex with men returned to clustered in Xixiang, Yuehai, Longhua, and Minzhi subdistricts. For the population change of app-using men who have sex with men before and after the Spring Festival, the largest inflow occurred in the Yuehai, Shatou, and Longhua subdistricts, while the most significant outflow was observed in the Longcheng and Donghu subdistricts (Figure 4A). Additionally, the population mobility of app-using men who have sex with men during the Spring Festival was mapped based on changes in geographical location at the subdistrict scale (Figure 4B). During the Spring Festival, 60,202 (38%) app-using men who have sex with men left Shenzhen, while 37,756 (62.7%) of them returned after the holiday. The distribution of the destination cities for these app-using men who have sex with men demonstrated a relatively centralized flow to other cities in China, with the largest mobility directed toward other cities within Guangdong province (67.7%). There was also lower mobility to Hunan province (7.9%) and other adjacent provinces, such as Jiangxi, Guangxi, and Hubei Provinces (approximately 3%-5%). In terms of age distribution, a higher proportion of those who left Shenzhen were aged 25-34 years and 35-49 years. In contrast, those who stayed were predominantly younger men who have sex with men aged 24

XSL•FO
RenderX



years or younger, as well as older adults aged 50-69 years (P<.001; Figure 5).

Discussion

Principal Findings

This study represents the first longitudinal observational research on the GSN app use, examining its genuine population size, spatiotemporal and behavioral patterns, and mobility through mobile big data in mainland China. This study found Shenzhen has a larger population of men who have sex with men than expected. The geographic distribution of app-using men who have sex with men in Shenzhen exhibited a clustered pattern in central and western Shenzhen, while their HTC uptake was more concentrated in central-eastern Shenzhen. Moreover, both relatively high internal and interprovincial mobility was observed among those app-using men who have sex with men. The findings provided a comprehensive view of the behaviors and dynamics of app-using men who have sex with men, offering valuable insights to inform enhanced prevention and intervention strategies and guide resource allocation. Moreover, our research demonstrates the potential of mobile big data to address critical gaps often overlooked by traditional research methods, providing more accurate, timely, and comprehensive insights into public health and disease prevention.

App Use

This study implied a large population of app-using men who have sex with men in Shenzhen from September 2017 to August 2018, surpassing previous estimates [31]. Moreover, the annual estimate of app-user or male ratio (2.58% among males aged 15-69 years) was relatively high in Shenzhen, compared to the daily estimates of Beijing and Shanghai (0.82% and 0.56% among males aged 18-64 years) from a concurrent experimental study [28]. Literature implied that overestimation might exist in economically developed countries characterized by higher urbanization, higher education levels, more in-migrants, and larger working-age populations [34]. Nonetheless, the population of men who have sex with men may have continued to grow along with the growth of the general population in Shenzhen since 2018, underscoring the increasing need for HIV prevention and intervention efforts targeting men who have sex with men in the region.

Our previous surveillance data indicated a rapid increase in app use among men who have sex with men in Shenzhen since 2016, with Blued being the most frequently used app, consistent with findings from previous data in Shenzhen and other cities [12,26]. An internet survey suggested men who have sex with men in southern China used Jack'd more frequently [35]. Founded in 2010, Jack'd has experienced significant growth, particularly among young men who have sex with men, boasting over 5 million users worldwide since 2014 [36]. Notably, nearly half of the app users were aged between 25-34 years, which aligns with other internet surveys [8,14,35]. In Shenzhen, the median age of new infections was 31 years in 2011-2019, with cases younger than 30 years more frequently observed within molecular transmission clusters [37]. Thus, tailored strategies are needed to enhance the effectiveness of HIV prevention initiatives targeting these younger men who have sex with men.

Spatiotemporal Distribution and SSH

The temporal distribution pattern of app-using men who have sex with men implied that these men who have sex with men tend to use the apps more frequently during work time (daytime) and social time compared to home time. It is reasonable to assume that app users initially seek potential partners through the internet before transitioning to offline social networking if they find a desirable match from the app. During home time, however, it is likely that most users prefer to rest. This finding suggested a clear temporal distinction: a more active search for connections during work and social hours, and a more relaxed,

XSL•FO
RenderX

less frequent engagement during home time. Regarding the geographical distribution, app-using men who have sex with men in Shenzhen exhibited spatial clustering in several subdistricts (Futian, Yuehai, Nanhu, Xixiang, Minzhi, and Longhua) at different time periods. Most clusterings occurred in Nanshan District for work time, Futian District for social time, and Baoan District for home time. This study, for the first time, revealed the spatial heterogeneity for gay dating app–using men who have sex with men in Shenzhen, suggesting that these men who have sex with men were unevenly distributed both at the subdistricts and district levels, as well as among the Hukou residents. As app-using men who have sex with men were more likely to have multiple sexual partners, practice receptive roles in anal sex, and use recreational drugs [12]. By recognizing the different contexts in which men who have sex with men engage with dating apps, public health initiatives can be designed to effectively reach this population at the right times and in the right settings. Traditional HIV prevention services (eg, condoms and lubricants distribution) and interventions (eg, antidrug campaigns) should be delivered more precisely to the identified hot spots based on both temporal and geographical distribution.

Meanwhile, compared to the distribution of app-using men who have sex with men, the prevalence of HTC among this population in Shenzhen showed obvious inconsistencies. HTC rates were concentrated in different subdistricts (eg, Cuizhu, Haishan, Xiangmihu, Nanshan, Shatoujiao, and Huangbei), with the highest clustering observed in Luohu, Futian, and Yantian Districts during social and home time. For work time, HTC is also clustered in Nanshan District. These findings implied that men who have sex with men might prefer to seek HTC services in central districts of Shenzhen, which had higher accessibility to health care [38], or choose these areas for convenience after engaging in high-risk sexual behavior during offline dating or gatherings.

Given the disparities in the distribution of app use and HTC service, it is crucial to allocate more HIV-related health care services (eg, HIV testing and counseling) to western Shenzhen, particularly in subdistricts of Baoan District. Furthermore, the mismatched distribution of app use and HTC and the availability of fee HTC service highlighted the need for outreach initiatives that extend beyond traditional health care settings. Implementing mobile clinics or pop-up testing stations in hot spots or underserved areas could help bridge the HIV testing gap.

Although our previous study implied that app-using men who have sex with men were more likely to take HIV tests, the prevalence of lifetime and recent HIV tests in the past year (70.2% and 50.2%) remained significantly below the UNAIDS target [39]. Furthermore, it is reported that the majority (40%) of the app-using men who have sex with men preferred to take HIV tests at CDCs and community-based organizations (eg, 258-RWG) due to stigma and confidential concerns [39]. Besides, traditional offline HTC services are also available at gay social venues, voluntary counseling and testing centers, or clinics, while the uptake of these services has not been optimal. Therefore, it is essential to prioritize location-tailored strategies for expanding HIV testing, particularly in identified geographical hot spots. Concurrently, innovative web-based prevention initiatives targeting app-using men who have sex with men emerged as a promising alternative. For instance, Blued launched an HIV testing campaign in 2015, which recommended the nearest health care facility or testing service for app users [27]. In light of these insights, future strategies could leverage GSN apps and smartphone tools to promote HTC services, ultimately contributing to the achievement of the first UNAIDS “95” goal.

Migration During the Spring Festival

During the 2018 Spring Festival, more than one-third of app-using men who have sex with men left Shenzhen, highlighting the high mobility of this population. A prior study also reported that about one-fourth of the gay dating app-using men who have sex with men lived in Shenzhen for less than 1 year [12]. The distribution of the destination cities for app-using men who have sex with men demonstrated a relatively centralized flow, with greater internal movement within Guangdong province and less interprovincial mobility to neighboring provinces such as Hunan, Jiangxi, Guangxi, and Hubei. Research suggested that immigrants from Jiangxi, Shaanxi, and Hubei provinces were the main sources of the predominant CRF01_AE subtype in Shenzhen [18]. Local statistics also reported that the immigrants in Shenzhen mainly came from Guangdong (35%), followed by Hunan, Sichuan, Guangxi, Hubei, and Jiangxi. A nationwide study further supported these findings, identifying Hunan, Guangxi, Hubei, and Jiangxi Provinces as the main source provinces for migrant men who have sex with men in Guangdong [28]. During the Spring Festival, the most significant changes in the population of men who have sex with men were observed in the Yuehai, Shatou, and Longhua subdistricts. Therefore, it is crucial to strengthen targeted and innovative prevention and intervention efforts in these areas to address the unique challenges faced by migrant men who have sex with men, such as app-based notifications or location-based services, to provide timely and targeted HIV prevention messages and services, particularly during periods of high mobility.

Limitations

First, the application of mobile internet has developed rapidly in China, especially in the last 5 years, which may have a significant impact on the behavioral characteristics of men who have sex with men, it would be valuable to collect more recent data to examine the evolution of the trend in the future. Second, as the study is based on mobile big data, there may be inherent biases in estimating the true population size. Third, regarding the geographical difference in app use and HTC, limited demographic data prevented us from differentiating the impact of resource availability from user selection bias. Moreover, it is difficult to distinguish male sex workers and noncommercial men who have sex with men, who may exhibit different HIV-related behaviors [40]. Therefore, future studies with more demographic factors (eg, occupation and income) and other socioeconomic determinants, are needed to differentiate selection bias. Finally, although gay dating app users are generally assumed to be men who have sex with men, it is possible that a small number of non–men who have sex with men individuals may also use the app for research purposes or by chance. However, as this group constitutes a negligible

XSL•FO
RenderX

portion of the overall population, their presence is unlikely to affect the results significantly and can therefore be disregarded.

Conclusions

Shenzhen has a large population of men who have sex with men using gay dating apps, predominantly aged 15-34 years. The uneven spatiotemporal distribution of app-using men who have sex with men and their HIV testing or counseling, as well as the mismatch between them, emphasizes the need to adapt the traditional venue-based prevention and intervention strategies to the identified hot spots area and the need for outreach initiatives that extend beyond traditional health care settings. Given the relatively high internal and interprovincial mobility of this population, leveraging smartphone-based behavioral monitoring could provide valuable insights for enhanced and innovative prevention and intervention strategies.

Abstract

Background: Gait impairments are common in stroke survivors, negatively impacting their overall quality of life. Therefore, gait rehabilitation is often targeted during in-clinic rehabilitation. While standardized assessments are available for inpatient evaluation, the literature often reports variable results when these assessments are conducted in a home environment. Several factors, such as the presence of an observer, the environment itself, or the technology used, may contribute to these differing results. Therefore, it is relevant to establish unsupervised capacity assessments for both in-clinic use and across the continuum of care.

Objective: This study aimed to investigate the effect of supervision on the outcomes of a sensor-based 10-meter walk test conducted in a clinical setting, maintaining a controlled environment and setup.

Methods: In total, 21 stroke survivors (10 female, 11 male; age: mean 63.9, SD 15.5 years) were assigned alternately to one of two data collection sequences and tested over 4 consecutive days, alternating between supervised test (ST) and unsupervised test (UST) assessments. For both assessments, participants were required to walk a set distance of 10 meters as fast as possible while data were collected using a single wearable sensor (Physilog 5) attached to each shoe. After each walking assessment, the participants completed the Intrinsic Motivation Inventory. Statistical analyses were conducted to examine the mean speed, stride length, and cadence, across repeated measurements and between assessment conditions.

Results: The intraclass correlation coefficient indicated good to excellent reliability for speed (ST: κ=0.93, P<.001; UST: κ=0.93, P<.001), stride length (ST: κ=0.92, P<.001; UST: κ=0.88, P<.001), and cadence (ST: κ=0.91, P<.001; UST: κ=0.95, P<.001) across repeated measurements for both ST and UST assessments. There was no significant effect of testing order (ie, sequence A vs B). Comparing ST and UST, there were no significant differences in speed (t_{39}=–0.735, P=.47, 95% CI 0.06-0.03), stride length (z=0.835, P=.80), or cadence (t_{39}=–0.501, P=.62, 95% CI 3.38-2.04) between the 2 assessments. The overall motivation did not show any significant differences between the ST and UST conditions (P>.05). However, the self-reported perceived competence increased during the unsupervised assessment from the first to the second measurement.

Conclusions: Unsupervised gait capacity assessments offer a reliable alternative to supervised assessments in a clinical environment, showing comparable results for gait speed, stride length, and cadence, with no differences in overall motivation between the two. Future work should build upon these findings to extend unsupervised assessment of both capacity and performance in home environments. Such assessments could allow improved and more specific tracking of rehabilitation progress across the continuum of care.

Introduction

More than 80% of stroke survivors experience gait impairments, and between 55% and 75% continue to experience functional problems 3 to 6 months after their stroke [1,2]. These impairments frequently lead to reduced activity levels and diminished community participation [3-5]. Due to this, one of the most common goals in gait rehabilitation is to enhance functional independence and quality of life [3,6-8]. Despite these efforts, many survivors continue to experience gait deficits even after discharge from their inpatient rehabilitation programs.

Within the clinical setting, observational gait analysis and scaled assessments are often used to identify gait deficits and functional improvements [9,10]. In these assessments, visual observation is used to qualitatively identify gait deviations. These types of assessments are popular due to their simplicity and availability. However, the literature indicates that gait and mobility parameters differ when assessments are conducted at home versus in the clinical setting; this difference may become more relevant as advancements in digital therapeutics and telerehabilitation offer promising avenues for long-term rehabilitation outside the clinic [9-14]. These differences in assessment outcomes could stem from various factors, such as the transition from a supervised to an unsupervised setting, the change in the environment itself, or technical limitations [11]. Therefore, to determine the feasibility of conducting accurate and consistent assessments in a home environment, it is essential to first isolate and address these variables in a controlled manner using a standardized clinical assessment.

Among the array of tools used in the clinical setting to evaluate walking capacity is the 10-Meter Walk Test (10-MWT) [15-18]. The test measures walking speed in meters per second over a distance of 10 meters, with the speed being indicative of functional outcomes and prognosis for stroke survivors [19-21]. In addition to providing a strong indicator of functional ability and being a predictor of health outcomes, the 10-MWT is a particularly valuable tool due to its applicability across populations, its convergent validity with other clinical gait capacity assessments, and the fact that it is standardized and easy to administer [22,23]. Moreover, combining the 10-MWT with wearable sensors, such as inertial measurement units, allows for the extraction of additional spatiotemporal gait parameters. These parameters are not only robust, but they enhance the interpretation of clinical assessment outcomes and aid in detecting motor recovery poststroke as well as predicting prognosis after stroke [24-26]. Future precision rehabilitation approaches will rely more strongly on the assessment of these kinds of granular gait metrics, making it relevant to validate these in current systems [27,28]. Standardized assessments to measure capacity, such as the 10-MWT may be complemented by data from continuous monitoring, which measures performance [29,30].

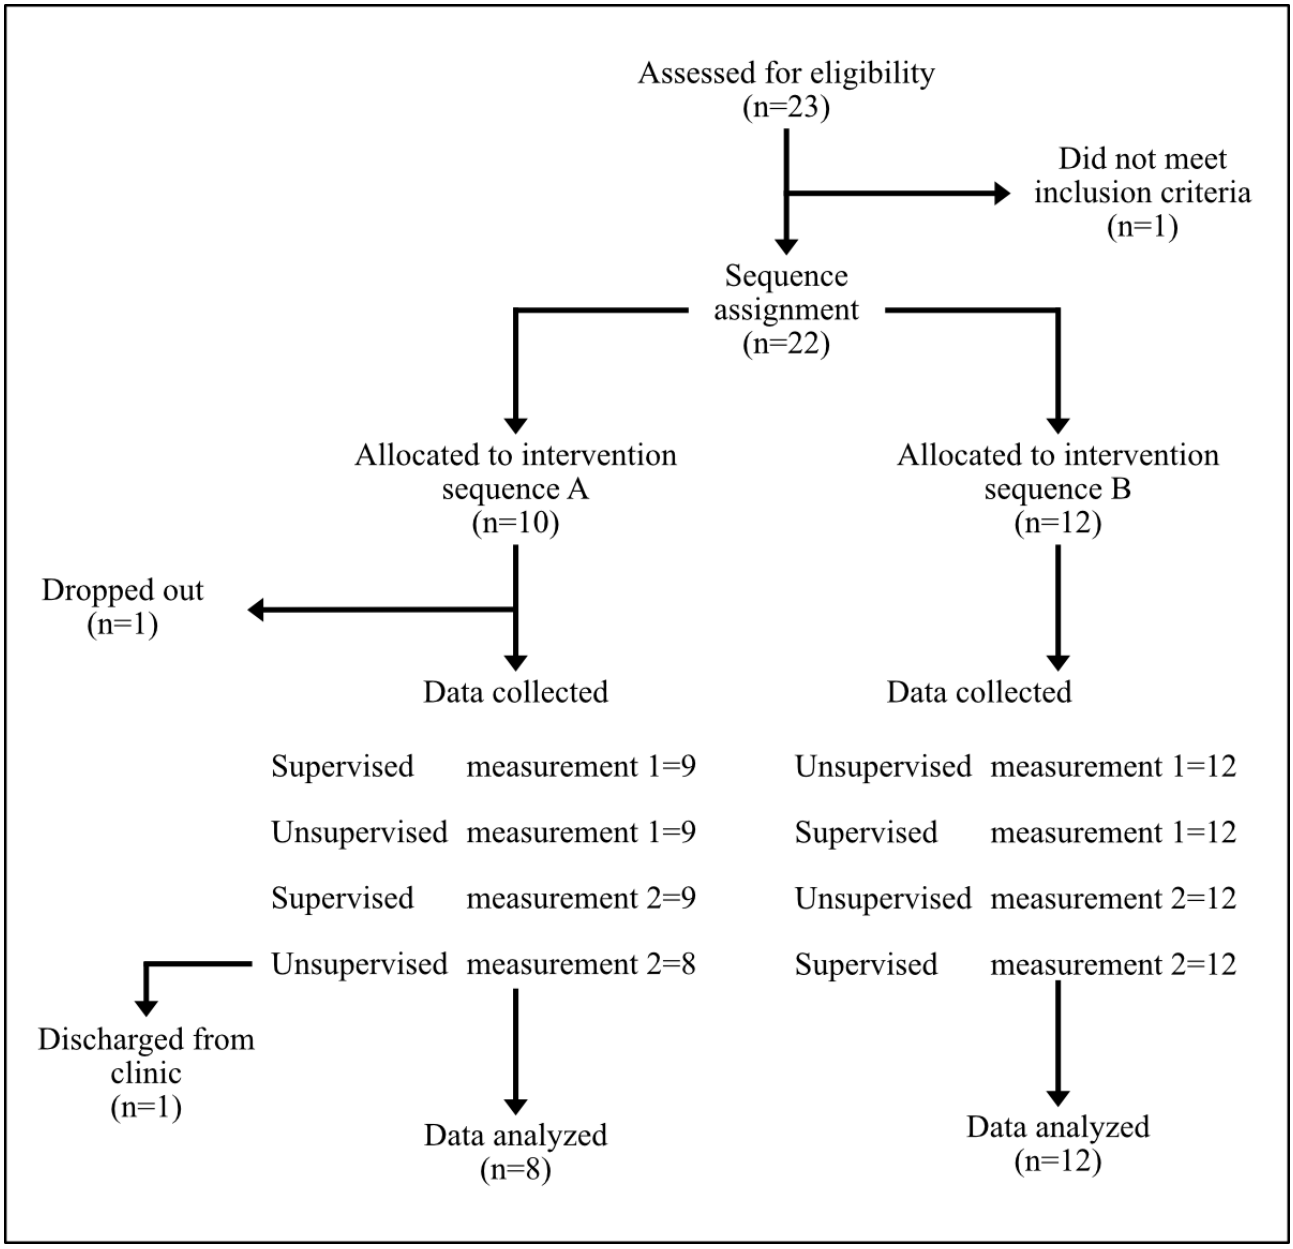
While unsupervised assessments and continuous monitoring are mostly associated with home settings, there are also many useful applications within a clinical environment. First, unsupervised assessments can reduce the assessment load on clinical staff, thus enhancing clinical efficiency [31]. Second, unsupervised assessments can be performed more frequently due to their independence from clinical planning, which allows insights into day-to-day fluctuations of test outcomes [11]. Third, enabling patients to perform their own assessments in an unsupervised manner can mitigate observer effects on outcomes [32]. Fourth, giving patients some level of autonomy concerning some aspects of their rehabilitation process can empower them and increase their involvement and ownership [33]. Finally, exposing patients to unsupervised assessments within a controlled, in-clinic context already prepares them to continue these across the home aspect of the continuum of care, removing learning effects and boosting adherence [34]. In synthesis, introducing unsupervised capacity assessments within the clinical setting has potential benefits on multiple levels, while also laying the foundation for assessments across the complete continuum of care.

For these reasons, this study investigates the supervision aspect of capacity assessments by maintaining a controlled clinical environment and using a simple-to-use tool that can easily be transferred outside the clinic. In other words, this study will determine whether a standardized gait capacity assessment conducted in the clinical setting without supervision maintains the same validity, replicability, and motivation as when conducted with supervision. We hypothesize that the unsupervised assessments will provide results that are as reliable and replicable as those collected in a supervised manner with no differences in motivation. This study will provide insights into the self-administration of gait capacity assessments, providing a basis for interpreting any potential differences that may arise in future studies expanding into home or less controlled environments.

Methods

Participants and Setting

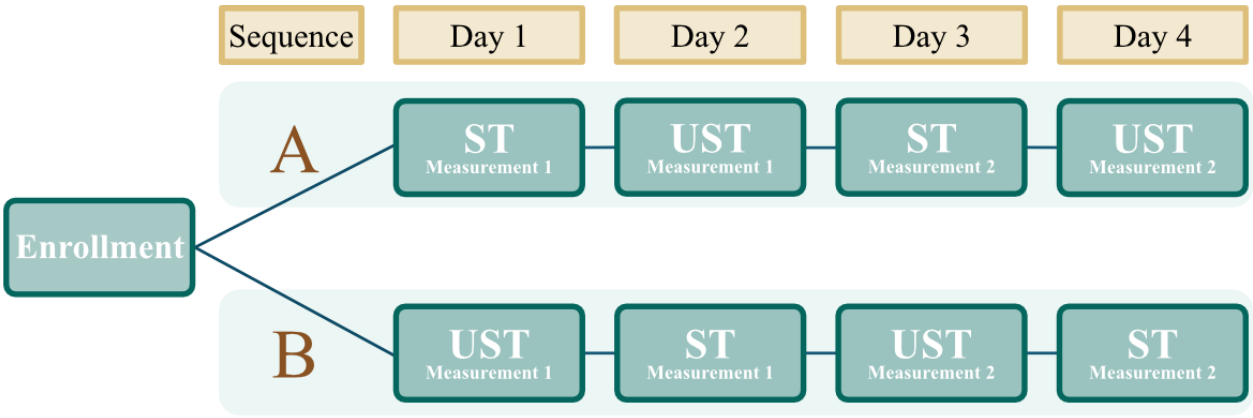
A convenience sample of 21 patients with stroke (10 female and 11 male), aged 40-89 (mean 63.91, SD 15.54) years, were enrolled in this study at the Swiss Neurorehabilitation Clinic “cereneo” (Lucerne, Switzerland). Enrollment took place between November 2021 and June 2023 and followed a cross-over design. All stroke survivors who were more than 1 month post stroke, aged 18 years or older, able to use a tablet, with a Berg Balance Score greater than 31, and the ability to walk for at least 2 minutes, met the inclusion criteria to participate in the study. Exclusion criteria were the presence of comorbidities potentially affecting gait (eg, polyneuropathy, orthopedic impairments, and orthostatic hypotension), uncorrected visual impairments, psychiatric comorbidities that



XSL•FO
RenderX

may affect the participants' ability to follow study protocols or other medical reasons that would hinder participation.

Experimental Procedure



The total experimental procedure for this study was conducted across 4 days, with a single testing session per day. Upon enrollment in the study, participants were sequentially assigned in an alternating fashion to one of 2 sequences (A or B) representing differing protocol sequences (Figure 1). This approach was chosen to ensure balanced group sizes and facilitate study logistics. While this method does not introduce selection bias in individual assignments, it may not fully control for potential confounding factors in group distribution. Sequence A began with the 10-MWT conducted under supervised test (ST) conditions, while Sequence B began with the 10-MWT conducted under unsupervised test (UST) conditions (Figure 2). Participants then alternated the assessment type over the remaining 3 days (Figure 2). Regardless of the sequence to which they were assigned, participants always completed both the ST and the UST twice during the 4 days.

Figure 1. Schematic diagram outlining the enrollment and allocation to the intervention sequences of the study.

XSL•FO
RenderX

Figure 2. Study groups showing how participants were allocated to either sequence A or sequence B upon enrollment. Participants in both sequences completed the 10-MWT twice while supervised and twice while unsupervised. 10-MWT: 10-Meter Walk Test; ST: supervised test; UST: unsupervised test.

The goal of the 10-MWT was to have participants walk a set distance of 10 m as fast as possible in order to evaluate gait capacity. Markers at the 0- and 10-m points delineated the walking path to ensure consistent data collection conditions. To objectively evaluate the outcome, participants completed the assessment while wearing an inertial measurement unit on each shoe.

For all STs, the therapist prepared the participant by attaching the inertial measurement units to the shoes and positioning them at the start line. The therapist then counted down the start, and the participant walked as fast as possible over the marked finish line. The therapist was responsible for starting the stopwatch using the tablet app and stopping it when the finish line was reached. The therapist was present for the entire setup and data collection but did not provide feedback or guidance.

The UST was conducted following the same procedure as the ST. However, there was no direct supervision of the tasks. During the UST, a therapist or nurse was available in the adjacent nursing room for technical assistance and support during the setup. The participants were required to go to this room and pick up the tablet and sensors before walking to the designated track. If participants were unable to attach the inertial measurement units to the shoes themselves, the nurses or therapists attached them in the nurses' office. Additionally, if the participants were unable to hold the tablet, for example, due to hemiparesis, the tablet was attached to the participant's arm via a strap so that they could operate it with one hand. Once at the starting line, the participants got in place and started the stopwatch using the tablet app before walking as fast as they could over the finish line. Once across the finish line, the participants stopped the time using the same stopwatch app. The participants then removed the sensors and returned them, together with the tablet, to the nursing office. During the UST, the only interaction with the therapist was to attach or remove the sensors in the nursing office if the participant could not do it alone.

In both conditions, participants were required to complete the Intrinsic Motivation Inventory on paper in the nurses' office. The participants were required to do this on their own with no help or interaction with the nurses or therapists. Participants in both sequences also always had a written information sheet available to them in both the ST and UST conditions, listing the required steps and acting as a user guide for the tablet app. In both conditions, there was no interaction between the participants and nurses or therapists, the only difference was that during the ST task, the nurse or therapist was there to start and stop the stopwatch and observe the data collection. If there were any problems, the data collection was repeated, either with the nurse or therapist, or independently for the ST and UST trials, respectively.

Data Collection Systems and Materials

For this study, demographic information was extracted by the clinical team from the clinical record and provided to the study team in a pseudoanonymized form. Gait data was collected using validated Physilog®5 (Gait Up), wearable inertial measurement units, to assess the spatiotemporal gait outcomes during the 10-MWT [35-37]. To keep the setup simple and easy for patients to use, only 2 sensors were used in this study. Each sensor was mounted on the top of the participant's foot, specifically over the laces of their shoes (Figure S1 in Multimedia Appendix 1). The sensors had a sampling rate of 128 Hz and collected acceleration and orientation data. Gait data was subsequently analyzed using the Gait Analyser software (V3.1; Gait Up), a valid and reliable tool for stroke survivors [35,36]. Information about participant motivation was also collected using the Intrinsic Motivation Inventory as a standard pen-and-paper questionnaire that participants filled out in the nurses' office when returning the sensors [38].

Statistical Analysis

Descriptive statistics of all gait parameters were calculated to provide an overview of the data. For each assessment, speed, stride length, and cadence were calculated as the mean values of the left and right sensors. These specific gait parameters were chosen to provide a simplified overview of changes in temporal, spatial, and combined spatiotemporal parameters. Additionally, changes in these parameters are important to capture are they represent a more cautious gait in the elderly population and are known to change poststroke [39,40]. All statistical testing was conducted for each of the 3 gait parameters. Normality was determined using the Shapiro-Wilk test (significance level α=.05), while the variances were determined using an *F* test

XSL•FO
RenderX

(α=.05). Corrections for multiple comparisons were done using the Holm-Bonferroni method.

Difference Between Repeated Measurements

In the first step, the measurements conducted on different days were compared via a paired *t* test to determine if there was any learning effect from measurement 1 to measurement 2 of the same assessment type. Additionally, using a 2-way random effect model and "single rater" unit, the intraclass correlation coefficient was computed to assess the agreement between the 2 measurements per assessment condition.

Sequence Effect

Next, to determine whether there was a sequence effect in the data, the difference in scores between the 2 measurements per assessment type in each sequence was calculated. For data found to be normally distributed and with equal variances, an independent samples *t* test was conducted between sequences (A vs B); for data found to be not normally distributed and with equal variances, a nonparametric Mann-Whitney *U* test was conducted. Significant differences between sequences A and B would suggest a sequence effect is present.

Supervised Versus Unsupervised Tests

The difference in scores between ST and UST measurements for each participant was determined using a student's *t* test and a nonparametric Wilcoxon signed-rank test, depending on the outcomes of the normality testing.

Intrinsic Motivation Inventory

To determine if there were differences in motivation, the subsections of the Intrinsic Motivation Inventory were analyzed. Depending on the normality of the data, either a paired *t* test or a Wilcoxon signed-rank test was used to determine if there was a change in motivation from the first to second measurement day per assessment in each sequence. Additionally, a Student *t* test or a Wilcoxon signed-rank test was conducted to determine if there was a significant difference in motivation scores between assessment types (ie, ST vs UST).

Ethical Considerations

This study was approved via waiver by the local ethics committee of the Canton of Lucerne, Switzerland (Req-2020-00995) and was carried out in accordance with the current version of the Declaration of Helsinki. The study protocol was explained both orally and in writing to eligible participants, and written informed consent was obtained before participation. Participants did not receive any compensation for their participation in this study, nor did they receive any direct benefit from their participation. To ensure privacy and confidentiality, all data were deidentified and securely stored in an encrypted database accessible only to authorized researchers. The wearable sensor data used for gait analysis were coded and stored separately from participant identifiers.

Results

Demographics

A total of 21 poststroke participants were recruited for this study (Table 1). All participants were able to complete all 4 days of testing. The majority of the participants were in the subacute phase and were largely community ambulators (Table 1) [41].

Table 1. Participant characteristics.

Characteristics	Values
Age in years, mean (SD)	63.91 (15.54)
Sex, n (%)	
Female	10 (48)
Male	11 (52)
Paretic body side, n (%)	
Left	16 (76)
Right	5 (24)
Months since stroke, mean (SD)	5.19 (10.73)
Stroke onset 1-6 months, n (%)	18 (85.71)
Stroke onset >6 months, n (%)	3 (14.29)
Modified Rankin Scale, mean (SD)	1.95 (0.59)
Household ambulators: <0.4 m/s, n (%)	1 (4.76)
Limited community ambulators: 0.4-0.8 m/s, n (%)	4 (19.05)
Community ambulators: >0.8 m/s, n (%)	16 (76.19)
Assistive device, n (%)	2 (9.52)
Rollator	1 (4.76)
Dropped foot stimulator	1 (4.76)
Foot orthoses, n (%)	3 (14.29)

Gait Outcomes

Difference Between Repeated Measurements

Shapiro-Wilk tests for normality showed that the results for speed, stride length, and cadence were normally distributed during each measurement, per assessment type and sequence (Table S1 in Multimedia Appendix 2). A paired samples *t* test subsequently determined that there were no statistically significant differences between the first and second measurements for each assessment type within each sequence (Table 2).

Table 2. Differences between repeated measurements.

Variable and sequence	Condition	*t* test[a] (*df*)	*P* value[b]	Adjusted *P* value[c]	95% CI
Speed					
A	ST[d]	0.492 (7)	0.64	>.99	–0.09 to 0.14
A	UST[e]	–0.064 (11)	0.95	>.99	–0.09 to 0.08
B	ST	–0.238 (11)	0.82	>.99	–0.08 to 0.07
B	UST	–5.10E–16 (7)	>.99	>.99	–0.06 to 0.06
Stride length					
A	ST	1.011 (7)	0.36	>.99	–0.05 to 0.12
A	UST	0.165 (11)	0.87	>.99	–0.06 to 0.07
B	ST	0.444 (11)	0.68	>.99	–0.05 to 0.08
B	UST	0.097 (7)	0.93	>.99	–0.12 to 0.13
Cadence					
A	ST	–0.322 (7)	0.76	>.99	–5.21 to 3.96
A	UST	–0.679 (11)	0.51	>.99	–5.41 to 2.86
B	ST	–0.132 (11)	0.90	>.99	–5.52 to 4.89
B	UST	0.353 (7)	0.73	>.99	–3.31 to 4.47

[a]Paired samples *t* test.

[b]$P \leq .05$.

[c]Holm-Bonferroni correction for multiple comparisons.

[d]ST: supervised test.

[e]UST: unsupervised test.

The intraclass correlation for speed found the ST (κ=0.93, adjusted $P<.001$) and UST (κ=0.93, adjusted $P<.001$) to both have excellent reliability across measurements. For stride length, the intraclass correlation was found to have excellent reliability for ST (κ=0.92, adjusted $P<.001$) and good reliability for UST (κ=0.88, adjusted $P<.001$). For cadence, both the ST (κ=0.91, adjusted $P<.001$) and UST (κ=0.95, adjusted $P<.001$) were found to have excellent reliability.

Sequence Effect

An independent samples *t* test found no sequence effect between sequences A and B for the normally distributed speed, cadence, and stride length (ST only; Tables S2 and S3 in Multimedia Appendix 2). A nonparametric Mann-Whitney *U* test equally found that there was no sequence effect between sequences A and B for the nonnormally distributed stride length (UST only; Table S2 and S4 in Multimedia Appendix 2). Before this, the results for the *F* test found no significant differences in variance across sequences (Table S5 in Multimedia Appendix 2).

Supervised Versus Unsupervised Tests

A paired-sample *t* test found that there was no significant difference between speed (t_{39}=–0.735, adjusted $P>.99$, 95% CI –0.06 to 0.03) and cadence (t_{39}=–0.501, adjusted $P>.99$, 95% CI –3.38 to 2.04) recorded when collecting data while supervised versus unsupervised (Figure 3). A pairwise Wilcoxon signed-rank test found that there was no statistically significant difference between the stride length (z=0.835, adjusted $P>.99$) collected during the ST versus UST. Additional results regarding the normality tests can be found in Table S6 in Multimedia Appendix 2.

The intraclass correlation coefficient was computed to assess the agreement between the supervised and unsupervised assessments of speed, stride length, and cadence (Table 3).

XSL•FO
RenderX

Figure 3. Distribution of data for speed (m/s), stride length (m), and cadence (steps/minute) during the ST and UST, with no significant differences found. ST, supervised test; UST, unsupervised test.

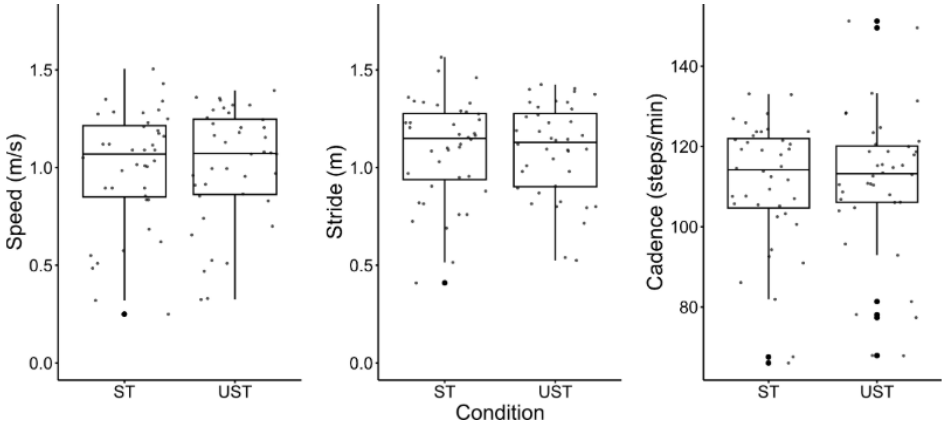

Table 3. Intraclass correlations between supervised and unsupervised assessments.

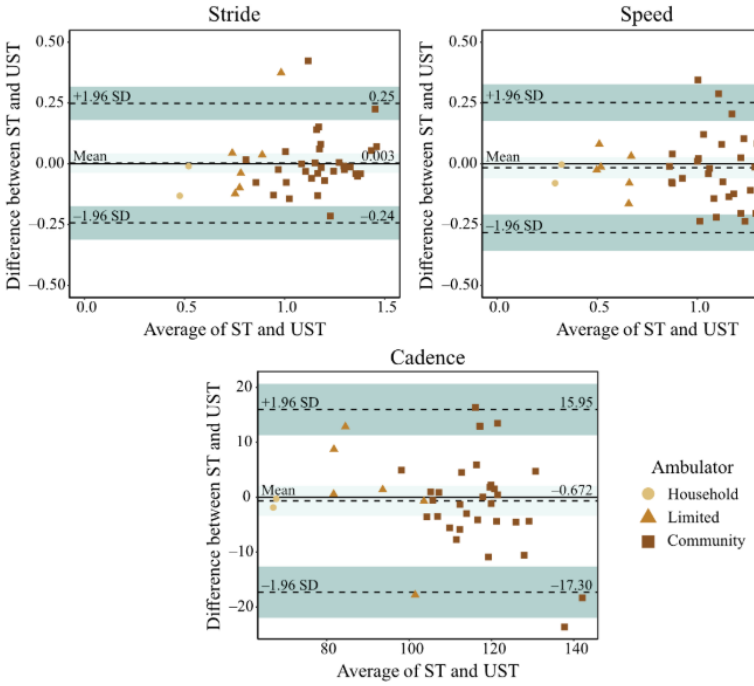
Variable	ICC value	*P* value[a]	*P* adjusted[b]	95% CI	Type of ICC[c]	Interpretation
Speed	0.90	<.001	<.001	0.81-0.94	ICC (A,1)	Good
Stride length	0.88	<.001	<.001	0.78-0.93	ICC (A,1)	Good
Cadence	0.88	<.001	<.001	0.79-0.94	ICC (C,1)	Good

[a]*P* value: 0.05.



[b]Holm-Bonferroni correction for multiple comparisons.

[c]Absolute agreement model for single measurement.

Bland-Altman Plots

The effect of the assessment condition on the speed was found to result in a mean difference of –0.016 (SD 0.137) m/s during the UST compared with the ST. For stride length, the mean difference was found to be 0.003 (SD 0.125) m during the UST compared with the ST. For cadence, the mean difference was found to be –0.672 (8.481) steps per minute during the UST compared with the ST. Based on the Bland-Altman plots, no proportional bias was observed for any variable (Figure 4).

Figure 4. Results from the Bland-Altman analysis showing the various effect zones when examining the ST and UST for speed, stride length, and cadence. The darker bands represent the upper and lower limits of agreement, while the lighter band represents the bias zone. Data points are separated into ambulator types, namely household, limited, or community. ST: supervised test; UST: unsupervised test.

Intrinsic Motivation Inventory Outcomes

The results of the Wilcoxon signed-rank test and paired-sample *t* test found that there are no significant differences in the motivation scores for the subscales of the Intrinsic Motivation Inventory between the ST and UST (Table 4).

Table 4. Comparison of the results of the Intrinsic Motivation Inventory, presented as its subscales, between the ST[a] and UST[b].

Subscale and condition	Mean (SD)	Score	*P* values	Adjusted *P* values[c]
Interest/enjoyment		–0.194[d]	0.42	>.99
ST	4.15 (1.62)			
UST	4.00 (1.70)			
Perceived competence		–0.068[d]	0.47	>.99
ST	5.14 (1.60)			
UST	5.18 (1.44)			
Effort/importance		–0.088[d]	0.47	>.99
ST	4.22 (0.83)			
UST	4.28 (1.19)			
Pressure/tension		–0.435[e]	0.67	>.99
ST	2.02 (1.55)			
UST	2.10 (1.43)			

[a]ST: supervised test.

[b]UST: unsupervised test.

[c]Holm-Bonferroni correction for multiple comparisons.

[d]*z*-score.

[e]*t*-score.

Examining the difference between measurements 1 and 2, there were no significant differences for the interest/enjoyment, effort/importance, and pressure/tension subscales during both the ST and UST. Conversely, there was a significant difference in motivation scores for the Intrinsic Motivation Inventory subscale perceived competence during measurement 1 (mean 4.04, SD 1.58) versus measurement 2 (mean 5.17, SD 1.40) of the UST (t_7=–2.979, P=.02, odds ratio 2.60, 95% CI –2.02 to –0.23) during sequence A. A significant difference between measurement 1 (mean 5.25, SD 1.33) and measurement 2 (mean 5.86, SD 1.13) was also found during sequence B (z=–1.716, P=.04). However, after applying the Holm-Bonferroni correction for multiple comparisons, the differences were no longer significant after adjustment (adjusted P values were .08 and .13, respectively). There were no differences between measurements in the perceived competence during the ST.

Discussion

Principal Findings

There is a considerable gap in our understanding of whether currently used standardized inpatient gait capacity assessments can be effectively performed in an unsupervised manner while maintaining the same levels of validity and replicability. Here, we specifically investigated the 10-MWT, a common measure of gait capacity, which is typically conducted under the supervision of a therapist to ensure accurate results. Our findings demonstrate that the execution mode of the 10-MWT, whether supervised by a health care professional or conducted autonomously by the participants themselves, did not result in significant differences in the measured gait parameters. These results suggest that patients are capable of accurately self-assessing their walking function without the need for direct supervision.

The main results of this study demonstrate that participants were able to maintain their execution ability without continuous guidance and feedback, suggesting that once an individual becomes familiar and comfortable with the assessment and related equipment, continuous supervision might not be necessary to preserve this ability. Moreover, these findings show the ability of stroke survivors to not only be able to carry out the test procedure, but also attach, connect, and start the required sensors with the help of a layperson after proper instruction. Getting patients involved in their own assessments may also promote greater flexibility and engagement in their rehabilitation process [42]. Moreover, therapists can efficiently monitor patients by leveraging reliable sensor systems for remote data collection, leading to more efficient treatment planning and timely interventions. This can not only reduce costs but also make rehabilitation more accessible and portable.

Enabling patients to conduct the assessments themselves could also have the added benefit of preventing experimenter-induced changes, which multiple studies have found to influence gait [32,43-45]. This is supported by work that found modifications in gait speed, cadence, step duration, and stride length, among others, in the presence of researchers [32,45-49]. Evidence also suggests that gait changes may even depend on the number of

XSL•FO
RenderX

observers present [32]. However, the exact relationship between gait parameters and observation remains unclear due to contradictory results, which are thought to arise from differences in study design. While the studies mentioned here involved passive observers, another factor that could influence performance in the real world is motivation.

Motivation remains a clear confounder in the reliability of motor assessments, both for simple and complex tasks. For instance, Kuhl and Koch [50], modeled motor performance as a dual task or multiple tasks, with most nonmotor components being dependent on the environment, personality, and priming. Concerning the environment, sex, expectations, and the behavior of the experimenter have long been known to have an effect on motor performance [51,52]. In terms of personality, Strickland [53] reported the effects of the need-for-approval on motor outcomes in the 1960s. Regarding priming, a recent study demonstrated that priming with positive or negative content before a test resulted in distinct differences in simple motor capacity in healthy college students [54,55]. Based on this literature, we suspected that motivational scores would drop when no active experimenter was present to administer the test. However, in this study, we did not find this to be true. In fact, there were no reported differences in overall motivation between the supervised and unsupervised assessments. Before the correction for multiple comparisons, the perceived competence score during the unsupervised assessment was significantly lower during the first measurement compared with the second. Despite this finding no longer being significant after corrections were applied, this difference could still represent an important aspect to consider, as individuals may be less motivated to continue doing an assessment if they feel incompetent while doing it. This could be further examined in future work to determine whether this effect truly exists or not. Additionally, strategies to ensure that the highest level of understanding and skill is achieved during the unsupervised assessments should be anticipated.

Limitations and Future Outlook

It should be noted that despite this study finding no changes in the motivation level between the 2 assessments, this finding is possibly biased, as participants were likely already highly motivated due to the study being voluntary. Despite this, there is currently no evidence to suggest that, when controlling for environment and setup, the presence or absence of an observer changes the motivation to complete the assessment.

To extend the generalizability of these findings to different environments, the next step would be to expand this work to the home environment. In doing so, future work would need to take into consideration the safety and feasibility of this setup outside of the clinical setting. While no participants in this study fell or were otherwise injured, a risk assessment should be conducted, including in other populations, to ensure patient safety. An additional aspect that may need to be considered for future work is cognitive ability, which was not examined in this study. As the majority of the participants were only mildly impaired, the applicability of the findings to patients with more severe impairment needs to be investigated. Finally, there are additional aspects, such as reduced costs and boosted self-efficacy, which were not considered here, that could be explored in future work as they could elucidate further benefits of autonomous assessments for clinics and patients.

Conclusions

This validation study, using easy-to-use wearable sensors, has demonstrated that the 10-MWT, a standardized gait capacity assessment, can be performed reliably whether professionally supervised or conducted autonomously, without significant differences in the measured gait parameters. Additionally, there was no self-reported difference in motivation for completing the 10-MWT when conducted under supervised or unsupervised conditions. The findings of this study are important as they demonstrate the validity of the unsupervised versus supervised 10-MWT inside clinics. Furthermore, the results provide a solid foundation for investigating the validity of the 10-MWT outside of the clinic in combination with continuous monitoring. Both topics will play an increasingly important role as the frequency and granularity of clinical assessments increase and researchers begin to focus more on monitoring survivors' rehabilitation progress and quality of life in the real-world setting.

Acknowledgments

The authors would like to acknowledge the therapists and nurses who assisted us with this study and helped carry out the data collection. This study was funded by the P & K Foundation.

Data Availability

All data generated or analyzed during this study are included in this published article and Multimedia Appendix 3.

Authors' Contributions

CEA performed the conceptualization of the study and handled the funding acquisition. ACN conducted the formal analysis. DG, SN, and MS carried out the investigation. MB and CEA managed project administration, resources, and supervision. ACN led the visualization and wrote the original draft, with support from GD. For review and editing, ACN took the lead, with support from GD, SN, MS, MB, and CEA.

Abstract

Background: Carbohydrate counting (CC) can be burdensome and difficulty with adherence has been reported. Automated CC through mobile apps offers innovative solutions to ease this burden.

Objective: This cross-sectional web-based survey aims to identify (1) perceived barriers to CC by Canadians living with type 1 diabetes (T1D) and (2) app features that would help reduce these barriers. The secondary objective aims to compare apps used by participants with the suggested app features.

Methods: People with T1D aged 14 years and older, living in Canada, were recruited through the BETTER Canadian registry, diabetes organizations, and social media. Participants completed a 39-question web-based survey (closed- and open-ended) to identify barriers in CC, preferred CC app features, and current app use. Respondents rated barriers and app features using a 5-point Likert scale. The features were cross-referenced in each app reported being used by participants. Descriptive statistics summarized barriers and app feature preferences, and statistical analyses identified differences by age, app use, and insulin modality. Mean scores (out of 5) were compared using 2-tailed *t* tests or nonparametric tests. Open-ended questions were analyzed using inductive thematic analysis.

Results: Participants (N=196; woman: n=145, 74%; mean age 40 [SD 17] years; mean diabetes duration 22 (14) years; relied on CC to determine insulin doses at mealtimes: n=178, 90.8%) reported barriers related to carbohydrate identification, nutrient interaction, and insulin dose calculation, as well as psychosocial factors. Preferred app features included nutrient analysis (165/196, 84.2%), personalization (151/196, 77.1%), insulin bolus calculation (145/196, 74%), and health care professional support (135/196, 68.8%). Among the 16 apps used by participants, most (12/16, 75%) supported nutrient analysis but only one offered bolus calculations or health care professional support, and none offered personalization. Users on injections reported greater barriers to blood glucose monitoring for insulin adjustments compared to exclusive pump users (mean score of 3.87, SD 1.22 vs mean 3.30, SD 1.28; *P*=.001). They also expressed higher needs for meal logs in an electronic food journal (mean 4.06, SD 1.18 vs mean 3.69, SD 1.17; *P*=.01), bolus dose suggestions (mean 4.37, SD 0.98 vs mean 3.84, SD 1.26; *P*=.001), and app personalization (mean 4.47, SD 0.86 vs mean 3.93, SD 1.21; *P*<.001). No significant differences were observed based on age or app use. The thematic analysis revealed participants' perceptions of suggested barriers and features, as well as new barriers such as calculation errors from unreliable food data and nutrition labels, fear of eating disorders, limited app reliability, and insufficient health care support, with suggestions for technology-based solutions.

Conclusions: CC mobile apps currently used do not meet the needs of people with T1D. A novel CC app with app features such as photo recognition, reliable nutrient values, and personalized bolus calculations could reduce the CC burden.

type 1 diabetes; carbohydrate counting; mobile apps; photo recognition; diabetes management; mHealth; mobile health; user-centered design; Canadian survey

Introduction

People living with type 1 diabetes (T1D; approximately 300,000 in Canada) need to be administered subcutaneous insulin to maintain stable blood glucose (BG) levels and prevent long-term complications [1,2]. Instead of a fixed bolus insulin regimen tied to predetermined meal plans, carbohydrate counting (CC) offers dietary flexibility by empowering individuals to tailor their mealtime insulin based on the carbohydrate content of their meals [3]. However, adherence to CC can be burdensome and difficult [4]. CC requires frequent BG monitoring, keeping food records, reading food nutrition labels, and weighing food portions. Additionally, calculations are time-consuming and prone to errors as they involve multiple factors such as the insulin sensitivity factor, insulin-to-carbohydrate ratio, and BG target [5,6]. Accurate CC is important because greater precision in carbohydrate counting improves insulin dosing accuracy and glycemic management, leading to lower glycated hemoglobin levels [7]. Further, greater differences in carbohydrate estimates are associated with higher glycemic variability [8]. This is significant considering that frequent or large glucose fluctuations may independently contribute to diabetes-related complications [9].

Automated CC through health technology introduces novel care solutions that can simplify CC for individuals living with T1D. The efficacy of smartphone or tablet apps in improving self-management among adults with diabetes is well-established [10-12]. The use of automated carbohydrate estimation compared to conventional methods (ie, manual calculations) led to improved accuracy in CC, reduced time spent in hyperglycemia, and improved BG variability [13,14]. However, the use of such apps is limited beyond research settings [15,16]. According to a survey, young participants lack awareness and have skepticism about the effectiveness of diabetes management apps, which have been shown to be reasons for not using them [16].

This highlights the necessity of involving people with T1D in the design process to create a more effective and user-centered app design that meets their needs. This is particularly important for adolescents, considering the unique psychological and social challenges they face [17]. Consequently, they may struggle to maintain motivation for self-care behaviors such as CC, as competing priorities often take precedence over the numerous demands of T1D management [18]. This challenge is compounded by the increased glycemic levels disproportionately observed from adolescence through young adulthood (approximately aged 14-24 years) [19]. Recognizing the vulnerability of this developmental stage, during which adolescents and young adults must develop new skills and competencies, it is essential to include adolescents in the development of new resources to gain insights into their specific needs [20].

To understand how a CC app can facilitate CC at mealtimes for people with T1D, the primary objectives of our study are to identify (1) the perceived barriers to CC and (2) the app features that would help reduce these barriers. The secondary objective is to compare apps being used by participants with the suggested app features to identify gaps for a novel CC app that aligns with user preferences and needs. We hypothesized that the needs of people with T1D regarding CC are not met with traditional manual tools or with the currently used apps.

Methods

Ethical Considerations

We received ethics approval for this study from the McGill Research Ethics Board (22-08-054-02). Participants were informed through the web-based platform (LimeSurvey GmbH) before accessing the survey, about its estimated length, the type of data collected, where the data would be stored, the duration of storage, the investigator's identity, and the purpose of the study. Informed consent was obtained before participation. All data collected were deidentified to ensure privacy and confidentiality and were hosted on secure McGill servers. No compensation was offered for completing the survey.

Participants

A national cross-sectional web-based survey was launched across Canada. Recruitment took place from November 2022 to November 2023 and used a nonprobability convenience sample. We sent an announcement through the newsletter to participants of the BETTER Canadian registry of people living with T1D (more than 3800 participants) [21] and through Canadian diabetes organizations and social media. People with T1D diagnosis, aged 14 years and older, and living in Canada, were eligible to complete a 30-closed and 9-open-ended question survey. Adolescent and adult participants provided digital consent before accessing the open voluntary survey. Parents who completed the questionnaire on behalf of their child with T1D were excluded as the aim was to gather insights and perceptions directly from individuals living with T1D.

Questionnaire and Data Collection

All data were self-reported. The survey was developed and adapted by researchers of T1D, certified diabetes educators, and health care professionals on the team, and subsequently tested by 3 patient-partners (ie, individuals with lived experience of type 1 diabetes who collaborate in research, to ensure a clear understanding of the questions). Questions related to barriers in CC were based on a literature review and proposed app features were based on the scientific literature as well as a manual search or testing of iOS and Android diabetes management apps. A list of identified barriers and proposed app features was compiled, and consensus was reached among researchers (AH and ASB) for the final items included in the

XSL•FO
RenderX

survey. The survey was created, in both English and French, on LimeSurvey hosted on McGill secure servers (LimeSurvey GmbH). The final questionnaire contained 13 demographic and diabetes management–related nonrandomized questions, 19 CC needs assessment questions and app use, and 7 questions on patient-provider communications, distributed over 6 pages or screens (Multimedia Appendix 1). Adaptive questioning was used to reduce the number and complexity of the questions. Respondents were able to review and change their answers before submission. The survey design ensured single-entry responses by disabling token-based response persistence and prohibiting multiple or updated responses with the same token. Only the completed questionnaires were considered for analysis. Respondents rated suggested barriers and app features on a 5-point Likert scale. The percentage of agreement was calculated based on the frequency of ratings that were either a 4=agree or a 5=strongly agree. Suggested app features were cross-referenced with the features of apps reported by participants to identify gaps and inform the development of a novel CC app aligned with user preferences and needs.

Statistical Analyses

All analyses were performed using IBM SPSS Statistics (version 27; IBM Corp). Variables are reported as frequencies, median with IQR, or mean (SD) was computed where indicated for scale variables. In addition to descriptive statistics for presenting barriers and app feature preferences, statistical analyses were conducted to identify any significant differences among respondents based on age (youths aged 14-24 years vs adults older than 24 years), consistent app use (every day or most of the days vs some of the days or rarely), and insulin administration modality (on injections or sometimes on an insulin pump vs on an insulin pump exclusively). A mean score out of 5 was calculated for each barrier and app feature and treated as a continuous variable to assess mean differences using either a 2-tailed *t* test or a nonparametric test, as appropriate. Open-ended questions were analyzed by 2 independent researchers (AH and AK), both with experience in diabetes care as clinicians (AH is a registered dietitian and AK is an MD student) and as student researchers. Their familiarity with the challenges faced by individuals with T1D and in conducting CC informed their interpretation of the open-ended responses. MAXQDA software (version 24; VERBI GmbH) was used to assist with the inductive thematic analysis and coding process. Individually, each researcher created a codebook, and then each code was discussed until agreement (100%) was achieved.

Results

Overview

A final sample of 196 eligible respondents provided consent and completed all the questions of the survey. The majority identified as women (n=145, 74%) and Caucasian (n=184, 93.9%). The median (IQR) age was 38 (24-54) years with just over a quarter of participants being youths aged 14-24 years (n=52, 26.5%). Over half of the respondents (n=110, 56.1%) use an insulin pump to administer insulin and almost all participants (n=191, 97.4%) use continuous glucose monitoring (CGM) systems (Table 1). Most respondents (n=178, 90.8%) use CC to determine mealtime bolus insulin and more than half (n=133, 67.9%) find it difficult to manage BG levels around mealtime with CC. Although the majority (n=147, 7%) believe apps could ease the CC burden, only 57 (29.1%) use apps to help with CC, and less than half of them (27/57, 47.4%) are satisfied with the apps used. A total of 16 unique apps were reported as being used by the respondents (Table 2). The most frequently used app was “MyFitnessPal,” reported by 17 of the 57 participants. This was followed by “Carbs & Cals,” “BolusCalc,” and “CalorieKing,” each used by 3 respondents.

[a]SNAQ: Simplified Nutritional Appetite Questionnaire.

The open-ended survey responses were analyzed using inductive qualitative thematic analysis, identifying 22 themes categorized as barriers to CC and app features to address these barriers (Figure 1). Although some themes were survey options, participants also introduced new barriers and features. Emergent themes included calculation errors due to unreliable food data and nutrition labels, limited app reliability, unmet diverse user needs, and fear of eating disorders associated with food

XSL•FO
RenderX

hyperfixation. Concealing calorie information through technology was suggested as a way to reduce this hyperfixation. Participants highlighted minimal perceived benefits of CC on BG trends and limited health care professionals' support due to time constraints, lack of nutrition knowledge, and narrow clinical focus. Alternative strategies were brought forward to avoid CC, such as avoiding carbohydrates, using CGM to correct BG, eating the same thing, or using trial and error.

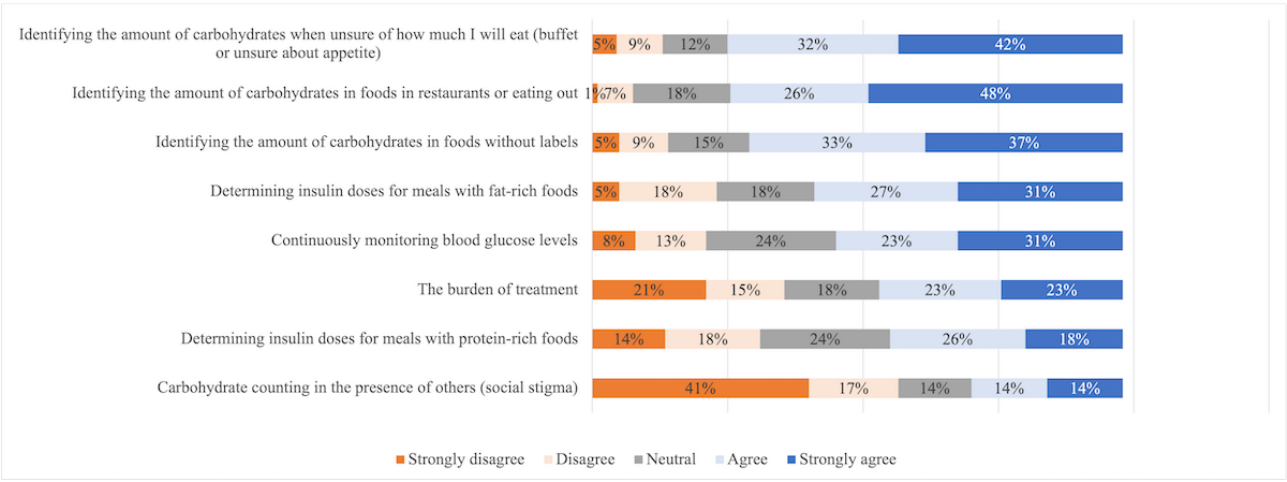

Figure 1. Emerging themes of reported barriers to carbohydrate counting (n=11) and app features (n=11) perceived to reduce these barriers, from the qualitative analysis of the open-ended questions. AI: artificial intelligence; BG: blood glucose; CC: carbohydrate counting; T1D: type 1 diabetes.

Barriers to CC

In terms of the barriers to CC that were suggested, identifying the number of carbohydrates to be consumed was the most agreed upon barrier whether it was in foods without labels (n=138, 70.4%; ie, rated scores of 4 or 5), in restaurants or when eating out (n=145, 74%), or when unsure about appetite (n=146, 74.4%; Figure 2). This was also reflected in participants' answers to the open-ended questions where quantifying portions was reported as a barrier for CC when eating homemade food or unknown ingredients, but also for food with labels where the serving size on nutrition labels was unclear or difficult to estimate. Conversely, counting CC in the presence of others or social stigma achieved higher rates of disagreement (n=56, 57.6%; ie, rated scores of 1 or 2). However, qualitative data analysis revealed a distinct perspective. Specifically, stigma manifested as feelings of blame and judgment. Participants expressed a fear of alienation, as well as apprehension about receiving judgment when eating sugary foods. It also included perceptions of stigma stemming from preoccupation with others' opinions, including health care professionals, and the fear of "ruining a good day" (Figure 1).

Figure 2. Stacked bar chart of participants' proportion of agreement with suggested barriers to carbohydrate counting.

App Features to Reduce CC Burden

Suggested app features with the most agreements were the option to view the food nutrition label (n=167, 85.2%) and the quantification of meal composition (n=165, 84.2%). Participants expanded upon this in the open-ended responses by suggesting photo recognition, visual cues, comparing pictures to estimate quantities, or shifting toward the selection of small-medium-large portions rather than exact grams to reduce the burden. Beyond estimating quantity, emphasis was also placed on reliable nutrient value by suggesting the inclusion of the source of nutrient information and a breakdown of the carbohydrate estimations (Multimedia Appendix 2). On the other hand, gamification features such as earning points or trophies achieved the most disagreement among respondents (n=75, 38.3%; Table 3). To simplify meal logging and keeping

XSL•FO
RenderX

a food journal, the majority of respondents agreed on adding a "Favorites" section (n=168, 85.7%), allowing users to save frequently consumed food items for convenient access and photo recognition features (n=156, 79.2%). Additionally, a significant majority (n=166, 84.7%) agreed on including options to log factors influencing glycemia such as alcohol intake, physical activity, and medications (Table 3). In the open-ended responses, participants also noted stress, sick days, menstrual cycle, sleep, time, and site of injections, as well as other medical factors (menopause and gastroparesis; Figure 2). Factors that would increase users' trust in CC apps include transparency about safety mechanisms to prevent accidental overdosing of insulin or hypoglycemia (n=147, 75%) and endorsements based on validated clinical trial results (n=146, 74.5%; Table 2). Additionally, open-ended answers highlighted participants' emphasis on users' feedback, consistency in results obtained from the app, and improved glycemic management outcomes (Figure 1).

Table 3. Agreement rates for suggested app features and factors reducing CC burden.

Suggested app feature	Rate of agreement, n (%)				
	1=strongly disagree	2=disagree	3=neutral	4=agree	5=strongly agree
Features that would be beneficial to include in a carbohydrate counting app					
Gamification (earning points or trophies)	50 (25.5)	25 (12.8)	42 (21.4)	40 (20.4)	39 (19.9)
In-app community building	17 (8.7)	31 (15.8)	55 (28.1)	40 (20.4)	53 (27)
Meal logs into a food journal	11 (5.6)	15 (7.7)	41 (20.9)	53 (27)	76 (38.8)
Support from health care providers	13 (6.6)	13 (6.6)	35 (17.9)	63 (32.1)	72 (36.7)

[a]BG: blood glucose.

App Features Comparison With Current Apps

Suggested app features were cross-referenced in each app (n=16) reported to be used by participants. It was found that, while most apps allow meal composition quantification, less than half display nutrition labels. Only 1 app calculated bolus dose, 1 app provided support from health care professionals, and none offered personalization for diabetes characteristics (Table 2).

Differences in Barriers and App Feature Preferences Among Users

Based on insulin administration modalities, the need to continuously monitor BG levels to adjust insulin ratios was a

XSL•FO
RenderX

more pronounced barrier among users on injections (mean score of 3.87, SD 1.22; ie, trending toward agreement) compared to those using insulin pumps exclusively (mean score of 3.30, SD 1.28; ie, trending toward neutral; *P*=.001). Additionally, users on injections expressed a greater need for specific features compared to exclusive pump users. This included the need for meal logs in an electronic food journal (mean score of 4.06, SD 1.18 vs mean 3.69, SD 1.17; *P*=.01), suggestions for bolus doses (mean 4.37, SD 0.98 vs mean 3.84, SD 1.26; *P*=.001), and app personalization (mean 4.47, SD 0.86 vs mean 3.93, SD 1.21; *P*<.001).

There were no significant differences in barriers or app feature preferences based on age or app use.

Discussion

Principal Findings

Participants reported carbohydrate identification barriers, nutrient interaction, and insulin dose calculation barriers, as well as psychosocial barriers. App features like photo recognition paired with nutrient values derived from validated databases, personalized bolus calculations, and tracking factors affecting BG levels were perceived to facilitate CC. Existing CC apps, used by people with T1D, fall short of meeting their preferred app features.

Comparison With Prior Work

Martinez et al [22] found that of the 80 existing apps for people with T1D, none met the criteria of an "ideal" app, suggesting a significant gap between what users want and what is available. App features for general T1D management, such as access to CGM and insulin pump records, personalization through goal setting and tailored recommendations, as well as insulin bolus calculations [22] were also reiterated by participants in this survey. On the other hand, reminders and rewards, that is, gamification features did not obtain major agreement in this survey despite being present in the literature as key features for diabetes management technology [22]. Several novel app features were suggested by participants and are worth noting. In fact, the fear of developing eating disorders was mentioned as a barrier to CC. The hyperfixation on food can lead to a heightened risk of developing disordered eating behaviors among people with T1D and is a well-established risk factor in the literature [23]. As such, concealing calorie information was suggested to promote a healthier relationship with food using technology. This perspective aligns with existing literature that highlights the importance of automated processes, which demand less input from the individual, as a means to alleviate the burden of treatment in T1D. A review demonstrated that the use of automated insulin delivery systems may reduce food management burden, by correcting CC inaccuracy, particularly when combined with adjunctive therapies (eg, GLP-1 receptor agonists and SGLT2 inhibitors) [24,25]. Although automated insulin delivery systems are at the forefront of diabetes research, fully closed-loop systems that do not require CC remain in development and are not yet available for people with T1D [26]. Additionally, factors such as future costs and user preferences underscore the need to provide alternative solutions, particularly accessible, comprehensive, and customizable CC apps. Meal entry through photo recognition could alleviate the cognitive burden on individuals with T1D during mealtimes and potentially facilitate full automation. This would enable users to receive bolus dose suggestions simply by taking a picture of their meal, without needing to process additional information. However, it is important to provide users with the option to access breakdowns of carbohydrate estimations and calculations upon request, as it was found to increase their trust in a CC app. Meal entry through photo recognition would also decrease the time required for CC and could potentially alleviate associated burdens. Participants expanded on the mental strain linked with CC, describing it as time-consuming, challenging to log multiple small snacks and corrections between meals, and restrictive when "not being able to eat right away." Another key barrier that was introduced was the limited use of CC apps. Beyond the 16 apps reported as being used by respondents, other available apps did not meet the reported preferred features. Although app-based insulin bolus calculators are available, they lack direct carbohydrate estimation and still require manual entry of meal composition or carbohydrate counts, meaning users must input this information manually rather than having it automatically recognized [5,27-31]. Separate apps can automatically count carbohydrates using photo recognition and food databases, but they do not incorporate bolus calculators [14,15,32]. This underscores participants' perception that current CC apps lack comprehensiveness. Moreover, existing apps frequently contain unreliable values [33], which can be attributed to users contributing information to the databases or relying on values from foreign databases. Participants reiterated this concern, highlighting unreliable food databases as external sources of errors. Another barrier to CC was the associated financial burden. As such, there may also be cost-related limitations when using CC apps. The apps used by participants all offered a free version, despite the option to upgrade to a premium version.

While the benefits of CC are well established in the literature [7,8], respondents perceived a limited use of CC when it comes to explaining BG levels and glycemic trends due to the multiple dietary and nondietary factors influencing BG levels. Similarly, a Canadian survey reported similar findings and revealed that 78% of the respondents (n=180) agreed that BG levels fluctuate even with appropriate CC, complicating diabetes management [34]. The most significant barrier reported was the difficulty in accurately identifying and counting carbohydrates. In fact, several research studies documented no significant changes in CC accuracy despite receiving education [4,35]. Additionally, more than half of this survey's respondents found determining insulin doses for high-fat meals to be a barrier to CC. Managing the delayed impact of fat on postprandial BG excursions is a well-established challenge in the literature [36-38]. Although clinical guidelines recommend meal-time insulin dose adjustments to mitigate glucose variability due to the impact of dietary fat [39-41], there is no consensus as to which insulin strategies to use. Strategies used to manage glycemic excursions following high-fat meals in T1D are numerous [42] but substantial interindividual differences exist in insulin dose requirements for fat and individualized advice based on postprandial BG monitoring for multiple hours afterward is required [43]. As such, the use of a CC app offering the ability

XSL•FO
RenderX

to track meal composition, as well as other nondietary influencing factors can help people with T1D understand BG levels and allow for personalized learning opportunities. Furthermore, machine learning models that use personalized insights from tracking apps could offer new opportunities for insulin dosage recommendations that account for protein and fat intake. Although the suggested psychosocial barriers received a lower agreement rate, they are still noteworthy as they were brought up in a different light by participants in the open-ended responses. Although CC in the presence of others is not as consequential, the fear of receiving judgment from others or feeling alienated, especially when eating sugary foods, was perceived as a barrier to CC. This was also demonstrated in a cross-sectional analysis of people with T1D perceiving stigma mostly as blame and judgment, including when eating sugary foods [44]. Only 69% of participants reported an agreement with app features providing support from health care professionals. The interpretation of this finding can be informed by qualitative analysis shedding light on stigma perception related to interactions with health care providers. Participants expressed feeling judged based on their BG values, which generated a fear of "ruining a good day," further complicating their condition management. This sentiment aligns with barriers mentioned by participants regarding the limited support from their health care team, who heavily focused on glycated hemoglobin levels rather than overall health and had limited knowledge of nutrition. They expressed the need for personalized learning opportunities that could be provided through CC apps by tracking their own trends and accessing educational modules while maintaining their privacy.

A final consideration is the potential for these features to improve CC and overall glycemic management while reducing the burden of CC. Given the challenges with CC around mealtimes, the need for technological solutions is evident. A recent meta-analysis, published in 2023, examining the effects of smartphone apps on glycemic control in youths with T1D found that apps with insulin or carbohydrate calculators were effective in reducing glycated hemoglobin (HbA_{1c}) levels [45]. In addition to improving accuracy, CC apps can help individuals understand their glycemic trends and how various factors impact their BG levels. Such an app can empower users to learn about their glycemic patterns and take control of their diabetes management, particularly in contexts where patient-practitioner communication may be limited. A CC app can streamline access to relevant information for health care professionals while enabling users to track and share key details for more meaningful discussions about their care.

Strengths and Limitations

Our results highlight the perceived barriers and preferred app features among individuals with T1D and should be interpreted with caution due to certain limitations. First, this study faced selection bias due to convenience sampling rather than random selection. Participants who completed the survey were likely more motivated, which may have resulted in an underrepresentation of certain barriers and app feature preferences. This limits the generalizability of the results, as the findings may not accurately reflect the diverse experiences of all individuals with T1D. Further, the homogeneous sample, with around 84% of the respondents identifying as Caucasian is not representative of most people with T1D and prevents the generalizability of the results. Nevertheless, 16% of this survey's respondents self-identified as Arabs, Asians, Blacks, and Latin Americans, among other ethnicities, as compared to 26% of Canadians self-identified as belonging to visible minorities according to the 2021 census by Statistics Canada [46]. Further, participant recruitment was extended to include adolescents as well as adults. This allowed including the perceptions of young adults who are transitioning to assuming responsibility for managing their diabetes from caregivers. Second, while surveys as a research method impose limitations on participants' responses and feedback, this was mitigated by incorporating open-ended questions. The thematic analysis provided a deeper understanding of participants' perceptions. Third, patient-reported outcomes brought additional value to our data and shed light on patient perspectives. Further qualitative studies with in-depth interviews could provide a better understanding of the diverse experiences of people with T1D, especially considering variations in treatment plans and differences between individuals using CGMs versus self-monitoring of BG levels, as most respondents in this survey were CGM users.

Future Directions

This study highlights the challenges faced by people with T1D and areas for improvement in diabetes management apps. Effective apps need comprehensive, automated CC features like photo recognition, easy access to frequently consumed meals, reliable nutrient values, and personalized bolus calculations. Personalization options, such as insulin administration modalities and individual factors affecting BG levels, are also essential for a user-friendly experience. An app incorporating these elements and validated food databases would be unique and novel. Ongoing end-user engagements in development and testing are essential for the high usability of the app.

Acknowledgments

The authors would like to acknowledge the Cardiometabolic Health, Diabetes, and Obesity Research Network for the mentorship award to ASB, as well as the contribution of patient partners involved in this research project. The material in this manuscript has previously been presented at the 17th International Conference on Advanced Technologies & Treatments for Diabetes (Florence, Italy; March 6-9, 2024) and the Vascular Conference (Montreal, Canada; October 25-29, 2023). This work was supported by Mitacs (grant number IT31370 ACC).

Data Availability

The datasets used and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

AH conceptualized the study, developed the protocol, consolidated the survey, conducted a formal analysis, wrote the original draft, and reviewed and edited the manuscript. AK participated in the analysis, contributed to the original draft, and reviewed and edited the manuscript. LJB, AS, and AF participated in the analysis and reviewed and edited the manuscript. ARF consolidated the survey and reviewed and edited the manuscript. MN reviewed and edited the manuscript. ASB conceptualized the study, developed the protocol, consolidated the survey, supervised the project, and reviewed and edited the manuscript. All authors reviewed the final manuscript. ASB is the principal investigator and guarantor of this work and, as such, has full access to all the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Conflicts of Interest

ASB received research funding from the Canadian Institutes for Health Research, Mitacs, Diabète Québec, and Fonds de recherche du Québec-Santé, as well as speaker fees from Dexcom.

Abstract

Background: Intensive care units (ICUs) handle the most critical patients with a high risk of mortality. Due to those conditions, close monitoring is necessary and therefore, a large volume of data is collected. Collaborative ventures have enabled the emergence of large open access databases, leading to numerous publications in the field.

Objective: The aim of this scoping review is to identify the characteristics of studies using open access intensive care databases and to describe the contribution of these studies to intensive care research.

Methods: The research was conducted using 3 databases (PubMed–MEDLINE, Embase, and Web of Science) from the inception of each database to August 1, 2022. We included original articles based on 4 open databases of patients admitted to ICUs: Amsterdam University Medical Centers Database, eICU Collaborative Research Database, High time resolution ICU dataset, Medical Information Mart for Intensive Care (II to IV). A double-blinded screening for eligibility was performed, first on the title and abstract and subsequently on the full-text articles. Characteristics relating to publication journals, study design, and statistical analyses were extracted and analyzed.

Results: We observed a consistent increase in the number of publications from these databases since 2016. The Medical Information Mart for Intensive Care databases were the most frequently used. The highest contributions came from China and the United States, with 689 (52.7%) and 370 (28.3%) publications respectively. The median impact factor of publications was 3.8 (IQR 2.8-5.8). Topics related to cardiovascular and infectious diseases were predominant, accounting for 333 (25.5%) and 324 (24.8%) articles, respectively. Logistic regression emerged as the most commonly used statistical model for both inference and prediction questions, featuring in 396 (55.5%) and 281 (47.5%) studies, respectively. A majority of the inference studies yielded statistically significant results (84.0%). In prediction studies, area under the curve was the most frequent performance measure, with a median value of 0.840 (IQR 0.780-0.890).

Conclusions: The abundance of scientific outputs resulting from these databases, coupled with the diversity of topics addressed, highlight the importance of these databases as valuable resources for clinical research. This suggests their potential impact on clinical practice within intensive care settings. However, the quality and clinical relevance of these studies remains highly heterogeneous, with a majority of articles being published in low–impact factor journals.

Introduction

Intensive care units (ICUs) provide care for critical patients at high risk of morbidity and mortality. These patients, due to their severity, require continuous monitoring and surveillance of clinical, biological, and imaging parameters. This generates a large amount of data, usually collected in electronic health records. Although collected for health care purposes, these data can also be used secondarily to address other objectives, which has become a key issue in recent years [1-3]. In addition to traditional epidemiological and clinical research, the secondary use of these databases allows the emergence of new research themes such as the development of diagnostic tools, decision support systems, or predictive models of therapeutic response [4,5]. However, due to the sensitive nature of health data and the technical, legal and ethical challenges, medical data are still difficult to access [6].

During the last decades, collaborative ventures have enabled the emergence of large open access databases [7]. Building on the opportunity of digital transformation, they facilitate data sharing on a large scale and enable knowledge creation more efficiently. Furthermore, they are part of an ecosystem in which science is more transparent, reproducible, and constitutes an effective lever for scientific integrity [8]. Since the 2000s, we have seen the release of several open access ICU databases [9]. The best-known example is the Medical Information Mart for Intensive Care (MIMIC) database, which integrates anonymized, comprehensive clinical data from more than 50,000 intensive care admissions from Beth Israel Deaconess Medical Center in Boston, Massachusetts [10,11]. These open databases have led to the production of numerous research works [12,13].

Currently, little effort has been made to analyze the medical literature generated from these open intensive care databases. Previous systematic reviews were interested in describing these databases to determine their exploitation potential [9] or focused on describing machine learning techniques used to train models from these databases [14]. However, none of them were interested in the research themes and their potential impact on clinical practice.

We propose a comprehensive synthesis of clinical research publications based on ICU open databases. A scoping review was used as the most suitable research methodology for mapping this research area [15]. Our objectives were to (1) examine the bibliometric characteristics and authorship patterns of these publications and (2) investigate the research themes and methodologies used. The objective was to glimpse the contribution of these open databases in intensive care clinical research.

Methods

Overview

The protocol adheres to the reporting guidance provided in the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [16] (Table S1 in Multimedia Appendix 1). The design of this study is conceived according to the Joanna Briggs Institute Reviewers' manual for evidence synthesis [17].

Eligibility Criteria

We selected studies based on the following criteria (Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- They were original articles based on open databases of patients admitted to intensive care units, covering all types of interventions and outcome measures.
- They were studies with a clinical aim (diagnosis, therapeutic, prognosis), where "clinical" pertains observations made on actual patients as opposed to theoretical, laboratory, or computer-based studies.

Exclusion criteria

- Studies on patients admitted outside of intensive care units.
- Studies where open databases were solely used for external validation.
- Studies not written in English.
- Systematic reviews and meta-analyses.

Search Strategy

First, the literature was searched for open access ICU databases. A recent review systematically identified publicly available adult clinical ICU databases [9]: Amsterdam University Medical Centers Database (AmsterdamUMCdb) [7], eICU Collaborative Research Database (eICU-CRD) [18], High time-resolution ICU dataset (HiRID) [19], MIMIC clinical databases version II, III, and IV [10,20,21].

We then used PubMed-Medline (US National Library of Medicine), Embase (Elsevier), and Web of science (Clarivate Analytics) to search articles published from the inception of each database to August 1, 2022. The search terms of the

XSL•FO
RenderX

different databases are included in Table S2 in Multimedia Appendix 1. A senior librarian [GK] developed and validated search queries. Finally, the references of the included articles were examined for potentially relevant medical articles that may have escaped the literature search.

Selection

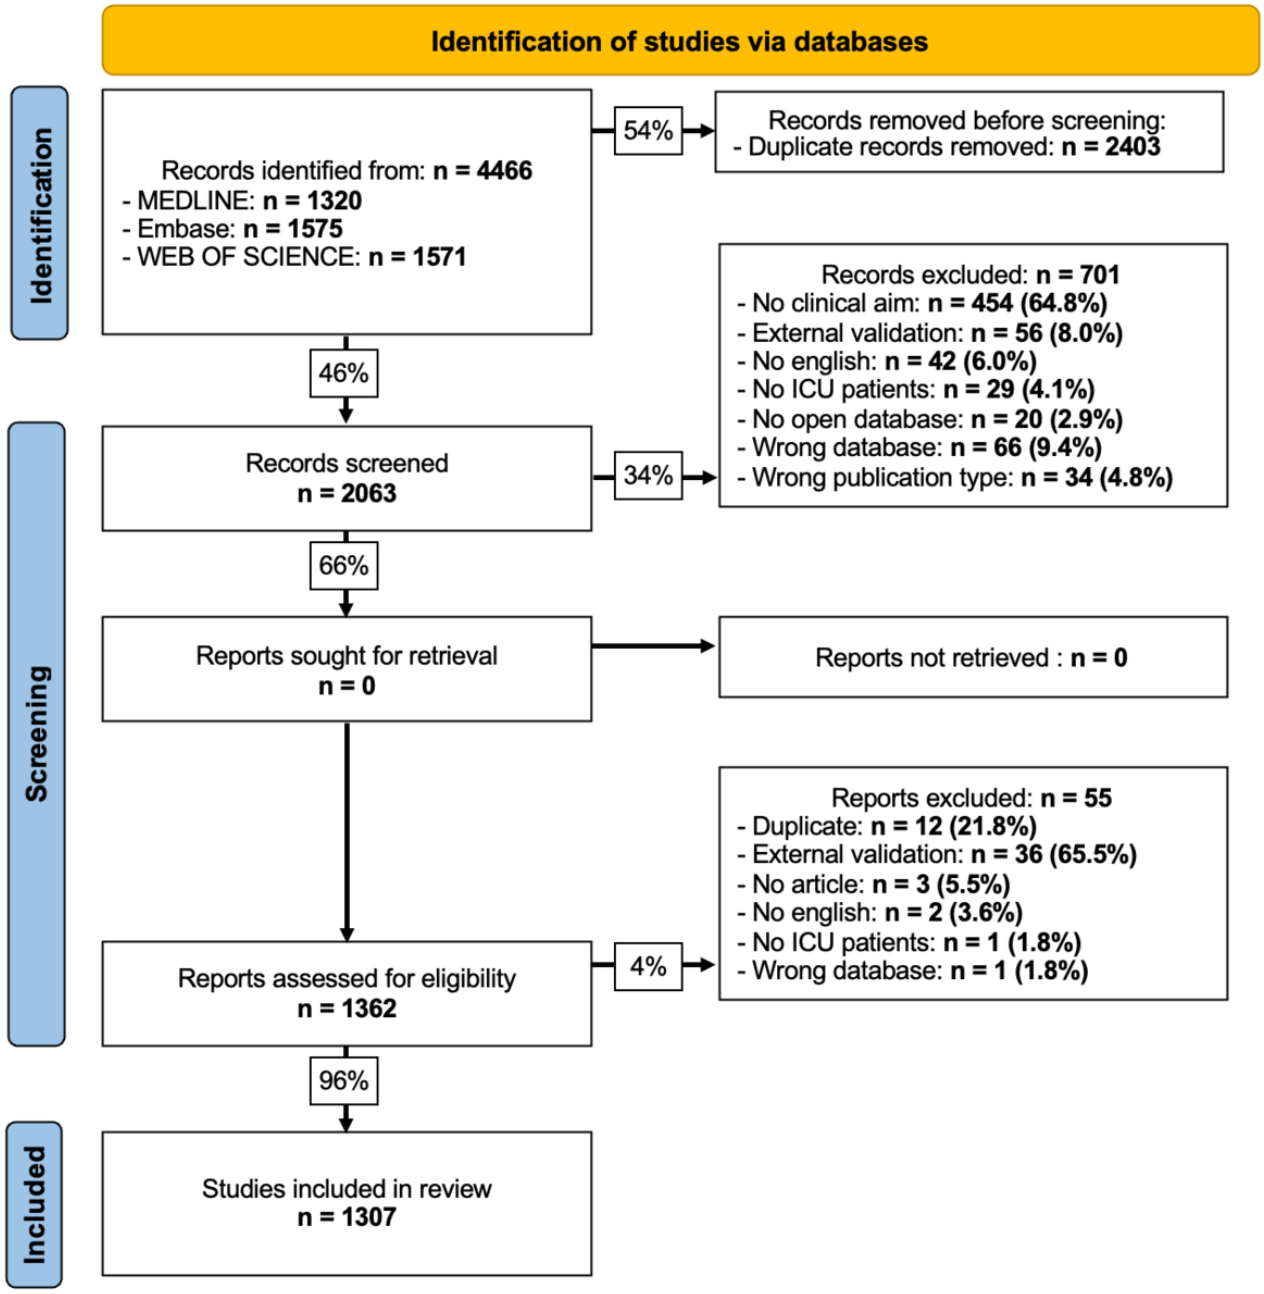
Two independent reviewers, a senior intensivist [BP] and a junior intensivist [JK], conducted the search strategy and retrieved the references. An initial selection was made after examining the titles and abstracts of the medical articles resulting from the search strategy. The reviewers [BP and JK] performed an initial blind and independent selection of the articles. Subsequently, the reviewers met to reach a consensus on any disagreements. If the 2 primary reviewers could not reach a consensus, the third reviewer, a health data engineer (AL), intervened to resolve the disagreements through arbitration. The disagreements typically revolved around the eligibility criteria for study inclusion. The selection process was facilitated using the Rayyan software [22].

Data Extraction, Collection, and Analysis

Medical articles were referenced by their Digital Object Identifier, the name of the first author, and the date of publication. Two reviewers [BP and JK] independently extracted data using a custom electronic form designed specifically for this study. The form was pilot tested with a random sample of 20 articles to ensure its effectiveness. Upon achieving consistent data abstraction ($\kappa \geq 0.8$) [23], reviewers proceeded with data extraction for the entirety of included articles using the Goupile software [24].

Data for journal research fields and impact factors were obtained from Web of Science [25]. In addition, research topics were predefined and listed in the research protocol. Collected data details are outlined in Table S3 in Multimedia Appendix 1. Results were aggregated into a table, organized with 1 column per database and 1 row per variable.

A descriptive analysis was then carried out on the gathered data using R (version 4.1.2; R Foundation for Statistical Computing) [26]. Categorical variables were summarized as counts and frequencies per category, while quantitative variables were expressed as medians and interquartile ranges. Bar charts were used to visualize the distribution of categorical variables and histograms and density curves for the quantitative variables. In addition, the temporal evolution of the studied variables was analyzed.



Results

Study Selection

From the inception of these databases up to August 2022, a total of 4466 publications were identified. After excluding duplicates, 2063 (46.2%) titles and abstracts were retained. Among these articles, 1362 (66%) met the inclusion criteria. Ultimately, 1307 (96%) articles were selected for the final analysis after thorough reading. The selection flowchart is shown in Figure 1, with the characteristics of the included studies are detailed in Table 1.

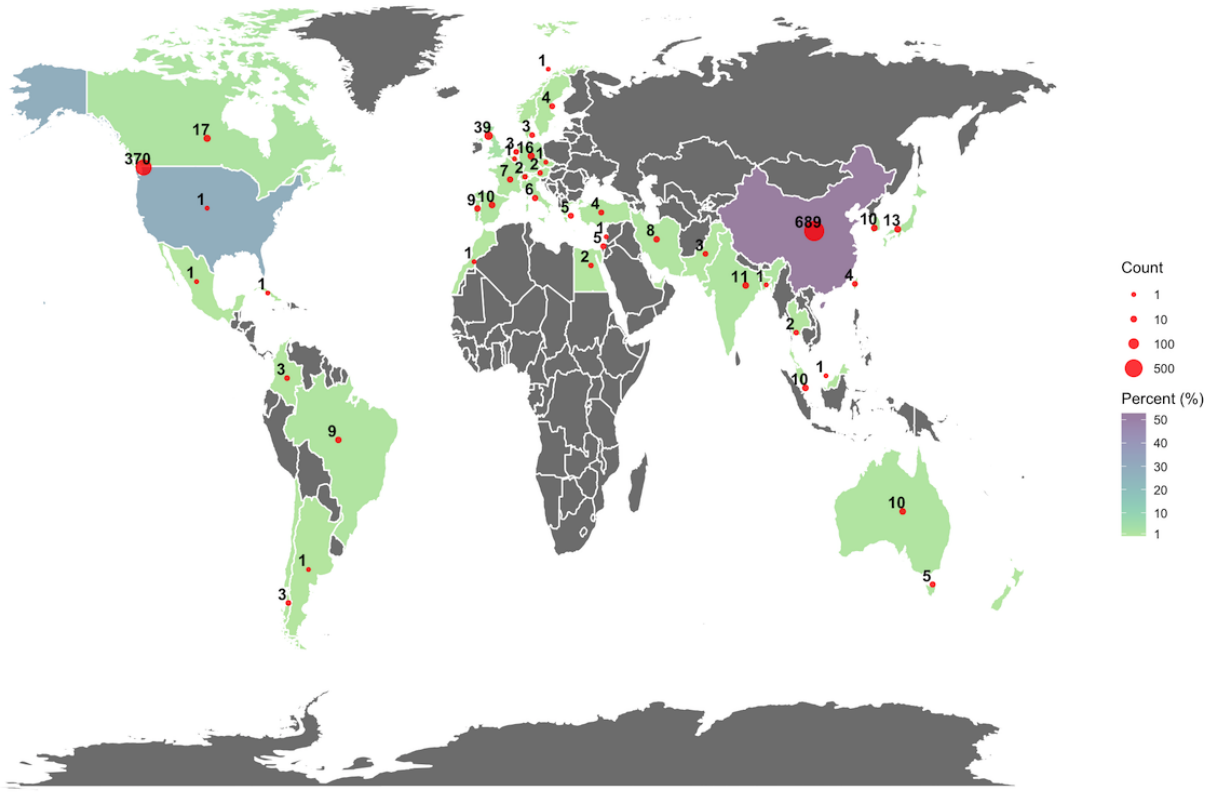
Article Information



Since 2016, there was a consistent rise in the number of publications using these databases. Most studies were published after the year 2020, with 967 (74.0%) publications. The MIMIC databases were the most frequently used. No publications using the HiRID database were identified (Table 1, Figure 2). China and the United States were the leading countries in terms of number of publications, with 689 (52.7%) and 370 (28.3%) articles, respectively. European countries contributed to 109 (8.3%) publications, led by the United Kingdom leading with 39 (3.0%) publications (Table 1, Figure 3).

Study Information

Studies included a median number of 4282 (IQR 1468-12,740) patients with a maximum sample size reaching up to 219,306 by combining patients from several databases. The median inclusion period was 11 (IQR 11-11) years (Table 1).

Research predominantly explored the cardiovascular system, particularly hemodynamics with 333 (25.5%) publications and infectious diseases, specifically sepsis with 324 (24.8%) publications. Renal failure and metabolic disorders were also heavily studied, with 231 (17.7%) publications, along with respiratory failure and mechanical ventilation, which had 203 (15.5%) publications. Notably, many studies investigated overall mortality among critically ill patients admitted to the ICU, with 178 (13.6%) publications (Table 3).

Furthermore, 422 (32.6%) studies investigated the entire population admitted to the ICU. Most studies focused on patients experiencing specific organ failures, represented in 818 (62.6%) publications (Table 4). Various exposure or prediction factors were evaluated. Biological data and vital signs were the most analyzed, featuring in 673 (51.5%) and 428 (32.7%) studies, respectively. Demographic information, medication prescriptions, and comorbidities were also widely included, with 332 (25.4%), 278 (21.3%) and 271 (20.7%) publications, respectively (Table 5). The most frequently assessed primary outcome was mortality, observed either within the ICU, the hospital, or after a certain period of time, across 878 (67.2%) studies (Table 6).

Statistical Methods Used and Results

Regarding the study objectives, 713 (54.6%) studies addressed an inference question, while 594 (45.4%) studies targeted a prediction question (Table 7, Table 8). Supervised learning and deep learning methods were the most commonly applied machine learning techniques, with 432 (33.1%) and 247 (18.9%) publications respectively (Table 7).

When examining specific models, logistic or linear regression was the predominant choice for inference questions with 396 (55.5%) publications (Table 9). Regarding prediction questions, logistic or linear regression was the most widely used classical machine learning method, surpassing survival models and generalized models with 281 (47.5%), 29 (4.9%), and 12 (2%) publications respectively. Neural networks were the most frequently applied advanced machine learning methods

XSL•FO
RenderX

outpacing tree-based methods and boosting methods, with 237 (40.0%), 186 (31.4%), and 169 (28.5%) publications respectively (Table 10).

Inference studies reported statistically significant results in 84% of cases. Furthermore, the prevailing performance measure in prediction studies was the area under the curve (AUC) with 436 (73.4%) studies. The median AUC value was 0.840 (IQR 0.780-0.890; Table 8).

Preexisting clinical scores were applied for comparison with the performance of prediction models implemented in the studies. The most used scores were SAPS (Simplified Acute Physiology Score), SOFA (Sepsis-related Organ Failure Assessment), and APACHE (Acute Physiology and Chronic Health Evaluation) scores, with 55 (42.6%), 24 (18.6%), and 14 (10.9%) publications, respectively. The median AUC for these scores was 0.733 (IQR 0.677-0.781; Table 8).

Discussion

Principal Findings

This review examined clinical publications from open databases in the field of intensive care. We observed a consistent increase in the number of publications from these databases since 2016, with the majority of articles being published after 2020. MIMIC databases were the most frequently used, while the countries contributing the most were China and the United States. Most studies were published in journals with an impact factor ranging from 3 to 6. Cardiovascular and infectious topics, particularly those related to hemodynamics and sepsis, were the most represented. Other significant subjects included renal failure coupled with metabolic disorders and respiratory failure with mechanical ventilation. The most studied outcome measure was mortality in the ICU. Biological data, vital signs, demographic details, medication prescriptions, and comorbidities were extensively used as exposure or predictor factors.

Regarding statistical methods, logistic regression was the most used model for both inference and prediction questions. Neural networks were the most frequently used advanced machine learning methods surpassing supervised and reinforcement methods. A majority of the inference studies presented statistically significant results. In prediction studies, the most recurrent performance measure was the AUC, with a median value of 0.840.

Comparison With Previous Work

The rising number of publications using open databases is steadily increasing, highlighting the potential impact of these resources on clinical research within intensive care. Collaborative initiatives have led to the emergence of large open-access databases, enhancing data availability in this field. Researchers have now access to data from numerous centers, enabling the production of robust results through larger sample sizes. Furthermore, this access has significantly boosted statistical power, enabling the study of specific topics and

XSL•FO
RenderX

populations that were previously overlooked due to insufficient sample sizes. In our review, the median sample size in the studies was 4282 (IQR 1468-12,740), in contrast to typical sample sizes in prospective studies among critical care patients, that barely reach a few hundred patients. In a literature review by van de Sande et al [27] studying machine learning in intensive care, the median sample size was 179 (IQR 94-1411) and 142 (IQR 40-380) across all prospective observational and clinical studies, respectively.

The wealth and diversity of information contained in these databases have opened a broad spectrum of research possibilities, resulting in a wide array of topics covered in publications. Our review categorized these into over 20 different categories. Cardiovascular, infectious, respiratory, and metabolic issues emerged as the most commonly studied research domains, mirroring the reality of clinical practice in intensive care [28]. Mortality in ICU was the most frequently analyzed outcome measure. In a literature review by Syed et al [14], which examined the application of machine learning using the MIMIC dataset, mortality prediction was also the most studied outcome measure, followed by sepsis prediction, cardiac events, and acute kidney injury prediction.

Despite the significant number and diversity of publications, the clinical relevance of studies from these databases remains heterogeneous. The results were often statistically significant but had limited effect sizes. Nevertheless, there are few criteria to objectively evaluate the clinical relevance of a publication. In addition, the quantitative nature of our analyses did not allow us to fully explore this aspect. A qualitative methodology specifically assessing clinical relevance would provide more insights and discussion points.

Recently, a bibliometric analysis study using machine learning and natural language processing methods Bidirectional Encoder Representations from Transformers (BERTopic) compared research topics in traditional intensive care unit studies and those conducted with open access databases. A total of 1307studies from open access databases were identified versus 145,426 traditional studies. Among these 1307 studies, the most predominant topic was sepsis and kidney injury, and over 40% of the articles were based on predictive models [29].

Toward Precision Intensive Care Medicine

In recent years, due to advancing technology, data availability, and the need to analyze increasingly larger databases, machine learning has emerged to develop increasingly accurate predictive models. Machine learning is a field of computer science and a part of artificial intelligence that defines both the science and engineering for which computer systems can analyze data and learn from the information contained within [30].

In our study, 594 out of 1307 (45.4%) publications used at least 1 machine learning model, with a significant increase in their implementation after 2015. The most commonly used machine learning method was logistic regression and neural networks. Literature review by Shillan et al [31], summarizing the characteristics and results of machine learning methods used in intensive care, found similar results. Nearly half of the studies identified in that review were published after 2015, and the most commonly used methods were neural networks, support vector machines, and decision trees.

Although the use of machine learning models in intensive care has increased in the scientific literature, their adoption in actual clinical practice remains limited or even absent at present. Machine learning models are often complex and require specialized skills to develop and implement. Their interpretation also poses a significant barrier to their use, with the phenomenon known as the “black box” issue [32]. Furthermore, these models need to be rigorously validated to ensure their reliability and accuracy. External validation of models on independent datasets is crucial to evaluate their performance under real-world conditions. In our review, the vast majority of publications analyzed came from databases implemented in the United States of America, limiting the generalizability of these models to the rest of the population. In addition, only 92 out of 2063 (4.5%) articles focused on external validation using an independent dataset, which is consistent with Shillan et al findings [31]. Furthermore, prospective clinical evaluation of these models is still rare. In a recent review, only 10 out of 494 (2%) articles clinically evaluated artificial intelligence in real clinical settings, with 5 studies being randomized clinical trials [27]. Finally, the use of machine learning models raises ethical and regulatory questions, particularly concerning data privacy, automated decision-making, and liability in case of errors. Clear guidelines and regulations must be established to govern the use of these models in a clinical context.

Strengths and Limitations

This study, to our knowledge, is the first to examine the contribution of open databases in clinical research in intensive care. This study follows a rigorous methodology, and its research protocol was made public before the study [33]. Furthermore, this review adopts a comprehensive approach by including all clinical research publications generated from open ICU databases. By examining a wide range of publications, it provides a detailed overview of research themes, methodologies used, and results obtained. This can assist clinicians and researchers in understanding how these databases can contribute to improving patient care in intensive care and offering a solid foundation for future research and discussions.

However, it is important to acknowledge the limitations of this literature review. First, only publications written in English were included, potentially introducing a linguistic bias. Second, there exists and inherent risk of publication bias in literature reviews. Published and accessible studies may not represent all research carried out on open databases in intensive care. Studies with negative or nonsignificant results are less likely to be published, potentially resulting in an overestimation of positive results. While several open ICU databases were included in the study, it is possible that there exist other databases that were not taken into account. This could limit the representativeness of the sampled studies. Finally, despite exhaustive research, no publications from the HiRID database were identified. With these limitations in mind, it is important to consider the results of this study with caution and interpret them in the appropriate context.

XSL•FO
RenderX

Conclusion

Open databases in intensive care have facilitated clinical research and provided new perspectives for enhancing care in intensive care. The abundance of scientific outputs resulting from these databases and the diversity of topics addressed highlight the importance of these databases as valuable resources for clinical research and suggest their potential impact on clinical practice in intensive care. However, the quality of studies and their clinical relevance remain highly heterogeneous among publications and are challenging elements to evaluate.

Authors' Contributions

BP and JK were involved in the design of the study, selection of articles, data analysis, and writing of the manuscript. GK was involved in the development and validation of the search queries. AL was involved in arbitration in case of a lack of consensus in the selection of articles and the validation of the final article. TC, GB, and JG were involved in the review and validation of the final manuscript.

Abstract

Background: Despite the ample benefits of physical activity (PA), many individuals do not meet the minimum PA recommended by health organizations. Structured questionnaires and interviews are commonly used to study why individuals perform PA and their strategies to adhere to PA. However, certain biases are inherent to these tools that limit what can be concluded from their results. Collecting data from social media channels can complement these studies and provide a more comprehensive overview of PA motives and adherence strategies.

Objective: This study aims to investigate motives for engaging in PA, as well as the associated strategies to achieve these goals, as stated by a large number of people on a social media site.

Methods: We searched for users' responses regarding PA motives and adherence strategies in Reddit forums dedicated to PA and analyzed the data using (1) unsupervised clustering to identify topics from the textual comments and (2) supervised classification to classify the comments into the detected topics. A panel of experts participated in both steps for annotation and validation purposes.

Results: We analyzed 1577 unique user comments (representing 1577 individual users); of those, 1247 were linked to physical appearance (mentioned in 298/1247, 23.9% of the comments) and improving physical (235/1247, 18.9%) and mental health (211/1247, 16.9%), indicating these as the main motivational factors. The main strategies people used to adhere to PA were habit formation (373/1247, 30%), goal setting (173/1247, 13.9%), enjoyable activities (151/1247, 12.1%), socializing (121/1247, 9.7%), using media (111/1247, 8.9%), using different apps to monitor PA (35/1247, 2.8%), and financial commitment (32/1247, 2.5%).

Conclusions: This study presented a novel approach using a language model to investigate why people engage in PA and the strategies they use to adhere to PA using wide-scale, self-disclosed content from popular social media channels.

KEYWORDS

motivation; physical activity; social media; Reddit; adherence

Introduction

Despite the established health benefits of physical activity (PA) [1-4], surveys from multiple countries have reported that more than 80% of adolescents and 27% of adults do not meet the World Health Organization guidelines [5-7]. Studying what motivates individuals to perform PA and what strategies assist them in adhering to PA can lead to improvements and developments in interventions aiming to increase PA levels. The most common way to examine people's motives and adherence strategies to PA is by using standardized questionnaires and structured interviews [8-13]. While these

XSL•FO
RenderX

studies using these data collection strategies have clear benefits, they also suffer from several inherent biases that limit what can be concluded based on their results. First, participants in these studies are likely unrepresentative of the population. The observed phenomenon can be attributed to the specific targeting of participants and the resultant self-selection bias, as those who volunteered to participate (ie, volunteer bias) possessed distinct attributes compared with those who declined [14]. Indeed, volunteering is a trait associated with sociodemographic factors, attitudes, and other personality traits of lifestyle behaviors [15,16]. Second, questionnaires and interviews can lead to response bias, given that they can confuse or prompt participants to answer in a particular manner [17,18]. Third, participants may interpret the studies' purpose or interviewers' intent and modify their responses to align with this interpretation, a phenomenon known as demand characteristics [19]. These biases might create a misleading picture of reality and lead to misclassification of the factors that motivate individuals to engage and adhere to PA.

One approach that can partially overcome these shortcomings is to collect information concerning motivation and adherence strategies to perform PA from social media channels. Social media allows people to share their experiences and opinions as they wish, mostly unrestrictedly. Moreover, the anonymity afforded by social media may allow for more uninhibited self-disclosure without worrying about potential exposure or various consequences [20-22]. Data gathered in this fashion has inherent biases, including selection bias of social media users proficient in using computers. Nevertheless, the difference in mediums and context allows researchers to complement the traditional approaches based on standardized questionnaires and structured interviews. The increased ease of use in implementing machine learning algorithms on free text has enabled researchers to collect data on social media posts at a massive scale. This method allows for larger sample sizes than traditional research methods and may avoid specific selection and response biases. Yet despite the widespread adoption of this research method within multiple scientific fields, it has been rarely implemented within exercise science, specifically in assessing motivation and adherence strategies for engaging in physical activity.

Of the various social media channels, Reddit is a highly popular website (861 million active users as of 2021) [23] in which users submit text, images, and videos to moderated boards (known as "subreddits"), which are then voted up or down by other users. The websites' users are primarily from the United States (47.13%) [24], skew young (36% under 30), male (63.8%), and from higher income brackets [25]. Discussions on Reddit are public to anyone (unless specifically designated as private), allowing for passive data collection. Reddit provides an application programming interface (API) for researchers with extensive access to data, making it a valuable source of information. Therefore, this study aims to determine the motivational factors and strategies to both begin and adhere to the PA of Reddit users based on their self-reported data.

Methods

Overview

We singled out Reddit from other social media platforms due to its large user base, comment ranking system, mode of posting (questions and answers within subject matter "communities," self-disclosure), and researcher-friendly API. The process we undertook to identify and extract data from posts on social media was to first decide upon keywords related to PA and motivation based on an initial search to identify relevant communities. Then, the next step was to identify relevant conversations within the selected subreddits. We will now elaborate on each step of this process:

Reddit Community Identification (Initial Examination, Sorting, and Filtering)

We ran a Google search of Reddit using the keywords "motivation" and "exercise" or "sport." This search returned 59 communities (ie, subreddits).

We began by excluding subreddits containing fewer than 100,000 users (19 groups) and non-English language groups (2 groups). Following initial examination of the remaining subreddits, we found that they could be broadly divided into 2 categories: "general" (25 groups) and "sports-related" (13 groups). Within these 2 categories, we observed that some subreddits were not topically related to our query (motivation in exercise and sport), but rather, they were geared toward other topics (eg, science, GARMIN, and sports leagues such as the NBA [National Basketball Association] and FIFA [Fédération Internationale de Football Association]) and were therefore excluded (17 and 5 from general and sport-related, respectively). Following further examination of the content of the conversations in the remaining sports-related subreddits (bodybuilding, judo, running), we observed that most of the discussions were of a technical nature (ie, best running strategy, bodybuilding tips) and were therefore excluded. We then selected for further analysis the 3 most popular (based on active user activity) subreddits from the categories identified: PA/sports-related (/r/bodyweightfitness, /r/crossfit, and /r/Fitness) and general advice (/r/askMen, /r/askWomen, and /r/askReddit).

Comment Identification

Comment Search and Initial Data Extraction

We searched the selected subreddits using the Reddit API for conversations containing the terms "motivation," "exercise," or "sport." From each of these discussions, we extracted the title, comments, and total "points" (a site metric that captures how many people liked each comment) and unique author identification number of individual comments.

Comment Filtration

In cases where a specific user made more than 1 comment across all the conversations captured by our query, a single comment was chosen randomly. This approach reduces biases of users who posted multiple comments, which can give more weight to their answers and bias the dataset toward prolific commenters rather than unique comments. Based on previous research in

XSL•FO
RenderX

this field [26,27], comments containing only emojis, URLs, non-English languages, or one-word responses were also excluded.

Data Analysis Procedure

To analyze the dataset generated by our data collection and filtration procedure, we used the following analysis pipeline that included 5 steps, as presented in Figure 1. Following the established steps during the development and evaluation of machine learning and artificial intelligence models, it is essential to ensure the accountability and reliability of these models [28,29]. All data analysis was carried out in Python version 3.9.13 (Python Software Foundation) using the fuzzy-c-mean 1.7.2 (FCM), pandas 1.5.3, NumPy 1.26.4, and umap-learn-0.5.6 packages.

Figure 1. Overview of the main steps of the data analysis pipeline.

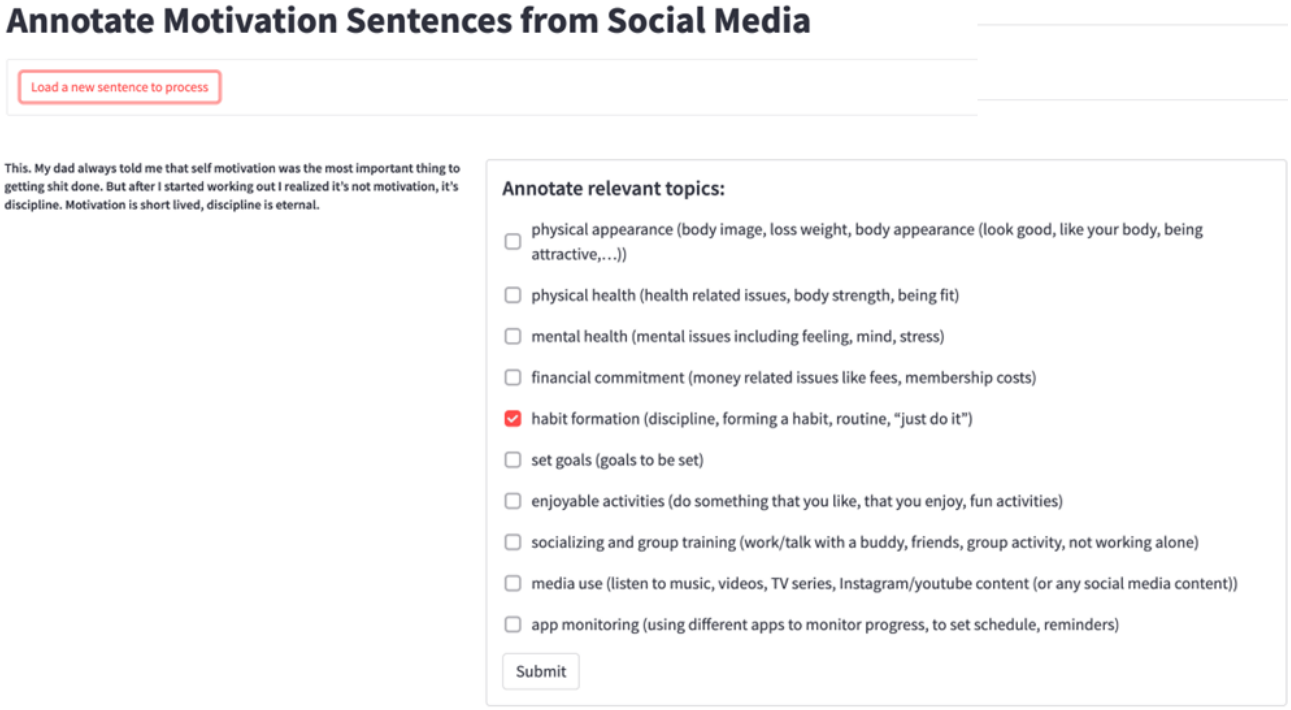
Step 1: Exploration and Initial Clustering

The first step aimed to explore the data and create initial clusters of topics (ie, motivations for engaging in PA) that appear in the text. First, we created embeddings, or vector representations, of each sentence to use for the clustering. Specifically, we encoded using the Sentence Bidirectional Encoder Representations from Transformers language model. We then reduced the high dimensionality of the embeddings using Uniform Manifold Approximation and Projection for Dimension Reduction, introduced by McInnes et al [30], implemented in umap-learn. Finally, we used a clustering algorithm FCM, with FCM implementation [31] to find groups within the data with the most similarity in the same cluster and the most dissimilarity between different clusters (this approach was chosen due to the observation that our data contains examples that discuss several topics). Specifically, this step allows finding groups of similar comments (which are converted to numerical data points) in the data by calculating the distance between data points (see subheading A.1 in Multimedia Appendix 1).

Step 2: Expert Tuning and Validation

To verify the clusters' topics, one of the co-authors (IH), with expertise in exercise science and motivation, reviewed several samples and proposed a topic title for each cluster. Then, 30 samples were randomly selected from each cluster, and 2 additional reviewers with similar expertise independently decided whether each sample matched the proposed cluster topic. Note that a sample could match several topics simultaneously. If both reviewers agreed on the topics, the sample was added to a pool of corrected annotated samples. Thus, at the end of this step, we had a high-quality representation of the different topics in the dataset.

Step 3: Supervised Text Classification



We classified the remaining nonreviewed comments into the topics identified in steps 1 and 2. This procedure's goal was to automatically classify the textual comments into one or more defined topics (Multimedia Appendix 2 [32-35]).

Step 4: Expert Evaluation

We implemented an additional round of expert evaluation of the classified comments. To minimize the risk of researcher bias, we recruited 5 graduate-level exercise physiology students rather than using the original 3 experts. We randomly sampled 30 instances from our data (not used in the first round of evaluation) and asked each expert to evaluate the classified data. Each expert was presented with a dedicated user interface (Figure 2). Each sample was displayed along with the possible topics (multiple choices were allowed) and a field to add comments using free text. Before beginning the annotation task, the reviewers (5 graduate-level exercise physiology students) underwent a familiarization procedure by reading the instructions and practicing on 3 fictitious examples, similar to comments from the dataset regarding topics and average comment length. Once the annotation task was completed, we aggregated the results and evaluated the quality of the classifier and the interrater agreement.

XSL•FO
RenderX

Figure 2. Annotation user interface used by subject matter experts.

Step 5: Reliability

To ensure reliable findings, the quality of the supervised classifier that identifies motivational factors and strategies was evaluated using both automatic metrics (precision, recall, and F_1-score) and an expert evaluation panel, as mentioned above in step 4. For the human evaluation, we used Fliess κ interrater reliability [36].

Ethical Considerations

This research did not require approval from the Tel Aviv University Ethics Committee as it was based on publicly accessible information that is legally protected and does not necessitate an ethics review. This position was confirmed by the head of the university's ethics committee. From a privacy perspective, we used data from Reddit, a platform where most discussions are publicly accessible to anyone, with or without a Reddit account (except for private subreddits). In addition, Reddit offers an extensive API that allows access to much of the platform's information. Strictly adhering to the rules and ethical guidelines of each subreddit, we only collected data from subreddits that explicitly allow research activities. Furthermore, to protect user privacy, we only recorded the comment ID without including any user information or the content of the comment itself, ensuring no personally identifiable information or data that could lead to reidentification was collected.

Results

Data Collection

We collected 2387 comments from 70 discussions published between 2017 to 2021. After completing the data filtration procedure, 1850 samples remained, submitted by 1850 unique users: 227 from /r/bodyweightfitness, 152 from /r/Fitness, 220 from /r/crossfit, 338 from /r/askReddit, 479 from /r/askMen, and 434 from /r/askWomen. Links and examples of the discussions can be found under subheading A.3 in Multimedia Appendix 1.

Primary Outcome

Our model classified the comments into 10 distinct topics, which we observed could be divided into 2 broad categories: motivational factors for initiating PA (motivations) and strategies or suggestions on staying motivated and adhering to PA (strategies), for a total of 1740 observations of identified topics, over 1247 comments. The motivations for participating in PA (frequency of appearance) were physical appearance (298/1247, 23.9%), physical health (235/1247, 18.9%), and mental health (211/1247, 16.9%). The main strategies people use to adhere to PA were habit formation (373/1247, 30%), goal setting (173/1247, 13.9%), choosing enjoyable activities (151/1247, 12.1%), socializing (121/1247, 9.7%), using media (111/1247, 8.9%), using different apps to monitor PA (35/1247, 2.8%), and financial commitment (32/1247, 2.5%). Representative examples per topic are presented in Table 1, with their sums and proportions in Table 2. For a breakdown of topic frequency by subreddit, see subheading A.4 and Figure S1 in Multimedia Appendix 1. The reliability and accuracy metrics of the topic allocation by the model were high. We observed substantial agreement between raters with a Fliess κ of 0.621. The subsequent automatic evaluation of the model's precision, recall, and F_1-scores were 0.86 for all metrics. For a detailed breakdown of this process, see subheading A.4 in Multimedia Appendix 1.

Table 1. Topics and representative comments examples.

Topic	Example comments
Motivational factors for initiating physical activity	
Physical appearance	
	Stand in front of the mirror. Naked.
	the ass of my dreams.
	Buy a scale. Understanding exactly how much your weight is changing has helped me.
Physical health	
	If I don't my fibromyalgia pain will get worse. That's a pretty daunting thought. I can just barely make it through the day as it is.
	I don't want to die of something that could have easily been prevented by having a basic level of fitness. It's really the only reason I work out. I'm pretty lazy.
	Good to stay healthy and live a long life.
Mental health	
	Exercise makes me happy, improves my mood and helps me be more productive overall.
	It helps my mental health.
	i try to do three to four, make two a priority found that my mental health (specifically anxiety) started to slide if i did less than two a week. There's a huge difference in my anxiety levels when my workouts are regular.
Strategies or suggestions on staying motivated and adhering to physical activity	
Habit formation	
	by starting-the more you do it, the better you'll feel, etc. it becomes a habit/vicious cycle.
	Motivation depends on emotions which are unstable. Discipline is the ability to maintain a habit even when the motivation isn't there.
	It's addictive. It's difficult to start but once you get going you can't get enough.
Goal setting	
	You really have to want it. If you don't care to change or don't have any numerical goals, you won't last. Set some goals and really strive to meet them.
	I have goals to make a high level rugby side and i need to be fit and strong to get there.
	I suggest picking a goal. Run a 5k, 10k, marathon, whatever. Do a one-legged squat, one-armed push-up, ten pull-ups, whatever. Picking goals and tracking my progress towards them has helped me.
Enjoyable activities	
	This exactly. I hate going on runs or going to lift weights at the gym. I can't get motivated to do that. But if I take a spin class or kickboxing or muscle endurance class I I love it. It's all about finding something you like.
	For me, having a sport/game/activity that I enjoy is my motivation. I work out in order to be able to have more fun in that sport/game/activity. With more strength and flexibility, I am more freely and thoroughly able to express myself through movement. I work out so that my play is even more fun!
	Do something fun for exercise. For example, I love basketball so I play basketball as an exercise but I still enjoy it and it doesn't even seem like work.
Socializing	
	I enjoy being around the people at my gym. They make showing up everyday fun.
	My foolproof method: get a gym buddy. It's hard to skip when you know someone is waiting for you at the gym.
	I have a friend from my gym meet me on zoom and we work out together.it Helps so much.
Media use	
	Music and proper clothes. throw on an exercise bra and shorts, plus some salsa music and i can work out for hours. Music is just good for energy.
	Play intense music. That's all it takes for me.
	Mhm my favourite workout YouTuber is Lily Sabri. She has many 5-7min videos, so after like a half an hour workout or live stream workout if you still feel like you have a bit more energy you can get one more work out quickly.
App monitoring	

XSL•FO
RenderX

Topic	Example comments
	Every day. I got a good streak going on my fitbit from March and I'm desperate not to break it.
	I'm using one of the Couch to 5K apps that basically tells you exactly what to do, tracks your progress etc.
	Use the IIFYM calculator to figure out how much to eat for your goals and be strict on tracking with myfitnesspal app. 100% you will see great results and never have to seek motivation outside again.
Financial commitment	
	Think about how much your paying, I'm NOT wasting $150 per month, get your ass to the gym.
	The cost.
	I think about how much I pay per month.

Table 2. Total number of comments per topic (and percentage) as classified by the model.

Topic	Comments (n=1247), n (%)
Motivational factors for initiating physical activity	
Physical appearance	298 (23.9)
Physical health	235 (18.9)
Mental health	211 (16.9)
Strategies or suggestions for staying motivated and adhering to physical activity	
Habit formation	373 (30)
Goal setting	173 (13.9)
Enjoyable activities	151 (12.1)
Socializing	121 (9.7)
Media use	111 (8.9)
App monitoring	35 (2.8)
Financial commitment	32 (2.5)

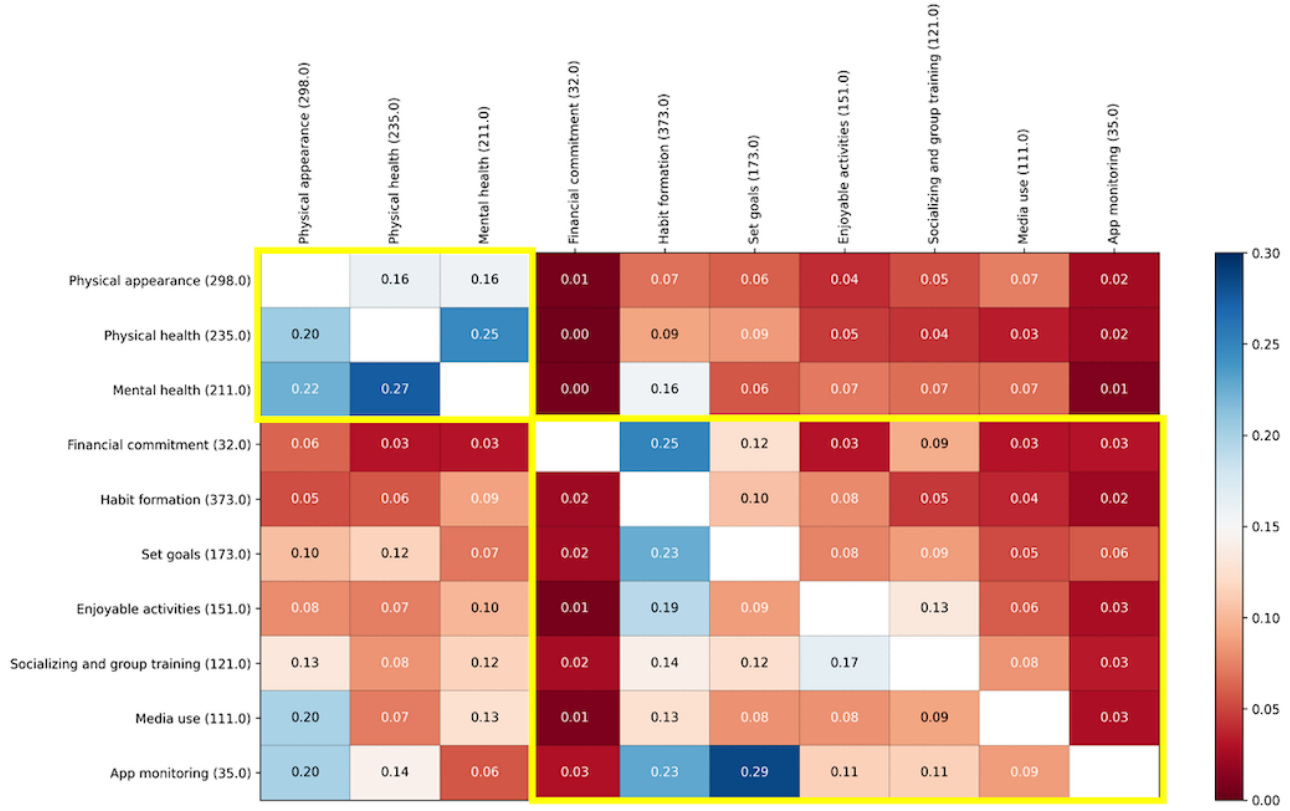
Additional Exploratory Analysis

Time Period

The lockdowns and social distancing behaviors associated with the COVID-19 pandemic were known to have caused significant changes in population PA levels [37]. Therefore, we examined the frequency distribution of the 10 identified topics during 2 periods of time: before the pandemic, defined as the period up to date that a public health emergency was declared in the United States (January 1, 2017, to January 31, 2020; 940 comments) and during the pandemic (February 1, 2020, to January 31, 2021; 307 comments). Specifically, to calculate the topic frequencies before the pandemic, we summed the number of comments per topic and divided it by the total number of comments during this period (940). A similar calculation was done for the duration of the pandemic period (307). We observed statistically significant differences between the 2 time periods (using a 2-sample *z* test for proportions) in all 3 motivations for engaging in PA (physical appearance: P=.01; physical health: P<.001; mental health: P<.001) and in 2 strategies (enjoyable activities: P=.04; financial commitment: P=.01), as depicted in Table 3.

XSL•FO
RenderX

Table 3. Overview of the motivations and strategies before and during the COVID-19 pandemic (2-sample z test for proportions).



Topic	Before COVID-19 pandemic	During COVID-19 pandemic
Physical appearance[a]	0.26	0.19
Physical health[a]	0.17	0.25
Mental health[a]	0.15	0.24

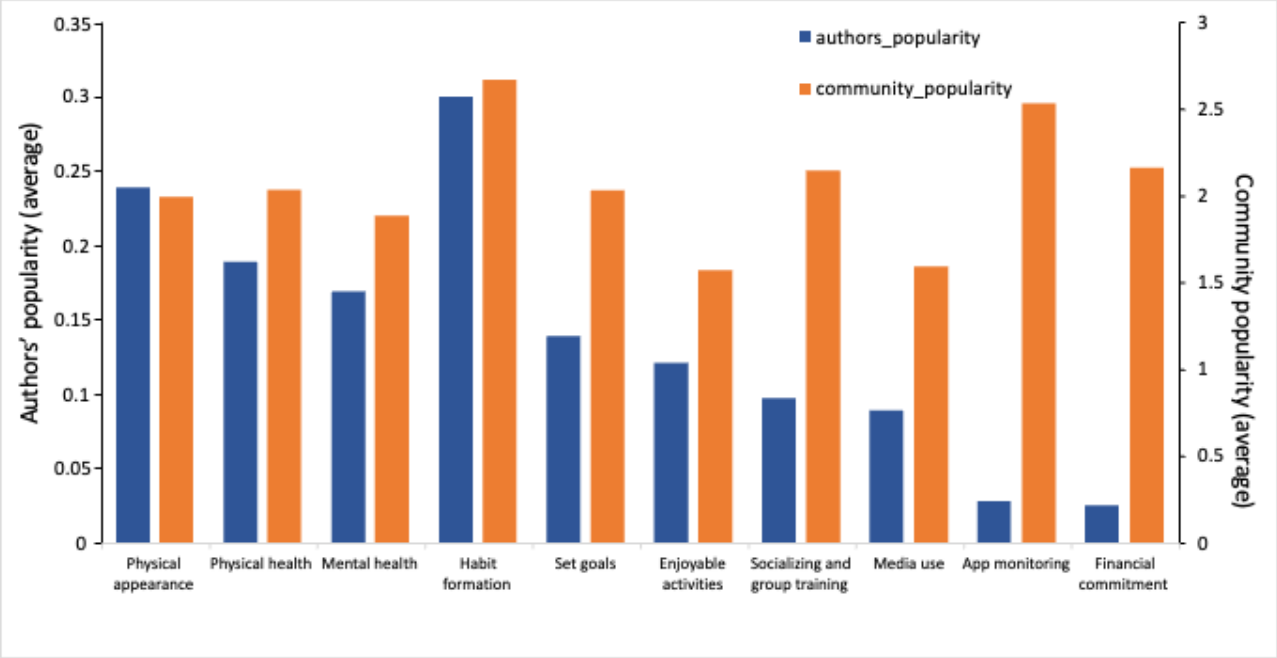
Financial commitment[a]	0.03	0.01

[a]*P*<.05.

Topic Co-Occurrence

We elected to examine patterns of topics mentioned in users' comments, that is, the probability of a Reddit user's comment containing combinations of topics (2 motivations or strategies). Out of 1740 unique observations of identified topics, 1278 incidences of topic co-occurrence were identified. Figure 3 presents a heat map of the co-occurrence probabilities, where each cell in the matrix presents the probability of a column's topic co-occurring with a row's topic, normalized by the total appearances of the row (as presented in Table 2).

Figure 3. Topic co-occurrences probabilities. Each cell is the probability of a row's topic appearing together with a column's topic (calculated as the number of co-occurrences divided by the total appearances of the row topic, that is, the number in parentheses). The cells within the 2 yellow outlines represent co-occurrence probabilities of motivations to motivations and strategies to strategies.



For example, given a comment labeled as discussing the topic of "physical health," the probability of that comment also discussing "mental health" was 0.25. We observed that the co-occurrences with the highest probabilities were combinations of "motivational factors/motivational factors" rather than "motivational factors/strategy."

XSL•FO
RenderX

Topic Importance

Some of the 10 identified topics may be considered more "important" than others by the users of the various Reddit communities studied here. The simplest method of defining importance would be by the frequency in which it appears in the dataset, as shown in Table 2. This metric can alternatively be described as the topic's popularity among comment authors (recall that the data filtration process allowed the inclusion of only 1 comment per author). As the Reddit API provided us with additional contextual data for each comment (comment "points"), we added the metric of topic importance using popularity "points"—how well those comments, and hence, topics, were received or recognized. Each Reddit comment is associated with points. The community members give points representing reaction agreement (or likes) on a specific comment. Thus, the more points a comment has, the more well-received a comment is by others. We used this point system as a proxy of topic popularity or importance. Specifically, we collected the total number of scores per topic and averaged them by the number of topic comments. We then compared the "popularity" of the 10 topics using the 2 measures proposed above. Figure 4 compares these 2 metrics, average authors versus average community importance, by topic.

Figure 4. Importance analysis per topic by the popularity of the authors and the community. Author popularity (per topic) = number of authors who wrote about the topic ÷ total number of authors. Community popularity (per topic) = total scores given to the topic by the community ÷ number of comments on the topic.

Discussion

Principal Findings

Our objective in this study was to explore motivational and adherence strategies for engaging in PA by using an unsupervised, multistep clustering technique to gather and analyze comments from Reddit forums. Our model classified the comments into 10 distinct topics, which we further categorized into 2 themes: motivations for initiating PA and strategies for maintaining motivation and adherence to PA. The main motives for individuals to engage in PA was their physical appearance (298/1247, 23.9%) and enhancing physical (235/1247, 18.9%) and mental (211/1247, 16.9%) health. The most prevalent strategy individuals used to adhere to PA was habit formation (373/1247, 30%), followed by goal setting (173/1247, 13.9%), enjoyable activities (151/1247, 12.1%), socializing (121/1247, 9.7%), using media (111/1247, 8.9%), using PA monitoring apps (35/1247, 2.8%), and financial commitment (32/1247, 2.5%). In addition, the frequency with which certain topics were mentioned together presented with certain patterns (Figure 3). For example, mental or physical health were often mentioned together with physical appearance (385/1247, 22% and 348/1247, 20%, respectively), and app monitoring or media use were often mentioned together with physical appearance (348/1247, 20% and 348/1247, 20%, respectively). These results shed some light on the multifactorial motivations underlying PA and hint at certain strategies individuals may gravitate to, depending on their primary motivational factor to initiate PA.

Comparing and contrasting our results to other studies using more traditional approaches presents challenges due to the different methodologies implemented. Nevertheless, our results are partly aligned with studies assessing PA motivation through questionnaires based on the Self-Determination Theory (SDT) framework, such as the Exercise Motivation Measurement scale (EMI-2) [38]. The EMI-2 takes the SDT spectrum of motivations and further divides them into subscales based on various topics (eg, "ill health avoidance," "social recognition"). For example, we identified 3 motivations for participating in PA (physical and mental health and physical appearance) consistent with the subscales identified in such studies. This supports our model's construct validity and SDT-based questionnaires' external validity, as our unprompted findings closely mirror several subscales of the established questionnaires. Yet, our results are

XSL•FO
RenderX

also misaligned with some of the literature. Regarding the EMI-2 scale, our model failed to identify specific "personal" and "social" motivation-related subscales, such as challenge, enjoyment, social recognition, and affiliation. We speculate that this misalignment stems from the unique characteristics of Reddit (public, online, anonymous posts) and the characteristics of the population that tends to use it (younger, male, western internet users) who may feel less inclined to discuss more personal motivations openly. We make this assumption with the caveat that we do not know if the demographic attributes of the subreddits we sampled truly mirror those of Reddit at large.

Our results seem to better align methodologically with qualitative studies based on semistructured interviews, showing a similar distribution of motivations in health-related topics [12,39,40]. For example, Ashton et al [40] identified 4 themes for motivators for PA among young adult men (a similar demographic to the average Reddit user): physical and mental health, physical appearance, social inclusion, and sport or performance. Here, we see that, similar to the quantitative literature, our model aligned with the health-related categories but did not identify social and personal motivational themes, such as skill development, support networks, community, relationships, and competitiveness. Direct comparison to qualitative studies on the topic is also challenging, given that they generally use thematic analysis as their research tool of choice. In contrast, we quantified the prevalence of topics within a large sample, as presented in this study, in a manner similar to qualitative content analysis. Furthermore, the process we used for assigning names to topic clusters, performed by a single reviewer without a formalized content analysis process, might have led to the misclassification of specific categories. Yet, a careful review of the text categorized by our model reveals a clear distinction between discussions on "how" to motivate oneself to engage in or adhere to PA versus the underlying "why" behind engaging in PA. We acknowledge this as a consideration for future research using wide-scale, self-disclosed content and recommend implementing established methods from the field of qualitative content analysis [41].

Several limitations of this study are worthy of discussion. First, the lack of data on the demographic attributes of the comment authors beyond platform-wide industry reports [25] limits our ability to associate the observed motivations and strategies with specific populations (ie, gender and age groups). Furthermore, although there are certain natural language processing techniques that can attempt to infer a user's gender based on previous comments written by the user, in our case, they were not able to assign gender to a large portion of our sample and thus excluded from the final analysis. Second, it is important to note that the questions that our analysis can answer are limited in scope as it was meant to be a proof-of-concept. The relatively simple queries we constructed were not designed to identify posts containing more detailed information, such as whether users were meeting minimal exercise standards, the location of exercise, or the results of implementing the identified strategies. In addition, all self-disclosed information, especially internet-based and pseudo-anonymous, must be interpreted with caution as the difference between disclosure and reality may be significant. Third, the "data-driven research" process used here allowed for substantial researcher degrees of freedom during the initial data selection and filtration process, potentially leading to selection bias, among others. Future studies could implement a more formalized process for topic classification and setting inclusion or exclusion criteria, enabling the answering of more complex questions and further refining our approach. Despite these limitations, incorporating human experts in auditing the automated results throughout the different stages of the analysis process is an essential strength of our methodology.

Conclusion

Our study introduces a novel usage of language models to harness the content shared on social media platforms to investigate the motivations and adherence strategies of individuals engaging in PA. Our findings further support the established literature and identified self-reported strategies implemented by this population for initiating and sustaining PA. The insights gained here provide valuable information and research tools for better understanding PA motives and adherence strategies. By leveraging self-disclosed data in an unprompted, nonresearch context on a large scale, we have expanded possibilities for research and gained more profound insights into people's thoughts, feelings, and opinions. This method has been successfully applied to various fields, and its application to PA and motivation represents a significant contribution. This study provides proof-of-concept for future investigations and opens new avenues for using language models in social media channels to study PA behavior and motivation.

Acknowledgments

Some minor use was made of ChatGPT (version 3.5, Open AI) for editing the abstract, specifically to reduce the word count.

Data Availability

The datasets generated during and/or analyzed during this study are available in the GitHub repository [42]. The JSON file includes the comment_id as "id" (as the textual content cannot be shared by the agreement rules); using the Reddit API, other researchers will be able to fully reconstruct the dataset. An example of the JSON file format is mentioned in Multimedia Appendix 2. Examples of the textual content can be found in Table 1.

Abstract

Background: With the rapid expansion of social media platforms, the demand for health information has increased substantially, leading to innovative approaches and new opportunities in health education.

Objective: This study aims to analyze the characteristics of articles published on the “Dr Ding Xiang” WeChat official account (WOA), one of the most popular institutional accounts on the WeChat platform, to identify factors influencing readership engagement and to propose strategies for enhancing the effectiveness of health information dissemination.

Methods: A total of 5286 articles published on the “Dr Ding Xiang” WOA from January 2021 to December 2021 were collected and analyzed. Additionally, a random sample of 324 articles was selected for detailed text analysis. Univariate analysis was conducted using the chi-square test, and multivariate analysis was performed using multivariable logistic regression.

Results: In 2021, the total number of reads for “Dr Ding Xiang” articles reached 323,479,841, with an average of 61,196 reads per article. Articles exceeding 100,000 reads accounted for 33.90% of the total. Most articles were published during the time slots of 8:00-10:00 AM, 11:30 AM to 1:30 PM, and 8:30-10:30 PM. Analysis indicated that the order of publication, style of the title sentence, number of likes, number of in-views, total likes on comments, and number of replies to comments were significantly associated with an article’s number of reads. Text analysis further revealed that the article’s reasoning approaches and concluding methods also had a significant impact on readership.

Conclusions: To enhance readership and the effectiveness of health communication, health-focused WOAs should consider key factors such as optimal publication timing, engaging title design, and effective content structuring. Attention to these elements can improve user engagement and support the broader dissemination of health information.

KEYWORDS

WeChat Official Accounts; Dr Ding Xiang; health communication; information dissemination; readership analysis

Introduction

The rapid expansion of social media has significantly increased the demand for accessible health information, fostering innovative approaches in health education [1-3]. Facebook is widely used to disseminate health content and build community support, especially in areas like chronic disease management, vaccination campaigns, and mental health [4]. Public health organizations, such as the Centers for Disease Control and Prevention and the World Health Organization, use Facebook

XSL•FO
RenderX

to establish digital platforms promoting preventive measures and healthy lifestyles [5]. Twitter's hashtag feature enhances its capacity for real-time communication in health education and emergency responses [6]. For example, during the COVID-19 pandemic, hashtags like #COVID19 and #HealthTips facilitated quick access to information and enabled user engagement [7]. YouTube has become a leading platform for health education videos on topics such as cardiopulmonary resuscitation, vaccines, and nutrition, with organizations and health influencers producing content to improve public understanding through visual demonstrations [8].

In contrast to Western social media, WeChat has become the leading channel for health communication in China, owing to its unique privacy features, strong social networking capabilities, and multifunctionality. Since its launch by Tencent in 2011, WeChat has evolved beyond a communication tool to offer social networking, marketing, media sharing, and utilities, making it an adaptable platform for mobile health engagement [9].

The WeChat official account (WOA) feature, introduced in 2012, allows organizations, businesses, and individuals to create public accounts to broadcast information and engage users. Through WOAs, users can receive notifications, read articles, engage with participatory content, and access various services [10]. This feature has been widely adopted for health information dissemination. For instance, the Wuxi Center for Disease Control and Prevention achieved high engagement by sharing articles on nutrition and food safety, highlighting that targeted content and strategic layouts can enhance reader interaction [11]. Similarly, health programs on WeChat, such as those aimed at improving parental health literacy, underscore the platform's effectiveness in delivering personalized health education [12].

WeChat's engagement features, including likes and comments, amplify user participation and promote the spread of health information. Studies suggest that user engagement, indicated by liking behavior, is closely linked to interest and approval [10]. WOAs are also instrumental in chronic disease management and patient education; for example, a WeChat-based management program for cough-variant asthma demonstrated significant clinical success [13]. Moreover, a life review program for patients with cancer highlighted WeChat's potential to provide psychological support and enhance quality of life [14]. During the COVID-19 pandemic, WeChat played a crucial role in health information dissemination and public health management [15], and was used effectively to promote health behaviors, such as encouraging HIV testing [16].

Overall, WeChat has demonstrated its effectiveness as a tool for health communication and education, providing a robust platform for enhancing public health literacy, improving disease management, and delivering essential psychological support. However, there is a need for further research into optimal posting strategies and the dissemination effects of WOA articles. Addressing these gaps is crucial for understanding dissemination effectiveness and refining posting strategies. Consequently, this study conducts both a general and detailed text analysis of the articles published by "Dr Ding Xiang" WOA in 2021, aiming to explore the factors that influence readership engagement with health-related WeChat articles. The goal is to provide a scientific basis for government departments to develop effective public account strategies and enhance the overall efficacy of health communication.

Methods

Study Materials

The "Dr Ding Xiang" WOA used in this study was established by Ding Xiangyuan, a prominent Chinese health care company founded in 2000. Ding Xiangyuan specializes in medical information services and health content, with a commitment to providing the public with scientific and authoritative health knowledge. The "Dr Ding Xiang" WOA serves as Ding Xiangyuan's public health education brand, focusing on disseminating reliable health information and enhancing public health literacy. All content is edited and reviewed by a professional team to ensure both accuracy and authority.

According to the 2019 China WeChat 500 annual list of public accounts released by the New Rank platform, "Dr Ding Xiang" ranked eighth out of 981,144 WOAs and secured the top spot among health care–related WOAs, with an average of more than 90,250 reads per article [17]. This ranking underscores the notable influence and representativeness of the "Dr Ding Xiang" WOA in disseminating health information. Therefore, a comprehensive analysis was conducted on 5286 articles published by the "Dr Ding Xiang" WOA from January 2021 to December 2021. Additionally, a sample of 324 articles was randomly selected for in-depth text analysis, using simple random sampling to ensure representativeness.

Data Collection

For the main analysis, data were sourced from the New Rank platform [18], accessed on September 20, 2022, a recognized authority in China for assessing the data value of WOA content. We collected and compiled data on 5286 articles published by "Dr Ding Xiang" in 2021. The dataset included various attributes such as time of publication, order of publication, style of the title sentence, presence of authors, originality of the articles, use of multimedia, number of likes, number of in-views, number of comments, total likes on comments, number of replies to comments, and total likes on replies to comments. This extensive dataset facilitated a detailed examination of the publication characteristics of each article.

For the text analysis, a sample of 324 articles was randomly selected to investigate specific text attributes, including the article's thematic contents, opening styles, reasoning approaches, and concluding methods. The objective was to identify factors that significantly influence readership and engagement with these health-related articles. By analyzing these attributes, we aimed to uncover elements that most effectively enhance audience interaction and engagement, thereby providing valuable insights for crafting successful health communication strategies on WOAs.

RenderX

Variables Assessment

The time of publication refers to the exact date and time when an article is made available to the public. This grouping is based on our observations of user behavior, which indicate that peak browsing and interaction times typically occur between 8:00-10:00 AM, 11:30 AM to 1:30 PM, and 8:30-10:30 PM. These periods likely align with daily commuting, lunch breaks, and evening leisure activities, respectively.

The order of publication indicates an article placement within a multiarticle push, where position 1 is the headline and typically receives the highest exposure, with up to 8 positions available per push. The style of the title sentences is categorized based on the presence of exclamation marks and question marks. An article is deemed to have an author if the author's name is signed beneath the title. Articles carrying an "original" tag are considered original. Beyond images and text, articles can also include videos and audio links; in this study, the inclusion of such elements is referred to as multimedia use.

Each article includes the "Like" and "In-view" buttons at the bottom right corner, from which the counts for likes and in-views are obtained. Here, it is important to clarify the specific function of "In-view" in this context. When a user clicks the "In-view" button, the article appears in the user's WeChat "Discover > Take a look > In-view" section, making it visible to the user's WeChat contacts. Unlike "Like," which merely indicates user appreciation, the "In-view" feature serves as a form of recommendation, enhancing the article's visibility among the user's social network.

Articles also feature a commenting function, with the number of comments determined by the total number of messages left on each article. Each comment also has a "Like" button, and the sum of all likes on comments constitutes the total number of likes on comments. When readers leave comments, both the operator and other readers can reply, and these replies are counted as comment replies. If readers agree with the replies, they can also like them, and the total number of likes on replies is recorded.

On the WeChat platform, the recommendation mechanism promotes content based on article interaction data, such as the number of likes and comments. Articles that receive higher levels of interaction are more likely to be recommended to a broader audience. Additionally, behaviors such as liking and commenting often lead to social sharing, where users may forward articles to their social circles or share them directly with friends [19]. Given these dynamics, the number of likes and comments on the WeChat platform serves not only as a user's response to the content but may also contribute to an increase in readership through both the recommendation system and social dissemination. Consequently, this study considers the number of likes and comments as potential factors influencing reading volume.

The article thematic contents included beauty and fitness (focusing on skincare, makeup, fitness, and weight loss), maternal and child health (covering obstetrics, gynecology, pediatrics, and early childhood education, targeting individuals planning to get pregnant, pregnant women, and parents of children aged 0-6 years), gender health (including topics on marriage, contraception, and sexually transmitted diseases), common diseases (covering prevalent health conditions), and non–health-related topics (such as product sales and recruitment).

The article opening styles included introductory style (introduced by the main subject, related topics, questions, or proverbs and sayings), case style (opening with personal or third-party cases), festive style (opening with mentions of festivals, seasons, or specific times of the year), social news (starting with a news event), and other styles (directly beginning with the main text content).

The article reasoning approaches used in the articles include specialized knowledge explanations (using professional knowledge to explain), data, guidelines, and experiment-based explanations (citing data, research guidelines, and experiments), case-based explanations (using specific cases to explain), and other forms (using various other forms of reasoning). To ensure consistency and comparability in categorization, articles were assigned to the appropriate category based on the predominant type of reasoning used. For instance, if an article primarily serves as an explanation of professional knowledge, supplemented by case studies, it would be classified as an "explanation of professional knowledge."

The article concluding methods include summary endings (refining and summarizing the main points of the article), supplementary tips (reemphasizing important content and adding relevant information), call-to-action endings (encouraging the audience to take specific actions), advertising and promotional endings (promoting product purchases and live broadcasts), and other endings (a few articles simply conclude with the main text content).

Quality Control

The data on the number of reads, number of in-views, number of likes, number of comments, total number of comments, number of replies to comments, total number of replies to comments, and other related metrics collected in this study were based on the statistics as of September 20, 2022. To ensure the accuracy of data entry for determining the article topic, opening style, reasoning form, and ending style, 2 coauthors were trained for this. They independently entered data for 324 randomly selected articles. In cases of disagreement, the final confirmation was made through discussion and consensus among a third author.

Statistical Analysis

Articles were categorized into 2 groups based on reading volume: a high-reads group (100,000 and above reads) and a low-reads group (fewer than 100,000 reads). Independent variables included the time of publication, order of publication, style of the title sentence, presence of authors, originality of articles, use of multimedia, number of likes, number of in-views, number of comments, number of total likes on comments, number of replies to comments, number of total likes on replies to comments, article thematic contents, article opening styles, article reasoning approaches, and article concluding methods. A chi-square test was used for univariate analysis, with

XSL•FO
RenderX

statistically significant variables included in a logistic regression model. A *P* value<.05 was considered statistically significant. All analyses were conducted using R (version 4.1; R Foundation for Statistical Computing). Model fit was assessed with the Hosmer-Lemeshow test, where a *P* value>.05 indicates a good fit (ie, no significant difference between observed and predicted values). To address multicollinearity, variance inflation factor (VIF) and tolerance values were calculated. A tolerance value of 0.1 or greater and a VIF value of less than 10 were considered indicators of no multicollinearity.

Ethical Considerations

This study was conducted using publicly available data from the New Rank platform, which was accessed in accordance with the platform's terms of service. All data included in this study were either anonymous or deidentified prior to analysis, ensuring that no personally identifiable information was collected or processed. As the study involved the observation of publicly available data and secondary analyses, no direct interaction with individuals occurred, and no formal ethical approval was required. To further protect privacy, the results are presented in aggregate form without identifying specific individuals or posts. These measures align with established ethical standards for research involving publicly accessible data.

Results

Basic Characteristics of Published Articles

According to real-time statistics on September 20, 2022, a total of 5286 articles were published on the "Dr Ding Xiang" WOA in 2021. On average, about 14 articles were posted daily. Each article garnered an average of approximately 61,196 reads, with the lowest recorded number being 3577 reads. Among these, 1792 (33.90%) articles surpassed 100,000 reads. The publication times of the articles were predominantly clustered into 3 periods: 8:00-10:00 AM, which saw 1733 (32.78%) articles; 11:30 AM to 1:30 PM, with 1892 articles (35.79%); and 8:30-10:30 PM, during which 1642 (31.06%) articles were published.

The articles accumulated a total of 273,712,120 likes, averaging approximately 518 likes per article. Additionally, they received 1,848,787 in-views, with an average of around 350 in-views per article. The total number of comments across all articles was 53,495, averaging about 10 comments per article. Collectively, likes on comments totaled 1,595,956, translating to an average of approximately 2856 interactions per article. The total number of replies to comments reached 20,722, averaging about 4 replies per article. Lastly, likes on replies to comments amounted to 5,573,912, with an average of roughly 1054 such interactions per article.

Univariate Analysis

The univariate analysis revealed that several factors were significantly associated with the number of reads for the articles. Specifically, the order of publication (χ^2_2=4040.2; *P*<.001), style of the title sentence (χ^2_3=66.1; *P*<.001), presence of authors (χ^2_1=219.8; *P*<.001), and originality of the articles (χ^2_1=1029.6; *P*<.001) were all important determinants. Additionally, the use of multimedia (χ^2_1=31.0; *P*<.001), as well as various engagement metrics such as the number of likes (χ^2_2=2290.0; *P*<.001), in-views (χ^2_2=2506.8; *P*<.001), comments (χ^2_2=2255.3; *P*<.001), total likes on comments (χ^2_2=2397.5; *P*<.001), replies to comments (χ^2_2=1750.4; *P*<.001), and total likes on replies to comments (χ^2_2=2306.4; *P*<.001) also showed significant impacts. These findings are further detailed in Table 1.

Multivariable Analysis

The multivariable analysis results indicated that several factors significantly enhanced readership. The order of publication had a considerable impact, with articles posted in the first to second positions showing an odds ratio (OR) of 745.654 (95% CI 358.061-1552.809; *P*<.001) and those in the third to fifth positions showing an OR of 2.719 (95% CI 1.391-5.315; *P*=.003). The style of the title sentence also influenced readership, particularly declarative sentences (OR 2.333, 95% CI 1.572-3.461; *P*<.001) and interrogative sentences (OR 1.928, 95% CI 1.297-2.867; *P*=.001). The number of likes significantly boosted readership, with likes in the range of 101-300 (OR 2.308, 95% CI 1.384-3.848; *P*=.001) and 301 and greater (OR 14.050, 95% CI 5.949-33.184; *P*<.001). Similarly, the number of in-views positively impacted readership, particularly for in-views in the range of 51-150 (OR 2.739, 95% CI 1.736-4.321; *P*=.001) and 151 and greater (OR 4.087, 95% CI 1.617-9.197; *P*<.001). The number of total likes on comments also boosted readership, with ranges of 101-1000 likes (OR 3.082, 95% CI 2.125-4.470; *P*<.001) and 1001 and greater (OR 9.747, 95% CI 5.515-17.226; *P*<.001). Additionally, the number of replies to comments had a positive effect, especially for comments liked 1001 times and greater (OR 9.747, 95% CI 5.515-17.226; *P*<.001) and the number of replies to comments reaching 6 and greater (OR 2.374, 95% CI 1.560-3.612; *P*<.001). These factors are summarized in Table 2.

The goodness of fit tests for the fitted binary logistic regression model was greater than the significance level of .05, which indicates the model adequately fits the data. In addition, the results also show that the VIF values of all independent variables are less than 10 and the tolerance values are greater than 0.1, indicating that the effect of multicollinearity on the model is negligible.

Text Analysis for the Selected Articles

The text analysis of the selected articles revealed a diverse distribution of topics. Beauty and fitness were the most common topics, comprising 80 (24.7%) articles, followed by common diseases with 77 (23.8%) articles. Maternal and child health, gender health, and topics unrelated to health accounted for 20 (6.2%) articles, 22 (6.8%) articles, and 95 (29.3%) articles, respectively. Regarding the opening form, introductions were prevalent in 203 (62.7%) articles, while case studies were used in 54 (16.7%) articles. Articles that began with festivals, social news, or other forms made up 22 (6.8%) articles, 18 (5.6%) articles, and 27 (8.3%) articles, respectively. In terms of reasoning forms, specialized knowledge was used in 160 (49.4%) articles, followed by data citation, research guidelines, and experiments in 47 (14.5%) articles. Experiments constituted the reasoning form in 12 (3.7%) articles, case studies in 40 (12.3%) articles, and other reasoning forms in 77 (23.8%) articles. As for the conclusions, 26 (8%) articles provided a summary, while hints and calls for action were each present in 42 (13%) articles. A significant number of articles concluded with advertisements and promotions, totaling 178 (54.9%) articles, with 36 (11.1%) articles using other forms of conclusions.

Univariate and Multivariate Analyses

The univariate analysis showed that the article opening styles (χ^2_4=10.6; *P*=.03), the article reasoning approaches (χ^2_3=23.7; *P*<.001), and the article concluding methods (χ^2_4=22.4; *P*<.001) significantly affected article readership, as detailed in Table 3.

XSL•FO
RenderX

Table 3. Univariate analysis of the readership of 324 articles on "Dr Ding Xiang" WOAa in 2021.

Variables	Total, n	High reads, n (%)	Low reads, n (%)	*P* value
The article thematic contents				.08
Beauty and fitness	80	40 (50)	40 (50)	
Maternal and child health	50	35 (70)	15 (30)	
Gender health	22	11 (50)	11 (50)	
Common disease	77	52 (67.5)	25 (32.5)	
Non–health-related	95	54 (56.8)	41 (43.2)	
The article opening styles				.03
Introductory style	203	123 (60.6)	80 (39.4)	
Case style	54	23 (43.6)	31 (57.4)	
Festive style	22	13 (59.1)	9 (40.9)	
Social news	18	12 (66.7)	6 (33.3)	
Other styles	27	21 (77.8)	6 (22.2)	
The article reasoning approaches				<.001
Specialized knowledge explanations	160	112 (70)	48 (30)	
Data, guidelines, and experiment-based explanations	47	21 (44.7)	26 (55.3)	
Case-based explanations	40	13 (32.5)	27 (67.5)	
Other forms	77	46 (59.7)	31 (40.3)	
The article concluding methods				<.001
Summary endings	26	7 (26.9)	19 (73.1)	
Supplementary tips	42	25 (59.5)	17 (40.5)	
Call to action endings	42	19 (45.2)	23 (54.8)	
Advertising and promotional endings	178	112 (62.9)	66 (37.1)	
Other endings	36	29 (80.6)	7 (19.4)	

[a]WOA: WeChat official account.

In the multivariate analysis, it was evident that specific reasoning approaches and concluding methods had substantial impacts on readership engagement. Articles citing data, guidelines, and experiment-based explanations (OR 2.288, 95% CI 1.132-4.623; *P*=.02), using case-based explanations (OR 4.713, 95% CI 2.169-10.237; *P*<.001), notably boosted readership. Conversely, certain concluding methods such as supplementary tips (OR 0.267, 95% CI 0.089-0.805; *P*=.02), Advertising and promotional endings (OR 0.243, 95% CI 0.092-0.641; *P*=.004), and other endings (OR 0.094, 95% CI 0.027-0.327; *P*<.001) were found to inhibit readership. These findings are comprehensively summarized in Table 4.

The goodness of fit tests for the fitted binary logistic regression model was greater than the significance level of .05, which indicates the model adequately fits the data. In addition, the results also show that the VIF values of all independent variables are less than 10 and the tolerance values are greater than 0.1, indicating that the effect of multicollinearity on the model is negligible.

Discussion

Principal Results

Our study reveals that headline and subheadline articles achieve significantly higher readership compared to subordinate articles. This is substantiated by previous research indicating that the first article typically garners the highest attention, with subsequent articles experiencing a sharp decline in readership. This can be attributed to the initial engagement creating a strong first impression, which diminishes as readers move through additional content [20]. Hence, crafting compelling headlines and engaging thumbnails becomes critical in capturing and retaining reader attention. These elements act as the primary hooks that encourage readers to click on and continue through the content, thereby enhancing the overall readership of subsequent articles [21].

Survey data from China provide insights into reader behavior, revealing that most readers skim the body text after reading the headline, highlighting the headline's pivotal role in capturing initial interest [22]. Our analysis emphasizes the importance of linguistic choices in headlines. Studies show that using emotion-laden words, third-person pronouns, and clear definitive articles can significantly enhance click-through rates by appealing to readers' emotions and curiosity [23]. Specifically, interrogative headlines, which pose questions, are particularly effective in engaging readers as they evoke a sense of suspense and intrigue. This finding aligns with research from ScienceDaily and Azura Magazine, which suggests that questions naturally stimulate curiosity and engagement [24,25].

However, titles with an exclamatory tone, often perceived as exaggerated or sensational, can lead readers to question the credibility of the content, thereby diminishing their trust. Research on health education communication highlights trust as a crucial factor in effective information dissemination [26]. While dramatic language and punctuation may capture attention quickly, they can also give the impression that the information is unreliable or inaccurate.

To address this, declarative or interrogative titles are recommended for conveying the article's core content authentically and effectively. Declarative titles clearly communicate the main idea, set accurate expectations, and establish a direct communication style, which is critical for building trust in health-related content. Conversely, interrogative titles stimulate curiosity by posing questions, encouraging readers to explore the content further without compromising its credibility. By fostering trust through accurate and engaging titles, authors can enhance reader satisfaction and promote meaningful, long-term interactions with health information.

The study highlights a significant relationship between article reads, likes, and engagement in the comment sections. This relationship may not only reflect users' interest in the content but may also indirectly impact reading volume through WeChat's recommendation mechanism and users' social sharing behavior. Driven by this recommendation mechanism, articles with higher interaction data receive greater exposure, while users' liking and commenting behavior can further stimulate retweeting within their social circles, thereby expanding the reach of the articles. Consequently, on the WeChat platform, engagement behaviors may serve both as a reflection of reading and as a potential influencing factor in enhancing reading volume.

This study's classification system is based on the varying impacts of reasoning types in articles published on WOAs [27]. Our findings indicate that explanations based on data, guidelines, experiments, cases, or other forms were read more frequently than specialized knowledge explanations. These formats make the content more relatable and easier to understand. Furthermore, summary endings were preferred over supplementary tips and advertising and promotional endings, as they save readers' time,

XSL•FO
RenderX

emphasize key points, and enhance the content's value, retention, and shareability [28,29].

The insights derived from this study hold critical implications for public health promotion and information dissemination. Effectively engaging readers through strategic headline crafting, linguistic choices, and participatory features can significantly enhance the reach and impact of health messages. By adopting these strategies, public health communicators can ensure that vital health information is disseminated widely and engaged with meaningfully, thereby promoting healthier behaviors and outcomes within the community.

Limitations

The strengths of this study lie in its empirical basis, comprehensive data collection over a 1-year period, and the bifurcated approach of general and text analysis, providing a well-rounded investigation of factors influencing readership. However, the study also has limitations. It focuses on a single public account, restricting the analysis to a longitudinal perspective without cross-sectional validation against other health-related WOAs. Additionally, WeChat readership metrics cap at 100,000 reads, preventing accurate assessment for articles exceeding this threshold and thus limiting readership as a true continuous variable. To address this, we dichotomized readership into “high reads” (100,000 reads and more) and “low reads” (less than 100,000 reads) for analysis. Finally, the text analysis relies on subjective definitions of the article’s thematic contents, the opening styles, the reasoning approaches, and the concluding methods, which may introduce bias despite the random article selection.

Conclusions

In summary, the study offers valuable insights into effective strategies for enhancing readership and engagement, which are crucial for successful health communication and promotion. By understanding and leveraging these factors, public health professionals can better capture and retain reader interest, ensuring that essential health information reaches and resonates with a broader audience.

Data Availability

The datasets generated and/or analyzed during this study are not publicly available due to privacy concerns and ethical considerations related to user interaction metrics (eg, likes, comments, and views) but are available from the corresponding author on reasonable request.

Abstract

Background: The digital landscape has become a vital platform for public health discourse, particularly concerning important topics like organ donation. With a global rise in organ transplant needs, fostering public understanding and positive attitudes toward organ donation is critical. Social media platforms, such as X, contain conversations from the public, and key stakeholders maintain an active presence on the platform.

Objective: The goal is to develop insights into organ donation discussions on a popular social media platform (X) and understand the context in which users discussed organ donation advocacy. We investigate the influence of prominent profiles on X and meta-level accounts, including those seeking health information. We use credibility theory to explore the construction and impact of credibility within social media contexts in organ donation discussions.

Methods: Data were retrieved from X between October 2023 and May 2024, covering a 7-month period. The study was able to retrieve a dataset with 20,124 unique users and 33,830 posts. The posts were analyzed using social network analysis and qualitative thematic analysis. NodeXL Pro was used to retrieve and analyze the data, and a network visualization was created by drawing upon the Clauset-Newman-Moore cluster algorithm and the Harel-Koren Fast Multiscale layout algorithm.

Results: This analysis reveals an "elite tier" shaping the conversation, with themes reflecting existing societal sensitivities around organ donation. We demonstrate how prominent social media profiles act as information intermediaries, navigating the tension between open dialogue and negative perceptions. We use our findings, social credibility theory, and review of existing literature to develop the OrgReach Social Media Marketing Strategy for Organ Donation Awareness. The OrgReach strategy developed is based on 5 C's (Create, Connect, Collaborate, Correct, and Curate), 2 A's (Access and Analyse), and 3 R's (Recognize, Respond, and Reevaluate).

Conclusions: The study highlights the crucial role of analyzing social media data by drawing upon social networks and topic analysis to understand influence and network communication patterns. By doing so, the study proposes the OrgReach strategy that can feed into the marketing strategies for organ donation outreach and awareness.

Introduction

Background

The current shortage of organ transplants necessitates fostering public understanding and positive attitudes toward organ donation. The critical need for organ donation in the United Kingdom is further highlighted by the staggering number of patients currently waiting for a transplant, which stands at 7489 at the time of writing [1]. Social media, as a crucial platform for public health discourse [2], can harbor topics like organ donation. While research has explored increasing donor rates, a gap exists in understanding how online information environments shaped by prominent voices influence public perceptions. This study addresses this gap by using social network analysis (SNA) to examine conversations about organ donation on X (formerly Twitter). Specifically, we investigate how prominent social media profiles and users seeking health information influence these conversations and the types and forms of advocacy.

While previous research has examined the link between public attitudes and external factors like health care environments [3-5], we shift the focus inward, investigating how individuals navigate and interact with organ donation information on the internet. This approach offers insights into donation practices and the development of commercial organizations in this space. Specifically, we use SNA on platform X to map connections and influence patterns among the most prominent user profiles during the initial stages of information-seeking related to organ donation. Our analysis focuses on three key areas: (1) identifying users occupying pivotal positions within the network, (2) examining the emergence and persistence of an "elite tier" as the network evolves, and (3) exploring thematic and topical trends across active user accounts and dedicated health organizations.

This study defines the "elite tier" as a group of highly influential users within the organ donation community on social media. These individuals are distinguished by their ability to shape information flow, disseminate knowledge, and mobilize social media discourse. We identify elite-tier members based on their influence on their network (as measured by their betweenness centrality). We use our findings to develop the OrgReach Social Media Marketing Strategy for Organ Donation Awareness.

Examining the Credibility of Organ Donation Information on Social Media

While credibility in social media contexts has received significant attention within social science, media and cultural studies, and internet health literacy research, a critical gap remains in understanding its dynamic nature. This gap specifically concerns how credibility evolves and shapes how individuals navigate and engage with health information on social media. For example, Alikunju and Sulochana [6] argue that authenticity and network visibility constitute the core elements of credible health information on the internet. We use credibility theory [7] to explore the construction and impact of credibility within social media contexts in organ donation discussions. Specifically, we are interested in understanding the frequency and occurrence of credible sources of information (ie, health care professionals or organ donation organizations) compared to less credible sources of information. We also aim to explore the impact of credible actors on network reach on social media platforms.

Related Work

Previous research has studied organ donor registration on Facebook [8] and how the platform allowed users to specify they were organ donors. The study found that the Facebook intervention dramatically increased Organ Donation registration within the United States. The study highlights the potential of social media platforms in increasing organ donation awareness on social media. Other studies have investigated the ethical challenges in the use of social media in relation to privacy and confidentiality, pointing to the fact that there are no national ethical guidelines in the United States in relation to social media use for fostering organ transplantation [9]. Other research has examined different approaches to promoting kidney donation using social media data [10], to examine the role of Twitter for organ donation awareness [11], and to identify opinion leaders on Weibo [12].

Although social media platforms have been around since the early 2000s, using PubMed, we find that the first papers specifically examining organ donation and social media (as reflected in their title) appeared to have been published in 2012. The first outputs were related to a large-scale study that examined how university students could use social media to generate awareness and support for organ donation [13] alongside a published case report [14]. Of the 17 papers PubMed located published between 2012 and 2024, the most appeared to be published in 2023 (n=4). Moreover, previous research has analyzed the change in attitude toward organ donation following an educational program [15] where teenagers disseminate content on social networks to raise societal awareness. However, to the best of our knowledge, we found no other studies that aimed to perform a topic identification-driven SNA of X data that developed a specific marketing strategy for organ donation awareness.

The overall aim of this study is to identify the topics discussed on X relating to organ donation, to identify popular content, and to develop a specific marketing strategy for organ donation awareness.

Methods

Key Assumptions

The "Methods" and "Results" sections of this study frequently mention X users within the network, which are our "nodes," a concept from SNA. When we refer to "edges," these are our connections between users and can include reposts, mentions, and replies to users. Additionally, the study uses "betweenness centrality" as a metric to gauge a user's influence within the network. This measures the extent to which a node influences the flow of information among other nodes. This study follows the methodological approach from previous research [16-18] applied to the topic of organ donation.

XSL•FO
RenderX

Stage 1: Data Retrieval

Data were retrieved from X mostly between October 2023 and May 2024, covering a 7-month period. NodeXL Pro was used to retrieve data using the search string "organ donation." This would retrieve any post that contained "organ donation" or who replied to, mentioned, reposted, or quoted in those posts. It is important to note that content was retrieved from X without limiting it to a specific country. However, platform demographics such as more US users will mean that our sample is likely to contain more content from English-speaking countries. This is important as there will be differences in responses across different countries and also because of differences between opt-in and opt-out systems.

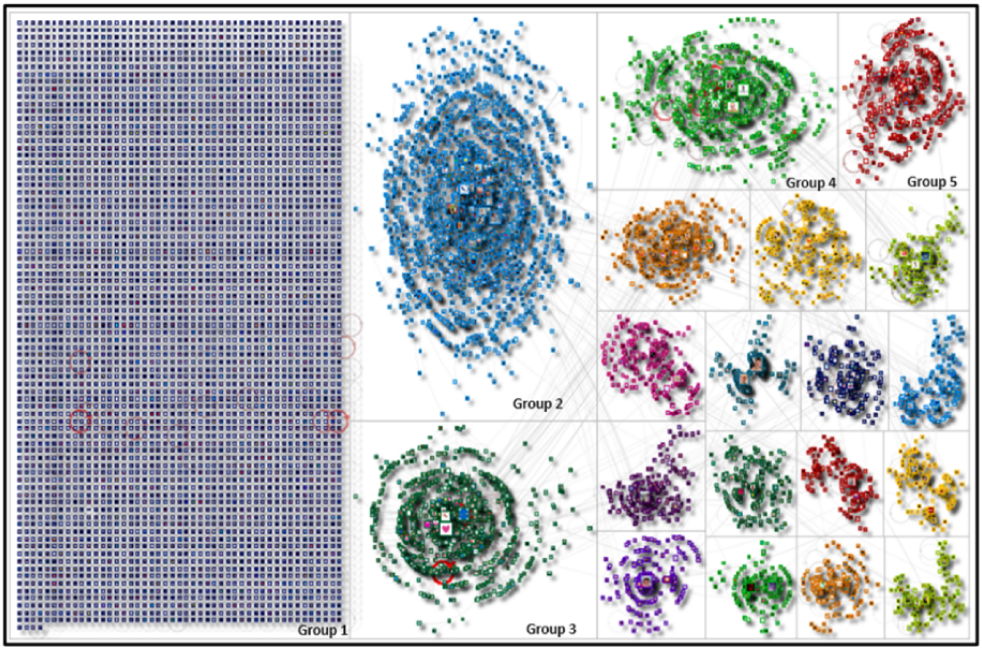
Stage 2: Data Preparation

Once data were retrieved, there were 20,124 users within the network and a total of 33,830 posts. These data were processed in NodeXL Pro (version 1.0.1.530) for further analysis. Within the network visuals, the edge colors are based on edge weight values. The edge widths were based on edge weight values. The vertex sizes (ie, the users) were based on in-degree values.

Stage 3: Data Analysis

The SNA method was used to analyze the data conducted in NodeXL Pro. The graph's vertices were grouped by cluster using the Clauset-Newman-Moore cluster algorithm [19]. The graph was laid out using the Harel-Koren Fast Multiscale layout algorithm [20]. We used thematic analysis [21] to develop themes and subthemes. After examining the groups through SNA, it was found that discussions within each group are multifaceted and are not confined to a single topic per group, but a multitude of conversations are taking place. Therefore, an analysis was conducted on the most shared content within the network overall. The 300 most popular posts (identified by finding the posts most reshared) had a total reshare value of n=3,975,866 with a total of n=6,398,623 favorites. We used a thematic analysis [21] of the top 300 posts until thematic saturation occurred. This thematic analysis involved a team-based coding approach where each post was assigned codes/labels by one author and then discussed and refined by the wider team. The labeling and analysis took place within Excel (Microsoft Corp). This allowed us to identify the most popular themes of discussions across the groups.

Ethical Considerations



This study examined data only in aggregate and no individuals who are not already in the public domain are mentioned or named in this study. Moreover, this study does not quote or use any content from any individuals, and only publicly shared information on the X platform is captured and analyzed. Ethical approval for this study falls under the institutional review board of Newcastle University (26055/2022). During the editing process, we drew upon generative language models (GPT-4o) and Grammarly to improve readability and identify typographical errors of existing human-authored text with oversight from the authors, but these models were not used to generate any content of their own. This was particularly useful as supported an author who is dyslexic.

Results

SNA and Qualitative Interpretation

Figure 1 shows a visual overview of how users connect with each other on X when conversing about organ donation and shows the top 20 groups. The network visual is simply a representation of groups that have formed based on user interactions (resharing, reposting, and replying to users). The largest group in the network (group 1) is an isolated group where users post without mentioning other users. There is one large community cluster (group 2) followed by three medium-sized community clusters (groups 3-5). The remainder of the groups (groups 6 to 20) consist of smaller community clusters.

Figure 1. Social network visualization of the organ donation X network (October 2023 to May 2024).

XSL•FO
RenderX

This analysis tells us that many individual posts are sent from users about organ donation (as noted from group 1), which include advocacy and stories. It also tells us that there are vocal conversations taking place by users who have formed their own communities and that some large, medium, and small communities on X are actively conversing about organ donation. The network visual also reveals that there is little interactivity between the groups.

The main themes and their subthemes from this analysis are presented below.

Theme 1: Ethical and Legislative Framework

Ethical Considerations and Debates

Users would discuss ethical concerns around organ donation, which would include mandatory donation and the use of human tissues in research.

Legislative and Policy Measures

Users would also converse about organ donation laws, transplantation regulations, and policies such as opt-out systems.

Controversy and Public Opinion

Users would also comment on controversial cases of organ harvesting and make claims that were not verifiable and potentially misinformation. Users would also hold debates and have critical discussions about organ donation.

Theme 2: Awareness, Advocacy, and Engagement

Awareness and Advocacy in Diverse Communities

Conversations by users included raising awareness of organ donation in minority communities and promoting global advocacy.

National and Cultural Engagement

Users would also discuss incorporating organ donation into national and cultural events to boost community involvement.

Impact of Public Figures and Influencers

Conversations also included the use of public figures and celebrities to advocate for organ donation and share their personal stories.

Theme 3: Recognition and Community Support

Recognition and Honor for Donors

Discussions included official recognition and public ceremonies for organ donors and their families.

Community Solidarity and Support

Within this subtheme, there were conversations and demonstrations of community support and consensus regarding organ donation efforts.

Theme 4: Personal Impact and Health Care Achievements

Inspirational Stories and Acts of Heroism

Within this subtheme, there were also personal accounts of donors who had made significant contributions by donating organs, and their stories were used to inspire others.

Health Care Achievements and Milestones

There were users, including health care professionals, who would celebrate key successes in organ donation and transplantation. These posts would also highlight positive recipient outcomes.

Additional Findings

Table 1 provides a ranking of the top 10 users posting on X within the network around organ donation. These users were defined as “elite tier” users as noted in the introduction due to their influential position within the network as measured by betweenness centrality.

The most influential user was the official NHS (National Health Service) organ donation account in the United Kingdom. Their user bio suggests active engagement with the public to improve and save lives through organ donation. They note that they respond to posts during specific hours, indicating a personalized approach to community interaction.

The second rank is held by the PMO (Prime Minister’s Office) India, which is the Office of the Prime Minister of India. This account’s high centrality score reflects its influence and broad reach in disseminating information related to organ donation within India. The account posted positive comments about organ donation, reaching a wide audience in India.

The third most influential user was Justin Trudeau, the 23rd Prime Minister of Canada. Trudeau’s user bio is presented in English and French, highlighting bilingual communication for broader outreach within Canada. Justin Trudeau has been a vocal supporter of organ donation on the X platform in the past, and the account appeared to be tagged into various conspiracies and potential mis and disinformation networks.

Ranks 4 through 10 were held by individual users worldwide, whom we categorized simply as “Citizens.” Some users had specific interests, such as a business-focused user and a heart transplant recipient. Of the users who disclosed their location, users derived from Canada, the United States, and the United Kingdom. This highlights that ordinary citizens with modest followings can hold significant positions within the network, contributing to discussions, spreading awareness, or advocating for organ donation.

Table 2 provides the top “domains” that users X posts were linking to. A domain analysis allows us to detect popular web pages. Table 2 highlights a wide-ranging effort to promote organ donation information across different types of websites, from government and health services to news media and social platforms. Link shorteners like bit.ly and ow.ly indicate a focus on social media sharing and tracking engagement with this content. The top-ranking domain, transplantnews.com, suggests a dedicated source of information that will likely serve as a hub

XSL•FO
RenderX

for those interested in the subject. These domains are further discussed below.

Discussing these, starting from the most popular web domain, we can see that the transplantnews.com domain is the most frequent linker to organ donation content (n=736). It is a specialized website focused on news related to organ transplants. The second rank is the Indian government's official domain, gov.in (n=311), which indicates a significant amount of content or references related to organ donation within the Indian government's online resources. In third place is dlvr.it (n=310), a content delivery network often used to manage and disseminate information across various platforms, suggesting widespread sharing of organ donation-related content.

Table 1. Top 10 influencers on X related to organ donation (October 2023 to May 2024).

Rank	Userhandle (anonymized if citizen)	Name	User bio	Location	Betweenness centrality
1	nhsorgandonor	NHS[a] Organ Donation	Saving and improving lives. Official account for the NHS Organ Donor Register. We love reading your tweets and reply to them between 0700-2300 #OrganDonation	United Kingdom	12713160.850
2	pmoindia	PMO[b] India	Office of the Prime Minister of India	India	9036848.857
3	justintrudeau	Justin Trudeau	Father, @liberal_party Leader, 23rd Prime Minister of Canada. | Papa, chef du @parti_liberal 23e premier ministre du Canada.	Canada	8986407.605
4	Citizen	Anonymized	Anonymized	Undisclosed	8105094.910
5	Citizen	Anonymized	Anonymized	Canada	7750991.313
6	Citizen	Anonymized	Anonymized	Undisclosed	7333731.145
7	Citizen Business Interest	Anonymized	Anonymized	United States	7301905.351
8	Citizen	Anonymized	Anonymized	Undisclosed	7215205.365
9	Citizen Political Influnfcner	Anonymized	Anonymized	United States	6379487.669
10	Citizen Heart Transplant Recipient	Anonomyized	Anonomyized	United Kingdom	6185548.502

[a]NHS: National Health Service.

[b]PMO: Prime Minister's Office.

Table 2. Top 10 domains on X related to organ donation (October 2023 to May 2024).

Rank	Top domains	Count, n
1	transplantnews.com	736
2	gov.in	311
3	dlvr.it	310
4	bit.ly	281
5	youtu.be	150
6	facebook.com	140
7	nm-4.com	128
8	ow.ly	109
9	nhs.uk	103
10	co.uk	98

In fourth place, we have bit.ly (n=281), a URL-shortening service. The relatively high count indicates that many shortened URLs linking to organ donation content have been created, highlighting a general trend of concisely disseminating this important information across different platforms. This practice likely enhances user accessibility and simplifies the process of sharing such links.

The fifth-ranked domain is youtu.be (n=150), the shorthand for YouTube signifies a moderate level of engagement with video content related to organ donation. This number reflects the efforts made to use multimedia platforms to raise awareness and educate the public about organ donation through videos, which can be a compelling way to convey the impact and importance of this act. Following that, facebook.com stands in

XSL•FO
RenderX

the sixth position (n=140). As a major social media platform, Facebook's role in spreading organ donation content is important. Although it ranks lower than some other domains, the figure indicates that organ donation discussions and information sharing are part of the social conversation on Facebook.

The domain nm-4.com is listed in seventh place (n=128), the short version of the full URL which points to an official website belonging to the Indian Prime Minister, this web page shared information about Narendra Modi's support toward organ donation. Ranking eighth is ow.ly (n=109), another URL-shortening service akin to bit.ly. Its use for organ donation content implies that there is an active effort to track engagement and reach of shared links on various social media and platforms on the internet. The ninth position is held by nhs.uk (n=103), the UK National Health Service's official domain. This domain's contribution highlights the UK health authority's commitment to educating and providing resources on organ donation to the public, reflecting the importance of institutional support in promoting health initiatives.

Finally, co.uk (n=98) encompasses a range of UK-based websites. This generic top-level domain's appearance in the top ten signifies that various UK entities collectively discuss and link to organ donation content. This points to a country-wide effort to endorse organ donation awareness and registration.

Table 3 provides an overview of the top 10 hashtags that users were using. In first place was the hashtag #organdonation (n=5413), which is the most widely used hashtag concerning organ donation discussions. The second most prevalent hashtag is #donatelife (n=1361). This hashtag resonates with the community's call to action for individuals to contribute to the cause of saving lives through organ donation. In third place is the hashtag #giftoflife (n=974). This hashtag emphasizes organ donation's life-saving and life-enhancing benefits, celebrating it as an altruistic gift a person can offer others. The fourth most popular hashtag was #organtransplant (n=867). This hashtag is likely used to share information, personal stories, and developments related to the organ transplant process.

In fifth place was #tissuetransplant (n=756), which points to discussions specific to the transplantation of tissues, another crucial aspect of the broader conversation on transplantation and organ donation. In sixth place was the hashtag #transplantnews (n=742), suggesting a focus on sharing news and updates related to transplant medicine and stories of individuals involved in the transplant process.

The seventh-ranked hashtag is #organtissue (n=478), and it brings to light the conversation about both organ and tissue donation, indicating a combined discourse that highlights the need for donations of all types of body tissues. The hashtag #kidneytransplant (n=359) takes the eighth spot, denoting a specific focus within the organ donation community on kidney transplants, reflecting the high demand and frequency of this type of transplant. The hashtag #transplant (n=339) was in ninth place. This more general hashtag indicates a broad discussion encompassing the entire spectrum of transplant-related topics. Finally, the hashtag #savelives (n=315) occupied the tenth position. This compelling and impactful call to action highlights the ultimate goal of organ donation: to save and improve lives.

Table 3. Top 10 hashtags on X related to organ donation (October 2023 to May 2024).

Rank	Top hashtags	Count, n
1	organdonation	5413
2	donatelife	1361
3	giftoflife	974
4	organtransplant	867
5	tissuetransplant	756
6	transplantnews	742
7	organtissue	478
8	kidneytransplant	359
9	transplant	339
10	savelives	315

Development of the OrgReach Marketing Strategy

Overview

We draw upon our results, our review of existing research [8-12], and social credibility theory [7] to develop the OrgReach Marketing Strategy. Specifically, we draw upon our results around:

- The nature of the network and the lack of cross-group conversations that were found in our SNA.
- Our insights into the opinion leaders within the network and their characteristics.
- The characteristics of the most popular posts that were sent in terms of retweets and favorites and the types of content that attracted reposts.
- The most popular web domains within the network in terms of link clicks and the types of studies that they were sharing.

We conceptualize the 5 C's (Create, Connect, Collaborate, Correct, and Curate), 2 A's (Access and Analyse), and 3 R's (Recognize, Respond, and Re-evaluate), which we name the

XSL•FO
RenderX

OrgReach Marketing Strategy. Each element is further outlined below.

The 5 C's

Create

Develop engaging and educational content related to your topics of interest. Emotional content, including images or video-based testimonials highlighting organ donation's need and impact on lives, may gain more visibility. To assess the appeal and educational effectiveness of content, organizations should continuously monitor engagement metrics (likes, shares, comments, and reach) to determine the popularity and engagement with content. Moreover, direct qualitative feedback from users and A/B testing of content could help provide further evaluation of content.

Connect

To build a strong community and foster conversations and connections between individuals, health care professionals, and advocacy groups. Using the search feature to find similar organizations and conversations and break down conversational silos on social media. To assess and evaluate whether organizations are succeeding in their network building, they can determine their social network metrics (network density, clustering, and cross-group interactions). Moreover, tracking follower and advocacy accounts, as well as user surveys, could help evaluate the success of connection-building.

Collaborate

Partner with influencers, health care organizations, and governmental bodies to collaborate on content creation, amplify the message, and reach a wider audience. Codevelop and share content and incorporate other "@" tags within posts. More credible influencers will likely lead to further impact. Organizations can select partners such as health care organization and governmental bodies based on the alignment of values and for influencers, their reach, and audience. More sophisticated analyses, such as engagement quality, influencer identification, and credibility assessments, can also be drawn upon in this phase to identify the quality and consistency of collaborative content.

Correct

Monitor and address any misinformation users share, ensuring the public receives accurate and trustworthy information about organ donation. Corrected information may lead to your organization's further visibility. Organizations can draw upon text-analysis tools, such as NodeXL Pro, introduced earlier, and this could help identify high-frequency keywords that can highlight the presence of misinformation. This analysis can be supplemented with sentiment and web-domain level analysis where the credibility of websites is assessed. Moreover, organizations can look to existing fact-checking resources and encourage community reporting of misinformation.

Curate

In addition to original content, organizations can handpick and share relevant stories, news, and data relevant to organ donation to keep the audience informed and engaged. Organizations can set up news monitoring on platforms such as Google News for relevant, credible content that can include stories that resonate emotionally with the target audience. Organizations should ensure content across diverse perspectives, including minority communities and different cultural approaches to organ donation. Organizations can also incorporate feedback loops, which provide social media followers to provide feedback on content that is shared.

The 2 A's

Access

Ensure that the information you share is accessible to everyone, removing barriers, that is, a public-facing social media account with an easy-to-find user handle. This further enhances credibility.

Analyze

Use SNA and credible influencer detection to understand audience behavior and refine strategies for better engagement and impact. Using this analysis and output of key users and content to feed back into the 5 C's.

The 3 R's

Recognize

Publicly acknowledge and celebrate the altruism of donors and the success stories of recipients to inspire others.

Respond

Establish a reliable and responsive communication channel through social media to answer queries and engage with the audience in real time.

Reevaluate

Continuously assess the strategy's effectiveness and make data-driven adjustments to improve outreach and advocacy efforts.

Discussion

Principal Findings

Previous research has studied the potential of social media platforms for increasing donor registrations and strategies for sharing organ donation-related content. This study contributes to the literature by providing insights into users' conversations around organ donation, identifying influencers, and uncovering the network structure of the elite tier and key URLs and hashtags. These findings were then used to develop the OrgReach Marketing Strategy to offer practical suggestions and strategies for organizations in this area. Our findings and their broader implications will be further discussed.

In our analysis, the structure of user interactions on X through SNA provided insights into the shape of the discourse surrounding organ donation. The largest group was where users would send isolated posts, suggesting that individuals share personal stories and advocacy messages independently. Large and smaller interactive community clusters indicated that more engaged discussions were also occurring, which are important for fostering support among users considering organ donation. The limited interactivity between the groups suggests the

XSL•FO
RenderX

potential for enhancing dialogue across different clusters to unite advocacy efforts and enhance the conversation around organ donation. By understanding these interactions, stakeholders could better tailor their communication strategies to increase awareness and participation in organ donation. This would allow stakeholders to maximize the role of social media as a tool for impactful advocacy.

Our analysis also revealed that a wide array of topics related to organ donation were discussed. These ranged from ethical debates and legislative discussions to advocacy efforts and personal impact stories. This study found that users engage in conversations about the ethical implications of mandatory donation, the use of tissues in research, and the effects of laws and opt-out systems. Controversial topics often include misinformation, which highlights the need for accurate communication. Advocacy through public figures and cultural events boosted awareness within the network, especially in minority communities. The recognition of donors and community support on X emphasized organ donation's societal value and inspirational potential.

The NHS Organ Donation account, a significant member of the elite tier, actively engages with the public through structured interaction hours, underscoring its commitment to saving lives. This highlights a strategic approach to online health communication, which may, in part, have led to the greater impact of the account. Influential leaders such as the PMO India and Canada's Prime Minister Justin Trudeau show how political figures can leverage their platforms to significantly impact public discourse on health issues. However, political figures can also be targeted for misinformation, as was the case with Trudeau's account. Moreover, the presence of anonymized citizens and public figures from diverse locations like the United Kingdom, Canada, and the United States among the top influencers indicates that organ donation discussions attract a wide range of contributors, from individuals sharing personal experiences to those with business or political interests. This provides a variety of viewings being shared.

The analysis of the top domains linked in these discussions revealed a strategic use of diverse online resources to promote organ donation. These included specialized news outlets such as transplantnews.com, as well as governmental and social media platforms. The variety in content distribution channels highlights the concerted efforts to maximize outreach and engage different audiences effectively. URL shorteners and content delivery networks highlight a sophisticated approach to content dissemination, ensuring that information reaches a broad audience efficiently and is easily shareable.

The analysis and identification of popular web domains, hashtags, and the development of the OrgReach Marketing Strategy aim to contribute to existing literature and provide practical suggestions and strategies for social media engagement and outreach.

Limitations and Future Research Agenda

This study focused on retrieving data from X (formerly Twitter). Therefore, our empirical findings would not capture discussions on other platforms like Facebook, Instagram, or specific Web forums. Future research could examine content across various platforms to provide a critical comparative perspective. Moreover, this study examines a single time slice and captures conversations across a specific 7-month period, and content may differ across other periods. Future research could retrieve and compare different periods to identify changes in influencers and conversations. Future research could also seek to test and validate the proposed OrgReach Social Media Marketing Strategy in real-world campaigns which would help to strengthen the practical applicability of the findings.

Moreover, it is important to note that this study examined content aggregately and did not stratify different countries. This is because certain countries operate under an "opt-in" to organ donation system, such as the United States, where campaigns typically emphasize individual registration. In opt-out countries, campaigns focus on promoting organ donation's altruistic and societal benefits to encourage families to make informed decisions. Based on these differing contexts, the study does not differentiate social media content or user interactions. The OrgReach Marketing Strategy could also be enhanced by incorporating specific guidance for campaigns tailored to these legislative frameworks.

Data Availability

The data sets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Despite the reinstatement of proactive human papillomavirus (HPV) vaccine recommendations in 2022, Japan continues to face persistently low HPV vaccination rates, which pose significant public health challenges. Misinformation, complacency, and accessibility issues have been identified as key factors undermining vaccine uptake.

Objective: This study aims to examine the evolution of public attitudes toward HPV vaccination in Japan by analyzing social media content. Specifically, we investigate the role of misinformation, public health events, and cross-vaccine attitudes (eg, COVID-19 vaccines) in shaping vaccine hesitancy over time.

Methods: We collected tweets related to the HPV vaccine from 2011 to 2021. Natural language processing techniques and large language models (LLMs) were used for stance analysis of the collected data. Time series analysis and latent Dirichlet allocation topic modeling were used to identify shifts in public sentiment and topic trends over the decade. Misinformation within opposed-stance tweets was detected using LLMs. Furthermore, we analyzed the relationship between attitudes toward HPV and COVID-19 vaccines through logic analysis.

Results: Among the tested models, Gemini 1.0 pro (Google) achieved the highest accuracy (0.902) for stance analysis, improving to 0.968 with hyperparameter tuning. Time series analysis identified significant shifts in public stance in 2013, 2016, and 2020, corresponding to key public health events and policy changes. Topic modeling revealed that discussions around vaccine safety peaked in 2015 before declining, while topics concerning vaccine effectiveness exhibited an opposite trend. Misinformation in topic "Scientific Warnings and Public Health Risk" in the sopposed-stance tweets reached a peak of 2.84% (47/1656) in 2012 and stabilized at approximately 0.5% from 2014 onward. The volume of tweets using HPV vaccine experiences to argue stances on COVID-19 vaccines was significantly higher than the reverse.

Conclusions: Based on observation on the public attitudes toward HPV vaccination from social media contents over 10 years, our findings highlight the need for targeted public health interventions to address vaccine hesitancy in Japan. Although vaccine confidence has increased slowly, sustained efforts are necessary to ensure long-term improvements. Addressing misinformation, reducing complacency, and enhancing vaccine accessibility are key strategies for improving vaccine uptake. Some evidence suggests that confidence in one vaccine may positively influence perceptions of other vaccines. This study also demonstrated the use of LLMs in providing a comprehensive understanding of public health attitudes. Future public health strategies can benefit from these insights by designing effective interventions to boost vaccine confidence and uptake.

Introduction

Cervical cancer remains a significant public health challenge worldwide. In 2020, the World Health Organization (WHO) launched a strategy to eliminate cervical cancer, aiming to achieve 90% coverage rate for human papillomavirus (HPV) vaccination by 2030 [1]. In 2023, the WHO released estimates of first-dose vaccination coverage for women in 133 countries, with a global average of 62%, and 15 countries have already met the WHO's target [2]. However, Japan presents a unique case among high-income countries, where HPV vaccination rates have remained critically low. Both bivalent and quadrivalent HPV vaccines were licensed and subsequently included in the national immunization program for girls in 2013 in Japan [3,4]. However, widespread reports of adverse events prompted the Japanese Ministry of Health, Labour and Welfare (MHLW) to suspend the proactive recommendation in 2013, leading to a sharp decline in public trust and a significant increase in cervical cancer incidence [5-13]. While proactive recommendations were reinstated in 2022, HPV vaccine uptake remains low [14-18].

To enhance HPV vaccination uptake in Japan, it is crucial to systematically analyze the trends of vaccine hesitancy. Existing literature reveals varying levels of hesitancy across different populations. Studies targeting parents consistently demonstrated significant hesitancy in the years preceding the updated recommendations, whereas surveys involving health care professionals, including those who are parents, showed higher confidence. A 2024 MHLW survey found comparable proportions of willingness, unwillingness, and uncertainty among both the target population and their parents. However, a critical gap in current research is the lack of longitudinal studies to track public attitudes toward HPV vaccination over time using consistent methodologies.

Understanding the factors influencing vaccine hesitancy is also essential. Studies have attributed this to persistent public distrust, misinformation, negative media coverage [15-20], and prolonged government suspension of recommendations, which heightened public concern [11]. The WHO Global Advisory Committee on Vaccine Safety emphasized the potential harm of policy decisions based on weak evidence, leading to the underutilization of safe and effective vaccines [21]. However, limited research has comprehensively investigated the long-term, dynamic influence of the key events and factors on HPV vaccine hesitancy in Japan.

In recent years, social media platforms have emerged as valuable resources for public health research. Comparing with the traditional survey research, social media can provide large volumes of real-time data that are readily accessible and searchable [22]. Among all the social media platforms, the user base of Twitter (subsequently rebranded as X) in Japan has grown significantly, with its share of users increasing from slightly more than 20% of the population in 2014 to approximately 45% in 2021 [23]. The platform's primary active user demographic, aged 13-39 years, substantially overlaps with the target age groups of vaccine-eligible adolescents and their parents, making it a relevant data source for analyzing public discourse on the HPV vaccine [24]. Twitter analysis has been applied to investigate public discourse surrounding HPV vaccination in various countries [25-28]. In Japan, Suzuki et al [29] analyzed 208 geotagged tweets, revealing an uneven distribution of users disseminating information related to HPV vaccination. Terada et al [19] examining 3623 tweets collected over a 7-month period, reported a predominance of negative sentiment associated with discussions pertaining to HPV vaccine safety and side effects. However, few works used large-scale social media analysis to comprehensively examine the evolution of public discourse concerning HPV vaccination over an extended period within the Japanese context.

Recent advancements in natural language processing (NLP) methodologies, particularly the integration of deep learning (DL) models, have significantly enhanced the accuracy and sophistication of social media analysis [30]. While traditional NLP techniques such as n-grams [31] and topic modeling [32] have proven valuable, DL models, especially the large language models (LLMs), have demonstrated significant potential for conducting sophisticated and nuanced analyses of social media data [33]. However, the application of LLMs to investigate HPV vaccine hesitancy in Japan remains an underexplored area of research.

This study aims to address these gaps by analyzing the long-term evolution of public attitudes toward HPV vaccination in Japan from 2011 to 2021 through Twitter data. Specifically, we use advanced NLP techniques, including stance analysis, time series analysis, topic modeling, and logic analysis, to:

1. Examine the dynamics of HPV vaccine confidence over time;
2. Identify changes in key factors influencing vaccine hesitancy; and
3. Explore the relationship between key events and shifts in public opinion, including interaction between vaccines.

By leveraging state-of-the-art NLP and LLM methods, this study provides a systematic, data-driven understanding of vaccine hesitancy in Japan. The findings will offer insights into the evolution of public perceptions and inform strategies to address vaccine hesitancy more effectively.

Methods

Data Collection and Preprocessing

This study used the Twitter application programming interface to collect Japanese tweets related to HPV vaccination between 2011 and 2021. The tweets were retrieved using various Japanese keywords for HPV vaccine. The number of tweets increased each year, resulting in 228,376 tweets. After excluding tweets with unrecognizable dates, 228,300 were retained for subsequent analyses. After data collection, the tweets were cleaned and preprocessed. Retweets were removed using the Python package *Tweepy* (Twitter) [34]. Web links, special characters, emojis, and ampersands were eliminated, and full-width English characters were converted into half-width lowercase characters.

XSL•FO
RenderX

Annotation

To facilitate model training and fine-tuning, 2.5% of the tweets per year were randomly selected for annotation. This study focused on public stance toward the HPV vaccine by using a 3-category annotation system: advocate, oppose, and unknown. The detailed category definitions are shown in Table 1.

Table 1. Definitions of stances to the human papillomavirus vaccine.

Category	Definition	Mock tweet example
Advocate	Affirmatively advocacy of the HPV[a] vaccine, highlighting its efficacy in preventing HPV-related diseases, the critical role of vaccination in public health, and positive vaccination outcomes. These messages distinctly advocate for the HPV vaccine's utilization, reinforcing its importance in health prevention measures.	Just got my HPV vaccine today! Feeling grateful for the science that protects us from cervical cancer. Highly recommend it to everyone eligible!
Opposite	Explicitly challenge or critique the HPV vaccine, focusing on concerns related to its efficacy, safety, or potential adverse effects. The critical perspective must be distinctly directed at the HPV vaccine in isolation, excluding broader criticisms of vaccines at large, political deliberations concerning vaccination policies, or financial considerations associated with vaccine procurement.	I'm skeptical about the HPV vaccine due to the side effects I've read about. More research is needed before making it a widespread recommendation. Let's be cautious.
Unknown	Neither explicitly endorse nor directly oppose the HPV vaccine. This category encapsulates tweets that voice opposition stemming from broad antivaxxers, policies, or concerns about the cost, without specifically expressing the advocate or opposite of the HPV vaccine itself. It also includes tweets that are too ambiguous, neutral, or irrelevant to ascertain a clear position concerning the HPV vaccine.	Why isn't the HPV vaccine free for everyone? If it's so important, shouldn't the government cover the cost? Still trying to understand the policy behind this.

[a]HPV: human papillomavirus.

The annotation team comprised 4 medical professionals, 3 of whom independently annotated each tweet. Tweets with unanimous annotations were classified as tier 1, those with 2 matching annotations as tier 2, and those without matching annotations as tier 3. Tier 1 data, which were deemed to have the highest consistency, used the initial annotations as the final labels. Tier 2 and 3 data underwent further consensus meetings, with the final labels determined by the last medical professional.

A total of 5758 tweets were annotated, with 5050 in tier 1, a total of 701 in tier 2, and 7 in tier 3. The Cohen κ values between each pair of the 3 major medical professionals (KG, YN, and ND) are shown in Table 2, which are all over 0.8 and at the agreement level of almost perfect. The distributions across the advocate, oppose, and unknown categories in the annotated data were 1646, 697, and 3415, respectively.

Table 2. Cohen κ between the annotations by each pair of medical professionals.

KG and YN	0.851
YN and ND	0.845
KG and ND	0.858

Stance Analysis With DL Models

Model Selection

To achieve the optimal results, we first selected the best-performing model. We compared several traditional NLP classification models with LLMs. Among the traditional models, we considered long short-term memory [35], Bidirectional Encoder Representations from Transformers (BERT) [36], and DistilBERT [37]. For the LLMs, we used Gemma-2-2b [38], Gemma-2-9b, and Llama-3.1-8b [39]. All uses of open-source LLMs in this work were conducted following approval and in strict accordance with their respective licensing agreements. We also evaluated the Gemini Pro 1.0 [40] using Google AI Studio during the free trial.

A 2-layer bidirectional architecture is designed for the long short-term memory model. The tweets were tokenized using the *Ginza* Python package (Megagon Labs) [41]. Owing to the manageable parameter size of this model, it was trained from scratch. For the BERT models, Tohoku BERT [42] and Line DistilBERT [43] were selected as baselines. A classification head was added to the first token of the final hidden layer of these models, and fine-tuning was performed using our tweet data, while keeping the BERT parameters frozen.

For LLMs, computational resource constraints prevented us from fine-tuning models with more than 10 billion parameters, whereas budgetary constraints precluded fine-tuning using application programming interfaces such as ChatGPT [44] or Claude [45]. Therefore, we opted for smaller open-source LLMs and tested both baseline, Quantization, and Low-Rank Adaptation fine-tuned versions on the tweet data [46]. For Gemini Pro 1.0, we fine-tuned the model directly using Google AI Studio. For all LLMs, we used the following prompt in Japanese, followed by the original tweet, as user prompts:

Does this tweet express a position against the HPV vaccine itself? Please classify this tweet as "advocate," "oppose," or "unknown." Do not make subjective assumptions; base your

XSL•FO
RenderX

decision solely on the content of the tweet. Answer only your position, and no explanation is required.

Given the significant class imbalance in the dataset, 5758 annotated tweets were split into training, validation, and test sets, with the proportion of each category maintained across the splits. To ensure a robust evaluation, 100 tweets from each category were randomly selected to form a test set. The remaining data within each category were partitioned into training and validation sets at a ratio of 4:1. Due to the training sample size limitation (<500) imposed by Gemini 1.0 Pro, a subset of 498 labeled tweets (distributed equally across the 3 categories at a ratio of 166:166:166) was used to fine-tune the model for the HPV vaccine stance classification task. The model performance was assessed using standard evaluation metrics, namely, precision, recall, and F_1-score. The details of the labeled dataset are listed in Table 3.

Table 3. Number of labeled tweets of different stances in the dataset.

Category	Train set, n	Validation set, n	Test set, n	Total, n
Advocate	2652	663	100	3415
Oppose	477	120	100	697
Unknown	1236	310	100	1646
Total	4365	1093	300	5758

To investigate the performance boundaries of the optimal model further, we explored the impact of varying category distributions within the training data. We experimented with different ratios of advocate, opposition, and unknown categories, specifically 166:166:166, 150:200:150, 125:250:125, 100:300:100, 75:350:75, and 50:400:50. For each ratio, the data were randomly sampled 3 times, the model performance was evaluated, and the results were averaged to ensure robustness.

After identifying the optimal category ratio, we fine-tuned the best-performing model 5 times using this ratio, each time with a new random data sample. The remaining labeled data were used for the performance evaluation, and the 3 models exhibiting the highest performance were selected for the final inference. For each unlabeled tweet, the 3 models generated independent predictions. If 2 or more models agreed with the predicted label, they were assigned to the tweet. When all 3 models produced different predictions, the tweet was classified as “unknown.”

Time Series Analysis of Stances

Following the stance classification of all tweets, a comprehensive time series analysis was performed on the extracted data to examine the evolution of public sentiments toward HPV vaccines in Japan between 2011 and 2021. The HPV vaccine supply and injection data were collected from the official website of MHLW. The raw data for vaccine supply lack fine-grained annual data and can be across 2 years, so the annual supply for some years were based on estimation; details are provided in Multimedia Appendix 1. We calculated the annual advocate rate from the tweets by *(number of advocate tweets)/(number of advocate tweets + number of opposed tweets)*. The difference between the monthly counts of tweets advocating for and opposing the HPV vaccine was calculated to capture the dynamic shifts and relative strength of each stance over time.

To identify significant structural breaks within the time series data, the pruned exact linear time (PELT) algorithm [47], a computationally efficient method for change-point detection, was used. These identified change points correspond to major shifts in public opinion regarding the HPV vaccine, potentially linked to specific events or information dissemination campaigns. By juxtaposing the time series analysis results with a timeline of key news events and public health policies, a comprehensive interpretation of the observed trends was achieved. This approach facilitates a deeper understanding of the factors influencing the public acceptance of HPV vaccines and provides empirical evidence for future public health interventions and policy decisions.

Latent Dirichlet Allocation Topic Modeling Analysis

In this study, we used latent Dirichlet allocation (LDA) [32] topic modeling, a widely used technique for extracting latent thematic information from large volumes of text data, to analyze Japanese tweets related to the HPV vaccine between 2011 and 2021. Using LDA modeling, we aimed to gain a deeper understanding of the specific perspectives held by Japanese Twitter users across different stances toward the HPV vaccine. To determine the optimal number of topics that best represented the thematic structure of the dataset, we experimented with various topic numbers, ranging from 1 to 50. For each configuration, the performance of the model was evaluated using perplexity and coherence scores [48]. Details of the optimal topic number selection are shown in Figures S1, S4, and S7 in Multimedia Appendix 2. After the optimal number of topics was selected, qualitative analyses were conducted to refine and interpret the final thematic content. Similar to Niu et al [49], we calculated the monthly average expectation of tweets belonging to different topics for a fine-grain time series analysis.

In line with prior research indicating that misinformation is an important factor in vaccine hesitation [19,50,51], we also investigated the impact of misinformation on the HPV vaccine. First, we identified topics that were likely to contain misinformation through group discussion, focusing on tweets with an estimated probability of more than 80% of belonging to those topics. We then used the Claude-3-opus model [45] to assess whether each tweet attempted to disseminate misinformation regarding the HPV vaccine. To validate the accuracy of the model’s classification, we randomly selected 25 tweets each categorized as misinformation and 25 categorized as non-misinformation by the model. Three independent volunteers evaluated the credibility of the information in these

XSL•FO
RenderX

tweets by cross-referencing reputable news sources and data from the MHLW [52]. The verification process was repeated 3 times to estimate the classification accuracy of the model.

Explore Relationship Between HPV Vaccination and COVID-19

Considering the chronological overlap between the duration of data collection and the COVID-19 pandemic, which is a significant historical health event, this study investigated the potential relationship between HPV vaccination and COVID-19. Specifically, the objective of this study was to determine whether the COVID-19 pandemic had an impact on public attitudes toward HPV vaccination. From our dataset, all tweets comprising the keyword "COVID-19" in both Japanese and English were extracted. In addition to the time series analysis and LDA topic modeling previously described, the correlation between all HPV vaccine–related tweets and the tweets incorporating the "COVID-19" keywords was examined. Moreover, specific time points where the total number of tweets and the tweets containing "COVID-19" keywords exhibited simultaneous increases were investigated. To estimate the percentage of tweets pertaining to pivotal events, 100 tweets were randomly selected 3 times at each time point. Three volunteers verified the number of tweets related to the paramount event, and the percentage of related tweets was calculated by averaging the 3 results and computing CIs. To gain a deeper understanding of the data spikes, the influence of COVID-19 vaccine–related pivotal events on peak time points was also assessed.

Furthermore, we investigated the potential causality between the stance toward the HPV vaccine and the stance toward COVID-19. Specifically, we analyzed tweets containing "COVID-19" keywords and expressing either an advocate or opposed stance. We used logic analysis by LLM to determine whether the tweet used the HPV vaccine as an illustrative example to convey the author's perspective on COVID-19 and vice versa. The Claude-3-opus model was directly used for inference, with the prompt instructing it to read the tweet and provide an output of "HPV to COVID" if the tweet used the HPV vaccine as an example to express an idea about the COVID-19 vaccine, "COVID to HPV" if the reverse was true, or "Not related" if neither was applicable. The classified tweets were tallied weekly and visually presented to demonstrate the results.

The manuscript was prepared in accordance with the iCHECK-DH: Guidelines and Checklist for the Reporting on Digital Health Implementations [53]. The IDs of the tweets used in this research are provided in Multimedia Appendix 3.

Ethical Considerations

This study used publicly available and accessible tweets. We assert that our analysis is compliant with Twitter's usage policy in aggregate form without identifying specific individuals who published the Twitter posts. Furthermore, the number of vaccination supply and injection downloaded from the MHLW are open government data. Therefore, the activities described do not meet the requirements of human subject research and did not require review by an institutional review board.

Results

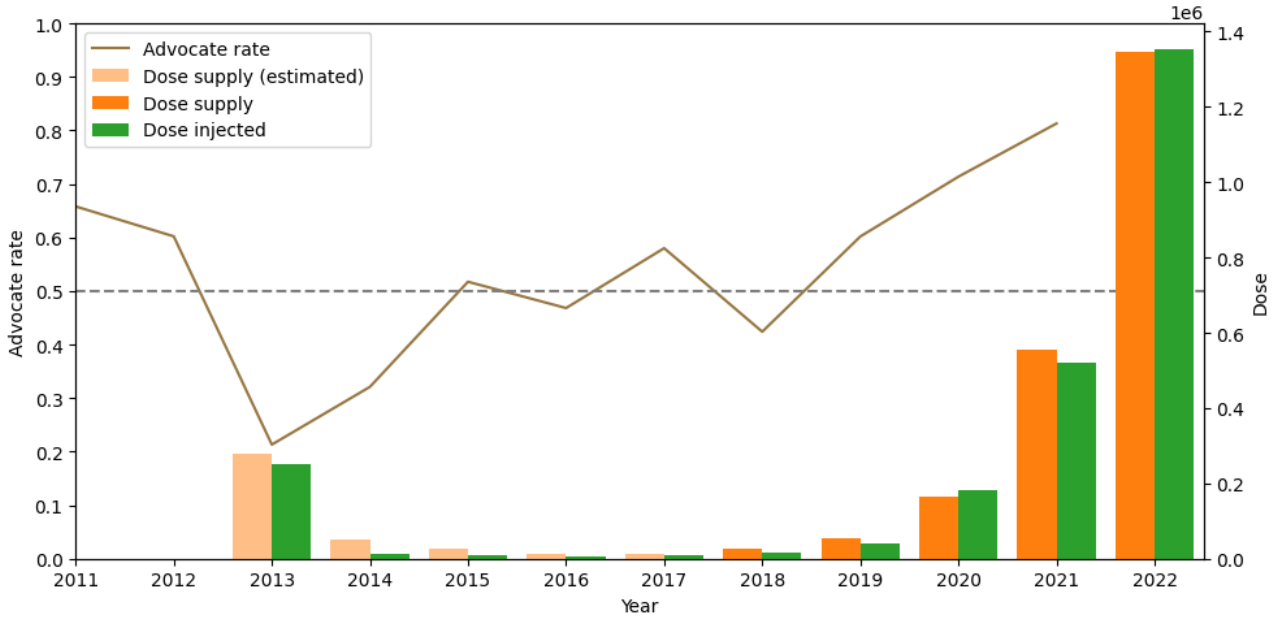
Model Selection

A comparison of all the models tested is shown in Multimedia Appendix 4. The F_1-scores of the fine-tuned larger models achieved better performance in most cases, except for Llama 3.1. This may be because it was not instruction tuned for Japanese corpora in advance. The fine-tuned Gemini 1.0 pro yielded the best results in our experiment, and we decided to perform the following steps based on Gemini 1.0 pro. Detailed results are shown in Multimedia Appendices 5 and 6.

Because the allowed number of tweets for fine-tuning Gemini 1.0 pro was fixed (<500), we experimented with different data ratios to determine the most effective category ratio to fine-tune the model. The results indicated that the model performed best when the ratio of the advocate, opposite, and unknown categories was 150:200:150. This ratio was consistent in the validation experiments, achieving the highest average F_1-score of 0.968, as shown in Multimedia Appendix 7. The detailed model performance for each ratio is shown in Multimedia Appendix 8.

After 5 rounds of random data selection and fine-tuning using the optimal data ratio, the performance of the fine-tuned Gemini 1.0 Pro model was evaluated using the remaining labeled data. The evaluation results showed significant improvements in precision, recall, and F_1-score for the fine-tuned model. The average F_1-score of the 3 best-performing models was 0.924, with a precision of 0.928 and a recall of 0.924. In comparison, the baseline performance of the untuned Gemini 1.0 Pro model on the same test dataset showed an F_1-score of 0.781, a precision of 0.829, and a recall of 0.796. This comparison clearly demonstrates the importance of fine-tuning for enhancing the performance of the model for specific tasks.

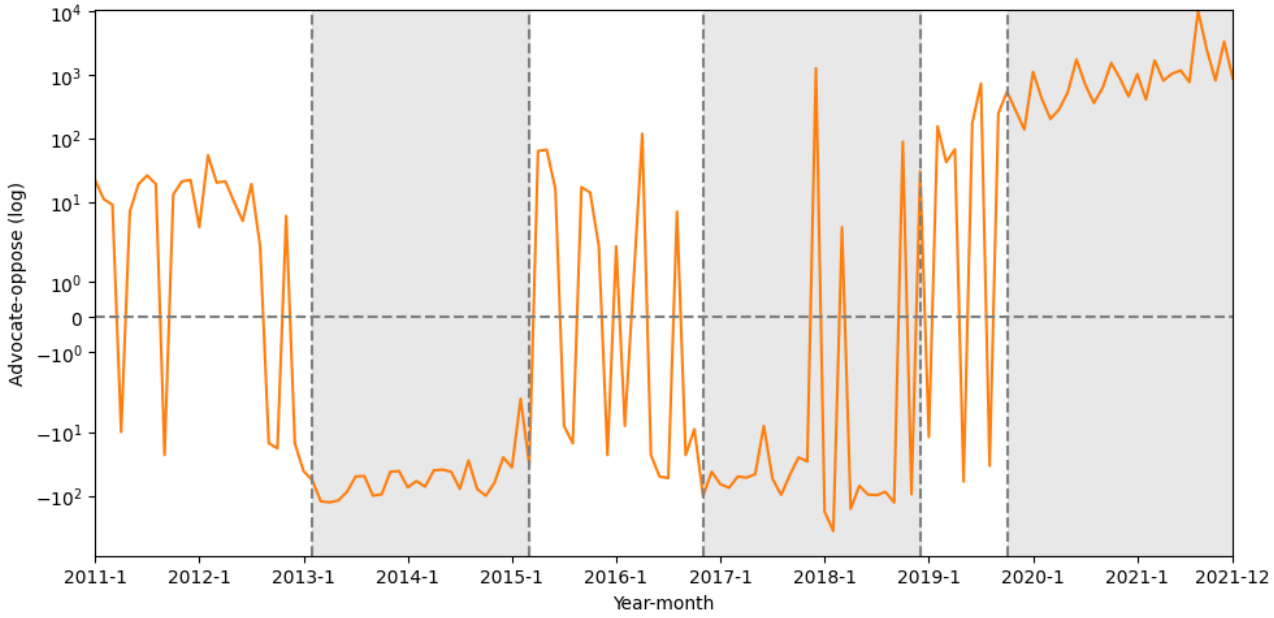
When classifying the unlabeled Japanese tweets, the results from the 3 best models were mostly consistent. Among all tweets, 86.85% (198276) received 3 identical result labels and 13.06% (29806) received 2 identical result labels. In cases where all 3 labels were completely inconsistent, these tweets were classified as unknown, accounting for 0.09% (209) of all the tweets.



Time Series Analysis of Stance

We first analyzed the trend of advocate rate toward the HPV vaccine from 2011 to 2021 and the HPV vaccine supply, injection from 2013 to 2022, as shown in Figure 1. It is noticeable that vaccine supply between 2013 and 2017 is based on estimation because of lacking fine-grained annual data. The lowest advocate rate appeared in 2013, when the Japanese government decided to suspend its recommendations for the HPV vaccine, which was announced only 2 months ago [54], leading to a sharp decrease of vaccine supply and injection 2014. The advocate rate recovered in 2 years and stayed to be around 50% until 2018, but the vaccine supply and injection stayed at an ignorable level. The advocate rate increased and stayed in a high level since 2019, during which 2020 witnessed numerous petitions urging the government to reinstate active

XSL•FO
RenderX

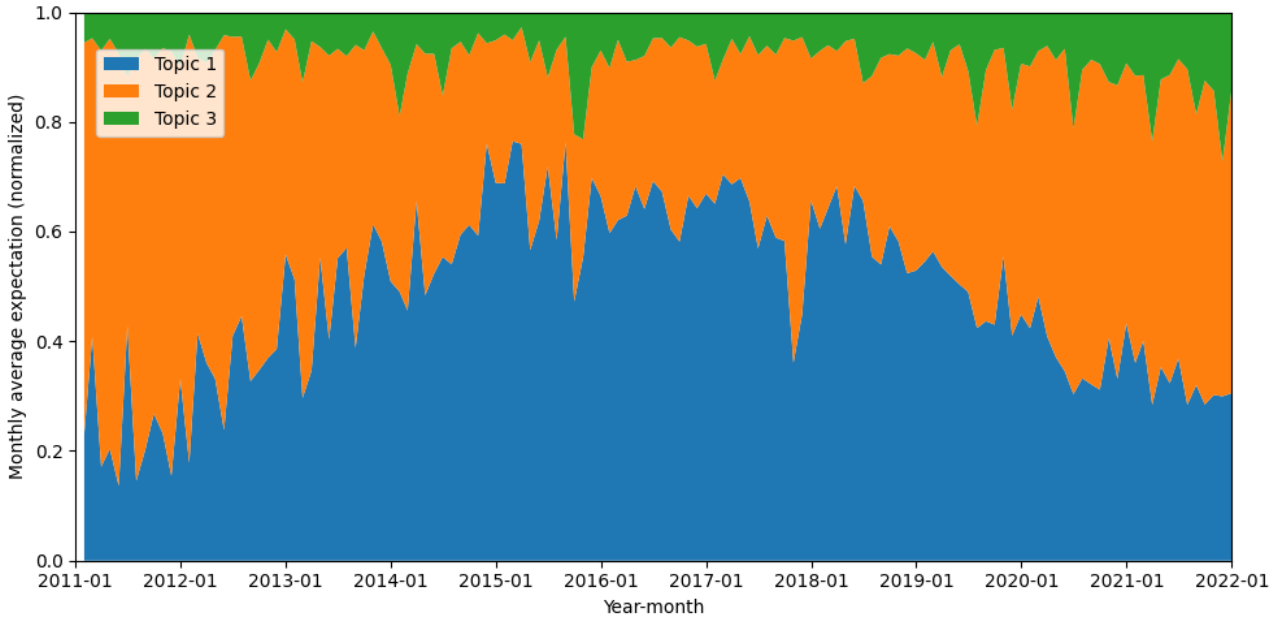


recommendations and prompt policy reviews [55]. The vaccine supply and injection started exponential growth since 2019, especially after the proactive HPV vaccine recommendations reinstated in 2022 [14-18]. Vaccine injected surpassed vaccine supply in 2020 and 2022, indicating that the vaccines remained last year were consumed.

Figure 1. Advocate rate toward human papillomavirus vaccine between 2011 and 2021 (line) and the number of vaccine supply and injection between 2013 and 2022 (bars). The vaccine supply from 2013 to 2017 was estimated based on Japanese Ministry of Health, Labour and Welfare (MHLW) official data due to lacking fine-grained annual data, and the vaccine supply after 2017 is from MHLW official data.

A time series analysis of the difference between advocates and opposed stances is shown in Figure 2, which shows several pivotal junctures marked by substantial shifts in the disparity between pro- and anti-HPV vaccination stances, suggesting notable fluctuations in public opinion. Overall, we can observe that there are 3 periods of fluctuation, and the 3 periods are relatively stable in stances. Using the PELT algorithm, we successfully discerned structural change points within the data, closely aligning with significant shifts in public attitudes toward HPV vaccines. Notably, these change points were observed in 2013, 2016, and 2020, coinciding with key public health events and policy developments. Beside the events in 2013 and 2020, in late 2016, widespread discourse surrounding vaccine safety was triggered by legal actions taken by individuals alleging adverse side effects [56].

Figure 2. Monthly differences between number of tweets of advocate and oppose stances. The significant low and high periods based on change points detected by pruned exact linear time are marked in gray.



XSL•FO
RenderX

LDA Topic Modeling Analysis

We separately applied LDA modeling to the tweets of advocates, opposes, and unknown stances. There are 3 best topic numbers for advocates and unknowns and 4 for opposition. Details of the top words and weights are provided in Multimedia Appendix 2. We then calculated the ratio of the monthly expectations of tweets belonging to different topics to obtain fine-grained insights into the weights of the topics in each stance.

The distribution of various themes within the "advocate" stance is illustrated in Figure 3. The proportion of "Scientific and Media Discourse on HPV Vaccine Safety" (topic 1) underwent a significant increase until 2015, subsequently experiencing a gradual decline. Conversely, the proportion of "HPV Vaccine Effectiveness and Broader Public Health Measures" (topic 2) diminished, reaching its lowest point around 2015, after which it exhibited a consistent increase. The proportion of "Policy and Advocacy for HPV Vaccination Promotion" (topic 3) remained relatively stable, although a slight upward trend has been observed since 2019.

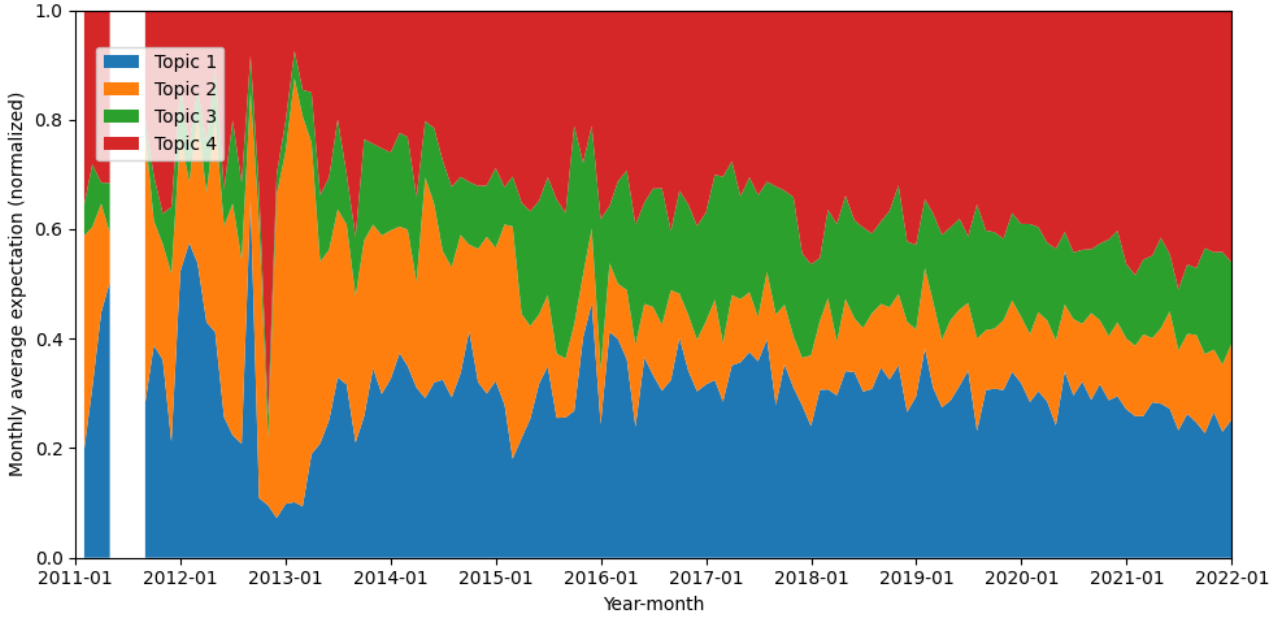


Figure 3. Monthly change of ratio of different topics in tweets of advocate stance from 2011 to 2021.

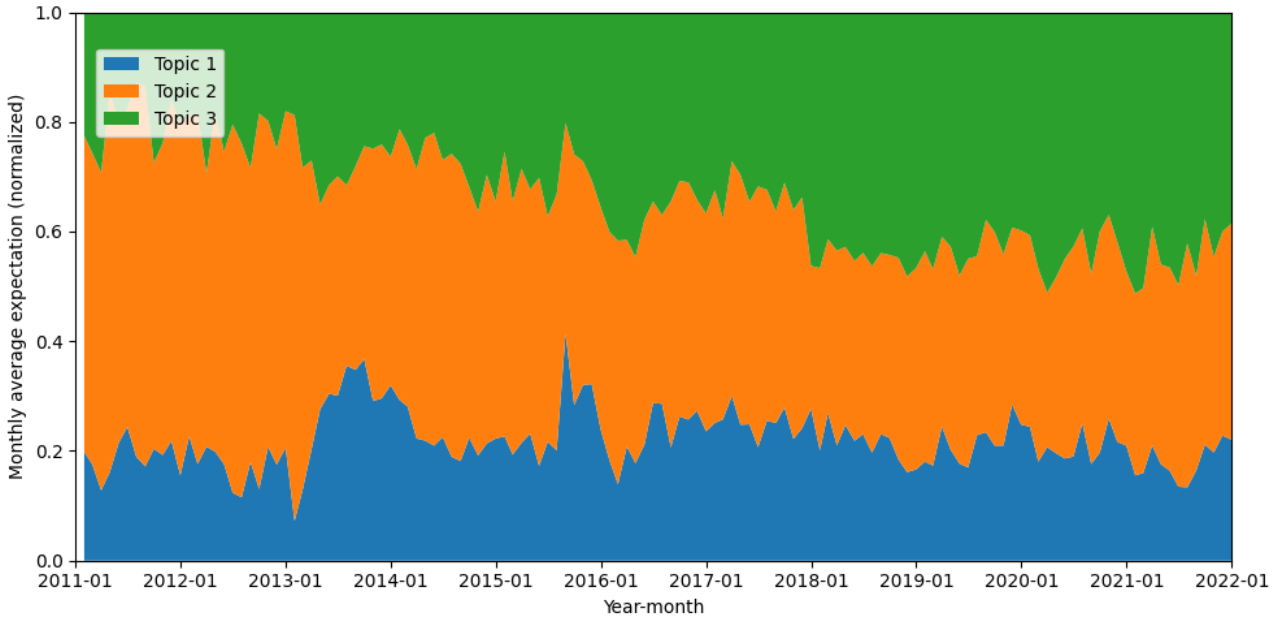
In the analysis of tweets expressing the "opposing" stance in Figure 4, "Skepticism and Opposition to Vaccination" (topic 2) demonstrated notable peaks in weight during the years 2013 and 2015, followed by a gradual decline and eventual stabilization of topic weight. The proportion of "Scientific Warnings and Public Health Risks" (topic 4) surged in late 2012, followed by a sustained increase throughout the decade, ultimately becoming the dominant theme within an opposing stance.



XSL•FO
RenderX

Figure 4. Monthly change of ratio of different topics in tweets of opposed stance from 2011 to 2021.

In the tweets classified as "unknown" by stance shown in Figure 5, "HPV Vaccine Efficacy and Public Health Initiatives" (topic 2) was the dominant theme prior to the year 2013 and then declined thereafter. Conversely, the proportion of tweets expressing "Opposition, Misinformation, and Activism Surrounding HPV Vaccination" (topic 3) displayed a gradual increase and has become the predominant theme since 2018. Notably, the theme of "HPV Vaccine Safety and Governmental Oversight" (topic 1) exhibited a gradual increase throughout the entire period under consideration.

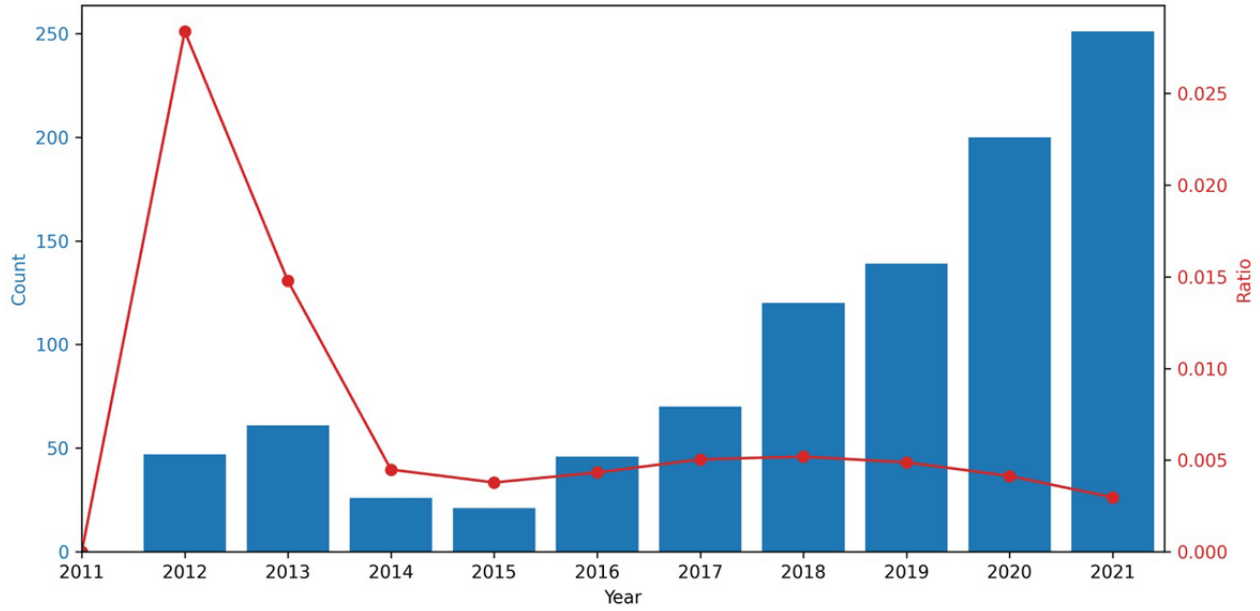


Figure 5. Monthly change of ratio of different topics in tweets where the stances are unknown from 2011 to 2021.

Then, we applied misinformation detection to certain topics. In tweets of opposed stance, we identified "Scientific Warnings and Public Health Risks" (topic 4) as the most likely to contain misinformation about the HPV vaccine. We extracted tweets with a probability of more than 80% belonging to this topic, yielding 3001 tweets. The misinformation classification results obtained using Claude-3-opus are shown in Figure 6. The classification accuracy, determined through random sampling and verification conducted thrice, ranged from 95% CI 89.74% to 100%. Our findings revealed that the prevalence of misinformation increased in most years, except for 2014 and 2015. The ratio of misinformation in HPV vaccine–related tweets began to spike sharply in 2012, followed by a rapid decline to its nadir in 2015. Subsequently, the ratio gradually increased, reaching a secondary, albeit lower, peak in 2018, after which it began to decline gradually.

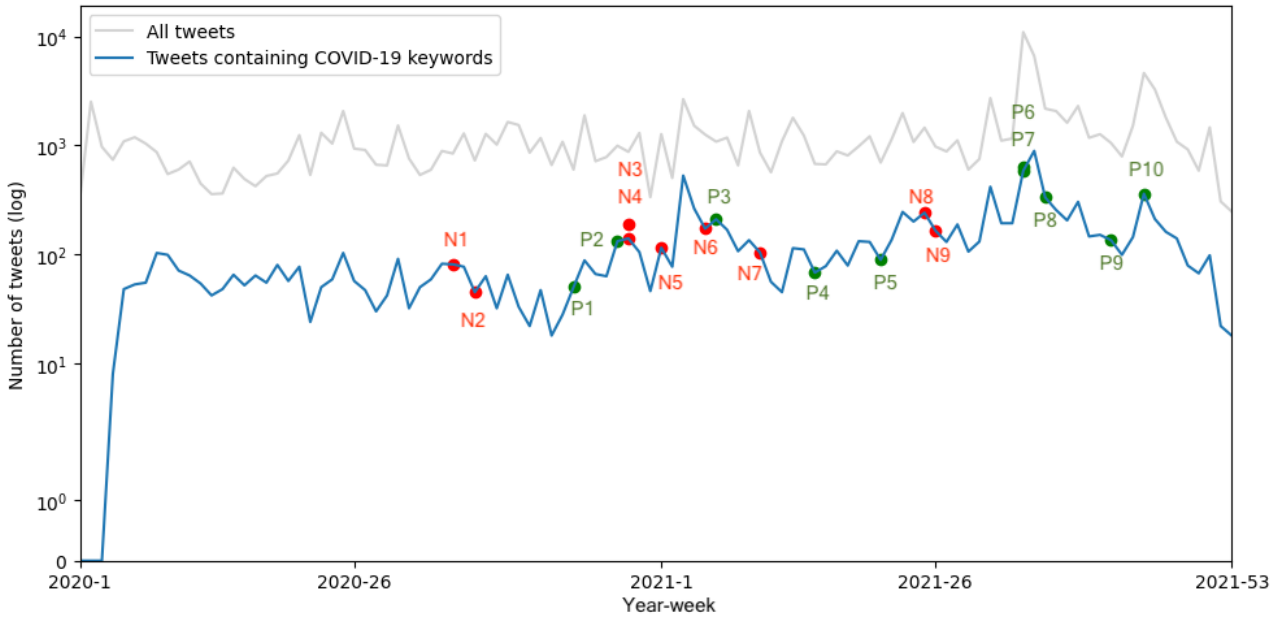

Figure 6. Count and ratio of tweets classified as misinformation. The bars show the total number of tweets detected as misinformation each year, and the line shows the ratio of the tweets containing misinformation within the total number of tweets of opposed stance each year.

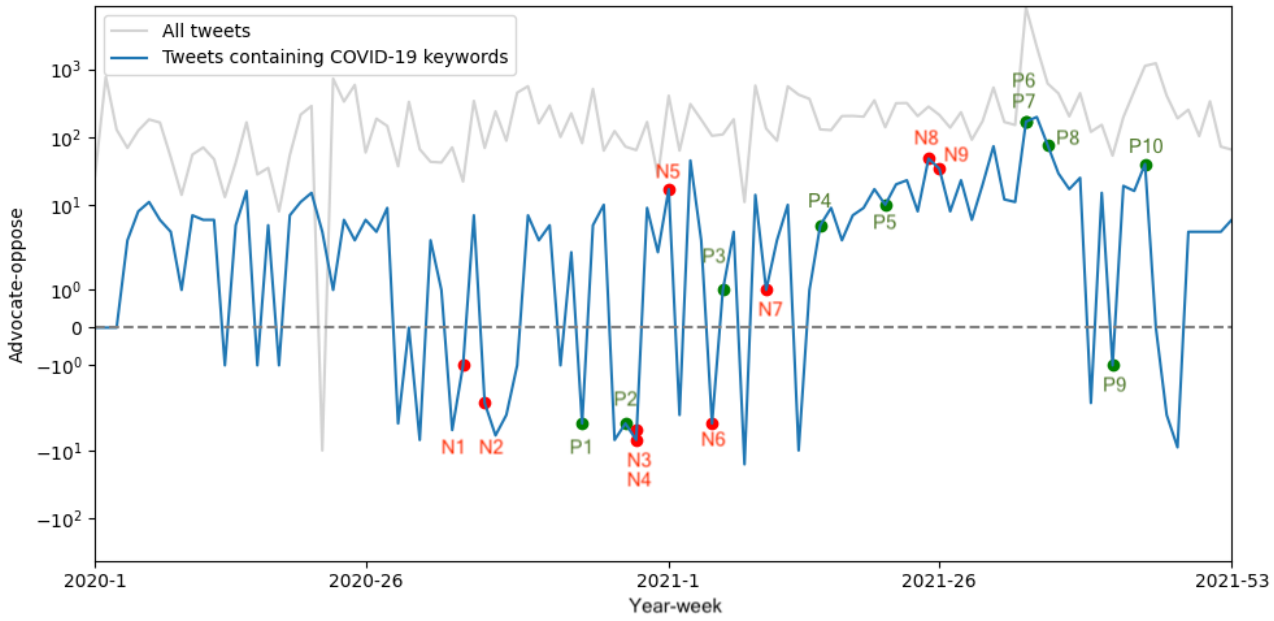
Relationship Between HPV Vaccination and COVID-19

We conducted a weekly time series analysis of tweets containing COVID-19 keywords, as illustrated in Figure 7. There are no tweets with "COVID-19" keyword in the first 2 weeks of 2020, so all the calculations began from the third week. The Pearson correlation coefficient (r) was 0.793 (P=1.59×10^{-23}), indicating a relatively high correlation between all tweets and those containing "COVID-19" keywords. The time lag for the highest cross-correlation was zero. Several peaks in both all tweets and tweets containing "COVID-19" keywords were observed in 2021 (week 3, weeks 34-35, and week 45), with the 34th-35th weeks exhibiting the highest peak during the entire study period, which coincided with a campaign to call for resumption of active HPV vaccination recommendations [57] (95% CI 37.0%-39.8% HPV vaccine-related tweets; 95% CI 1.5%-9.1% tweets with "COVID-19" keywords).

Figure 7. Number of all tweets related to human papillomavirus vaccine (gray), and the tweets containing the "COVID-19" keywords (blue), with key events related to COVID-19 vaccine marked. The points beginning with "N" are negative key events that may lead to opposition to COVID-19 vaccines, and the points beginning with "P" are positive key events that may lead to advocacy to COVID-19 vaccines.

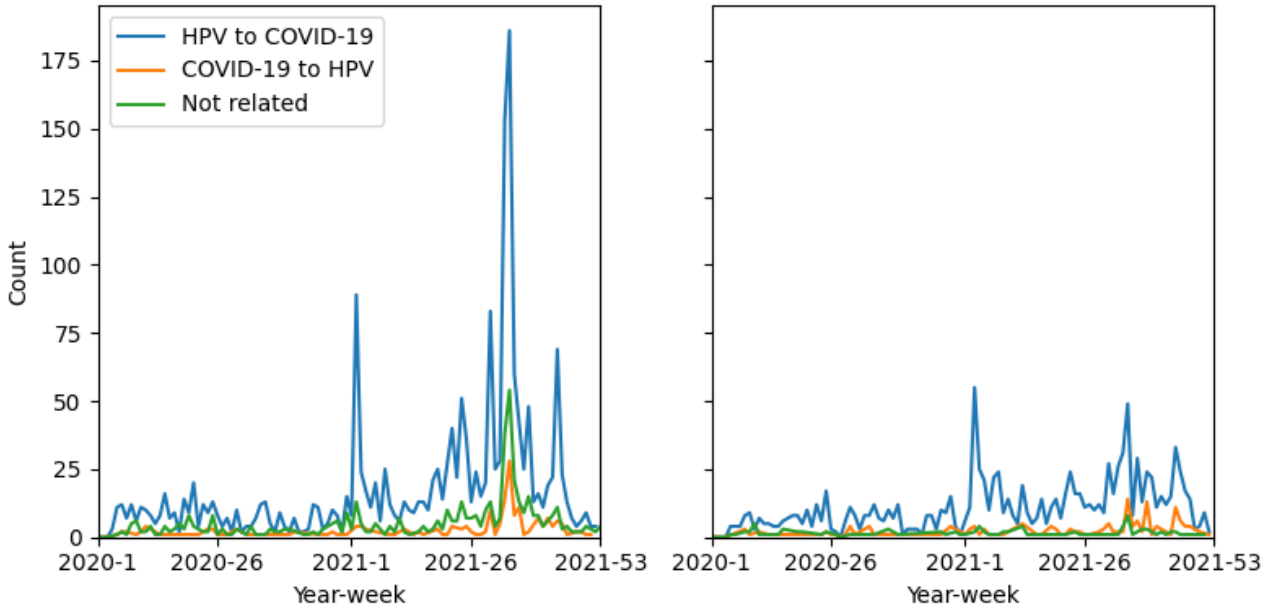


A comparative analysis was performed to examine the differences between advocate and opposed stances in both the overall tweet corpus and the subset containing the "COVID-19" keyword, as illustrated in Figure 8. The r between advocate and oppose sentiment differences is substantial (r=0.723; P=6.09×10^{-18}), with no temporal lag observed in the highest cross-correlation. In the broader context of all HPV

XSL•FO
RenderX

vaccine–related tweets, advocacy sentiments generally prevailed over opposing sentiments. However, for tweets containing "COVID-19" keywords, the dominant stance fluctuated over time. Both datasets exhibited a pronounced peak in advocacy during weeks 34-35 of 2021, whereas opposing sentiments dominated in week 22 of 2020 for all tweets.

Figure 8. The difference between tweets of advocate stance and oppose stance for all human papillomavirus vaccine tweets (gray) and tweets containing the "COVID-19" keyword (blue), with key events related to COVID-19 vaccine marked. The points beginning with "N" are negative key events that may lead to opposition to COVID-19 vaccines, and the points beginning with "P" are positive key events that may lead to advocacy to COVID-19 vaccines.



We additionally assessed the impact of COVID-19 vaccine–related events on the volume of all HPV vaccine–related tweets and tweets containing the keywords "COVID-19." Details of the key events were gathered from Japan Broadcasting Corporation (NHK) [58] and are provided in Table S1 in Multimedia Appendix 2. As illustrated in Figure 7, it is evident that the key events do not consistently result in peaks in tweet volume for both all HPV vaccine–related tweets and tweets containing the keywords "COVID-19." Furthermore, as depicted in Figure 8, positive and negative events do not always lead to an increase in the number of supportive or opposing stances.

LDA was conducted on tweets containing COVID-19 keywords advocating for and opposing stances. Multimedia Appendix 2 shows detailed results. To investigate nuanced changes in topic weights over time, the expectation of tweets belonging to different topics for both advocate and opposition stances was calculated, as shown in Multimedia Appendix 2. Analysis of these data revealed no significant changes in the proportions of different topics between 2020 and 2021.

Finally, we investigated the potential causal relationship between attitudes toward HPV and COVID-19 vaccines using logical analysis. To evaluate the accuracy of Claude-3-opus in performing the classification task without fine-tuning, we randomly sampled 100 tweets 3 times and allowed 3 volunteers to judge the correctness. The accuracy is 95% CI 72.92%-91.74%. The weekly classification results are shown in Figure 9. The "HPV to COVID-19" category predominated throughout the entire study period for both supportive and opposing stances. Notably, tweets advocating for vaccines consistently outnumbered those opposing vaccines across all categories.

Figure 9. Weekly number of tweets with "COVID-19" keywords, using HPV vaccine as example to share stance to COVID-19 vaccine ("HPV to COVID-19"), using COVID-19 vaccine as example to share stance to HPV vaccine ("COVID-19 to HPV"), or neither ("Not related") in 2021. (A) Result on tweets with advocate stance. (B) Result on tweets with opposed stance. HPV: human papillomavirus.

Discussion

Principal Findings

In this study, we used traditional NLP models and LLMs to perform a stance analysis of social media content, focusing on the public discourse around the HPV vaccine. Our findings demonstrate that LLMs provide a more nuanced understanding of public attitudes than traditional sentiment analysis, revealing critical insights into factors influencing vaccine hesitancy, such as confidence, complacency, and convenience. Specifically, we observed a slight increase in public advocacy and vaccine confidence toward HPV vaccines over time, influenced by policy decisions, media coverage, and public communication efforts. The WHO's 3Cs model (Confidence, Complacency, and Convenience) proved instrumental in framing these dynamics and offers a pathway for policy makers to address vaccine hesitancy in Japan. We also observed some evidence of the positive influence of stance toward HPV vaccine on the stance toward COVID-19 vaccine.

Confidence pertains to trust in the vaccine's safety, efficacy, and the health care system responsible for its administration and plays a key role in the stance toward the HPV vaccine in Japan. In our analysis, we observed significant fluctuations in the public stance toward the HPV vaccine, which were closely linked to government policy decisions and media coverage. The 2013 suspension of the HPV vaccine recommendations by the Japanese government was a key moment that led to a sharp decline in public trust. This decline can be attributed to increased public uncertainty and fear regarding vaccine safety, as shown in the time series analysis. The LDA topic modeling results also support this, showing a decline in the proportion of tweets related to "HPV Vaccine Efficacy and Public Health Initiatives" (topic 2) where the stance is unknown after 2013, while "Opposition, Misinformation, and Activism Surrounding HPV Vaccination" (topic 3) gradually became the predominant theme since 2018, highlighting growing public distrust and misinformation. Conversely, the resurgence of advocacy in 2020 reflected an improvement in public confidence, which likely influenced efforts to reinstate vaccine recommendations. This is directly shown by the exponential increase in vaccine supply and vaccine uptake and also reflected in the increased proportion of tweets related to "Scientific and Media Discourse on HPV Vaccine Safety" within the advocacy stance, which showed a significant increase until 2015, followed by a gradual decline, indicating ongoing advocacy efforts. Our findings illustrate that confidence is highly sensitive to policy decisions and that restoring public trust after a decline requires consistent and clear communication.

Furthermore, we explored the role of misinformation in undermining public confidence regarding HPV vaccinations. The spike in the ratio of tweets containing misinformation in 2012 likely contributed to the significant drop in vaccine confidence observed the following year, which aligns with findings from other studies [59-61]. From 2014 onward, the ratio of misinformation exhibited slight changes but remained consistent. The overall number of misinformation tweets increased in most years, indicating the persistent and long-lasting impact of misinformation. Therefore, addressing misinformation is essential for restoring and maintaining public trust in vaccines, because unchecked misinformation can severely erode public confidence and contribute to vaccine hesitancy.

Complacency refers to the perceived necessity of vaccination, which diminishes when individuals consider the risk of vaccine-preventable diseases low. Adjei Boakye et al [62] found that "not necessary" was consistently among the top reasons cited by parents for not vaccinating their children against HPV between 2010 and 2020. The topic "HPV Vaccine Efficacy and Public Health Initiatives" under the "unknown" stance experienced a sharp decline post-2013, indicating diminished public engagement and perceived necessity. The perceived low

XSL•FO
RenderX

risk of HPV, combined with concerns about its side effects, may contribute to a reduced sense of urgency regarding vaccination. However, our time series analysis showed that complacency began to decrease in 2020 as advocacy efforts intensified, and the public became more aware of the risks of HPV and the benefits of vaccination. The upward trend in the topic "HPV Vaccine Effectiveness and Broader Public Health Measures" within the "advocate" stance since 2015 further reflects this shift toward increased awareness and decreasing complacency. This shift underscores the importance of proactive communication regarding the risk of vaccine-preventable diseases to counteract complacency.

Convenience encompasses factors such as availability, affordability, and accessibility of vaccination. In our study, the importance of convenience became evident when analyzing the periods of increased advocacy for HPV vaccination. The vaccine doses injected surpassed the doses supplied in 2020 and 2022, indicating that the inject number may be limited by the supply. Also, the resurgence of advocacy in 2020 coincided with governmental initiatives aimed at improving access to the HPV vaccine, including the reintroduction of public recommendations and enhancement of vaccination services. This alignment is reflected in the relatively stable proportion of tweets related to the topic "Policy and Advocacy for HPV Vaccination Promotion" within the advocacy stance, which exhibited a slight upward trend since 2019. These changes may encourage efforts to facilitate access to vaccination services and play a critical role in influencing public willingness to get vaccinated over time.

In addition to the findings regarding the HPV vaccine, we also noticed that stances toward the HPV vaccine may influence stances toward the COVID-19 vaccine during the COVID-19 pandemic. Specifically, our logical analysis revealed that increased confidence in the HPV vaccine might lead to higher confidence in the COVID-19 vaccine. Tweets categorized under "HPV to COVID-19"—which used the HPV vaccine as a reference point for the COVID-19 vaccine stance—predominated throughout the study period for both supportive and opposing stances. Notably, vaccine advocacy consistently outnumbered opposition across all categories, suggesting that rising confidence in one vaccine may positively affect confidence in others.

The findings of this study provide actionable insights for public health policies and interventions in Japan. First, improving confidence in vaccines requires transparent and consistent communication from government bodies and health care professionals, particularly during crises. Proactively addressing misinformation through targeted campaigns on social media can help rebuild public trust. To tackle complacency, educational programs highlighting the risks of HPV and the benefits of vaccination should be prioritized. Finally, enhancing convenience by ensuring vaccine availability, affordability, and accessibility—such as expanding vaccination services and public recommendations—can significantly increase uptake. The policy makers should also keep in mind that vaccine hesitance in one disease can affect all vaccines. These strategies collectively align with the WHO's 3Cs model to combat vaccine hesitancy effectively.

Our results demonstrate that stance analysis using LLMs provides a more nuanced understanding than traditional sentiment analysis. Unlike traditional sentiment analysis, which captures general emotional tones, LLMs can identify specific stances such as supportive, opposing, or neutral positions, allowing for a deeper comprehension of public attitudes and decision-making processes. Moreover, the successful application of LLMs highlights their potential as powerful tools for social media analysis, providing deep insights into public health discourse by capturing more complex logic, such as causality and context-specific nuances. These results not only validate the effectiveness of our methodology but also provide strong empirical support for using LLMs for similar tasks in the future.

In future work, we plan to explore why LLMs outperform traditional models by focusing on factors such as the model size and external information. We are also considering building an LLM to identify misinformation regarding HPV vaccines with higher accuracy. We also plan to collect social media data about other vaccines such as COVID-19 to make more solid causality analysis toward the relationship among attitudes toward vaccines. These efforts have refined our understanding of LLMs and improved public health strategies.

Limitations

Our study has several limitations, including the fact that social media users may not represent the entire population, which limits the generalizability of our findings. We used only X (Twitter) data in this research, which may also affect the representativeness. In addition, these models may introduce classification errors, particularly when addressing nuanced or ambiguous stances and logic. Other factors including but not limited to the biased training data, outdated information, domain adaptation issues, and hallucinations of the LLMs can also lead to inaccuracy of the statistical results. In the logic analysis of relationship between attitudes toward HPV and COVID-19 vaccine, lacking data related to COVID-19 vaccine, we are not able to further prove the causality with methods such as Granger causality tests or structural equation modeling. Furthermore, the keywords used to collect data may have led to the omission of relevant tweets or the addition of irrelevant tweets, potentially affecting the comprehensiveness of our analysis.

Comparison With Prior Work

Our work stands out from prior studies because of the scale and depth of the dataset, which includes 10 years of tweets in Japanese, providing a comprehensive view of public attitudes over time. We applied both traditional NLP methods and cutting-edge LLMs, which allowed us to analyze nuanced shifts in public sentiment and stance with greater precision. Unlike traditional surveys that provide snapshots of attitudes, our approach captures real-time changes in public discourse. Furthermore, compared with studies relying on Google search trends, our analysis offers more fine-grained insights into specific stances and topics, highlighting not just information-seeking behavior but also the underlying attitudes that drive vaccine hesitancy or advocacy.

XSL•FO
RenderX

Conclusions

In this study, we provided a decade long examination of public discourse on HPV vaccination in Japan by analyzing social media content with traditional NLP models and LLMs. We also contextualized the complex factors influencing stances toward HPV vaccines under the WHO's 3Cs model. Public confidence fluctuated significantly in response to government actions and media coverage, indicating the sensitivity of trust in policy decisions, whereas complacency was affected by perceived risks and proactive advocacy. Convenience is crucial for improving vaccine accessibility and for shaping the public's willingness to be vaccinated. Moreover, we provided some evidence showing that confidence in one vaccine, such as HPV, may influence confidence in others, such as COVID-19, highlighting interconnected public health narratives. Addressing misinformation, enhancing communication, and improving accessibility remain the key strategies for building trust and reducing hesitancy. Future public health strategies can benefit from these insights by designing effective interventions to boost vaccine confidence and uptake.

Abstract

Background: Social media data provide a valuable opportunity to explore the effects that Alzheimer disease (AD) has on care partners, including the aspects of providing care that have the greatest impacts on their lives and well-being and their priorities for their loved ones' treatment.

Objective: The objective of this social media review was to gain insight into the impact of caring for someone with AD, focusing particularly on impacts on psychological and emotional well-being, social functioning, daily life and ability to work, health-related quality of life, social functioning, and relationships.

Methods: We reviewed social media posts from 4 sources—YouTube (Google), Alzheimer's Association, Alzheimer Society of Canada, and Dementia UK—to gain insights into the impact of AD on care partners. English-language posts uploaded between May 2011 and May 2021 that discussed the impact of AD on care partners were included and analyzed thematically.

Results: Of the 279 posts identified, 55 posts, shared by 70 contributors (4 people living with AD and 66 care partners or family members), met the review criteria. The top 3 reported or observed impacts of AD discussed by contributors were psychological and emotional well-being (53/70, 76%), social life and relationships (37/70, 53%), and care partner overall health-related quality of life (27/70, 39%). An important theme that emerged was the emotional distress and sadness (24/70, 34%) associated with the care partners' experience of "living bereavement" or "anticipatory grief." Contributors also reported impacts on care partners' daily life (9/70, 13%) and work and employment (8/70, 11%). Care partners' emotional distress was also exacerbated by loved ones' AD-related symptoms (eg, altered behavior and memory loss). Caregiving had long-term consequences for care partners, including diminished personal well-being, family and personal sacrifices, loss of employment, and unanticipated financial burdens.

Conclusions: Insights from social media emphasized the psychological, emotional, professional, and financial impacts on individuals providing informal care for a person with AD and the need for improved care partner support. A comprehensive understanding of care partners' experiences is needed to capture the true impact of AD.

Introduction

Alzheimer disease (AD) is the most common form of dementia [1]. Worldwide, an estimated 55 million people were living with AD in 2019, and by 2050 a projected 139 million people will be living with AD [2]. Common symptoms of AD include memory impairment, disorientation, loss of function, and mood or behavior changes [3]. In the final and most severe stage of dementia, cognitive and functional abilities are significantly impaired, resulting in an increasing need for care and support [4]. Most individuals caring for a person living with AD are informal care partners (ie, a relative or a friend), and globally more than 70% of informal care hours are provided by women [5].

Caring for someone with AD can impact on care partners' health-related quality of life (HRQOL) and emotional well-being [6-10]. Care partners experience an increased burden and more distress as AD severity increases [11-14] and may experience a greater burden than care partners for individuals with other chronic diseases [15]. There is also evidence that care partners experience greater activity impairment, absenteeism (ie, absence from work), impairment related to presenteeism (ie, reduced productivity while at work), and overall work impairment than individuals who are not care partners [16]. Effective disease-modifying treatments for AD are beginning to emerge, representing the potential to address the unmet needs for those living with AD and their care partners. To inform treatment goals in AD and fully characterize the potential value of emerging treatments, it is important to understand the practical, emotional, and financial impacts of the disease, particularly on loved ones providing informal care.

Previous research has evaluated the indirect cost implications of providing informal care to people living with AD or evaluated the caregiving burden using clinical outcome assessments [5,6,16,17]. However, these evaluations do not represent the lived experiences of care partners, the aspects of providing care that have the greatest impacts on their lives and well-being, or their priorities for their loved ones' treatment. Social media data provide a valuable opportunity to explore the impacts that AD has on care partners outside the formal research context. The objective of this study was to gain insight into the impact of caring for someone with AD, with a particular focus on impacts to daily activities, psychological and emotional well-being, HRQOL, work and finances, social functioning, and relationships.

Methods

We conducted an iterative pragmatic review of publicly available social posts shared on global platforms (eg, YouTube [Google]), as well as advocacy websites and independent blogs and forums of interest, with relevant data on the care partner experience of AD.

Data Identification and Collection

The following parameters were used to guide the manual identification and collection of social media data:

1. Date range: A historical search of social media posts sourced from May 2011 to May 2021.

2. Language: English language only.

3. Media types: YouTube, news blogs, patient organizations, forums, and comments.

4. Different combinations of keywords were used to optimize the approach for identifying social media posts relevant to the project objectives. Key search terms and potential search strategies are presented in Table 1.

Table 1. Social media review key search terms and potential search strategies.

Concept	Key search terms	Example potential search strategy [a]
Care partner experience	"caregiver", "care-partner", "carer", "family*", "husband", "wife", "story", "journey", "narrative", "experience", "diary", "blog", "forum"	(caregiver OR care-partner OR carer OR family OR husband OR wife) AND (story OR journey OR narrative OR experience OR diary OR blog OR forum)
AD[b]	"Alzheimer*", "dementia", "senile", "mild cognitive impairment", "early onset dementia", "cognitive dysfunction", "neurocognitive disorder", "cognitive impairment", "memory clinic"	(Alzheimer* OR dementia OR senile OR mild cognitive impairment OR early onset dementia OR cognitive dysfunction OR neurocognitive disorder OR cognitive impairment)
Impact of AD on care partner	"impact", "burden", "effect", "quality of life", "family life", "family activities", "relationships", "health", "money", "money worries", "expense", "expensive", "cost"	(impact OR burden OR effect OR quality of life OR family life OR family activities OR relationships)

[a]Boolean operators were used where supported by search function.

[b]AD: Alzheimer disease.

In addition to YouTube, a total of 6 advocacy websites were identified as containing potentially relevant data; the terms and conditions of each website were reviewed. Only publicly accessible videos and comments were reviewed from YouTube; that is, no videos that required logging into YouTube or required the researcher to subscribe were collated. Each of the advocacy websites was contacted to ask for permission to include the data posted on their website in the review. In total, 3 advocacy websites granted permission, and 3 either refused permission or were unresponsive to the request. Only advocacy websites that granted permission to be included in the review—Alzheimer's Association, Alzheimer Society of Canada, and Dementia UK—were accessed.

The target population for review included people with a self-reported diagnosis of AD and care partners or family members of people with a self-reported diagnosis of AD. Video footage and discussion blogs were manually reviewed by

XSL•FO
RenderX

experienced qualitative researchers to determine eligibility for inclusion in the review. The prespecified eligibility criteria for the social media posts are presented in Textbox 1.

Textbox 1. Social media post inclusion criteria.

- The contributor has a self-reported diagnosis of mild cognitive impairment or dementia due to Alzheimer disease (AD) or is a self-reported carer or care partner or a family member of someone with mild cognitive impairment or dementia due to AD.
- At the time of the post, the contributor was an adult (aged 18 years or older). Where age was not reported, the contributor's adult status was researcher-determined based on post content and video images.
- The post is relevant to the contributor's experience of caring for someone with AD, including the impact of their AD treatments or management.
- Posts are in the English language.
- Post was uploaded between May 2011 and May 2021.

Data Extraction

The social media posts (ie, videos and comments posted on YouTube and patient stories posted on the 3 selected advocacy websites) were reviewed manually by experienced qualitative researchers, and relevant social media data were extracted and recorded within a Microsoft Excel spreadsheet for analysis. Each post, blog, video, or comment included in the review was given a unique source identification number, and each contributor was assigned a unique contributor identifier. An initial deductive approach used a top-level coding framework to organize the extracted social media data by key themes, such as symptoms, disease history, HRQOL impacts, and treatment experience. Throughout the data extraction process, the research team met regularly to review and reflect on the data extracted. These points of researcher reflection included cross-checking contributor characteristics to ensure that any contributors who had posted across multiple platforms had not been double counted and only new information had been extracted in the second record, as well as a topline quality review of the data extracted. These sessions also allowed for the researchers to harmonize on the data extraction process.

Data Analysis

Once all the social media data had been extracted and categorized using the top-level framework, the data were reviewed qualitatively by 2 researchers (RC and RM). A reflexive thematic analysis [18] of the aggregated social media data extracted from the posts was conducted, in which a theme was described as content that captured data relevant to the research objectives. Specifically, a deductive approach was initially used to code the social media data to address the study objectives, and descriptive codes were used to capture the concepts of interest. The coded data were then inductively analyzed within and across each category, with new codes added as concepts emerged from the data. This "bottom-up" approach is synergetic with the unsolicited and unregulated nature of social media data, as the approach allows the data to direct the analysis and the identification of new and important findings not predetermined by the research scope. Concepts were then used to generate patterns in the way that care partners described their experiences and perceptions related to looking after someone with AD. Patterns that emerged within and across the data were used to develop themes, with care partner experiences and perceptions summarized within each key theme.

The analysis approach and findings were reviewed by a third independent researcher (LD), and the interpretation of the social media data and the identification of themes and concepts were discussed to ensure the confirmability of the results. Once the themes and concepts were agreed, where appropriate, descriptive summaries were accompanied by frequency counts (and percentages) of the number of contributors discussing a specific theme.

Demographic information (eg, gender and age) was extracted, along with any accompanying disease information, where available. Notably, because social media data exist outside the research context, key demographic and diagnostic characteristics were not always available for contributors.

Ethical Considerations

This study was submitted to RTI International's institutional review board committees for ethical approval and was determined not to constitute research involving human participants (STUDY00022118). No informed consent was obtained, as the data analyzed in the study are publicly available. No personally identifiable information was included in the analyses. Modified quotations (supporting statements) are used to illustrate the key themes that emerged from the social media data. Modified quotations are used to ensure that the anonymity of the contributor is maintained, and their identity is protected. There were no participants to be compensated, as this study did not constitute research involving human participants.

Results

Post and Contributor Characteristics

Of the 279 social media posts identified, 55 met the review criteria (21 blog posts, 21 videos, and 13 comments) (Figure 1); the remaining posts were excluded from the review because they did not meet the criteria for inclusion (eg, no relevant data included within the post, outside the prespecified date range). The 55 posts were shared by 70 contributors (4 people living with AD and 66 care partners or family members) who discussed self-reported or observed impacts of AD on care partners and family members. Table 2 provides the gender and age of contributors by contributor type (ie, care partner or family member and person living with AD) and for the total sample. Contributor age at the time of the social media post was not widely available; 90% (63/70) of contributors did not report their age in the social media post.

Impact of AD on Care Partners

A range of impacts of AD on care partners and family members was discussed in the social media posts shared by the 70 contributors. The 3 most frequently reported or observed impacts of AD on care partners and family members were noted in relation to care partners' psychological and emotional well-being (53/70, 76%), their social life and relationships (37/70, 53%), and their overall HRQOL (27/70, 39%). Contributors also reported impacts on care partners' daily life (9/70, 13%), work and employment (8/70, 11%), and physical health (5/70, 7%). The key impacts of caring for someone with AD on care partners and family members that emerged from the social media data are summarized in Figure 2.

Figure 2. Key impacts of Alzheimer disease on care partners and family members reported by a person living with Alzheimer disease, care partner, or family member (n=70). AD: Alzheimer disease; ADL: activity of daily living; QOL: quality of life.

XSL•FO
RenderX

Emotional and Social Impacts

Care partner or family member contributors discussed a range of emotions experienced in relation to caring for someone with AD. Contributors noted feelings of frustration, concern, and fear in relation to the progressive symptoms of AD (eg, memory loss and delusions) and subsequent changes in behavior (eg, repetitive questions and aggression). The behavioral symptoms of people living with AD had a substantial impact on care partners and family members; 6 out of 70 (9%) care partner or family member contributors reported that the person living with AD had become aggressive and displayed violent behavior toward them. Furthermore, 1 contributor noted the need for patience when caring for someone with AD, and another highlighted that the primary care partner experience was a lonely existence regardless of support from family and friends.

The most profound impact on the psychological and emotional well-being of care partners and family members was the emotional distress and sadness (24/70, 34%) associated with the phenomenon of "living bereavement" or "anticipatory grief," that is, grieving the loss of a person even before their physical body dies [19]. The deterioration of the memories and personhood for the person living with AD was a traumatic and heartbreaking experience for care partners and family members, who had to witness the gradual loss of their loved one. Several contributors noted that, while the person living with AD was still alive, they were grieving their loss due to the significant changes in the person's mental health as well as their cognitive and physical functioning. This was particularly salient for care partners and family members of people with early-onset AD, who "lost" their loved one earlier than anticipated; one family member described feeling that his mother had been "missing" for most of his life. The final stages of AD were also distressing for care partners and family members, who described the person living with AD as a "shell" that was simply waiting to "shut down." Their loved one's death presented care partners and family members with contrasting emotions—relief that their duty of care was now complete but sadness because the last vestiges of the person were gone. One care partner noted that the grief they experienced once their loved one had died was different from the "living grief" they had endured while the person had been alive.

Over 50% of the contributors (37/70, 53%) noted that caring for someone with AD had an impact on the social life and relationships of the care partner or family member. The impact of AD on the relationship between the care partner and the person living with AD was discussed by 9 out of 70 (13%) care partners or family member contributors, specifically the strain on or deterioration of this relationship. For care partners of parents with AD, this entailed a loss of their parental relationship and its associated support system, whereas for care partners of spouses with AD, this meant the loss of intimacy with their partner. Another key theme was the impact of care responsibilities on the relationships between the care partner or family member and their wider family (9/70, 13%). The duty of care for the person living with AD took precedence in family life; contributors noted that they would have to "sacrifice" their own family needs to accommodate their care partner obligations. However, care partner or family member contributors stressed the importance of family support (8/70, 11%) for the care partner, particularly shared family responsibility for care for the person living with AD, which helped to strengthen familial bonds. Changes in family dynamics were another component that emerged from the social media data in relation to the impact of AD on the social life and relationships of care partners and family members (6/70, 9%). Care partners and family members experienced a role change within the family unit, and family members were expected to assume additional responsibilities to adjust to the new family "norm." Care partners and family members discussed the impact that their care responsibilities had on their social life (2/70, 3%). One care partner commented on changes to their relationships with friends; although some friends provided support, others did not; ultimately, their social circle decreased in size.

Impact on Daily Life and Ability to Work

Out of 70, 9 (13%) contributors commented on the detrimental impacts on care partners' and family members' daily lives because of the responsibility of caring for a person living with AD. Direct responsibility for the self-care needs of the person living with AD (eg, feeding, bathing, and toileting) was noted by 5 (7%) contributors, whereas 1 (1%) contributor commented that they provided assistance to the person living with AD to enable the individual to perform their own daily activities. Contributors also reflected on the challenges experienced by care partners and family members to perform their own daily activities (2/70, 3%), including interference resulting from the person living with AD's cognitive symptoms (eg, forgetting where they had moved objects) or the minimal time available for care partners and family members to focus on their own needs.

Contributors commented on the disruption that caring for a person living with AD had on their ability to work (8/70, 11%). Half of these contributors (n=4) noted that they had to stop working or were unable to work because of their care partner duties. For others (n=4), it necessitated a change to the structure of their work life, such as reduced working hours, working from home, less work-related travel, and flexible working hours to accommodate the care needs of the person living with AD. Although some employers were able to accommodate the need for a flexible work-life approach, this was not always possible. Care partners noted that there were limited career choices that would permit the flexibility needed to provide care.

Impact on Well-Being and HRQOL

The stress or burden of caring for a person living with AD was attributed to a deterioration in the care partners' own physical health (3/70, 4%). The prioritization of the person living with AD's well-being resulted in cases of care partner illness, hospitalizations, and diminished well-being (2/70, 3%). However, 2 care partners out of 70 (3%) recognized the importance of prioritizing their own health, as well as the health of the person living with AD, and made positive lifestyle changes (eg, increased exercise and reduced alcohol consumption) to maintain and improve their physical health. This positive approach was considered by 1 care partner out of 70 (1%) to be the most effective plan to provide long-term care for her husband.

XSL•FO
RenderX

Care partners' and family member contributors' overall HRQOL and anticipated future life plans were hindered by their responsibility as a care partner and the needs of the person living with AD. Care partner and family member contributors (9/70, 13%) noted that the responsibility of caring for a person living with AD was multifaceted as it required balancing their care responsibilities with their family roles and obligations, arranging additional support or developing a contingency plan if they were incapacitated for any reason, and handling the logistical duties associated with the person living with AD's end of life (eg, reviewing wills, insurance policies, and mortgages). Caring for the needs of the person living with AD became the main priority in the care partner's life (6/70, 9%) and, according to some contributors, required complete dedication "24 hours, 7 days a week." Furthermore, 1 care partner contributor noted that she had dedicated 10 years of her life to self-education on AD and caring for her partner. However, the progressive nature of AD and the unpredictability of AD symptoms (6/70, 9%) meant that care partners had to continuously adapt to the changes in the behavior and symptoms of the person living with AD. The need to adapt to the person living with AD's circumstance was highlighted by 4 contributors out of 70 (6%), who noted that they had made significant changes to their lives (eg, relocation and renovation of existing home) to accommodate the needs of the person living with AD. Ultimately, providing care for someone with AD had long-term consequences on the lives of care partners and family members; out of 70, 4 (6%) contributors discussed how their lives had deviated from their anticipated life path (eg, career change and moving back in with parent).

Care Partners' Experiences of AD Treatment and Management

Care partners and family member contributors discussed treatment hopes or expectations (3/70, 4%). The potential development of a cure for AD was appealing for contributors, as was the potential for a novel treatment that could slow disease progression. In addition, 2 care partner contributors commented on the importance of involving the person living with AD in treatment decisions. Contributors' discussions pertaining to decision-making in AD management focused predominantly on the factors that premeditated the decision by care partners and family members as to whether the person living with AD required formal full-time medical care at inpatient care facilities (6/70, 9%). Key factors discussed in the difficult decision to transfer an individual with AD from informal "at-home care" to formal "inpatient care" included crisis events or the realization that the needs of the person living with AD and the disease progression could be accommodated only with inpatient facility care (4/70, 6%).

Among the 13 contributors out of 70 (19%) who commented on the burden on care partners and family members associated with AD treatments or management, three key themes emerged, such as (1) limited support for care partners (6/70, 9%), (2) financial challenges (5/70, 7%), and (3) travel burden (3/70, 4%). Contributors commented on the challenges associated with navigating different services and health care systems (eg, difficulties accessing treatments or management options and benefits); 3 contributors (4%) lamented the absence of a single point of contact for assistance with access to treatment or management information and support. For these contributors, the process of navigating the health care system was time-consuming and created additional stress for themselves and the wider family. This process was further complicated by the contributor-perceived limited support for the diverse population of people living with AD, such as non–English-speaking individuals, people with early-onset AD, and people with AD who live in rural areas. Difficulties experienced with navigating or accessing AD-specific care services were also a factor contributing to the substantial financial responsibility assumed by care partners and family members. Contributors noted that they had not anticipated or planned for the high costs associated with the care needs of a person living with AD (ie, full-time care, memory care facilities, and assisted living). Furthermore, 1 care partner highlighted the difficult choice between becoming a full-time carer for the person living with AD and having the ability to meet that person's financial needs. Another aspect of the burden of AD treatment or management on care partners was the considerable time commitment required to accompany the person living with AD to their frequent medical appointments.

Discussion

Principal Findings

The social media data collected in this study yielded insights into the impact to care partners and family members of providing care for people living with AD and the management of the disease. While positive elements associated with providing care for a person living with AD were discussed in the social media data, the posts emphasized in particular the concept of "living bereavement" or "anticipatory grief" for care partners and with that the need for improved coping strategies and interventions to enable care partners to better manage this phenomenon. Anticipatory grief permeates the experience of the care partner, which can involve decades of providing care for the person living with AD [19]. Accordingly, previous research has highlighted that it is important to consider anticipatory grief in conceptual models of care partner burden to help clarify how different stressors influence individual care partner outcomes and to enhance the understanding of the care partner experience [20].

Care partners' and family members' candid posts also highlighted the psychological, social, and financial impairments associated with becoming a care partner. Contributors reflected on the role of caring for a person living with AD as a full-time commitment and responsibility in which the needs of the person living with AD were often prioritized to the detriment of the care partner's own needs, family life, and well-being. Providing care could also result in potentially daunting financial challenges and concerns.

Care partners' treatment hopes and expectations, as expressed in the social media posts, focused predominantly on the possibility of a curative treatment in the future but also on the immediate need for treatments that could slow or prevent disease progression. Care decisions focused principally on the difficult and often distressing determination by care partners or family members that the person living with AD was now at a stage

XSL•FO
RenderX

where they would benefit from formal full-time medical care at an inpatient care facility. AD treatments and management strategies had a substantial burden on care partners and family members; contributors noted limited support available for care partners and the financial and travel challenges associated with the management and treatment needs of a person living with AD.

Findings from the social media review are broadly consistent with the published evidence on the experiences of care partners in AD. Notably, studies conducted in the United States, Brazil, China, and Japan have found that care partners of people living with AD experience depression, anxiety, and high levels of stress [7-10]. For example, a study evaluating the experiences of 125 US care partners and 60 demographically similar control participants (non–care partners) found care partners more likely than control participants to experience clinically significant depression (40% vs 5%), and 26% of care partners used antidepressants [7]. Our results provide additional and unique insights into the individual contributor experiences underlying the emotional impacts of providing informal care for a loved one with AD.

Of note, it has been estimated that time spent providing informal care for people with AD amounted to 82 billion hours in 2015, equivalent to more than 40 million full-time workers, and this number is projected to increase to the equivalent of 65 million full-time workers by 2030 [5]. Further, a majority of informal care partners in AD are women [5], who may experience disproportionate impacts to their professional lives and opportunities as they manage their care responsibilities. Insights from social media contributors complement this evidence by providing rich data on care partners' lived experiences and the impacts they experience beyond time spent caregiving and indirect impacts to their work productivity.

Care partner contributors also expressed frustrations with navigating the health care system, in particular with the lack of a single point of contact for access to treatment. This consistent unmet need for people living with AD and their care partners is well-recognized in the AD community. Improving the AD care journey for individuals living with AD and their care partners was a strategic recommendation in the Alzheimer's Disease International's 2022 World Alzheimer's Report, but implementation is still limited in many countries [2].

The emergence of novel therapies offers the promise of slowing or halting disease progression for people living with AD. To comprehensively evaluate the value of novel therapies, it is critical to first document the magnitude of the societal impact of AD; however, the qualitative experiences and perspectives of informal care partners in AD have been underrecognized and can be challenging to measure via traditional research methods. Insights from this social media review, which is underpinned by published evidence on the care partner experience, provide unsolicited insights into care partners' experiences with the practical, emotional, and financial challenges they face, and provide directions for future research to explore these impacts through formal research channels. Ultimately, as the therapeutic landscape evolves, the perspectives of care partners, as well as people living with AD, should be integrated into value assessment frameworks in AD [21].

This social media review provides a unique approach to exploring the experiences and challenges associated with caring for people living with AD potentially not captured through traditional research methods. Nonetheless, limitations of the methodology are noted. First, social media data are not driven by any specific research question or objective; thus, they exist outside the formal research context. There is an inherent reliance on contributor self-identification and self-reported diagnoses that are not verifiable. Social media data were retrospectively collected from posts in the public domain; information pertaining to contributor demographic characteristics, location information and access to care, and the clinical characteristics of their loved one with AD or the level of insight about their disease was not consistently available. Limitations of sample size must be considered; some of the themes identified from the social posts are based on a small number of contributors, and the degree to which the theme is relevant to the wider populations of people living with AD and care partners could be challenged. Different platforms are used by different demographic groups, and there is a potential bias toward populations who are more likely to use the specific sites selected for the review, more likely to reside in the included countries, or more likely to be engaged and proficient with digital technologies. Furthermore, only English-language posts were reviewed. Finally, there is the potential for self-selection and publication bias.

Conclusions

The candid social media posts from 70 contributors provide valuable insights on the responsibilities and complications of caring for someone with AD, as well as the shortcomings of current AD programs to sufficiently support care partners in successfully balancing the dichotomy of their caregiving role and their own personal needs. It is critical to understand the true impact on care partners of providing informal care—including difficulties with their health and well-being, emotional and social functioning, and professional lives—and the unmet needs that they face. With this understanding, we may begin to define AD care models to support care partners as they navigate the AD care journey with their loved one. Furthermore, characterizing the care partner experience positions the AD research community to define and measure therapeutic goals for novel treatments that not only allow people living with AD to maintain their cognitive functioning and daily activities but also enable care partners to balance their informal care responsibilities with their well-being and professional responsibilities.

Abstract

Background: Faced with multiple challenges, informal caregivers often turn to online support communities for information and support. While scholarly attention has focused on experiences expressed by informal caregivers in these communities, how caregivers' challenges and emotional expressions vary across different health contexts remains understudied.

Objective: We aimed to examine and compare the challenges discussed by informal caregivers of general older adults and those of patients with Alzheimer disease and related dementia, as well as their emotional expressions, on Reddit. In addition, we examined how informal caregivers expressed their emotions in response to various challenges.

Methods: We collected posts from 6 subreddits, including 3 subreddits on caregiving for older adults and 3 on caregiving for patients with Alzheimer disease and related dementia. Using topic modeling, we identified topics discussed by caregivers in the collected posts. We further used deep reading to contextualize these topics and understand the challenges behind them, conducted sentiment analysis to investigate their emotional expressions, and used Spearman rank-order correlation to examine the relationship between the obtained topics and emotions.

Results: In total, 3028 posts were retrieved, including 1552 from older adult–related subreddits and 1476 from Alzheimer disease–related subreddits; 18 key topics were identified, with the most frequent topics being *expressing feelings* (2178/3028, 71.93%) and *seeking advice and support* (1982/3028, 65.46%). Other topics covered various challenges in caregiving, such as *duration of medical care* (1954/3028, 64.53%), *sleep and incontinence* (1536/3028, 50.73%), *financial issues* (1348/3028, 44.52%), and *nursing home* (1221/3028, 40.32%). There was a positive, negligible correlation between *expressing feelings* and *seeking advice and support* (ρ=0.09, *P*<.001). Other topics also showed positive, negligible or weak correlations with these 2 topics but in distinct patterns. Posts from older adult–related subreddits were more focused on practical caregiving issues and *seeking advice and support*, whereas posts from Alzheimer disease–related subreddits emphasized health- and medical-related topics and *expressing feelings*. Caregivers in both contexts predominantly expressed negative emotions (older adults: 1263/1552, 81.38%; Alzheimer disease: 1247/1476, 84.49%), with caregivers in Alzheimer disease–related subreddits exhibiting slightly greater *fear* and *sadness* (*P*<.001). Specific challenges were significantly correlated with negative emotions: *duration of medicalcare* was positively, weakly correlated with *anger* (ρ=0.25, *P*<.001), *fear* (ρ=0.25, *P*<.001), and *sadness* (ρ=0.22, *P*<.001). *Medical appointments* were positively, negligibly correlated with *anger* (ρ=0.10, *P*<.001), *fear* (ρ=0.09, *P*<.001), and *sadness* (ρ=0.06, *P*<.001). *Sleep and incontinence* (ρ=0.14, *P*<.001) and *finances* (ρ=0.24, *P*<.001) were positively, weakly correlated with *anger*.

Conclusions: By identifying the challenges and feelings expressed by caregivers for general older adults and caregivers for patients with Alzheimer disease and related dementia, our findings could inform health practitioners and policy makers in developing more targeted support interventions for informal caregivers in different contexts.

Introduction

Background

Many countries are faced with the challenge of an aging society. An aging society increases the likelihood that older adults live longer while coping with increased chronic diseases, thus underscoring the need for long-term care services [1,2]. Most older adults receive long-term care within their own residences, often relying on assistance from informal caregivers—family members, friends, and neighbors who provide unpaid care to people with health or functioning needs [1,3]. In the United States, 22.3% of adults provided such care or assistance in the past month, 10.4% of whom provided daily care for people with dementia or other cognitive impairment disorders [4]. Similar patterns are observed in some European countries, such as the United Kingdom and Germany [5].

Given the increasing prevalence of informal caregiving over the coming years, it is important to understand the challenges faced by informal caregivers of older adults [1,2]. Upon assuming the caregiving role, informal caregivers need to handle multiple tasks and responsibilities, including assisting with financial management, assisting with medical decision-making, and providing emotional support for their loved ones [1,2]. These responsibilities often conflict with caregivers' existing roles and personal needs, leading to stressful experiences [1,2]. While caregiving may also bring positive experiences, such as finding satisfaction in caring for loved ones [6] and improving the caregivers' sense of mastery [7,8], the demands often take a heavy toll on the caregivers' health and well-being [9,10].

However, caregiving experiences may vary across different situations and contexts [11-13]. The Caregiver Stress Theory, a stress processing theory that is specifically created to account for variance in the stress experience of caregivers, specifies that factors related to the caregiving context, such as years of providing care, age, and the health status of care recipients, can influence every part of the stress process [10]. For instance, spouse caregivers experienced greater levels of stress caring for their loved ones as compared to adult child caregivers [14]. The theory also outlines 2 sources of caregivers' stress, namely primary and secondary stressors [10]. Primary stressors refer to sources of stress that are directly related to acts of caregiving, such as the challenge from the care recipients' diseases and symptoms and assisting with daily living tasks, and secondary stressors are those indirectly related to caregiving tasks, such as conflicts with other family members and social restrictions [10,15]. This framework thus provides a holistic understanding of the challenges that caregivers face in their caregiving journey and the factors affecting different caregiving experiences [10,15].

Particularly relevant to this study are the experiences of informal caregivers of people with Alzheimer disease and related dementia and general older adults. Compared to caregivers of general older adults, caregivers of people with Alzheimer disease and related dementia are likely to spend more time on caregiving responsibilities, ranging from bathing and feeding to assisting with toileting [16]. In addition, these caregivers perceive higher levels of physical and emotional burdens [17,18] and experience increased depression rates [16,19]. These differences highlight the importance of understanding caregiving experiences by considering the health status of care recipients [11,13]. Hence, this study aims to examine and compare the challenges faced by informal caregivers of people with Alzheimer disease and related dementia and those taking care of general older adults to advance the understanding of the factors affecting different caregiving experiences.

Informal Caregivers in Online Support Communities

The rise of online support communities (OSCs) has provided informal caregivers of older adults with an avenue to connect and communicate with similar others [20,21]. These OSCs are embedded across computer-mediated platforms, such as Facebook, Reddit, and CaringBridge, allowing caregivers to share caregiving-related experiences and seek information and support [22-24]. Participation in OSCs has been shown to help caregivers solve caregiving-related issues, reduce feelings of isolation, improve self-efficacy in the process of caregiving [21,25], and improve overall well-being [26,27].

The interactions between caregivers in OSCs also offer valuable insights into their challenges [28,29] and their responses to said challenges [30]. Existing content analysis studies have provided evidence of the experiences of caregivers for either general older adults [30] or people with Alzheimer disease and related dementia [17,28,29,31]. They found that these caregivers often revealed caregiver burdens [17,24], exchanged social support [31], and engaged in stress-coping behaviors across OSCs [30]. However, limited research has directly compared the experiences of caregivers of people with Alzheimer disease and related dementia and general older adults revealed in OSCs [32]. Unpacking this is important as the knowledge can capture the complexity of the caregiving experience and the role of the caregiving context in shaping the unique challenges faced by caregivers. This suggests that a comparative study on the different experiences communicated by informal caregivers of general older adults and those caring for people with Alzheimer disease and related dementia in OSCs is necessary to better understand the unique needs for both groups.

Emotional Expression in OSCs

Beyond sharing information about specific challenges, messages in OSCs can also reveal caregivers' emotional experiences [33,34]. Caregiving can evoke a range of emotional responses among caregivers when facing challenges [35]. For example, anger may arise from the disruptive behaviors of the care recipient and strained relationships between the caregiver and the care recipient [35]. To cope with these emotions, caregivers often engage in the social sharing of emotions—openly

XSL•FO
RenderX

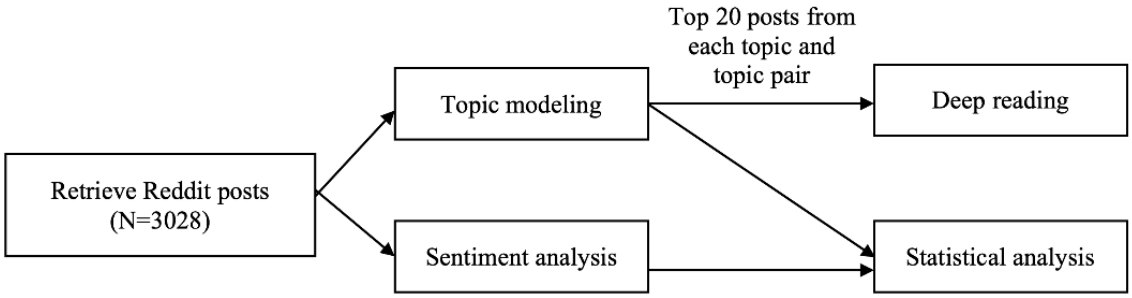
communicating with others about emotion-eliciting events and their emotions (eg, joy, fear, anger, or sadness) [36]. Anonymous web-based communities such as Reddit provide a safe space for caregivers' social sharing, where they may feel freer to share negative emotions compared to face-to-face settings or other identifiable groups, as these communities reduce social norms and alleviate privacy concerns [37,38]. Through this process, individuals can regulate their emotional experiences [39,40] and gain support and validation from others [41,42], which in turn reduces emotional distress [43].

While existing studies have examined informal caregivers' emotional expressions in OSCs [18,30], 2 research gaps remain. First, little is known about how informal caregivers express emotions when responding to different caregiving challenges. Investigating the relationship between various caregiving challenges and emotional expressions can advance research on caregiver stress and coping. This knowledge, in turn, can inform more targeted support interventions to improve caregivers' well-being. Second, it remains unclear how caregivers in different contexts, such as caregivers of general older adults and caregivers of people with Alzheimer disease and related dementia, express their emotions in OSCs. Faced with varying stressors and experiences, these 2 caregiver groups likely experience and express emotions differently. Comparing the patterns of emotional expression can contribute to a deeper understanding of the psychological needs of caregivers in different contexts, thus facilitating the development of targeted emotional and psychological interventions.

Objectives

This study seeks to address these research gaps by analyzing discussions on Reddit among informal caregivers of older adults, including those taking care of general older adults and people with Alzheimer disease and related dementia. Reddit is a popular anonymous community that allows people to share experiences and seek support [44]. Many subreddits are established to support informal caregivers of older adults, including those especially for caregivers of people with Alzheimer disease and related dementia [17,24]. Therefore, Reddit provides a valuable source of data to investigate how different informal caregivers share their challenges and emotions in OSCs.

This study has 4 objectives. First, it aims to identify the topics discussed by informal caregivers of older adults on Reddit and the underlying challenges they face. Second, it aims to examine how these topics vary between caregivers of general older adults and caregivers of people with Alzheimer disease and related dementia. Third, it aims to investigate how informal caregivers of older adults express emotions in response to different topics and challenges. Fourth, it aims to compare the patterns of emotional expression between the 2 caregiver groups. Our research questions (RQs) are as follows:



- RQ1: What kinds of topics were discussed on Reddit by informal caregivers of older adults, and how do these topics reflect informal caregivers' challenges?
- RQ2: What are the differences in topic distribution in subreddits for informal caregivers of general older adults and those caring for people with Alzheimer disease and related dementia?
- RQ3: What types of emotions were expressed by informal caregivers of older adults in relation to different topics on Reddit?
- RQ4: How do the emotions in Reddit posts differ across subreddits for informal caregivers of general older adults and those caring for people with Alzheimer disease and related dementia?

Methods

Overview

To understand the experiences and feelings of informal caregivers of general older adults and people with Alzheimer disease and related dementia, we applied computer-assisted text analysis, including topic modeling and sentiment analysis, to posts from Reddit communities related to older adults and Alzheimer disease and related dementia caregiving. The computational methods were complemented by a qualitative deep reading, where we selected the top 20 posts from each topic and topic pair for qualitative analysis to provide deeper insight into the obtained topics [45]. In addition, we carried out correlational analysis within and between the topic scores and sentiment scores to identify associations between topics and sentiments. Figure 1 shows our research design.

Figure 1. Research design.

Data Collection

We focused on subreddits specifically designed to support informal caregivers of both general older adults and people with Alzheimer disease and related dementias. To identify relevant subreddits, we searched using the keywords "aging/older/elder" combined with "care/caregiver" for discussions about caring for older adults and "Alzheimer/dementia" combined with "care/caregiver" for those related to Alzheimer and dementia care. We then reviewed each subreddit's description to ensure

XSL•FO
RenderX

that it was a forum for informal caregivers of either the general older adult population or those with Alzheimer and related dementia. The selected subreddits for informal caregivers included r/AgingParents, r/eldercare, r/elderlycare, r/Alzheimers, r/dementia, and r/DementiaHelp. Other caregiver-related subreddits that were not specifically designed to support these caregiver populations were excluded from our data analysis for the purpose of this research.

We used the Reddit application programming interface (API) to retrieve top-level posts from these 6 subreddits. We retrieved up to 1000 of the most recent posts from each of these subreddits, on August 6, 2023, as the Reddit API only provides the 1000 most recent posts at the time of retrieval. For subreddits with fewer than 1000 posts at the time of retrieval, all posts were retrieved.

Topic Modeling

We carried out topic modeling to uncover common topics that occur within this dataset. Topic modeling is a class of natural language processing methods that produces a set of topics from a text dataset, along with a table that indicates how strongly each of these topics occurs in each document.

We used a standard pipeline for topic modeling across the corpus of posts. First, we removed stop words, split the documents into terms with an n-gram range of 1 to 3 (thus allowing up to 3 words per term), and applied term frequency–inverse document frequency weighting to the document–term count matrix [46], which is a process that gives more weight to rarer but possibly more significant terms.

We then applied nonnegative matrix factorization (NMF), which factors the document-term matrix into a pair of document-topic and topic-term matrices [47]. The document-topic matrix shows which topics are present in each document, while the topic-term matrix shows how strongly each term is associated with each topic. We chose NMF rather than a clustering method like BERTopic [48] as we anticipated that each post could belong to multiple topics rather than to a single cluster. We also opted for NMF over latent Dirichlet allocation as NMF tends to give topics that are more meaningful and "more in line with human judgment" than latent Dirichlet allocation [49].

We carried out NMF with 10, 15, 20, and 25 topics. As the number of topics increased from 10 to 20, we observed additional meaningful topics appearing. However, increasing to 25 topics resulted in less coherent topics or splitting existing topics into subtopics. On this basis, we decided to take the results of NMF with 20 topics. From these 20 topics, we excluded 2 topics that consisted mainly of moderator posts about subreddit rules, resulting in a final 18 topics.

Deep Reading

After topic modeling, we used a qualitative deep reading method, following the computation grounded theory by Nelson [50], to interpret the results. This deep reading involved closely examining representative texts for each topic identified from topic modeling and contextualizing key terms to uncover their meanings. By combining computational findings with this human-centered interpretation, we validated patterns identified from topic modeling and offered a comprehensive interpretation of the data [50].

The 2 authors, one specializing in social science and the other in natural language processing, independently reviewed the key terms and top 20 posts for each of the 18 topics to better understand what each topic was about and how the key terms were used within each topic. We individually named and defined each topic, identifying recurring themes. We then compared our findings and resolved any disagreement through discussion to clarify the meaning and context of each topic. For strongly correlated topic pairs, we examined representative posts that scored highly on both topics to better understand when and how these topics co-occur.

We selected the 20 posts that had the highest topic weight in each topic, as these posts contained the most key terms from an individual topic and were thus more representative of the topic [51]. Analyzing these top documents is a common practice in computational grounded theory, which enables a systematic and unbiased examination of the data [50]. This approach ensures that the selected documents accurately represent each topic while allowing for efficient analysis without the burden of interpreting the full dataset. Following prior studies analyzing the top 10 to 20 documents [50,52], we chose the top 20 posts of each topic for qualitative deep reading.

To ensure the rigor and trustworthiness of findings, this study used the interpretive paradigm to ensure the credibility, dependability, and confirmability of our analysis [53]. First, to enhance credibility (ie, the results of qualitative analysis adequately represent multiple realities), we discussed our data collection and analysis procedures with senior colleagues who had expertise in qualitative research. Second, dependability (ie, the consistency of data analysis) was achieved by documenting our thoughts during the deep reading process and engaging in frequent discussions to resolve any inconsistencies. Third, to ensure that researchers' interpretations of data were nonprejudiced (ie, confirmability), we reflected critically on our own perspectives during the deep reading and included verbatim quotes to support the inferences presented in the results. These steps minimized researcher bias in handling data and enhanced the objectivity of our findings.

Sentiment Analysis

We also used the CrystalFeel sentiment analysis API [54] to extract sentiment scores for each post. The CrystalFeel algorithm uses a mixture of lexicon- and word-embedding–based approaches to generate emotional intensity scores and has been validated on human-annotated test samples (achieving correlations of 0.765, 0.818, 0.788, and 0.765 with human annotations on fear, anger, joy, and sadness intensity, respectively) and used in multiple studies for sentiment analysis of social media posts [55,56]. We used CrystalFeel to generate continuous intensity scores (ranging from 0 to 1) for the 4 basic emotions (anger, fear, joy, and sadness), and an overall 5-point sentiment score ranging from −2 (very negative) to +2 (very positive).

XSL•FO
RenderX

Statistical Analysis

To uncover associations between topics and emotions, we computed the Spearman rank correlation coefficient (ρ) among topic weights, and between topic weights and emotion scores. The Spearman rank correlation coefficient reflects the presence of a monotonic (but not necessarily linear) relationship between variables. We chose the Spearman rank correlation coefficient instead of the Pearson correlation coefficient because the distributions of topic weights resulting from NMF were nonnegative and highly skewed toward 0 [57]. The correlations between topic weights in this study reflect the degree of co-occurrence of topics across posts: a higher correlation between two topics indicates that those two topics are more likely to occur within the same post.

Following commonly used guidelines for interpretation (eg, [58]), correlations with a magnitude between 0 and 0.09 were considered negligible, while correlations with a magnitude between 0.1 and 0.39 were considered weak. Note that in our sample, correlations of magnitude >0.06 were significant at $P<.001$.

Ethical Considerations

Before collecting data for this content analysis study, we obtained approval from the Nanyang Technological University's Integrity Review Board (IRB-2023-258) under the exempt review category. Secondary research on existing or publicly accessible datasets, such as our study on Reddit posts, qualifies for this category. Additional informed consent from human subjects is not required for secondary analyses of research data. In compliance with the Integrity Review Board guidelines, we also protected the privacy and confidentiality of individuals by anonymizing users whose data were being analyzed and removing any identifiable information from the posts. No compensation was offered, as this study did not involve direct participation or recruitment of individuals. By strictly following these guidelines, we ensured that this study does not lead to adverse outcomes for human subjects.

Results

Dataset Description

In total, 3028 posts were retrieved from Reddit. Table 1 shows the breakdown of the number of posts retrieved from each subreddit.

Table 1. Number of posts retrieved from each subreddit (N=3028).

Subreddits	Posts, n (%)
Older adults–related posts	1552 (51.25)
r/AgingParents	937 (30.94)
r/eldercare	490 (16.18)
r/elderlycare	125 (4.13)
Dementia-related posts	1476 (48.75)
r/Alzheimers	916 (30.25)
r/dementia	547 (18.06)
r/DementiaHelp	13 (0.43)

Topic Descriptions and Interpretation (RQ1)

Through topic modeling and deep reading, we identified 18 topics discussed by informal caregivers and the underlying challenges they faced (Table 2). By reviewing the key terms and top 20 posts within each topic, we named and described each topic and grouped the topics into 7 overarching themes. Representative posts within each topic are provided in Multimedia Appendix 1.

XSL•FO
RenderX

Table 2. Topic labels, key terms, and descriptions from each topic, along with the topic counts and frequency[a] (N=3028).

Topic, topic name, and description		Topic count, n (%)	Key terms
Theme 1: expressing feelings			
T1	Expressing feelings: discussing feelings about circumstances, including sadness, guilt, helplessness, frustration, stress, and anger.	2178 (71.93)	"just, like, feel, know, things, really, time, feel like, want, does, life, think, make, say, day, hard, people feeling"
Theme 2: seeking advice and support			
T4	Seeking advice and support: asking for advice in dealing with circumstances, often in the form of questions.	1982 (65.46)	"help, advice, need, does, house, needs, getting, need help, refuses, family, lives, want, health, trying, live, suggestions, looking, support"
Theme 3: health and medical concerns			
T2	Duration of medical care: discussing the care recipient's health or behavioral issues, or the need for long-term medical care.	1954 (64.53)	"did, said, hospital, told, days, got, doctor, ago, went, day, today, weeks, week, going, months, called, hospice, just, years, took"
T9	Dementia: seeking or providing information about dementia	1605 (53.01)	"dementia, family, people, loved, diagnosed, people dementia, vascular dementia, vascular, caregivers, person, diagnosed dementia"
T7	Alzheimer: seeking or providing information about Alzheimer disease	1584 (52.31)	"alzheimer, early, onset, early onset, disease, diagnosed, onset alzheimer, early onset alzheimer, diagnosis, years, stage, experience, memory"
T3	Aging and declining health of parents: discussing the aging and the declining health status of parents	1572 (51.92)	"parents, aging, parent, health, life, years, live, aging parents, care, elderly, old, support, time, don, kids, issues, love, age, mental, situation"
T8	Sleep and incontinence: discussing sleep problems in general, or specifically incontinence.	1536 (50.73)	"bed, sleep, night, day, time, hours, door, room, toilet, does, bathroom, sleeping, gets, goes, sleeps, walk, wake, fall, diaper, incontinence"
T12	Medical appointments: discussing different types of medical appointments and experiences with such appointments	1082 (35.73)	"appointment, make, doctor, make appointment, bad, make doctor, said make appointment, memory gotten really, just yelled, make"
Theme 4: care facilities and services			
T6	Memory care facility: discussing memory care facilities for the care recipient, often seeking recommendations for such facilities, or describing their experiences with facilities	1396 (46.10)	"care, memory care, memory, facility, care facility, memory care facility, facilities, needs, need, area, elder, home care, residents, unit"
T11	Nursing home: discussing nursing home for the care recipient, often seeking recommendations for such facilities, or describing their experiences with facilities	1221 (40.32)	"home, nursing, nursing home, care, hospital, home care, medicaid, homes, rehab, nursing homes, home health, work, health, pay"
T10	Assisted-living facility: discussing assisted-living facilities, often seeking recommendations for such facilities, or describing their experiences with facilities.	1160 (38.31)	"living, assisted living, assisted, facility, living facility, assisted living facility, independent living"
Theme 5: care recipients and family relationships			
T14	Parents (mom): mentioning issues in dealing with mom	1571 (51.88)	"mom, sister, caregiver, dog, live, brother, care mom, care, mom, job, dad, mom does, best, mom diagnosed, taking, getting, don, moms, work, hours"
T16	Parents (mother): mentioning issues in dealing with mother	1534 (50.66)	"mother, sister, father, years, time, year, law, away, lives, old, year old, died, siblings, cat, family, passed, brother, care mother, come, mother law"
T15	Parents (dad): mentioning issues in dealing with dad	1525 (50.36)	"dad, mum, brother, home, years, just, want, does, months, help dad, ago, mom dad, dad does, live, care dad, angry, old, father, point, away"
T18	Grandparents: mentioning grandparents in general, or specific grandparents, often talking about their health problems.	1178 (38.90)	"grandma, grandpa, grandparents, aunt, grandmother, family, uncle, want, know, care grandma, does, live, home, help grandma"

XSL•FO
RenderX

Topic, topic name, and description		Topic count, n (%)	Key terms
Theme 6: financial, legal, and insurance issues			
T5	Finances: discussing finance-related matters, such as bills or handling of the ward's assets. Many also mention power of attorney.	1348 (44.52)	"money, account, bank, poa, card, pay, house, attorney, credit, financial, power, finances, power attorney, trust"
T19	Long-term care insurance: discussing long-term care insurance, often asking for recommendations for long-term care insurance providers.	1182 (39.04)	"term, long term, long-term care, term care, long, insurance, care, term care insurance, care insurance, insurance, policy"
Theme 7: technological issues			
T13	Cell phone and devices: discussing phones and related devices, descriptions of difficulties encountered by the care recipient in using such devices, and requests for recommendations of devices.	1605 (53.01)	"phone, use, hearing, alert, elderly, looking, recommendations, device, app, cell, aids, hearing aids, watch, cell phone, devices"

[a]Frequency refers to the percentage of posts with nonzero weights for that topic.

Theme 1 (ie, topic 1), named *expressing feelings*, accounted for the largest proportion of the topic distribution. Posts on this topic mentioned the posters' feelings about circumstances, usually including negative feelings, such as sadness, guilt, helplessness, and frustration. The second most influential theme, theme 2 (ie, topic 4), was *seeking advice*. Posts under this topic focused on asking for advice in dealing with problems, often in the form of questions.

Other themes covered a wide variety of caregiving-related issues. Theme 3 (ie, topics 2, 3, 7, 8, 9, and 12) discussed health and medical issues related to the care recipient, including duration of medical care, dementia, Alzheimer, aging and declining health of parents, sleep and incontinence, and medical appointments. Theme 4 (ie, topics 6, 10, and 11) was about different types of care facilities and services, including memory care facilities, nursing homes, and assisted-living facilities. Theme 5 (ie, topics 14, 15, 16, and 18) focused on care recipients and family relationships, talking about either the posters' mother, father, or grandparents. Theme 6 (ie, topics 5 and 6) was about financial, legal, and insurance issues, including finance-related issues such as bills or assets, often mentioning power of attorney, and long-term care insurance. Theme 7 (ie, topic 13) discussed technological issues, especially cell phones and hearing aid devices.

We also explored the relationships between different topics to have a more detailed understanding of these topics (Table 3). All correlations between topics were negligible (0-0.09 in magnitude) or weak (0.1-0.39 in magnitude).

[a]Correlations with *P*<.001 are italicized according to the strength and magnitude of the correlations.

[b]Not applicable.

There was a positive negligible correlation between the two most frequently discussed topics, *seeking advice and support* and *expressing feelings* (ρ=0.09, *P*<.001). Other topics also showed positive, negligible or weak correlations with these two topics but in distinct patterns. Topics related to health and medical concerns, such as *duration of medical care* (ρ=0.18, *P*<.001), *aging and declining health of parents* (ρ=0.10, *P*<.001), *sleep and incontinence* (ρ=0.11, *P*<.001), and *medical appointments* (ρ=0.09, *P*<.001), were positively, weakly or negligibly correlated with *expressing feelings*. In addition, 3 of these topics—*aging and declining health of parents*, *sleep and incontinence*, and *medical appointments*—were also positively, weakly correlated with *seeking advice and support*, with Spearman ρ values of 0.13, 0.12, and 0.11, respectively (all *P*<.001).

Topics related to care facilities and services, including *nursing home* (ρ=0.12, *P*<.001) and *assisted-living facility* (ρ=0.09, *P*<.001), as well as financial topics such as *finances* (ρ=0.13, *P*<.001) and *long-term care insurance* (ρ=0.09, *P*<.001), were

XSL•FO
RenderX

positively, weakly or negligibly correlated with *seeking advice and support*.

To interpret the challenges caregivers faced, we analyzed representative posts that scored high in the above topic combinations by deeply reading. When discussing the *duration of medical care* of the care recipient, such as the care recipient's health or behavioral issues, posters usually expressed negative feelings, such as helplessness and frustration, as a means of venting or seeking comfort. For example, one caregiver shared his fear and uncertainty following his grandmother's abnormal behavioral problems due to dementia:

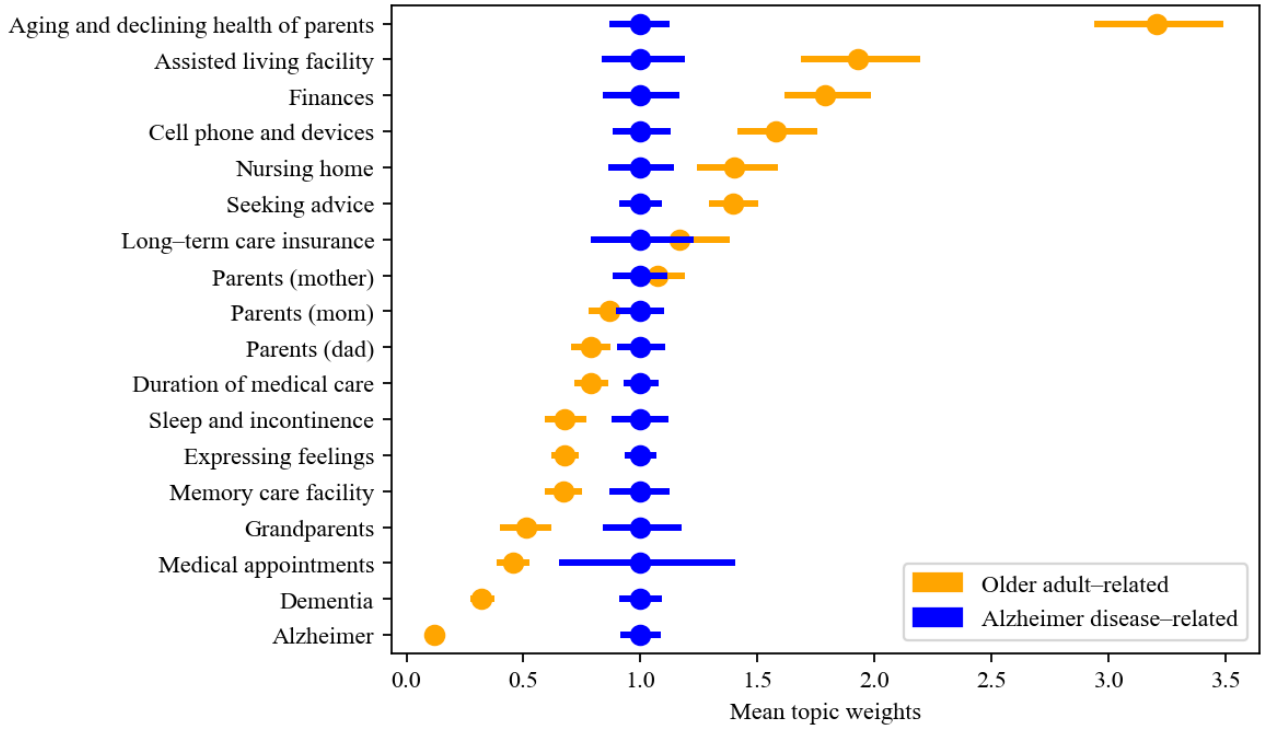
> *So my grandma (90) was quite healthy in body and mind until this April... she started showing signs of dementia: More severe forgetfulness, language problems, episodes where she didn't seem like she is "now"...I have no experience or expertise with dementia and frankly I am very scared right now...It just seemed so sudden and such a radical change.*

In contrast, posts discussing more practical issues in caregiving, including health and social services, insurance, and financial topics, tended to seek advice or help. For example, a caregiver expressed the need to secure an affordable nursing home:

> *The hospital called my grandmother and said her husband was being discharged and to pick him up. He has dementia and diabetes... how can we find a home he can afford when his income is below the "needed rate"? We've called many various services and no one seems to be able to help or give guidance.*

Caregivers discussing health and medical issues, including aging and declining health of parents, sleep and incontinence, and medical appointments, tended to express both feelings and a need for advice. For example, posts about sleep and incontinence usually directly sought advice to solve the problem while also revealing the emotional toll on caregivers:

> *I help (pretty much am the main) care for my MIL...The problem is bedtime. She doesn't like to be alone. She wanders around every 15 minutes and will not go to bed...It's cold and I'm tired and miserable and I feel so guilty for hiding like this...Any suggestions what I can do to get space so I can sleep? I'm starting to lose my sanity.*



Topic Distribution Comparison (RQ2)

Comparing the topics discussed in subreddits for informal caregivers of general older adults and those caring for people with Alzheimer disease and related dementia, we found that while all topics were present in posts from both older adult–related and Alzheimer disease–related subreddits, certain topics were more prevalent in one community than the other (Figure 2). Posts from older adult–related subreddits tended to be *seeking advice and support*. Compared with Alzheimer disease–related subreddits, they showed greater interest in talking about *aging and declining health of parents*, and care facility–related topics, such as *assisted-living facilities and nursing homes*. In addition, they also focused more on financial, legal, insurance, and technical issues (ie, *finances*, *long-term care insurance*, and *cell phones and devices)*.

However, posts from Alzheimer disease–related subreddits tended to be *expressing feelings*. They showed greater interest in other health- and medical-related topics, such as *duration of medical care*, *sleep and incontinence*, and *medical appointments*. They also tended to talk more about *dementia*, *Alzheimer*, and *memory care facilities*—the topics in relation to Alzheimer and related dementia.

XSL•FO
RenderX

Figure 2. Comparison of mean topic weights between older adult– and Alzheimer disease–related subreddits. Horizontal bars represent 95% CIs for the mean topic weight. Weights for each topic are normalized such that the mean topic weight for Alzheimer disease–related subreddits is 1 and sorted according to the normalized mean topic weight for older adult–related subreddits.

Emotions in Relation to Topics (RQ3)

We analyzed the relationships between 18 topics and emotions obtained from sentiment analysis to understand how caregivers expressed emotions in response to various topics. The results (Table 4) indicated that most topics were positively but weakly correlated with negative emotions and sentiments. The only topic that had a positive, weak correlation with positive sentiment was *cell phones and devices* (ρ=0.20, *P*<.001).

The topic *duration of medical care* was positively, weakly correlated with a set of negative emotions, including *anger* (ρ=0.25, *P*<.001), *fear* (ρ=0.25, *P*<.001), and *sadness* (ρ=0.11, *P*<.001). Similarly, *medical appointments* were positively, negligibly correlated with these emotions, including *anger* (ρ=0.10, *P*<.001), *fear* (ρ=0.09, *P*<.001), and *sadness* (ρ=0.06, *P*<.001). The topics *sleep and incontinence* (ρ=0.14, *P*<.001) and *finances* (ρ=0.24, *P*<.001) were both positively, weakly correlated with *anger*.

While the topic of *Alzheimer* was negatively, weakly correlated with *anger* (ρ=−0.10, *P*<.001), it was positively, weakly correlated with *fear* (ρ=0.10, *P*<.001). The topic of *dementia* was positively, weakly correlated with *fear* (ρ=0.12, *P*<.001) and *sadness* (ρ=0.09, *P*<.001).

Emotions Comparisons (RQ4)

Approximately >70% (older adults: 1117/1552, 71.97%; Alzheimer disease: 1095/1476, 74.19%) of posts from both the Alzheimer disease– and older adult–related subreddits expressed an overall negative sentiment, with an additional 10% (older adults: 146/1552, 9.41%; Alzheimer disease: 152/1476, 10.30%) expressing a very negative sentiment (Table 5). In contrast, approximately 10% (older adults: 184/1552, 11.86%; Alzheimer disease: 138/1476, 9.35%) of posts expressed positive sentiments, and very few expressed very positive sentiments. The distribution of overall sentiment scores was similar between the 2 subreddit types.

Table 5. Distribution of sentiments across Alzheimer disease–related and older adult–related subreddits.

	Number of posts, n (%)	
	Alzheimer disease–related subreddits (n=1476)	Older adult–related subreddits (n=1552)
Very positive	2 (0.14)	2 (0.13)
Positive	138 (9.35)	184 (11.86)
Neutral	89 (6.03)	103 (6.64)
Negative	1095 (74.19)	1117 (71.97)
Very negative	152 (10.30)	146 (9.41)

Regarding the expression of specific emotions, *joy* was much less present in both types of subreddits compared with negative emotions (Table 6). In addition, there was slightly more *fear* and *sadness* expressed in the Alzheimer disease–related subreddits than in the older adult–related ones.

Table 6. Comparison of emotion values across Alzheimer disease– and older adult–related subreddits[a].

	Emotion scores, mean (SD)	
	Alzheimer disease–related subreddits	Older adult–related subreddits
Fear[b]	0.51 (0.09)	0.48 (0.10)
Sadness[b]	0.49 (0.08)	0.47 (0.08)
Anger	0.46 (0.07)	0.46 (0.08)
Joy	0.26 (0.08)	0.26 (0.08)

[a]The value of each emotion score is a continuous variable ranging from 0 (ie, a message not expressing the emotion at all) to 1 (ie, a message expresses an extremely high intensity of the emotion).

[b]The differences were significant at *P*<.001.

Discussion

Principal Findings

To provide insights into the challenges and emotional experiences of informal caregivers of older adults, this study combined computer-assisted text analysis (ie, topic modeling and sentiment analysis) with qualitative analysis (ie, deep reading) to analyze the topics, challenges, and emotions expressed by informal caregivers of general older adults and people with Alzheimer disease and related dementia on Reddit. We identified 18 topics from informal caregivers' posts, with posts predominantly focusing on expressing personal feelings and seeking advice and support. These posts revealed various challenges faced by informal caregivers, including managing care recipients' health and medical issues and other practical issues. When discussing these caregiving-related challenges, informal caregivers either expressed their negative feelings or sought help from other forum members.

Our analysis also revealed differences in topics and emotions expressed by users in subreddits for informal caregivers of general older adults and those for people with Alzheimer disease and related dementia. While caregivers of general older adults focused more on practical topics, such as care facilities, caregivers of people with Alzheimer disease and related dementia discussed more about their loved one's health and medical problems, such as dementia disease. In addition, the posts of caregivers of people with Alzheimer disease and related dementia expressed higher levels of negative emotions, such as fear and anger, although posts from both subreddits revealed an overall negative sentiment. Notably, we found that informal caregivers had distinct emotional expressions when discussing different topics. Posts about the duration of medical care were positively weakly correlated with a complex set of negative

XSL•FO
RenderX

emotions, including anger, fear, and sadness. When talking about sleep, incontinence, and financial issues, informal caregivers tended to express anger, while Alzheimer disease–related topics were positively but weakly correlated with fear. The findings indicate a nuanced relationship between caregivers' challenges and their emotional expressions.

Comparison With Previous Works

Existing studies have provided evidence that caregivers often turned to web-based communities, such as Facebook [29] and blogs [28], to share caregiving-related experiences and seek desired information. Similarly, our study found that expressing feelings and seeking advice were predominant topics on subreddits for informal caregivers. According to social support research, both expressing feelings and seeking advice are effective strategies for eliciting social support from others. Expressing feelings, particularly negative ones, may signal a need for emotional support [59,60]. Therefore, the findings suggest that Reddit serves as a platform where caregivers seek social support to cope with caregiving challenges [61].

By combining topic modeling and deep reading, this study also identified specific challenges revealed in web-based discussions among informal caregivers, including managing the health and medical issues of their loved ones, dealing with family relationships, and handling practical caregiving tasks, such as finding appropriate care facilities. These findings align with previous research on informal caregivers' web-based self-disclosure [17,29,62]. For example, analysis of Facebook posts by Bachmann [29] found that caregivers of patients with Alzheimer disease face diverse challenges concerning extended activities of daily living, such as dealing with sleeping disorders, selecting health facilities, and managing medical appointments and tests. The results of this study also complement self-reported data from informal caregivers of older adults [63,64]. For instance, a qualitative study in 4 European countries found that informal caregivers reported facing multiple challenges and needs related to the management of care for older adults [63]. Consistent with these studies, our findings demonstrate the multiple challenges faced by informal caregivers and highlight the need for further research to address their specific needs in caregiving.

Our study adds to prior research on caregivers' challenges by examining the relationship between specific challenge-related topics and the ways caregivers seek support on the web. Previous research has primarily focused on either informal caregivers' sharing of challenges on the web [29-31] or how they seek social support [60] as separate phenomena. In contrast, this study reveals informal caregivers' support-seeking patterns in relation to various challenges by examining topic co-occurrence. When encountering uncontrollable challenges, such as the care recipients' behavioral issues and the progression of Alzheimer disease and related dementia, caregivers were more likely to express feelings in their posts. In comparison, when facing practical-oriented topics that require solutions—such as finding appropriate assisted-living facilities and managing financial and insurance issues—caregivers were more likely to ask for advice on subreddits directly. Moreover, when facing complex health and medical issues, caregivers often combined seeking advice and sharing personal feelings. These findings suggest that informal caregivers may adopt different support-seeking strategies depending on the nature of their challenges. However, the relationships between challenge-related topics and support-seeking strategies were either negligible or weak. Future research could further investigate the stress-coping process in caregiving to understand how caregivers cope with their various challenges.

This study also provides evidence for the unique challenges faced by informal caregivers in 2 caregiving contexts. Prior studies have mainly focused on web-based discussions of one caregiver population, either informal caregivers of general older adults [30] or those taking care of people with Alzheimer disease and related dementia [17,28,29,31], without directly comparing the 2 groups. This study compared the topics these 2 caregiver populations discussed, revealing differences in their concerns and support-seeking behaviors. Informal caregivers of general older adults were more likely to discuss practical topics, including care facilities and financial, legal, insurance, and technical issues. In contrast, caregivers of people with Alzheimer disease and related dementia tended to focus on health and medical-focused issues, such as sleep and incontinence problems and Alzheimer disease, and expressed their feelings more frequently in their posts. The findings are consistent with studies emphasizing the complexities faced by caregivers of people with Alzheimer disease and related dementia in health and medication management tasks. For example, a survey by Riffin et al [65] found that caregivers of people with Alzheimer disease and related dementia encountered greater challenges in managing health-related tasks than caregivers of older adults without Alzheimer disease and related dementia. Hence, future research can examine the distinct challenges faced by informal caregivers in different contexts.

Furthermore, the differences in discrete emotions expressed by informal caregivers of general older adults and caregivers of people with Alzheimer disease and related dementia also mirror the premise of the Caregiver Stress Theory [10] that caregiving contexts shape individuals' experiences. Previous studies have found that caregiving burden, especially emotional burden, can vary across different types of caregivers, especially among dementia and nondementia caregivers [11,13]. Compared with caregivers of older adults, caregivers of people with Alzheimer disease and related dementia face the irreversible progression of functional decline in their loved ones [66] and experience worries and anxiety [13,66]. Our study adds to this understanding by providing evidence that caregivers of people with Alzheimer disease and related dementia tended to disclose higher levels of fear and sadness on Reddit. A similar pattern was also identified through the positive weak correlation between Alzheimer disease–related topics and caregivers' expressions of fear and sadness. These findings underscore the importance of further investigating the unique emotional experiences of informal caregivers in the context of Alzheimer disease and related dementia care.

The negligible or weak correlations between topics and emotions provide a nuanced understanding of informal caregivers' web-based social sharing of emotions [36]. Our study found that discussions on the duration of medical care and medical

XSL•FO
RenderX

appointments had a complex set of negative emotions, including anger, fear, and sadness. This finding corroborates earlier research showing that dealing with long-term medical care of their loved ones is an emotionally distressing process that often elicits negative emotions [1]. In addition, our study found that informal caregivers tended to express anger when discussing financial issues. While previous studies have mainly focused on the financial burden faced by informal caregivers of older adults, they have often overlooked specific barriers and caregivers' emotional responses to them [67,68]. Through deep reading, we found that many caregivers felt angry about the barriers they encountered when trying to manage their care recipient's assets and applying for the power of attorney. This implies caregivers' dissatisfaction and frustration with financial and legal systems in supporting their caregiving responsibilities.

Notably, this study found a negative weak correlation between the topic of Alzheimer disease and expressions of anger. Previous survey-based research has found that feelings of anger were prevalent in caregivers of people with Alzheimer disease and related dementia [69], and the presence of disruptive behaviors in people with Alzheimer disease and related dementia was positively correlated with their anger expression [35]. Different from existing studies, our findings suggest that when caregivers were discussing Alzheimer disease, they were less likely to express anger or resentment. One possible explanation for this discrepancy is that informal caregivers of patients with Alzheimer disease may develop a heightened sense of empathy and understanding toward the care recipient over time [70]. The increase in empathy may lead to reduced anger emotions and corresponding emotional expression in their online discussions [70]. Another possible explanation is the difference in how emotional expressions were measured in this study compared to prior research. To address these discrepancies, further studies adopting other research methods are warranted to investigate caregivers' emotional responses and expressions toward Alzheimer disease–related topics.

Implications

This study contributed in 2 aspects to the literature on the use of OSCs in informal caregiving. First, by illustrating specific challenges and emotional expressions of caregivers of general older adults and caregivers of people with Alzheimer disease and related dementia, this study suggests the importance of examining caregiver stress and coping by considering the role of caregiving contexts, especially the health status of care recipients. Second, this study was the first to empirically examine the correlation between topics and emotional expressions among informal caregivers of older adults. By providing evidence of how informal caregivers express their feelings in response to various caregiving-related challenges, the findings offer a foundation for future research to develop a more nuanced understanding of the patterns of web-based emotional sharing, particularly in relation to the nature of challenges.

Practically, the findings of this study could inform health practitioners and policy makers on how to support the 2 caregiver populations. We found evidence that informal caregivers sought advice and expressed feelings on a variety of caregiving-related matters in OSCs, such as the care recipients' health and medical issues; dealing with family relationships; and practical topics, such as finance, insurance, and technology. The findings bring to light the needs of caregivers for both informational and emotional support in various aspects, which can inform support interventions and services to meet the needs of the population. For example, addressing financial issues through clear guidance on managing assets and applying for power of attorney could benefit caregivers.

Caregivers of people with Alzheimer disease and related dementia discussed more about the medical and behavioral issues of their care recipients, such as duration of medical care, sleep, and incontinence. This underscores the need for targeted support interventions, such as education and training sessions on Alzheimer disease and related dementia-specific caregiving skills. In addition, the frequent expression of negative emotions, especially among caregivers of people with Alzheimer disease and related dementia, suggests the importance of emotional health interventions. OSCs such as Reddit can serve as a valuable forum for caregivers to share experiences and gain emotional support from their peers. To foster this, OSC moderators should encourage open sharing and facilitate supportive interactions among caregivers.

Limitations and Future Works

This work has several limitations. First, we focused on the topic distribution and emotional expression across informal caregivers of general older adults and people with Alzheimer disease and related dementia, while not examining other caregiver populations. A potential direction for subsequent studies is to compare the challenges faced by informal caregivers of older adults with different diseases, such as stroke and diabetes, in a more nuanced manner. This can provide stronger evidence for how specific caregiving contexts, such as the health status of the care recipients, shape caregivers' experiences. Second, this study only investigated the characteristics of informal caregivers' communication patterns on Reddit, a platform dominated by users from the United States. According to previous studies, informal caregivers of older adults also use other OSC platforms, such as Facebook groups and CaringBridge. Future studies could compare topics and emotions expressed by informal caregivers across platforms to enhance our understanding of the role of different OSCs in supporting informal caregivers.

Third, web-based community users may differ from the broader population of informal caregivers in terms of socioeconomic status and media literacy. Therefore, the findings of this study cannot be generalized to all informal caregivers. This limitation stems from the study's specific focus on understanding how caregivers use OSCs to share challenges and emotions. Future research could address this by including nonusers of OSCs and comparing their experiences with those of OSC users, providing a more comprehensive understanding of informal caregivers' experiences across diverse contexts. Fourth, the research methods of this study only allowed us to have a general understanding of informal caregivers' challenges and feelings. Although we adopted qualitative approaches to analyze themes and meanings of representative posts to complement the results

XSL•FO
RenderX

of computer-assisted text analysis, we still cannot infer caregivers' perceived stress and their actual emotional well-being status. Future research could combine computer-assisted text analysis with other methods, such as interviews or surveys, to have a more comprehensive understanding of caregivers' experiences and needs.

Conclusions

In this study, we examined web-based discussions among informal caregivers of general older adults and people with Alzheimer disease and related dementia on Reddit, including their challenges and emotional expressions and their relationships. Informal caregivers discussed a wide range of caregiving-related challenges on Reddit but they varied across caregiving contexts. Caregivers' web-based messages also indicate a high level of negative emotions, including fear, anger, and sadness. In addition, caregivers expressed distinct emotions in response to various challenges, depending on the nature of these challenges. Taken together, this study elucidated informal caregivers' actual problems and needs in different caregiving contexts, thereby providing suggestions for health practitioners and policy makers to develop more targeted support interventions.

Abstract

Background: Uncomplicated urinary tract infections (uUTIs) affect more than half of women in their lifetime and can impact on quality of life. We analyzed social media posts discussing uUTIs to gather insights into the patient experience, including aspects of their disease management journey and associated opinions and concerns.

Objective: This study aims to gather patient experience insights by analyzing social media posts that discussed uUTI.

Methods: A search string ("urinary tract infection" [UTI] or "bladder infection" or "cystitis" or "UTI" not "interstitial cystitis") was used to identify posts from public blogs and patient forums (June 2021 to June 2023). Posts were excluded if they were not written in English or discussed complicated UTI (posts that mentioned "pregnancy" or "pregnant" or "trimester" or "catheter" or "interstitial"). Posts were limited to publicly available sources and anonymized. The primary objective was to gather patient perspectives on key elements of the uUTI experience, including health care professional (HCP) interactions, diagnosis, treatment, and recurrence.

Results: In total, more than 42,000 unique posts were identified (mostly from reddit.com; 29,506/42,265, 70%) and >3600 posts were analyzed. Posts were most commonly from users in the United States (6707/11,180, 60%), the United Kingdom (2261/11,180, 20%), Canada (509/11,180, 5%), Germany (356/11,180, 3%), or India (320/11,180, 3%). Six main themes were identified: symptom awareness and information seeking, HCP interactions, diagnosis and management challenges, management with antibiotics, self-management, and challenges with recurrent UTI. Most posts highlighted the importance of seeking professional medical advice, while some patients raised concerns regarding their HCP interactions and lack of shared decision-making. Patients searched for advice and guidance on the web prior to consulting an HCP, described their symptoms, and discussed lifestyle adjustments. Most patients tried self-management and shared their experiences with nonprescribed treatment options. There was general agreement among posts that antibiotics are necessary to cure UTIs and prevent associated complications.

Conclusions: Social media posts provide valuable insight into the experiences and opinions of patients with uUTIs in Canada, Germany, India, the United Kingdom, and the United States. The insights from this study provide a more complete picture of patient behaviors and highlight the potential for HCP and patient education, as well as better communication through shared decision-making to improve care.

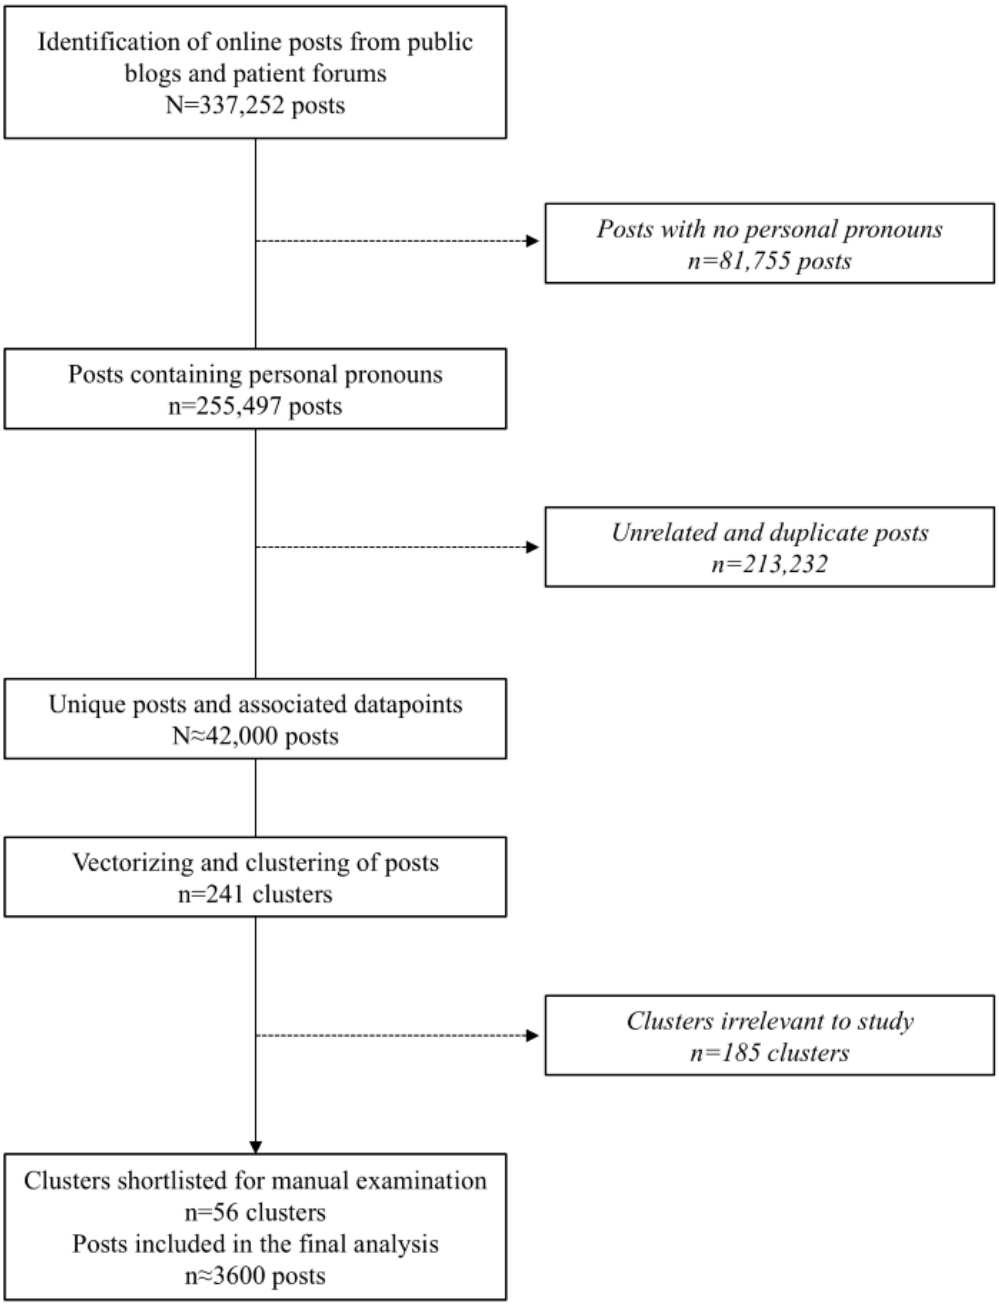
Introduction

Urinary tract infections (UTIs) affect >50% of women in their lifetime [1,2], which can necessitate multiple health care professional (HCP) visits and antibiotic prescriptions, and have a substantial impact on quality of life [3,4]. Determinants of this quality-of-life impact include the capacity for symptoms to affect everyday activities (including sex, sleep, work, and exercise) and the emotional toll of disease management [5,6]. Frustration and helplessness are key examples of the emotions reported by patients with UTIs [5,7]. Most evaluations of patient perspectives of UTIs have focused on individuals recruited from clinical settings [8,9], but these data may be limited in terms of the information that patients are willing to share with researchers and the sample size may be small and not representative of the whole patient population. Other studies have gathered the views of patients with UTIs via web-based surveys [4,10-14].

Social media has become a part of everyday life for many people, with an estimated 4.89 billion users worldwide in 2023 [15]. This number is expected to reach 5.85 billion by 2027 [15]. Many patients use social media sites to source medical information prior to obtaining information in person [16]. These platforms thus represent a promising route by which we can learn about the concerns and experiences of patients without recruiting them from care settings or through research panels [17]. Analyzing patient discussions on social media may provide unique insights into the real-life experiences of patients beyond what can be learned using traditional research methodologies [17]. To our knowledge, only 2 studies have been published that present information about patients with UTI, extracted directly from web-based platforms (one of which was not UTI-specific) [16,18].

We analyzed social media posts discussing uncomplicated UTIs (uUTIs) to gather insights into the patient experience, including aspects of their disease management journey and associated opinions and concerns. uUTI (also known as “acute cystitis”) is a condition characterized by pyuria and a documented microbial pathogen on urine culture, often accompanied by local signs and symptoms such as lower abdominal discomfort and dysuria. uUTI is limited to nonpregnant females with no known relevant anatomical or functional abnormalities in the urinary tract and no comorbidities [19]. A quantitative analysis was also conducted to assess the proportion of posts discussing key uUTI therapies, home remedies, and HCP specialties. Refer to Multimedia Appendix 1 for “Patient Lay Summary” of this article.

Methods



Postidentification and Processing

A search string (“urinary tract infection” or “bladder infection” or “cystitis” or “UTI” but not “interstitial cystitis”) was used to identify online posts from Veeva Link data sets comprising multiple public blogs and patient forums from June 2021 to June 2023, as shown in Figure 1. Identified posts were subjected to natural language processing. Posts were excluded if they did not contain personal pronouns (to identify self-reports; examples of personal pronouns include I, me, my, mine, and myself), were not written in English, were deemed spam or advertisements (identified by manual inspection), discussed complicated UTI (identified as posts using the terms “pregnancy” or “pregnant” or “trimester” or “catheter” or “interstitial”), or were duplicates. Non–English-language sources, special characters, emojis, or website URLs included in the posts, duplicate posts, or posts that included terms associated with complicated UTIs were removed. Each post was assessed and clustered with other semantically similar posts.

The remaining posts were clustered into themes based on semantic similarities. Posts were embedded into a high-dimensional space using the all-mpnet-base-v2 transformer model and the dimensionality was reduced with Uniform Manifold Approximation and Projection [20] using the BERTopic framework [21] before clustering via HBDSCAN [22]. Model hyperparameters, such as minimum cluster size (n=10), were guided by intrinsic assessment of cluster quality such as coherence scores and extrinsic assessment of cluster quality through manual review. Topic interpretation for each cluster was aided by assessing the term frequency-inverse document frequency of keywords, and the GPT4 large language model was used to identify tangible themes for the clusters. The extracted keywords and GPT4 representations were assessed to determine which of the clusters warranted further manual examination to extract qualitative insights on uUTIs in terms of disease experiences, treatment experiences, prevention of UTIs, and experiences with HCPs. Clusters not relevant to uUTIs in these contexts were rejected.

Figure 1. Data collection, extraction, and analysis.

End Points and Analyses

The primary objective was to gather patient perspectives on key elements of the uUTI experience, including HCP interactions, diagnosis, treatment, and recurrence. Patient quotes are presented for each theme, and insights of interest are discussed alongside key datapoints (including website domains and countries of origin).

Quantitative data were also gathered to evaluate the frequency of posts discussing drugs and home remedies (including specific examples of each) and HCP specialties. This information is presented as a percentage of the total posts per country for countries with a sufficient sample size (the United States, the United Kingdom, Canada, Germany, and India). This analysis was performed prior to the launch of the Pharmacy First scheme (launched in the United Kingdom, January 2024) [23].

Ethical Considerations

This research used secondary data only, was nonclinical and noninterventional, and was for patient experience insight purposes only, to support the current paucity of published data on patients' perspectives with UTI. Institutional review board and research ethics committee approvals were not required nor sought because the research did not meet the requirements for needing ethical approval, per section 1.3 of the EphMRA guidelines [24]. The ethical principles established by the Declaration of Helsinki were respected. Consent to use data from the identified posts was considered implicit due to the published terms and conditions of each platform and the website privacy agreement with users (where relevant). Posts were limited to publicly available sources and anonymized to ensure that no personally identifiable information was included.

Results

Posts Included in the Analysis

A total of 337,252 posts were identified using the search string and 255,497 remained after filtering for those using personal pronouns (Figure 1). Removal of non-English posts, special characters, emojis, website URLs, posts deemed spam or advertisements, posts discussing complicated UTI, and duplicates gave ≈42,000 unique posts. The web-based source and geographic distribution of these posts is shown in Table 1. Most posts were taken from reddit.com (29,506/42,265, ~70%) and were most often from users in the United States (6707/11,180, 60%), the United Kingdom (2261/11,180, 20%), Canada (509/11,180, 5%), Germany (356/11,180, 3%), or India (320/11,180, 3%). After clustering, ≈3600 posts were identified for final analysis and manually examined to extract qualitative insights. Key takeaways were identified from each cluster, leading to the identification of 6 main themes from these posts. These themes were symptom awareness and information seeking, HCP interactions, diagnosis and management challenges, management with antibiotics, self-management, and challenges with recurrent UTI. Key patient quotes are included in Table 2.

Table 2. Select patient quotes organized by theme.

Theme	Definition and verbatim quotes[a]
Symptom awareness and information seeking	• This theme showcases a wide range of experiences and concerns related to UTI[b] symptom awareness, prevention strategies, emotional impact, and peer support. The topic centers on UTI symptoms and guidance for managing suspected cases. • "After exhausting all my options with doctors and gynaecologists, I am now turning to reddit and other women who may be able to help. I've been a sufferer of frequent UTIs for most of my adult life […] Every time I have a period, or am about to have a period, I develop a UTI, there seems to be no rhyme or reason on whether it'll happen just before or just after, but without fail, I'll always get one." • "It sounds like you have a urinary tract infection. It's pretty easy to treat but you do need to go to a doctor or urgent care […] to be sure." • "So my friend recently got a bladder infection (we think) she's a bit nervous about going to the doctor for various reasons, so we're looking for natural suggestions that might work […] She doesn't have any serious symptoms yet, just the general discomfort while peeing and the constant urge to pee and unintentional leaking but we just don't want it to escalate and want some tips before going to a doctor." • "You can try taking cranberry tablets they work for some people. Also drink plenty [of] water after and try to pee again if you can! If the problem persists you can get an antibiotic to take each time you have sex from the doctor."
HCP[c] interactions	• This theme predominantly revolves around the frustration individuals with UTI symptoms feel when seeking treatment from HCPs. • "Doctor has suggested [low dose antibiotic] as I feel like I have cystitis symptoms all the time for last 2 months, got to wait 6 months to see urologist to see what problem is. My GP[d] said they don't have the answers, a lot of it is trial and error. I know myself better than them so I'm always looking and trying different things." • "I went to the Dr because I suspected a bladder infection. Gave all my symptoms. […] Only after pushing did he condescendingly ask if I'd feel better if I provided a urine sample. I said yes. He couldn't look me in the eyes when he gave me a prescription for you [guessed] it, a bladder infection. I've learned that if I'm dealing with my [health] to push back if I feel I am not listened to." • "It took visits to my general physician (who, in less words, told me 'Just stop having sex' LOL), my gynecologist, and then a urologist she recommended, before I got relief. I'm gonna tell you, have your girlfriend see a FEMALE urologist, if you can. Male urologists unfortunately don't always keep up with female urinary research (it's extremely behind male urinary research, too) and having someone who could relate to me and understood my pain as a female/AFAB[e] was HUGE."
Diagnosis and management challenges	• This theme primarily centers around obstacles that individuals experiencing UTI symptoms encounter when seeking an accurate diagnosis from HCPs. • "OMG!!! I knew I had a UTI and the [….] doctor kept refusing to test saying it was probably an STD[f]. It was not an STD and when the results for the UTI came back it showed I had a staph infection in my bladder." • "The first time I was quite happy to go through the rigamarole of giving a urine sample and getting antibiotics. After a few episodes of this happening, the antibiotics started playing with my gut and causing issues there […] four years in I have a system that has worked well enough for me." • "I had a WOMAN doctor tell me the blood coming from an intense bladder infection was… and I quote, 'Probably a miscarriage.' I had been going through a divorce for months and hadn't had any physical contact, let alone the [contraceptive] I was on. She didn't even ask. The bias against women's health is incredibly ingrained in the entire system." • "He put me on Flagyl, which immediately gave me a yeast infection, put me on another med, got the UTI back. He put me on Flagyl again, and another yeast infection. Apparently it's a side effect. This cycle went on about 8 times, and every time, I told him the meds weren't working and giving me more problems. But he's the doctor and knows best, right? Weeks later, I'm in ICU[g] literally clinging to life with sepsis, because of an 'undiagnosed UTI'." • "Doing a more in-depth test cannot hurt […] it's sad all they do is dip stick, culture, cipro […] I would have never found my staph infection in my bladder had I not tested further using the advanced next generation sequencing DNA test."

XSL•FO
RenderX

Theme	Definition and verbatim quotes[a]
Management with antibiotics	• This topic focuses on physician-led treatment approaches to managing UTIs, including personal experiences with the antibiotic use, their pros and cons, and potential side effects. • "I had, maybe still have, a super resistant [*Pseudomonas*] UTI. I'm still having occasional burning in the bladder area and occasional back pain a week after stopping [antibiotic] (really bad side effects, had to stop after 4 days, but doctors said I took enough of it) […] my urine is clear now despite my symptoms. They still sent it for culture and I'm waiting on that to come back. I am so distressed from this, it's taking a huge toll on me as it's been going on for over two weeks back and forth with doctors. Also, especially after reading about [*Pseudomonas*], I feel like I won't be able to get rid of it and who knows what will happen to me." • "I had this same problem for years. At one point I had 5 UTIs in 4 months. Every time it would be after sex with my husband. The doctor cultured it but could never identify what specifically was causing the UTI. Finally, when I saw my gynecologist she gave me a prescription for [antibiotic]. I take one pill right after sex. I've been UTI free for the last 15 years." • "I ask because the [antibiotic] is causing me a lot of pain in the left leg and I'm scared to continue it […] I had three of the six I was told to take before I stopped because I couldn't sleep or walk well from the pain (which slowly died down over the day I was off them) but now I've taken a fourth because the UTI scares me." • "If [antibiotic] hasn't worked after the 1st course we generally want to switch to something else rather than bombard the body with long-term antibiotics. That's just a recipe for an ongoing yeast infection, lowered gut health and a massive case of [*Clostridium difficile*] diarrhea."
Self-management	• This topic focuses on self-management approaches to treating UTIs, including recommendations regarding different approaches to managing UTIs such as home remedies. • "UTIs are more common in women than men. If you are male definitely go to the doctor […] If you are female, you are supposed to go to the doctor, but honestly most just drink water and low sugar cranberry juice until they're fine because they're so common. If you get a fever, definitely go to the doctor." • "Stop just using cranberry juice every time you have a UTI!! So many [women] go through so much unnecessary pain and worsen their UTIs just because they think drowning themselves in cranberry juice will help. Cranberry juice/cranberry supplements can HELP PREVENT UTIs, once you have one, your best friend is going to be antibiotics, pain killers, and WATER to flush out bacteria." • "Just wondering if anyone has tried D-Mannose for recurrent UTI? I have a prescription for [antibiotic] to take after intercourse or when I feel a UTI coming on but I take it so often that I'm worried about antibiotic resistance. I use Azo a lot but it stains... I'm trying to find something to help as a preventative." • "I've had great success with using D-Mannose. Since I had a UTI in [February] I was left with chronic low-level symptoms that didn't go away—awareness, bladder burning, frequency. My culture came back negative but after reading about embedded infections I began to suspect that it was an infection that was just going undetected. I use powder D-Mannose (more potent than capsules). After about a week of high dosing (4× a day) my symptoms were greatly reduced, almost completely." • "I used to get UTIs, and having to go to the doctor placing me on different kinds of antibiotics. Some worked, some didn't so I wound up having to go back to the doctor which winds up to be very expensive [...] I came across a video on YouTube where this girl [...] said she was taking a probiotic plus something for UTIs. She was taking a product called D-Mannose. I ordered it from Amazon, and I have to say that it has worked for me."
Challenges with recurrent UTI	• This topic primarily centers on individuals' experiences with recurrent UTIs. Discussions focus on personal experiences, physical and mental burden, and methods used for both treatment and prevention. • "I don't know if my fourth and most recent [antibiotic] is working against this, and my doctor won't be in for the next five days. I'm so tired of this! I know that rUTIs[h] is a thing, but to have these literally back to back? No day to breathe without wondering if this will be when I go septic and die? I almost wish that this will kill me at this point." • "I've been to urologists and a [urogynaecologist] in addition to my [gynaecologist]. No one can give me answers. My cystoscopy was fine and after that, the [urogynaecologist] said to just take dmannose daily, drink 3-4 liters of water a day, and good luck. I refuse to believe this will be my life now [...] There HAS to be some resolve." • "I've struggled with recurrent UTIs for about 15 years and tried every single supplement and herb I could find info about. I often react very poorly to antibiotics (ranging from allergic reactions to intestinal yeast infection, oral thrush, diarrhea for weeks, flu-like symptoms, I [hate] taking antibiotics) so I avoid them whenever possible, I'll do anything to cure UTIs at home before resorting to antibiotics." • "LOOKING FOR ADVICE! I suffer from recurring urinary tract infections. When I go to the doctor, they just put me on antibiotics for a few days and the infection usually goes away […] I don't want to be on antibiotics that often and ruin my microbiome. However, I don't want to risk permanent damage to my kidneys by not treating the UTIs properly. I am looking for tips on how to better prevent them moving forward."

[a]Quotes have not been edited, except for omission of text where deemed appropriate (indicated by [...]) or correction of spelling or grammar, removal of drug names, and definition of non–standard abbreviations for clarity (indicated by corrected or new text).

[b]UTI: urinary tract infection.

[c]HCP: health care professional.

[d]GP: general practitioner.

[e]AFAB: assigned female at birth.

[f]STD: sexually transmitted disease.

[g]ICU: intensive care unit.

[h]rUTIs: recurrent urinary tract infections.

Symptom Awareness and Information Seeking

Many posts were from individuals seeking guidance or recommendations for when faced with UTI symptoms and methods for managing symptoms at home. Posts shared personal experiences (including physical and mental symptoms, HCP and patient experience, and impact on daily life and activities) with UTIs and expressed support for fellow individuals with UTIs. Patients value the ability to form virtual networks and communities with others facing the same challenges. Some posts provided recommendations for pain relief and symptom management strategies. One post stated, “So many [women] go through so much unnecessary pain and worsen their UTIs just because they think drowning themselves in cranberry juice will help. [...] Once you have one, your best friend is going to be antibiotics, pain killers, and WATER to flush out bacteria.”

Some posts highlighted a tendency for patients to seek guidance on the web prior to consulting an HCP. Some patients do this because they feel uncomfortable approaching an HCP or because they prefer to determine the severity of their symptoms on the web before seeking professional help. One post highlighted this hesitancy: “My friend recently got a bladder infection (we think) she’s a bit nervous about going to the doctor for various reasons [...] She doesn’t have any serious symptoms yet [...] but we just don’t want it to escalate and want some tips before going to a doctor.”

Notably, many posts stressed the importance of seeking professional medical help when confronted with UTI symptoms. One post said, “It’s pretty easy to treat but you do need to go to a doctor or urgent care [...] to be sure.”

HCP Interactions

Posts frequently discussed difficulties obtaining a medical appointment. Some patients highlighted long waiting times and others were advised to visit the emergency department, which was often deemed an inappropriate course of action. One post stated, “Doctor has suggested [low dose antibiotic] as I feel like I have cystitis symptoms all the time for last 2 months, got to wait 6 months to see urologist to see what problem is.” Patients who had attended appointments often discussed the tendency for HCPs—particularly males—to be dismissive of the impact of their UTI symptoms. Some patients equated this to trivializing their pain and discomfort. In contrast, female HCPs were reported to be more empathetic and demonstrated a deeper comprehension of the specific requirements of female patients. One post read, “Have your girlfriend see a FEMALE urologist, if you can. Male urologists unfortunately don’t always keep up with female urinary research.”

The medical approaches relayed in the posts demonstrated a lack of shared decision-making. Many HCPs prescribed treatments without engaging in comprehensive discussions with patients. This practice led patients to feel frustrated, particularly when treatment was ineffective or had unfavorable side effects. Some posts offered advice for navigating HCP appointments, including specific diagnostic evaluations or treatments to advocate for, and which to avoid. The importance of advocating for personal preferences was emphasized. One patient said, “I’ve learned that if I’m dealing with my [health] to push back if I feel I am not listened to.”

Diagnosis and Management Challenges

Many patients commented on complex diagnostic processes or a lack of diagnostic workup before receiving a prescription. The restricted sensitivity of urine culture tests was discussed (particularly for less prevalent strains or infections with minimal bacterial presence) and some posts advocated for more sensitive assessments such as the MicroGenDX diagnostics test (which combines quantitative polymerase chain reaction with 16s/18s next-generation sequencing). One post read, “Doing a more in-depth test cannot hurt [...] it’s sad all they do is dip stick, culture, cipro [...] I would have never found my staph infection in my bladder had I not tested further using the advanced next generation sequencing DNA test.” Patients also reported instances of misdiagnosis while experiencing UTI symptoms, including diagnoses of period cramps or sexually transmitted infections. One patient said, “I knew I had a UTI and the [...] doctor kept refusing to test saying it was probably [a sexually transmitted disease (STD)]. It was not an STD and when the results for the UTI came back it showed I had a staph infection in my bladder.” Misdiagnosis led to a loss of trust in HCPs.

Posts also discussed the provision of inadequate treatment by medical professionals. One read, “I went to the [doctor] because I suspected a bladder infection. Gave all my symptoms. [...] Only after pushing did he condescendingly ask if I’d feel better if I provided a urine sample. I said yes. He couldn’t look me in the eyes when he gave me a prescription for you [guessed] it, a bladder infection.”

Some patients felt that treatment decisions should be informed by comprehensive diagnostic evaluations. Instances of antibiotic prescribing without consideration of the specific bacteria present were highlighted. These situations often led to ineffective treatment that necessitated multiple rounds of therapy.

Management With Antibiotics

There was consensus among posts that antibiotics are necessary to cure UTIs and prevent associated complications.

XSL•FO
RenderX

Nitrofurantoin was the most frequently mentioned antibiotic, followed by ciprofloxacin, but many patients said that they were frustrated with medical interventions as they continue to experience UTIs despite good adherence. Few posts described situations where HCPs conducted microbiological cultures and sensitivity testing to identify the most appropriate antibiotic for their UTI. Some patients expressed a preference for more convenient doses, with 1 patient explaining that this was due to the need to "choke down pills [twice a day]" on [antibiotic].

Side effects of antibiotic therapy were also discussed and concerns regarding antibiotic resistance led some patients to seek alternative therapy. One patient asked, "Just wondering if anyone has tried D-Mannose for recurrent UTI? I have a prescription for [antibiotic] [...] but I take it so often that I'm worried about antibiotic resistance. [...] I'm trying to find something to help as a preventative."

Patients who chose not to take certain classes of antibiotics reported opting for home remedies or other antibiotics instead. Discussed side effects included nausea, potential lung toxicity, and an increased risk of yeast infections. A small number of patients discussed HCP warnings about potential tendon-related side effects when taking certain antibiotics. Patients also discussed concerns regarding the associated black box warning and some reported experiencing leg and back pain while on treatment. One post said, "It has 3 black box warnings and has caused healthy people horrible side effects." Another said, "[Antibiotic] is causing me a lot of pain in the left leg and I'm scared to continue it." Within the posts, there were no references to shared decision-making when prescribing antibiotics.

Self-Management

Over-the-counter and home remedies for UTI were the most common topics among posts but opinions on them varied. Some patients preferred self-management as it helped them feel in control of their treatment. These patients may have also felt frustrated with the care they received or with having to return to the doctor multiple times. One patient said, "I used to get UTIs, and having to go to the doctor placing me on different kinds of antibiotics. Some worked, some didn't so I wound up having to go back to the doctor which winds up to be very expensive."

Patients with a positive view of home remedies shared their experiences with nonprescribed treatment options, including hydration, D-mannose, cranberry, probiotics, and herbal supplements (uva ursi). Opinions on cranberry juice and supplements were more divided; this seemed to be the case among both patients and HCPs. One post about cranberry products read, "If you are female, you are supposed to go to the doctor, but honestly most just drink water and low sugar cranberry juice." Another said, "Stop just using cranberry juice every time you have a UTI!! So many [women] go through so much unnecessary pain and worsen their UTIs just because they think drowning themselves in cranberry juice will help."

Challenges With Recurrent UTI

Posts about recurrent UTI consistently highlighted the burden of persistent and incapacitating symptoms and their association with feelings of anxiety and helplessness. One post read, "No day to breathe without wondering if this will be when I go septic and die[.] I almost wish that this will kill me at this point." Factors contributing to the emotional toll of recurrent UTI included a perceived loss of bodily control and a negative impact on intimate relationships. Some posts discussed the use of long-term, low-dose antibiotics to prevent recurrence but lacking effectiveness and side effects were also mentioned. Many patients turned to over-the-counter remedies such as D-mannose and cranberry products to prevent recurrence. Success with these approaches was limited. One patient said, "I've struggled with recurrent UTIs for about 15 years and tried every single supplement and herb I could find info about. I often react very poorly to antibiotics [...] I'll do anything to cure UTIs at home before resorting to antibiotics." Other patients reported lifestyle changes (such as reducing caffeine and alcohol intake and stringent hygiene routines) to combat recurrent UTI and some reported positive outcomes of these changes.

Quantitative Outcomes: Antibiotics, Home Remedies, and HCP Specialties

All countries (Canada, Germany, India, the United Kingdom, and the United States) were included in the analysis of 9619 posts mentioning antibiotics, home remedies, and HCP specialists. Most posts (7270/9619, 76% of those included in the quantitative analysis) discussed antibiotics only, 13% (1290/9619) mentioned home remedies only, and 11% (1059/9619) mentioned both antibiotics and home remedies, as shown in Figure 2. The proportions of posts mentioning antibiotics and home remedies were similar across Canada, the United Kingdom, and the United States, but specific drugs (including antibiotics and pain relief) were discussed less frequently in the posts than home remedies. Cranberry and D-mannose were the most discussed home remedies.

Figure 3 shows that, among posts mentioning HCP specialties, specialist HCPs (urologists, obstetricians or gynecologists, and urogynecologists) were mentioned more frequently in posts from the United States (670/875, 77%) and Canada (44/71, 62%) than from the United Kingdom (329/646, 51%). Only 3% (21/646) of posts from the United Kingdom discussed nurse practitioners or urgent care versus 27% (19/71) in Canada and 22% (190/875) in the United States. Mentions of pharmacists were also much more frequent in Canada (10/71, 14%) than in the United Kingdom (14/646, 2%) or the United States (18/875, 2%).

XSL•FO

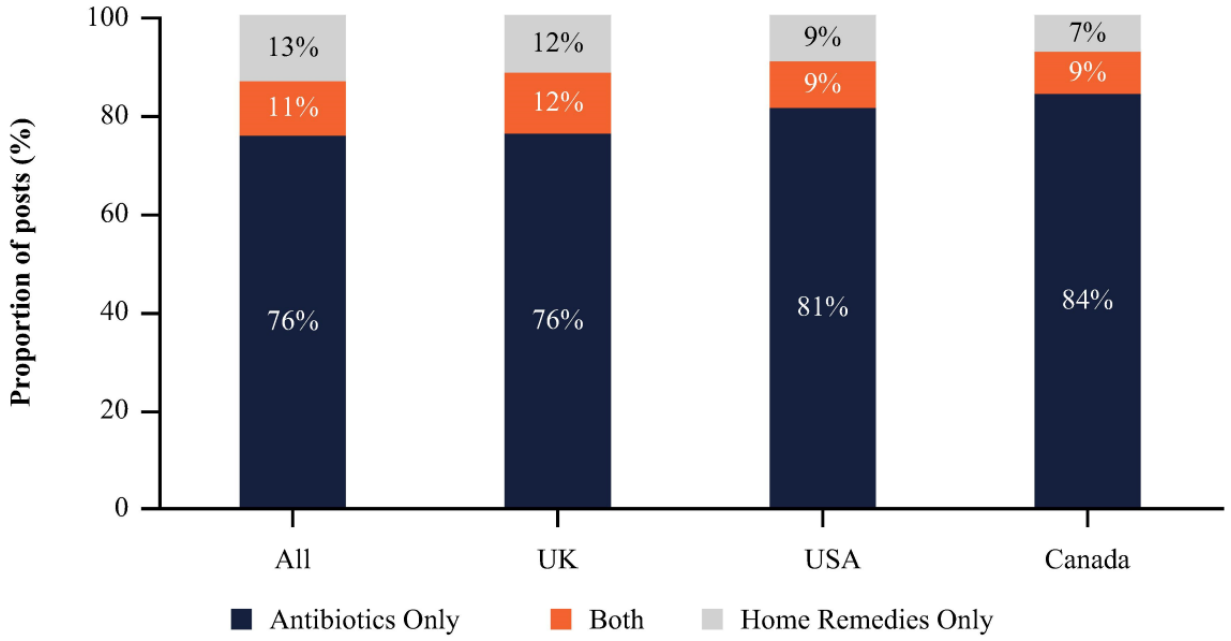
Figure 2. Proportions of posts mentioning antibiotics only, home remedies only, or both antibiotics and home remedies. Home remedies included D-mannose, cranberry products, probiotics, and herbal supplements.



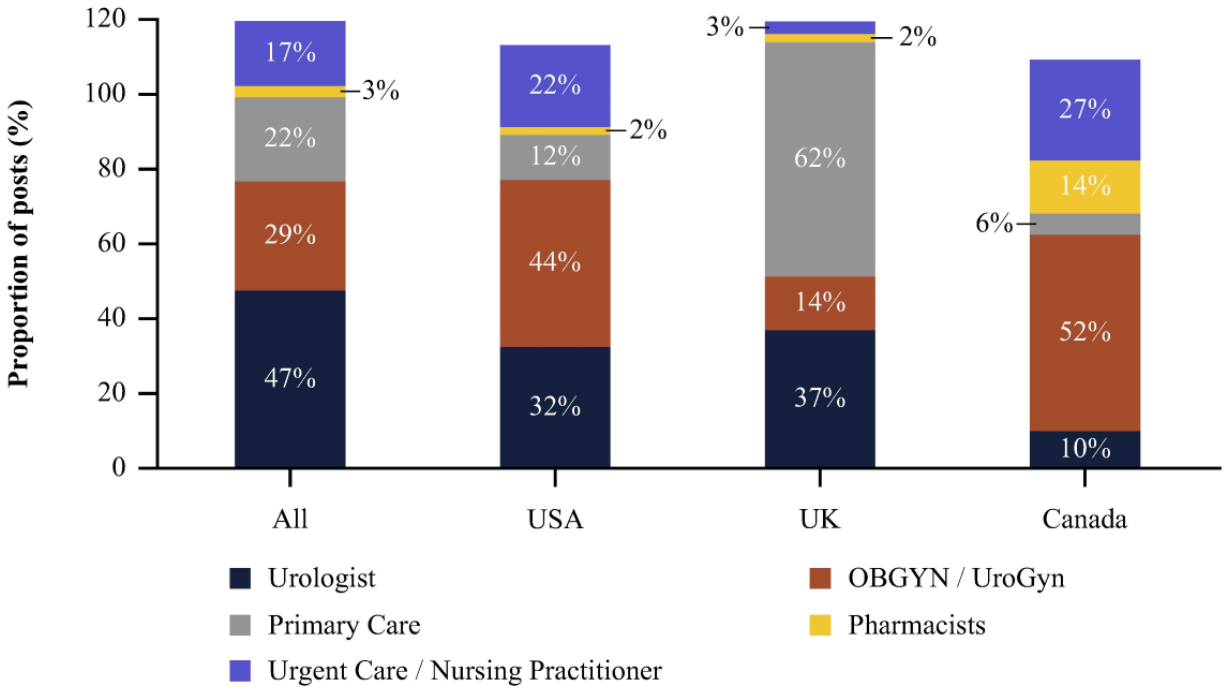


Figure 3. Proportions of posts mentioning health care professional specialties. OBGYN: obstetrician/gynecologist. UroGyn: urogynecologist.

Discussion

Principal Findings

This retrospective social media study highlighted the strength of the web-based uUTI community, in which patients provide one another with emotional support and recommendations based on personal experience. Topics and behaviors observed in this study were somewhat aligned with those noted in the only preexisting, large-scale social media analysis of uUTI, including information-seeking, antibiotic treatment, and alternative therapy [18]. In addition to these topics, our study raised some further themes, including discussions about interactions with HCPs, as also observed in the study by Flower et al [8]. These insights have important implications for the patient journey and challenges associated with recurrence and should supplement existing data to provide a more holistic view of patient experiences and opinions of uUTI.

Patients in this study tended to search for advice on the web before consulting an HCP, and most posts stressed the importance of seeking professional help. Nevertheless, not all patients obtained medical appointments easily or were satisfied with their HCP interactions once an appointment was secured.

XSL•FO
RenderX

Patients also reported that some HCPs lacked empathy and knowledge of the potential emotional, mental, and physical impact of uUTIs on patients. Others were frustrated with treatments prescribed following inadequate discussions. These sentiments are reflected in the findings of previous qualitative studies of UTI [7,11]. In one such study, 35% of 466 survey respondents highlighted dismissive or unempathetic HCP behavior and many described difficulties accessing care [11]. Another study noted miscommunication between patients and HCPs as a barrier to appropriate prescribing [7]. Effective HCP communication regarding the advantages and drawbacks of certain therapies is essential to foster meaningful shared decision-making. Some posts also highlighted female HCPs as more empathetic than males. This is important because HCP empathy can improve patient satisfaction, increase adherence, and enhance outcomes [25,26]. Patients in a prior clinical study based in an obstetrics and gynecology department reported preferences for female HCPs because of their empathy and competence [27].

Most patients in this analysis also discussed the importance of antibiotics to cure their UTI. However, some patients had concerns about antibiotic use related to persistent symptoms and to the knowledge that repeated use of antibiotics may lead to antibiotic resistance, prompting them to seek alternative therapy. Hesitance in using antibiotics has also been associated with concerns that antibiotics may not be effective in the future; some women would rather understand how and why they got the UTI and how to prevent it in the future [7]. These concerns could be alleviated by ensuring that patients receive appropriate information on prevention and potential antimicrobial resistance, are prescribed the most appropriate treatment (especially those at risk of developing symptoms due to antibiotic-resistant bacteria), and feel empowered to engage in shared decision-making during treatment discussions with HCPs. Risk factors associated with antibiotic resistance in UTI include older age, which could be due to previous antibiotic exposure [28], and recurrent UTI [29].

Fears of antibiotic resistance in UTI may be linked to the common misconception that antibiotic resistance is a quality intrinsic to patients, rather than to the bacteria causing an infection [7,18]. This phenomenon may explain the prior observation that women with UTI are generally willing to accept treatment options with a longer time to resolution or a higher risk of side effects to avoid resistance [12]. Combined with factors such as hesitancy to see an HCP and frustration with care, fears of resistance may also contribute to the prevalence of posts about home remedies for UTI. This was the most common topic in our study. Many posts highlighted experiences with cranberry products and D-mannose, which are supported by mixed (positive and negative) and low-level clinical trial evidence, respectively [30]. In fact, a prior social media study identified that 53% of web-based recommendations had some supporting evidence (including cranberry products and D-mannose) but 43% were not supported by science. These unsupported recommendations included hygiene routines and dietary modifications such as avoiding alcohol and caffeine [16]. Web-based recommendations should be taken with care as the people advising may not be medical professionals. According to the European Association of Urology Guidelines on Urological Infections, clinicians may recommend cranberry products and D-mannose to reduce recurrent UTI episodes in patients, providing they inform them of the weak evidence base supporting this [31]. Overall, there are few studies and a lack of robust data investigating these recommendations, and this is an ongoing challenge in UTI research. It is interesting that, despite lacking placebo-controlled data and evidence for these approaches, a substantial number of posts in our study reported success when using them to prevent recurrent UTI; however, the true efficacy of these measures using placebo-controlled trials is undetermined.

The quantitative results obtained were unsurprising and reflect geographical variations in access to health and everyday practice behaviors. For example, while patients in Canada and the United States can access specialists without needing a referral, in the United Kingdom, National Health Service specialist appointments require a referral from a general practitioner. This is reflected in the high proportion of patients mentioning primary care (402/646, 62%) in UK posts. Similarly, pharmacists were mentioned more frequently in Canada because of the expanded scope of their role, which includes the capacity to prescribe antibiotics for UTI, as opposed to countries where it does not.

Patients from this analysis tended to seek information via social media before approaching an HCP, which underscores a potentially important opportunity for information outreach. Patients seeking information related to health online is becoming increasingly popular [32]; this need is emphasized by the fact that many patients lack preexisting knowledge regarding the cause, diagnosis, and treatment of UTIs [33]. Currently, however, many posts on social media sites are from sources that are not peer-reviewed and may contain misinformation [16,34]. Literature has highlighted that poor health literacy may affect the usefulness of social media interventions, which may result in health inequity [35]. One analysis on the video-sharing platform TikTok found that 75% (224/300) of identified videos about antibiotics were from non-HCPs, but HCP videos were significantly more relevant, significantly less biased, and significantly more likely to have an educational focus [34]. This highlights the need for accurate and successful advocacy for patients. An emphasis on creating HCP-led educational content for these platforms may help patients who seek health information via social media to identify the correct care sooner. Educating patients in this way could improve their communications with HCPs and drive shared decision-making. However, it is crucial to note that some HCPs may lack up-to-date knowledge on the testing and treatment approaches for uUTI, especially recurrent UTI, leading to patients feeling misunderstood [14]. It is important that both HCPs and patients are educated on uUTI and shared decision-making. This approach might also limit the potential for negative patient-HCP interactions driven by the acquisition of suboptimal information from non-HCPs on the web [36]. One notable obstacle may be the lack of social media use among HCPs: a 2021 analysis of 650 HCPs at 10 top American hospitals showed that more than 70% had at least 1 social media profile but among these, almost 90% had not posted in the prior month [37].

XSL•FO
RenderX

Limitations

This study had some limitations that must be considered when interpreting the outcomes. Demographic data were not collected and most content was posted by users in Canada, the United Kingdom, and the United States (mainly due to the inclusion or exclusion criteria for the posts); views from some patient groups and from other countries may be underrepresented. One patient group that may be particularly underrepresented is older patients, who may use social media less than their younger counterparts. It is also possible that patients posting on social media may have had more troublesome UTI experiences (such as more impactful symptoms or a worse treatment journey) than those who chose not to post on social media. While every effort was made to limit results to those associated with uUTI, some cases of complicated UTI or comorbidities may have been included, which could have an impact on the analysis. Posts from closed forums were not included in the analysis. Valentine-King et al [11] reported that surveys may be distributed using an international internet platform, reaching a larger group of patients, not limited to a particular practice, health network, or country. This may increase the variety of responses and experiences [11], although participation could still be limited for older patients or those with no or limited access to technology [38].

Conclusions

This analysis of more than 42,000 social media posts provides valuable insight into the experiences and opinions of patients with uUTI in Canada, Germany, India, the United Kingdom, and the United States. Many patients sought information on the web before seeking professional medical care, which emphasizes the importance of peer support in the UTI patient journey and the value of accessible web-based resources for patient education. Women reported difficulties accessing care and inadequate interactions with HCPs, characterized by dismissive behavior and lacking diagnostic evaluations. Although the importance of antibiotics was widely appreciated, many patients noted hesitance toward them or dissatisfaction with their efficacy and side effects. Patients highlighted fears and concerns about risks of antimicrobial resistance which, if proactively discussed by HCPs with patients, could further improve patient-HCP interactions. Alternative treatments were discussed frequently but not all were supported by scientific evidence. Overall, the insights gleaned in this study provide a more complete picture of patient behaviors and highlight the potential for HCP and patient education in addition to improved communication with HCPs to improve care.

Acknowledgments

Medical writing support for the development of this manuscript, under the guidance of the authors, was provided by Rosie Robson, MSc, of Ashfield MedComms, an Inizio company, and funded by GSK. Trademarks are the property of their respective owners (metronidazole [Flagyl]; Sanofi).

Conflicts of Interest

MLK is the CEO and founder of Live UTI Free Ltd. None declared for JMP and NK. AM and AB are employed by, and hold financial equities in, GSK. This research was funded by GSK.

Abstract

Background: In Chinese traditional culture, discussions surrounding death are often considered taboo, leading to a poor quality of death, and limited public awareness and knowledge about palliative and end-of-life care (PEoLC). However, the increasing prevalence of social media in health communication in China presents an opportunity to promote and educate the public about PEoLC through online discussions.

Objective: This study aimed to examine the factors influencing public engagement in PEoLC discussions on a Chinese social media platform and develop practice recommendations to promote such engagement.

Methods: We gathered 30,811 PEoLC-related posts on Weibo, the largest social media platform in China. Guided by the elaboration likelihood model, our study examined factors across 4 dimensions: content theme, mood, information richness, and source credibility. Content theme was examined using thematic analysis, while sentiment analysis was used to determine the mood of the posts. The impact of potential factors on post engagement was quantified using negative binomial regression.

Results: Organizational accounts exhibited lower engagement compared to individual accounts (incidence rate ratio [IRR]<1; *P*<.001), suggesting an underuse of organizational accounts in advocating for PEoLC on Weibo. Posts centered on PEoLC-related entertainment (films, television shows, and books; IRR=1.37; *P*<.001) or controversial social news (IRR=1.64; *P*<.001) garnered more engagement, primarily published by individual accounts. An interaction effect was observed between content theme and post mood, with posts featuring more negative sentiment generally attracting higher public engagement, except for educational-related posts (IRR=2.68; *P*<.001).

Conclusions: Overall, organizations faced challenges in capturing public attention and involving the public when promoting PEoLC on Chinese social media platforms. It is imperative to move beyond a traditional mode to incorporate cultural elements of social media, such as engaging influencers, leveraging entertainment content and social news, or using visual elements, which can serve as effective catalysts in attracting public attention. The strategies developed in this study are particularly pertinent to nonprofit organizations and academics aiming to use social media for PEoLC campaigns, fundraising efforts, or research dissemination.

Introduction

Background

Palliative and end-of-life care (PEoLC) provides physical, psychological, and spiritual support to patients living with life-limiting conditions and terminal diseases, improving their quality of life and assisting their families [1]. Despite its importance, global public awareness and knowledge about PEoLC is limited [2-4], especially in China. Within the context of traditional Chinese culture, discussions about death and dying have historically been considered taboo [5]. As a result, individuals nearing the end of their lives often face societal and familial moral constraints, hindering their ability to autonomously make end-of-life decisions [6]. China has the largest aging population, with a notably increasing rate [7]. However, in 2015, the quality of China's palliative care was ranked merely 71st among 80 countries or regions worldwide [8]. The coverage rate of PEoLC service in China is only 1% [9], substantially lower than in Europe, America, and other high-income regions [10]. Studies [11,12] suggested that over 80% of Chinese patients with cancer are unaware of palliative care, although the majority support it and desire more information. Hence, there is an urgent need for public education and promotional efforts about PEoLC to address the increasing unmet demands.

Social media provides a channel for PEoLC promotion and education. Kate Granger, an English geriatrician, shared her stories at the end-of-life and described the involvement of palliative care during her patient journey on Twitter (since rebranded to X), attracting around 48,000 followers [13]. Taubert et al [14] produced and delivered video resources on YouTube and Twitter to improve communication in "do not attempt cardiopulmonary resuscitation" decisions in palliative illness in 2016. After less than 6 months, the video reached nearly 100,000 hits and the comments were extremely positive and encouraging. During the COVID-19 pandemic, people actively participated in a series of tweet chats using the Twitter hashtags #comcomcovid, #PallANZ and #PalliCovid hosted by different PEoLC organizations [15,16]. These online chats helped to support both professionals and community capacity for end-of-life care within the emerging landscape of the COVID-19 pandemic. These studies indicated that social media promotion for PEoLC could help to increase public knowledge and awareness, reduce the stigma of talking about death and dying and attract more engagement. The WHO public health model of palliative care emphasizes the importance of educating both the public and professionals to facilitate palliative care integration into health care systems [17]. Social media, with its vast reach, serves as a unique platform for disseminating PEoLC-related information to a broad audience, including young people, who are often future caregivers, patients, practitioners, and policymakers. As critical stakeholders, young social media users are also highly active in disseminating information, amplifying the reach of PEoLC education. Engaging them in this dialogue not only informs their own decision-making but also promotes greater public awareness [18]. Moreover, social media helps bridge the knowledge gap between professionals and the public, making PEoLC education more accessible and aligned with contemporary public health advocacy.

However, to date, research on PEoLC promotion has predominantly focused on English-language platforms in developed countries (eg, the United States and the United Kingdom) [19]. It is essential to extend PEoLC promotion efforts through social media to underserved regions, for example, China. Social media has demonstrated effectiveness in promoting health equity in populations at risk for disadvantage [20]. Therefore, social media may consequently help address the knowledge gap of the public about PEoLC in underserved regions.

Evidence suggests that public participation in interactions on social media will increase effective cognition [21]. It has been studied that public engagement on social media can improve the awareness of health-related information, a sense of belonging, and social connection [20]. Hence, public engagement behaviors with PEoLC-related content on social media, such as commenting, liking and forwarding PEoLC posts, are likely to increase public awareness and knowledge of PEoLC and make changes in PEoLC-related behaviors. It is necessary to understand how to promote public engagement with PEoLC discussions on social media. This study aims to investigate for the first time the factors influencing public engagement of PEoLC posts and explores best practice recommendations for enhancing such engagement on Chinese social media.

Conceptual Model and Research Hypotheses

The elaboration likelihood model (ELM) of persuasion is a theory of information processing that suggests there are 2 routes, central and peripheral routes, to persuasion [22]. In line with the ELM, we systematically distinguished between 2 information processing routes for individual engaging decisions (to engage or not): the peripheral route and the central route. ELM indicates individuals tend to show a higher likelihood of elaboration when they have strong motivations and the ability and individual knowledge to thoughtfully consider the underlying value of social media posts. Here, the central route of the ELM can be used to explain the engaging decision of the users. In contrast, when individuals' motivations and abilities are limited, the likelihood of elaboration is low and individuals will, in turn, rely on simple cues and second-hand information. Therefore, the peripheral route of the ELM can elucidate users' engaging decisions.

Importantly, past research suggested that post content characteristics generally influenced motivation and the ability to engage with posts that lead to the central route [23,24]. Common content characteristics include content theme and content mood [25-29]. Content theme is defined as the overarching subject, topic, or central idea that is being conveyed

XSL•FO
RenderX

or discussed within the textual content of a post. It is now well established from a variety of studies that content theme plays a critical role in increasing health-related post engagement. Holly and colleagues [25] studied 500 diabetes-related Facebook posts to explore the effect of content themes on engagement behavior. They observed posts related to diabetes symptoms information and positive self-identity had higher sharing while posts related to negative facial expressions, social support, and crowdsourcing had higher commenting. Their findings were consistent with another study [30] that focused on cancer-related posts on Sina Weibo, a Chinese social media platform, which found that social support and cancer treatment attracted the highest number of users and received the greatest number of retweets, comments, and likes. Another recent study [26] collected the COVID-19 pandemic-related videos on one Chinese streaming video platform and identified video content theme emerged as the most critical factor influencing engagement. They observed that emotional-focused messages that psychologically coped with the COVID-19 pandemic situation have more attractiveness compared with problem-focused messages that physically specified risks and strategies. Taken together, these studies suggested content theme is one of the important influencing factors of post engagement, and emotional content (such as social supports) tended to have more engagement in health care communication. Hence, we proposed the first hypothesis:

- The content themes have different effects on public engagement of PEoLC posts on the Chinese social media platform.

Another important central factor of post engagement is content mood. Mood is defined as the emotional tone or atmosphere conveyed by the post content. When individuals are exposed to emotional content on social media, they are likely to share their mood and this further promotes their engagement behaviors, such as sharing, liking, and commenting [31,32]. Previous research established that the influence of post mood differs within various contexts. Bhattacharya et al [27] focusing on Facebook posts from US health agencies accounts found that posts which expressed positive sentiment generated more engagement. However, another study [28] which also focused on US health agencies' accounts on Twitter found that post mood was not significantly associated with the level of engagement. Xu and Zhang [29] demonstrated that tweets with positive emotions increased the level of retweets, but content showing anger reduced those retweets. Thus, the effect of mood factors differed between diverse platforms, regions, and health topics. This led to our second hypothesis:

- The mood positively affects public engagement of PEoLC posts on the Chinese social media platform.

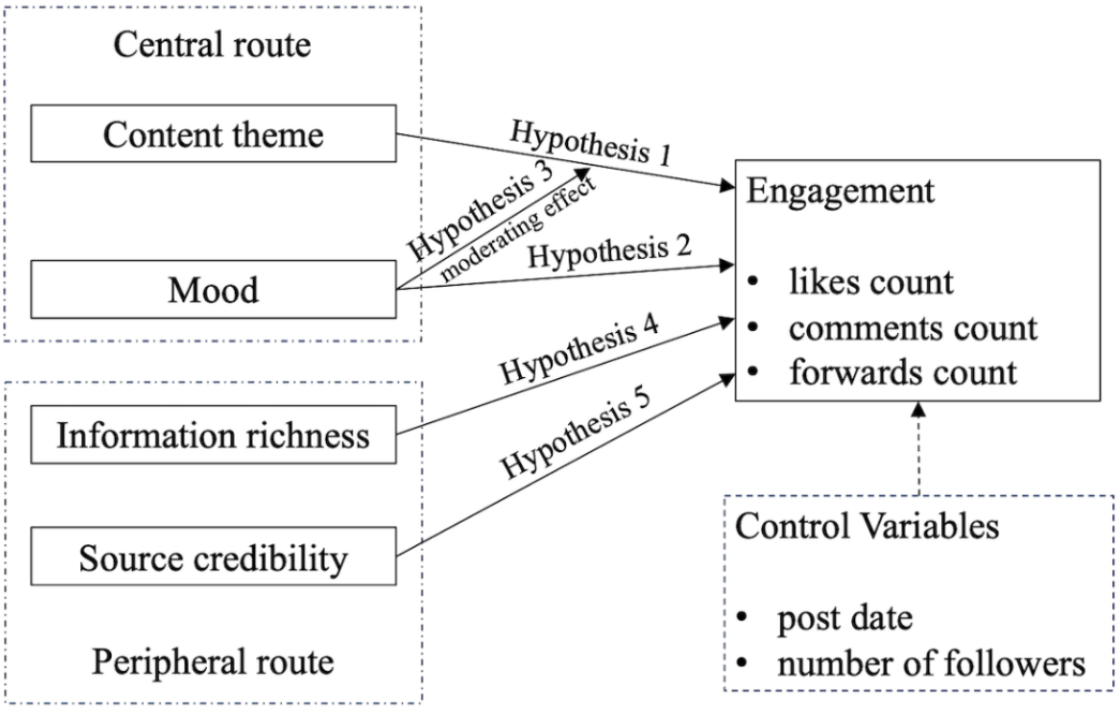
Furthermore, post mood was possible to moderate the effects of other influencing factors on post engagement. Chen et al [33] analyzed the content published by the Chinese government's official TikTok account during the COVID-19 pandemic. They demonstrated that the relationship between video content theme and citizen engagement was moderated by the emotional valence of video titles. For instance, videos related to the government handling of the pandemic and guidance for stakeholders that positive titles received a greater number of shares. Likewise, Tang et al [34] supported this view that for a certain type of social media content, positive sentiment can achieve a higher level of engagement behavior. Another study on Sina Weibo [35] found that news related to the COVID-19 pandemic crisis evoking negative emotions had higher engagement than those with positive emotions. Accordingly, the third hypothesis was proposed to test the moderating effect of mood on content theme and post engagement:

- Post mood has a moderating effect on the relationship between content theme and public engagement of PEoLC posts on the Chinese social media platform.

Previous literature [36-40] suggested information richness and source credibility commonly influence post engagement through the peripheral route. Information richness is defined as visual or textual formatting elements (such as visual cues, and external links) that contribute to the comprehensiveness and vividness of information within a post [41]. Many recent studies have shown that information richness may positively affect post engagement. Bhattacharya et al [27] analyzed >45,000 Facebook posts from health agency accounts. They identified Facebook posts with more visual cues, such as photos generated more engagement. This is supported by others who observed significant and robust positive effects of visual cues on post engagement [36,37]. During the COVID-19 pandemic, Ngai et al [38] examined 608 the COVID-19 pandemic posts published by an official news account and found links to external sources fostered sharing behaviors. This led to our fourth hypothesis:

- The information richness positively affects public engagement of PEoLC posts on the Chinese social media platform.

Source credibility is defined as the attractiveness, trustworthiness, and expertise of a post's publisher according to the source credibility model [42-44]. In the online environment, source credibility was evaluated on the basis of the social cues provided by the publisher in the site network, such as publisher type. Existing literature indicated that user engagement can be affected by different kinds of publishers (eg, health agencies, influencers, and noninfluencers) [39,40,45]. For instance, Kostygina et al [45] tried to investigate source features of Twitter messages in an antitobacco campaign and found using social influencers as message sources could generate more sharable content (eg, campaign hashtags) and greater volume of tweets and reach per day. Xu et al [40] demonstrated that during the COVID-19 pandemic, original posts from official health care accounts on Sina Weibo were more likely to generate more user engagement compared with reposts. Therefore, we proposed the fifth hypothesis:



- The source credibility feature, such as the publisher types have different effects on the public engagement of PEoLC posts on the Chinese social media platform.

We attempted to understand these influencing factors from the peripheral and the central route. Two dimensions (content theme and mood) of the central route and 2 dimensions (information richness and source credibility) of the peripheral route were selected and tested as shown in Figure 1. Furthermore, according

XSL•FO
RenderX

to ELM theory, individuals' decisions are influenced by their motivation and ability, which determine the different processing routes undertaken. Therefore, in turn, we can also gain some basic ideas of social media users' motivations and ability for PEoLC content from their preference to the peripheral or the central route when engaging with PEoLC discussion.

Figure 1. A conceptual framework to explore factors influencing post engagement.

Methods

Data Collection and Preprocessing

We collected Weibo posts dating from September 1 2009 to December 12 2022 through Python (version 3.8.3; Python Software Foundation). Sina Weibo (hereafter referred to as Weibo; Weibo Corporation) is a major social media platform in China, with >575 million monthly active users as of 2024 [46]. It plays a key role in shaping digital discourse and influencing cultural trends in the country. Often described as China's equivalent of Twitter, Weibo allows users to create short-form content and engage in interactive discussions. User interactions on Weibo primarily include 3 key actions: sharing, commenting, and liking posts. Figure 2 illustrates the typical structure of a Weibo post, providing an example of the platform's interface and its user interaction mechanisms.

Keywords that were used to retrieve palliative care–related posts, such as "姑息治疗 (palliative care)," "临终关怀 (hospice care)," "生命终末期 (end-of-life)" are listed in Multimedia Appendix 1. To ensure the comprehensive inclusion of palliative care–related keywords, we (1) summarized common keywords used in previous studies [47-49]; (2) consulted experts in palliative care; and (3) conducted a "snowball" search strategy (starting with a small set of search keywords and iteratively expanding it by examining posts retrieved by these keywords and identifying additional keywords). Since the original concepts were in English, YW translated these concepts into simplified Chinese and engaged 2 bilingual Chinese speakers (HZ and YZ) to check translations. Disagreements in wording and meaning were resolved through further discussion.

Data preprocessing was further conducted. First, we detected and deleted posts published by bot accounts. A bot account on a social media platform entails an automated digital entity capable of emulating human interactions, and its potential harms encompass the dissemination of misinformation, manipulation of public discourse, and distortion of authentic engagement dynamics within the digital sociocultural landscape [50]. We identified one account as a bot account if it is abnormally active (published >30 posts a day) [51]. Second, we coped with missing data and outliers. We deleted posts with missing values or outliers in any variables in metadata. There were 2 reasons for doing so. The first was filling in these missing values with a replaced value will inevitably lead to bias. The second was that the total amount of records was large enough to tolerate a very small part of records being deleted [52,53]. Third, we manually went through the rest of the posts and excluded 1565 posts which were irrelevant to PEoLC. Some posts made jokes using PEoLC-related terms, for example: "My phone doesn't work anymore. I need hospice care for my phone." Since they cannot contribute to our understanding of PEoLC online discussion, we decided to consider them as noisy data and deleted these posts. Subsequently, we obtained 30,811 palliative care–related Chinese posts published by 20,764 distinct users. All Python (Python Software Foundation) and R scripts (R Foundation for Statistical Computing) used for data collection, preprocessing, and analysis were available from a GitHub (GitHub Inc) repository [54].

Figure 2. An example of Weibo posts.

Operationalization of Variables

Public engagement with PEoLC discussion on Weibo was the dependent or response variable of our study and it was reflected in 3 dimensions: sharing, liking, and commenting behaviors. Public engagement could be used to measure the popularity and attractiveness of social media posts [55]. If a post had high engagement on social media, then we call this post *viral* and it has higher exposure. We captured this objective data using web crawlers. An example of how the objective data were shown in a Weibo post is illustrated in Figure 2. In our study, public engagement in a Weibo post (engagement) was calculated by summing the values of these 3 indicators, a common practice in other social media research [55], as follows:

$$\text{Engagement}_i = \text{likes count}_i + \text{shares count}_i + \text{comments count}_i$$

Content theme was assessed based on 7 thematic categories, encompassing: personal experiences or stories about PEoLC, educating, discussion about entertainment work (film, television series, and books), reflections on palliative care and death, PEoLC activities or achievements, controversial social news, and fundraising. YW and YZ applied thematic analysis [56] to identify themes. This followed a multistage process, commencing with data familiarization, wherein researchers immersed themselves in the dataset to gain a deep understanding of the content. Subsequently, we generated initial codes, followed by theme development, constant comparison, and refinement of themes to ensure their coherence and relevance. We specifically applied thematic analysis to the content pertinent to PEoLC, ignoring the potential presence of irrelevant content within a post. In cases where a post encompassed multiple themes, the predominant theme was determined on the basis of the theme exhibiting the most distinct characteristics. To ensure analytical rigor, the level of agreement between the 2 reviewers (YW and YZ) for the thematic analysis was determined using Cohen κ. Intercoder reliability by κ coefficient was 0.87 (95% CI 0.89-0.85; P<.001). A κ statistic of 0.81 to 1.00 indicates an “almost perfect” strength of agreement. The findings, emerging themes, and their interpretations are presented in Table 1, which provided an in-depth exploration of PEoLC-related topics discussed on Chinese social media.

XSL•FO
RenderX

Table 1. Content themes of palliative and end-of-life care (PEoLC) related Weibo posts.

Themes	Example quotes
Theme 1: personal experiences or stories	
Talking about individuals' experiences with palliative care	"I went to Puren Hospice Hospital for a consultation. The doctor said that my dad can be admitted to their hospital, and if the ward is available my mom can also live in, so that the patient can enjoy the last time with their families. I felt that I have finally found a direction to solve the problem I have been suffering from for a long time."
Theme 2: educating	
Elucidating the scientific aspects of palliative care, including its definition, meaning, and development status	"Hospice care is to provide physical, psychological and spiritual care and humanistic services to help patients spend the last journey of their life with dignity by controlling their pain and discomforting symptoms and guiding their family members to get rid of their sadness as soon as possible before the end of their life."
Theme 3: discussion about entertainment work (film, television series, and books)	
Discussing palliative care–related films, television series, or books	"It's quite good to have this type of TV drama. I was even more shocked by the story in episode 7, which was really good. It is about death, the deceased and their families, the funeral home staff, the hospice...We can discuss a lot and feel strength and warmth from the sadness."
Theme 4: reflections on palliative care and death	
Reflecting on death or palliative care–related topics	"I am speechless. China is lack of death education and Chinese avoid to face up to life and death, which leads to the next generation who do not understand the value of life and then do not know how to care for the dying. For the sake of 'filial piety,' human suffering is prolonged. Repressing human nature is the most antihuman."
Theme 5: activities or achievements	
Reports about palliative care activities or achievements	"From 11th to 17th October, the Hospice of the Affiliated Hospital of Guangdong Medical University held a World Palliative Care Day publicity campaign with the theme of 'Love each other, spread palliative care to help what we need.' The activities included community and hospital visits and stalls, with the aim of promoting the importance of hospice care, paying attention to the quality of life of poor advanced cancer patients and their families."
Theme 6: controversial social news	
A controversial social phenomenon related to palliative care (eg, the legalization of euthanasia in certain countries or protest against the establishment of a hospice center)	"Recently, a community in Xi'an met with collective opposition from owners when it built a care center for the disabled elderly. Many residents said that the hospice affected the quality of life of the residents and hoped that the property owners would choose a new site."
Theme 7: fundraising	
Reports on fundraising initiatives and solicits contributions	"The monthly donation programme is now live! Become a monthly donor for palliative care, have one less cup of coffee a month, and share your love and warmth to the children who are sick and undergoing chemotherapy."

Mood was measured by a post's sentiment score. The sentiment score, ranging from 0 to 1, conveyed the negative sentiment to the positive sentiment of a post. We obtained the content of all posts through web crawlers and then applied sentiment analysis to calculate the sentiment scores through Baidu application programming interface (API). The Baidu API, based on deep neural network, was selected since it has better performance in judging the sentiment of palliative care–related posts compared with other popular Chinese sentiment analysis models such as SnowNLP. SnowNLP intrinsically recognized terms such as "death," and "dying" as negative terms, while these terms were comparatively neutral in the Baidu API. For instance, a post saying "对于剩余寿命无多的终末期患者，姑息治疗主要为患者提供临终关怀及善终服务" ("For patients who are terminally ill with little time left to live, palliative care focuses on providing end-of-life care and hospice services") obtained a sentiment score of 0.92 through Baidu API while obtaining a sentiment score of 0.07 through SnowNLP.

Information richness was measured by 4 indicators: whether a post had pictures or videos or not, whether a post used hashtags or not, whether a post tagged other users or not and the number of Chinese characters included in a post [38,57]. We obtained the content of all posts through web crawlers first. Then, we applied regular expression in Python to detect pictures, videos, webpage links, hashtags, and tagging other users and applied the count function in Python to calculate the number of Chinese characters.

Source credibility was measured by a post's publisher type. In empirical social media research, publisher type is frequently used as a proxy for source credibility, as it is readily available and easy to operate [58-60]. While this measure provides a general indication of perceived credibility, it does not encompass the full spectrum of attributes, such as trustworthiness, expertise, and attractiveness. The highly subjective nature of these attributes, coupled with the variability of social media platforms,

XSL•FO
RenderX

complicates efforts to capture them through standardized metadata alone. Indeed, previous research has identified a lack of consensus on how to operationalize these measures across platforms [61]. Hence, this study used publisher type to measure source credibility. There were 6 types of publishers: individual users (15,356/30,811, 49.84%), influencers (5312/30,811, 17.24%), governments and hospitals (3265/30,811, 10.6%), enterprises (3133/30,811, 10.17%), media and press (2196/30,811, 7.13%), nonprofit organizations (1549/30,811, 5.03%). We captured the publisher type shown on the publisher's profile using web crawlers. The difference between individual users and influencers is the social media impact. Influencers are individuals who have a significant following on social media and can influence the opinions and behaviors of their followers. Therefore, they have a greater social media impact compared with other individual users.

In addition, the number of days a post was published and the number of followers that the publisher had were extracted as controlled variables to account for their potential influence on the dependent variable based on previous literature [62,63]. Descriptive statistics of the study variables are summarized in Table 2.

XSL•FO

Table 2. Descriptive statistics of study variables.

Construct and description	Values
Total number of posts, n (%)	30,811 (100)
Content theme variables	
Content theme, n (%)	
Theme 1: personal experiences or stories	6400 (20.77)
Theme 2: educating	4546 (14.75)
Theme 3: discussion about entertainment work (films, television series, and books)	4588 (14.89)
Theme 4: reflections on palliative care and death	5352 (17.37)
Theme 5: activities or achievements	7741 (25.12)
Theme 6: controversial social news	767 (2.49)
Theme 7: fundraising	1417 (4.6)
Mood variable	
Sentiment score (ranges from 0, negative, to 1, positive), mean (SD)	0.74 (36)
Information richness variables	
Post used hashtags or not, n (%)	
Yes	10,275 (33.35)
No	20,536 (66.65)
Post tagged other users or not, n (%)	
Yes	4355 (14.13)
No	26,456 (85.86)
Video and image count (number of videos and images included in a post), mean (SD)	1.27 (2.08)
Character count (number of Chinese characters included in a post), mean (SD)	248.3 (366.43)
Source credibility variables	
Publisher type, n (%)	
Individual users	15,356 (49.84)
Influencers	5312 (17.24)
Governments and hospitals	3265 (10.6)
Enterprises	3133 (10.17)
Media and press	2196 (7.13)
Nonprofit organizations	1549 (5.03)
Controlled variables	
Days (number of days a post was published), mean (SD)	1283 (998.04)
Follower count (number of followers the publisher had), mean (SD)	7.63 (3.45)
Dependent variable or response quantity	
Comment count (number of comments a post received), mean (SD)	6.182 (123.18)
Like count (number of likes a post received), mean (SD)	18.51 (565.39)
Forward count (number of forwards a post received), mean (SD)	15.29 (449.35)
Engagement (number of comments, likes, and forwards a post received), mean (SD)	39.98 (844.61)

Statistical Analysis

Our dependent variable was engagement that exhibited overdispersion (engagement: mean 39.98, SD 844.61; skewness=62.09, kurtosis=5150.66). A significant number of Weibo posts rarely received shares, likes, or comments, while others received a high number in comparison. To deal with this overdispersed count data, we modeled the engagement using negative binomial regression. We first estimated the impact of information richness, source credibility, mood, and content theme on public engagement. The regression model was as follows:

XSL•FO
RenderX

$$\ln(\text{engagement}_i) = \text{Intercept} + b_1\text{content theme}_i + b_2\text{mood}_i + b_3\text{information richness}_i + b_4\text{source credibility}_i$$

We then explored whether the impacts were contingent upon the emotional valence of each post's content theme. The regression model was as follows:

$$\ln(\text{engagement}_i) = \text{Intercept} + b_1\text{content theme}_i + b_2\text{mood}_i + b_3\text{mood}_i \times \text{content theme}_i + b_4\text{information richness}_i + b_5\text{source credibility}_i$$

All analyses were conducted using R (version 4.0.2; R Foundation for Statistical Computing).

Ethical Considerations

As this study used publicly available data, it was exempt from institutional ethics review. To protect participant confidentiality, all personally identifiable information in original posts was anonymized before analysis. Data retention adhered to the principle of minimal necessary storage. In addition, Chinese posts included in the manuscript were translated into English and paraphrased so that they cannot be traced back to the original users.

Results

Descriptive Analysis

A total of 30,811 Weibo posts published from September 1, 2009, to December 12, 2022, were used for building regression models. The distribution of these posts' engagements was largely dispersed, with 14,344 (46.55%) posts receiving 0 engagements (ie, 0 likes, 0 comments, and 0 shares), 15,516 (50.36%) posts receiving 0 to 100 engagements and 951 (3.09%) posts receiving >100 engagements. The annual average engagements of PEoLC-related Weibo posts increased every year from 10.09 in 2012 to 65.57 in 2022. The average engagement of posts varied between post content themes and publisher types. Posts related to theme 6 (controversial social news) had the highest average engagement (mean 205.82, SD 3539.17), followed by posts related to theme 1 (personal experiences or stories; mean 51.28, SD 837.21). Posts related to theme 2 (educating) received the least average engagements (mean 12.18, SD 254.08). Posts published by the media and press attracted the most average engagements (mean 116.17, SD 2326.55), followed by influencers (mean 112.69, SD 1224.51). Posts published by the government and hospital accounts received the least average engagements (mean 7.40, SD 45.19).

Hypothesis Testing

Table 3 presents the estimates of 2 negative binomial regression models that predicted the engagement of PEoLC-related posts on the Chinese microblogging platform—Weibo. Hypothesis 1 assumed the content themes could have different effects on post engagement. As the content theme was a categorical variable, we treated personal experiences or stories as the reference group. Model 1 presented in Table 3 showed that discussion about entertainment work (films, television series, and books; incidence rate ratio [IRR]=1.37; $P<.001$) and controversial social news (IRR=1.64; $P<.001$) were positively correlated with post engagement, compared with personal experiences or stories. Posts related to educating (IRR=0.48; $P<.001$), reflections on palliative care and death (IRR=0.77; $P<.001$), PEoLC activities or achievements (IRR=0.64; $P<.001$), and fundraising (IRR=0.14; $P<.001$) were negatively associated with post engagement. Consequently, hypothesis 1 was supported.

[a]IRR: incidence rate ratio.

[b]RF: reference factor.

[c]Not available.

Hypothesis 2 proposed the more positive the mood of a post, the more engagement it received. However, model 1 presented in Table 3 showed the sentiment score had a significantly negative association with post engagement (IRR=0.78; *P*<.001). The IRR meant a 1-unit increase in sentiment score could result

XSL•FO
RenderX

in a 22% decrease in the number of post engagements. Hence, hypothesis 2 could not be supported by our results.

To test hypothesis 3, we built model 2 to enter the interaction effects between content themes and post mood based on model 1. The results in Table 3, model 2, showed that post mood had a slight moderate effect on the relationship between content type and post engagement. Specifically, theme 2 with positive mood was positively associated with post engagement (IRR=2.68; *P*<.001). When we tested hypothesis 1, theme 2 (educating) was negatively associated with post engagement. This indicates post mood could moderate the effect of content theme on post engagement. Interestingly, only theme 2 with a positive mood was related to high engagement, the other topics with a negative mood were related to high engagement. Hence, hypothesis 3 was supported.

Hypothesis 4 proposed that information richness was positively associated with the level of public engagement of PEoLC posts, namely the post that had more information was likely to receive greater public engagement. Model 1 in Table 3 showed 4 variables representing information richness where all had positive and statistically significant associations with post engagement (used hashtags or not: IRR=1.39; *P*<.001; tagged other users or not: IRR=5.54; *P*<.001; videos and images count: IRR=1.03; *P*<.001; and characters count: IRR=1.00; *P*<.001). The IRR values indicated that posts with hashtags were associated with a 1.09-unit increase in public engagement, while posts tagging other users were linked to a 5.54-unit increase, both compared to posts without these respective features. Hypothesis 4 was therefore supported by the results.

Hypothesis 5 posited the level of public engagement of a PEoLC post was affected by the source, namely the type of publisher. Since publisher type was a categorical variable, we treated individual users as the reference group. Model 1 in Table 3 showed that when compared with individual users, the other publisher types were negatively and significantly associated with post engagement. The IRR values suggested that when compared to posts published by individual users, those from influencers (*P*=.01), governments and hospitals (*P*<.001), enterprises (*P*<.001), media and press (*P*<.001), and nonprofit organizations (*P*<.001) resulted in different levels of decrease in the number of engagements. Consequently, hypothesis 5 was supported.

Discussion

Principal Findings

This study represented the first attempt to identify how online discussions promote public engagement in PEoLC in China. Given the prevailing limited awareness of palliative care in low-income regions [64,65], the use of social media as a digital platform for promoting and educating the public about PEoLC is imperative. This study examined the multifaceted factors influencing public engagement with PEoLC-related posts from 4 dimensions (ie, content theme, mood, information richness and source), drawing upon the ELM to expound on these influences. Our results identified that these 4 dimensions exerted significant and distinct effects on engagement. These findings provided a valuable understanding of the existing levels of public engagement with PEoLC-related content on social media. Moreover, they offered guidance to content developers, including event organizers, nonprofit organizations, and academics, on leveraging social media to disseminate research, launch health campaigns, raise funds, and educate about PEoLC to the wider public.

First, our results identified that posts published by government entities, health care institutions, and organizations tend to attract comparatively lower levels of engagement when contrasted with posts from individual accounts. This highlights the potential underuse of organizational accounts in their role of public education and advocacy for PEoLC. Most organizational accounts still adhere to the conventional model of unidirectional communication on Weibo, characterized by didactic scientific presentations and formalized achievements reporting. Effective management and content curation of these accounts are paramount, as they hold the potential to both raise awareness about palliative care and then inspire charitable contributions in support of PEoLC [66].

Furthermore, our analysis indicated that the content theme significantly impacts the level of public engagement with posts. Specifically, we observed that engagement tended to be higher for themes related to entertainment and social matters, while it exhibited a slightly lower level of engagement for informational content. This finding aligns with previous research which demonstrated that content about entertainment on social media tends to elicit greater public engagement [67,68]. This pattern is not solely a manifestation of the intrinsic entertainment and sociable characteristics of social media platforms. It may also be attributed to the fact that leveraging entertainment works (films, books, or television) or current social news as a channel to contact participants offers an efficacious approach for educating individuals about sensitive health topics, such as palliative care within a real-world context [69-72]. By exploring the portrayal of palliative care in books, television dramas, or social news, the public has a chance to be exposed to the concepts of “hospice care” and “palliative care” among others, thereby fostering collective reflection and discussion. For instance, the Chinese television series “Song of Life,” which depicted a palliative professional’s working experiences prompted a discourse concerning the feasibility of establishing hospices in a residential area on Chinese social media. Recent years have witnessed China’s production of some high-quality film and television content about palliative care. Notably, our study reveals that the use of film and television productions to initiate public discourse and engagement on social media platforms has proven to be effective. Given the relatively low acceptance and awareness levels surrounding the topic of palliative care in low-income regions, entertainment education on social media may indeed offer a promising strategy for raising awareness and public understanding and decreasing inequality. The Lancet Commission on the Value of Death also highlighted the significance of the normalization of death communication through mass media and entertainment work [73]. Our results provide empirical evidence for this proposal.

We also identified that the positive mood of a post negatively impacted public engagement around PEoLC-related posts. This

XSL•FO
RenderX

is in contrast with previous studies in which a more positive mood in health-related posts attracts more engagement [27]. This phenomenon could be attributed to the sensitive nature of PEoLC, which is related to death and dying. In China, with a general lack of death education and the dominance of traditional Chinese ethical culture, topics related to palliative care are still seen as taboo. The Chinese tradition of filial piety, where children are expected to seek permission from their parents, exerts substantial societal, moral, and public opinion pressure on parental end-of-life decisions [12]. Consequently, it is still difficult for the public to view this concept positively. Therefore, a relatively negative or serious approach to the discussion of PEoLC is more acceptable to the public in the context of Chinese culture, even on social media. Beyond the Chinese cultural context, PEoLC-related posts may display distinctive attributes in comparison to more generalized health care content, warranting further investigation in this area.

Ultimately, our investigation revealed that information richness exerted a positive influence on engagement. Specifically, posts characterized by a greater volume of content, a higher frequency of tagging other users, the incorporation of more hashtags, and the inclusion of more images or videos were correlated with higher engagement levels. This discovery aligns with the outcomes of previous research [27,74-76] in health care communication. In doing so, our study further substantiates a previous observation within the domain of health care social media research, which underscores the notion that the more informative, diverse, and vivid the mode of expression, the greater the attention and engagement garnered by health-related communication in the realm of social media.

According to ELM theory, although post content and mood as central cues could change or form attitude with higher persistence, peripheral cues may play more crucial roles in the context of PEoLC promotion. The ELM theory emphasizes that if the public's motivation or ability to process the issue-relevant information is low, persuasion can occur by a peripheral route in which processes invoked by simple cues in the persuasion context influence attitudes [77]. Considering the relatively limited awareness and understanding of PEoLC among the Chinese public, stakeholders may benefit from using peripheral routes, such as information richness and source credibility when promoting PEoLC on online platforms.

Recent research suggests that older adults in China prefer accessing palliative care information through electronic media [78]. This finding underscores the potential of online platforms, including social media, as effective tools for promoting and educating the public about PEoLC. While older adults may not be frequent users of social media, young social media users, often their significant others, can play a critical role in disseminating PEoLC information, influencing health care decisions at both individual and community levels. This, in turn, can enhance the overall quality of end-of-life care within society. In the Chinese cultural context, where end-of-life care decisions often involve multiple stakeholders, including family members and health care providers, engaging diverse groups through social media can help facilitate the integration of PEoLC into the broader health care system. Social media platforms, therefore, hold significant potential for enhancing public understanding and improving the quality of care for vulnerable populations, such as the elderly.

Implications and Strategic Suggestions

On the basis of the study findings, we developed some practical strategies to help individuals or organizations to boost public engagement about PEoLC-related discussions or campaigns on social media platforms (Textbox 1 [79]). These strategies suggest content developers or account operators follow certain patterns during the content development process. These recommendations provide valuable guidance, particularly for organizational accounts, which may face challenges in attracting engagement. This bears special significance for nonprofit organizations, where social media accounts may serve as a pivotal channel for fundraising. As our findings were based on Chinese social media platforms, these strategies may work more effectively within similar cultural contexts and PEoLC development levels.

Textbox 1. Practical strategies to help individuals or organizations to boost public engagement about palliative and end-of-life care (PEoLC)-related discussions or campaigns on social media platforms.

- Use trending entertainment works and social news as a trigger—when developing PEoLC-related content on social media, the strategic incorporation of trending entertainment works and social news may be a compelling approach to enhance user engagement. Content developers can use entertainment works or social news as a lead-in to start their content or only attach these trending hashtags (such as #Song of Life##Do you agree to have a hospice in your community#) in their posts. The inherently captivating nature of trending topics in entertainment and social events provides a dynamic backdrop against which PEoLC-related content can be situated, sparking user curiosity and interaction. By using trending entertainment works and social news as catalysts, content creators can intrigue the audiences thinking in a real situation and thus achieve their intended purpose of promoting or educating.
- Try to engage influencers in promotion or education—influencers, often recognized for their expansive reach and persuasive capacities, offer a unique opportunity to enhance the visibility and impact of PEoLC messaging on social media. Concrete strategies to realize this encompasses collaborating with influencers who have a personal connection to PEoLC, encouraging them to share personal narratives, insights, and experiences, and endorsing PEoLC resources, materials, and campaigns on their channels. Organizations must realize that it is not enough to limit content distribution merely to their followers, who have already shown interest in the topic of PEoLC. Rather, organizations could interact with social media influencers who have much more diverse followers, to engage a wider audience with little knowledge of PEoLC. In addition, organizations could hold influencer-led awareness campaigns, live question and answer sessions, and educational webinars on both organizations' and influencers' accounts. By harnessing the influence of these advocates, organizations are more likely to significantly amplify their reach and raise public awareness of PEoLC on social media.
- Content works better with visual cues—visual elements, such as figures and videos, not only enhance the esthetic appeal of posts but also play a pivotal role in conveying complex concepts and eliciting emotive responses. Visual cues provide audiences with the opportunity to firsthand experience the dilemmas faced by stakeholders in PEoLC and immerse themselves in the personal narratives of these individuals, thus fostering an understanding of the profound significance and relevance of PEoLC. These digital affordances (eg, geotags, images, videos) provide vulnerable groups such as PEoLC stakeholders with an opportunity to gain more exposure on social media and then raise public awareness. Moreover, visual elements can transcend language barriers and resonate on a universal level, further broadening the reach and resonance of the PEoLC message globally. In this context, it is necessary for palliative care communication to incorporate visual elements to enhance understanding, foster empathy, and increase engagement on social media platforms.

Limitations

While the results of this research provide valuable insights, they must be viewed in light of certain limitations. The primary limitation pertains to the use of Weibo as the sole platform for analyzing PEoLC-related posts. While Weibo is one of the most extensively used social media platforms in China, with a user base exceeding 575 million monthly active users, it represents just one facet of the broader social media landscape. However, the platform's significant reach and influence in the Chinese context provide a robust foundation for the study, thereby mitigating the potential limitation of not, including other platforms. In addition, the process of keyword selection for retrieving relevant posts on Weibo presented its challenges. Despite our rigorous approach, using 3 diverse methods to ensure a comprehensive inclusion of keywords, there remains a marginal possibility that certain terms used in informal contexts might have been overlooked. It is also noteworthy that terms such as "euthanasia" were deliberately excluded from our search parameters. Although sometimes associated with hospice care in China, the term is often misinterpreted as "suicide" in social media discourse. This strategic exclusion was aimed at reducing the influx of irrelevant data, thereby enhancing the relevance and quality of our dataset. A further limitation is that the operationalization of source credibility based solely on publisher type may not fully capture the perceived trustworthiness, expertise, or attractiveness of the source. While publisher type is commonly used in previous studies, it provides only a partial view of credibility in social media environments. Future research should explore additional or alternative variables to more comprehensively assess source credibility. Besides, the extensive data collection period (2009-2022) introduces potential variability in the results due to the evolving social media landscape and changing user behaviors over time. However, existing literature suggests public attitudes and behaviors toward PEoLC remained relatively stable during this period [3,80]. While aggregating engagement factors over the years may potentially obscure period-specific patterns, it provides a comprehensive overview of long-term trends. Moreover, this extended timeframe ensures a substantial dataset, which improves the statistical power, generalizability, and robustness of the regression models [81]. Nevertheless, future studies may benefit from temporal segmentation to capture nuanced shifts in engagement patterns across different periods. We also consider a multimodel research by incorporating text, image, and video content analysis in detecting engagement patterns in the future.

Conclusions

While death is a universal and inevitable experience, discussions surrounding it are often avoided in China. This reluctance highlights the urgent necessity to enhance public understanding and awareness about PEoLC in the country. This study pinpoints social media as a promising tool for advancing PEoLC and igniting public engagement on related topics within the Chinese context. Drawing from the ELM theory, our study unveils distinct characteristics of PEoLC-related posts on social media that capture public attention. Acknowledging these unique traits, we have formulated targeted strategies aimed at bolstering public involvement in PEoLC discourse. These strategies include leveraging influencers, using entertainment or social news as catalysts, and integrating visual cues. By adopting these approaches, organizations can effectively communicate with the community, promoting PEoLC in a manner that is both accessible and compelling to the public. This study also holds the potential to catalyze a broader cultural shift toward open and constructive conversations about death and dying in China.

Abstract

Background: Suicide is a critical public health issue in adolescents worldwide. Internet addiction may play a role in the increased rate of suicide attempts in this population. However, few studies have explored the relationship between pathological internet use and suicide attempts among adolescents.

Objective: This study aimed to conduct a prospective cohort study to examine whether higher severity of pathological internet use was associated with an increased risk of suicide attempts among Chinese adolescents.

Methods: A total of 782 adolescents were recruited from a middle school from November 2020 to December 2020 and followed up for 6 months. An online self-reported questionnaire was used to collect the participants' demographic data and assess their mental health. The Depression, Anxiety, and Stress Scale–21 items (DASS-21) was used to evaluate depression, anxiety, and stress. The Chen Internet Addiction Scale–Revised (CIAS-R) was used to assess the symptoms and severity of pathological internet use. χ^2 test and ANOVA were used for intergroup comparison, and logistic regression analysis was used to examine the relationship between the severity of pathological internet use and suicide attempts. We also used a restricted cubic splines model to investigate the pattern of the association.

Results: The participants had an average age of 12.59 (SD 0.64) years, with the majority being of Han ethnicity (743/782, 95.01%) and more than half being male (426/782, 54.48%). Most participants had no previous history of depression (541/782, 69.18%), anxiety (415/782, 53.07%), or stress (618/782, 79.03%). The rate of newly reported suicide attempts was 4.6% (36/782). A significant positive association was observed between internet addiction and suicide attempts (odds ratio 3.88, 95% CI 1.70-8.82), which remained significant after adjusting for age, sex, ethnicity, anxiety, depression, and stress (odds ratio 2.65, 95% CI 1.07-6.55). In addition, this association exhibited a linear pattern in the restricted cubic spline regression model.

Conclusions: This study suggested that internet addiction, rather than internet overuse, was associated with a higher likelihood of suicide attempts, which highlighted the importance of addressing internet addiction symptoms among Chinese adolescents for suicide prevention.

Introduction

Suicide has emerged as a major public health concern globally recently, as it has brought significant challenges to human beings with severe consequences [1]. Over the past 5 decades, suicide remains the only contributor to rising mortality [2]. Globally, suicide ranked as the fourth leading cause of mortality among adolescents aged 15 to 19 years, as cited in a 2021 report by the World Health Organization (WHO) [3]. In the United States, it was reported that there were 2744 suicides among adolescents aged 10-19 years in 2019, positioning suicide as the second most common cause of death [3]. Therefore, reducing suicide‐related deaths has become a national priority in the United States, with more than US $22 million spent per year on suicide prevention. However, the suicide rate in the United States has not significantly declined [4]. China also faces the same challenge. Although the overall suicide rate in China has declined, the suicide rate among young people has remained high [5]. It is broadly recognized that suicide attempts may be the most significant predictor for completed suicide [6-9]. According to the data released by the National Trauma Data Bank, the mortality rate was 13% among adolescents aged younger than 20 years who attempted suicide [10]. A previous study indicated that teenagers who engaged in suicide attempts were 30 times more likely to die by suicide [11]. In addition, compared with those engaging in other forms of injury that lead to hospitalization, individuals with suicide attempts often have higher severities of injury, higher demands for health care services, and higher mortality [12]. Thus, examining the factors contributing to suicide attempts is crucial for the prevention of suicide among adolescents.

The internet has become increasingly accessible and necessary in the daily lives of adolescents. In China, internet access was available in 98.4% of elementary and middle schools in 2019 [13]. Meanwhile, in 2020, approximately 13.5% of all internet users were adolescents (aged 10-19 years) [14]. Proper internet use can help improve social skills, promote self-learning, and diversify recreation [15,16]. However, due to the highly time-consuming nature of the internet, an increasing number of adolescents have internet overuse, spending even more time using the internet than sleeping or studying [17]. In severe cases, excessive internet use may lead to clinically significant dysfunction and distress among adolescents [18,19]. This new form of behavioral addiction is listed as a tentative disorder named internet addiction. Internet addiction has also been increasing in Mainland China, with a reported prevalence of 10.4% to 26.5% among adolescents [20,21]. Earlier studies suggested a link between internet addiction and an increased incidence of suicide attempts [22,23]. A meta-analysis demonstrated that even after adjusting for demographic factors and depressive symptoms, those who experienced internet addiction continued to show a higher frequency of suicide attempts (pooled adjusted odds ratio [OR] 1.559) [23]. Some cross-sectional studies also indicated a link between internet addiction and suicidal behavior. For example, a study showed that adolescents with internet addiction had a greater likelihood of attempting suicide than those without this problem [24,25]. In addition, a 1-year follow-up study revealed that internet addiction was predictive of self-destructive behaviors among adolescents [26]. However, most previous studies are cross-sectional, which precluded the inference of causality. Furthermore, limited studies have investigated the relationship between the severity of pathological internet use and suicide attempts. Thus, in this prospective cohort study, we aimed to examine whether higher severity of pathological Internet use was associated with an increased risk of suicide attempts among Chinese adolescents [23].

Methods

Study Population

In this prospective cohort study, a 2-stage cluster sampling design was used to enhance the feasibility and representativeness. The sampling frame consisted of all public secondary schools across all districts in Changsha, as provided by the local education bureau. In the first stage, 1 public secondary school was randomly selected from the sampling frame. In the second stage, all students in grades 7 and 8 from the selected school were included in the study, resulting in a total sample of 1162 students (609 in grade 7 and 553 in grade 8). The selected school is comparable with most public secondary schools in the area in terms of size and demographic factors, such as gender ratio and socioeconomic background. This makes the school representative of the student population in Changsha and similar cities.

Recruitment occurred from November 2020 to December 2020, and follow-up data were collected from May 2021 to June 2021. Adolescents completed a standardized, self-administered questionnaire distributed through WeChat, one of the largest social media platforms in China. Before the commencement of the survey, we provided comprehensive training to schoolteachers on the procedures for distributing the questionnaire, offering guidance, and assisting students with difficulties. Data were collected from self-reported questionnaires administered through WeChat. All variables were collected through WeChat with the support of school personnel.

With the assistance of the school personnel, we obtained informed consent from both the adolescents and their parents. The participants accessed the survey using their parents' mobile phones and provided electronic informed consent on the first page of the survey. Upon completion, we thoroughly checked the data to ensure the data quality. Questionnaires were considered unqualified if the completion time was excessively short, if there were evident logical inconsistencies in responses, or if critical answers were missing.

Inclusion criteria of participants for the baseline and follow-up surveys were as follows: (1) middle school students aged 11-17 years, (2) with no severe medical conditions that prevented them from completing the survey, (3) capable of comprehending and finishing the questionnaires, and (4) provided a formal agreement to participate in the research. Participants who reported suicide attempts at baseline were excluded from the follow-up study. At baseline, 1162 grade 7-8 students were recruited, among whom 78 refused to participate. Therefore,

XSL•FO
RenderX

1084 students completed the survey at baseline. For the follow-up survey, 135 individuals were excluded due to suicide attempts at baseline, and 167 were excluded for refusal to participate; thus, 782 participants were included in the follow-up survey.

Assessment

Confounders

Sociodemographic Characteristics

Demographic variables, including sex, age, and ethnicity, were collected from the participants.

Depression, Anxiety, and Stress

The Depression, Anxiety, and Stress Scale–21 items (DASS-21) was used to assess participants' levels of depression, anxiety, and stress during the previous week [27]. The assessment includes 3 subscales: Depression, Anxiety, and Stress. Each of these subscales comprises 7 items that are evaluated using a 4-point Likert scale, which ranges from 0 (not at all) to 3 (most of the time) [28]. The thresholds were set at ≥13 for depression, ≥7 for anxiety, and ≥10 for stress [27]. The DASS-21 has shown high internal consistency (Cronbach α=0.92), indicating its good cross-cultural validity [29].

Exposures: Pathological Internet Use

Based on the conceptual framework, we used the Chen Internet Addiction Scale–Revised (CIAS-R) to assess the severity of pathological internet use [30]. The CIAS-R is a widely used instrument for evaluating pathological internet use, particularly in the Chinese context [31]. This self-reported scale includes 19 items, where each item is evaluated using a 4-point Likert scale that ranges from 1 (complete noncompliance) to 4 (complete conformity). The Chen Internet Addiction Scale (CIAS) total score varies between 0 and 76, with higher scores indicating more severe pathological internet use [32]. According to the total score, participants were further divided into 3 groups: the normal internet use group (<46), the internet overuse group (46-52), and the internet addiction group (≥53) [32]. The CIAS has proven to be a reliable and valid measure of pathological internet use among adolescents [30,33,34].

Outcomes: Suicide Attempts

Suicide attempts refer to the act of self-injuring that a person engages in with the intention of taking their own life. In this study, suicide attempts were defined as "someone trying to hurt themselves on purpose with the intention of ending their life, but it did not succeed" to tailor to junior high school students' comprehension levels. The question "Have you ever tried to commit suicide?" [22] was used at baseline to measure suicide attempts, and the question "Have you tried to commit suicide in the past 6 months?" was used to measure suicide attempts during the 6-month follow-up.

Statistical Analysis

In this study, the χ^2 test was used to compare categorical variables across groups. Continuous data are shown using mean and SDs, and the comparison of continuous variables between groups was conducted using ANOVA. The relationship between pathological internet use and suicide attempts was examined using logistic regression analysis using 3 models. Model 1 was used to examine the unadjusted OR; Model 2 was used to examine the adjusted OR after controlling for age, sex, and ethnicity; and Model 3 was used to examine the adjusted OR after adjusting for age, sex, ethnicity, anxiety, depression, and stress. The restricted cubic splines model was used to investigate the pattern of the association between the CIAS and suicide attempts after adjusting for age, sex, ethnicity, anxiety, depression, and stress. Finally, a post hoc power analysis was performed using G*Power 3.1 (Heinrich Heine University Düsseldorf) to evaluate the statistical power of the logistic regression analysis. The modeling of restricted cubic splines was conducted with R (version 4.2.3; R Foundation for Statistical Computing), while SPSS (version 26.0; IBM) was used for all additional statistical analyses. A 2-tailed P<.05 indicated statistical significance.

Ethical Considerations

This study protocol was examined and endorsed by the Ethics Committee of Central South University's Second Xiangya Hospital (K009). With the assistance of the school personnel, we obtained informed consent from both the adolescents and their parents on the first page of the questionnaire. The personal details of the participants were kept confidential, and a distinct study identification number was allocated to every participant for data entry, management, and analysis. The participants received free psychological assessments and medical help when needed as compensation for their participation.

Results

The analysis included 782 participants, whose average age was 12.59 (SD 0.64) years. Among these participants, more than half were male (426/782, 54.48%), and the majority were of Han ethnicity (743/782, 95.01%). Most of the participants reported no previous history of depression (541/782, 69.18%), anxiety (415/782, 53.07%), or stress (618/782, 79.03%). The rate of newly reported suicide attempts was 4.6% (36/782). Table 1 presents the comparison of demographic and clinical characteristics of participants among the normal internet use group, the internet overuse group, and the internet addiction group. The 3 groups showed significant differences in ethnicity (P=.03), depression (P<.001), anxiety (P<.001), stress (P<.001), and suicide attempts (P=.003). Compared with the normal internet use group, the internet overuse group and the internet addiction group were more likely to have stress, anxiety, depression, and suicide attempts after 6 months (P<.001 for stress, P<.001 for anxiety, P<.001 for depression, and P=.003 for suicide attempts).

[a]NIU: normal internet use.

[b]IO: internet overuse.

[c]IA: internet addiction.

[d]SA: suicide attempts.

The associations between pathological internet use and suicide attempts across various models are presented in Table 2. Compared with the normal internet use group, the internet addiction group consistently showed a higher risk of suicidal attempts in Model 1 (crude OR 3.88 95% CI 1.70-8.82), Model 2 (adjusted OR 3.88, 95% CI 1.65-9.11), and Model 3 (adjusted OR 2.65, 95% CI 1.07-6.55). The restricted cubic spline regression model showed a linear association between CIAS and suicide attempts (Figure 1). Furthermore, internet overuse was also linked to an increased risk of suicidal attempts, but the association lacked statistical significance. The post hoc power analysis indicated that the statistical power of this study was 82.60% based on a sample size of 782 participants, an α level of .05, and the event probability under the null hypothesis of 3.45%.

Discussion

Principal Findings

To our knowledge, our research represents the initial investigation into the association between varying degrees of pathological internet use and suicide attempts among Chinese adolescents, using a prospective cohort design. Our findings suggested that the risk of suicide attempts was higher in individuals with internet addiction, even when controlling for variables such as age, sex, ethnicity, anxiety, depression, and stress. Furthermore, the restricted cubic splines model supported the linearity of the association between pathological internet use and the risk of suicide attempts.

This study found a notable association between internet addiction and suicide attempts through the 6 months of follow-up, which is in line with previous findings [35]. A study involving 8098 Chinese college students showed that those with internet addiction were at a higher risk for suicidal behaviors, with a prevalence of 21.4% [22]. Furthermore, a 1-year longitudinal study revealed that internet addiction was predictive of self-destructive behaviors, including self-harm and suicidal behaviors [26]. Furthermore, 2 meta-analyses also indicated that internet addiction was positively associated with suicidal

XSL•FO
RenderX

behaviors [23,36]. Some reasons might explain this association. First, individuals with internet addiction have a greater chance of exposure to online content involving suicidal thoughts and behaviors, which may result in imitation of suicidal behaviors [37], especially for individuals with mental health problems [38]. Second, risk factors for both suicidal attempts and internet addiction, such as depression, anxiety, and low socioeconomic status, seem to overlap [39,40]. Third, alternative explanations for the link between internet addiction and suicide attempts may involve brain and cognitive dysfunctions.

For instance, internet addiction is often comorbid with some mental health disorders involving impairment of impulse control, such as attention-deficit/hyperactivity disorder and substance use disorders, suggesting the impulsive nature associated with internet addiction [41,42]. Furthermore, a magnetic resonance imaging study showed that individuals with internet addiction had impaired prefrontal lobe function, which might lead to decreased ability of impulse control or even cognitive deficits [43]. Therefore, adolescents with internet addiction may exhibit a propensity for risky decision-making, such as suicide attempts [44].

After adjusting for age, sex, ethnicity, stress, anxiety, and depression, the OR of suicidal attempts decreased from 3.88 (95% CI 1.70-8.82) to 2.64 (95% CI 1.07-6.55). Still, the link between internet addiction and suicide attempts continued to be significant. A study conducted in Korea revealed a significant positive association between internet addiction, depression, and suicidal thoughts among adolescents [45]. A study involving Chinese middle school students also pointed out that internet addiction was linked to suicide attempts among adolescents, and the association might be mediated by depression and bullying behaviors [46]. This association may also be related to the proneness of comorbidity of internet addiction and other mental health problems such as depression, decreased self-esteem, lower tolerance to frustration, and emotional distress [47,48], which also increases the risk of suicidal attempts. Some studies suggested that the connection between internet addiction and suicide attempts might be mediated by these comorbidities, which, therefore, increased the risk of suicide attempts [49].

Interestingly, this study found that internet overuse did not have a significant association with suicide attempts, indicating that suicide attempts might only be related to internet addiction, which is more severe. This aligns with an earlier study on university students, which showed that most of the mental health problems in participants with mild internet addiction were comparable with or slightly above the average. However, the rates of mental health problems sharply increased in those with moderate to severe internet addiction [50]. Some other studies suggested that engaging with the internet at levels below addiction may increase the feeling of being accepted and alleviate feelings of loneliness and shame instead of leading to severe consequences [51].

Limitations

Some limitations need to be addressed. First, this study did not collect the specific dates of suicide attempts during the follow-up. This study only used a fixed 6-month follow-up period, which may introduce potential bias to our study results. Future studies should consider adding the specific dates of suicide attempts to get a more robust conclusion. Second, although we controlled for key risk factors such as anxiety, depression, and stress, which are known to influence suicidal behaviors, other important factors, such as academic burden and parent-child relationship, were not included in our analysis. Future research needs to include a broader range of risk factors and intermediate processes (eg, suicidal ideation) to get a more comprehensive understanding of the risk factors of suicide attempts. Third, the participants' internet addiction and clinical correlates were collected using self-report questionnaires and scales, which might have resulted in bias such as recall bias and social desirability bias. Future studies should consider using diagnostic interviews to get more accurate assessments. Fourth, the sample was recruited from 1 middle school in Hunan Province, China, and may not represent students from other schools in other areas. Future multicenter studies across various schools and regions are needed to get a more representative sample and improve the generalizability of our results. Finally, suicide attempts were assessed based on a single self-reported question instead of a standardized scale, hindering the cross-comparison with other studies using standard measurement tools [52]. For instance, Yang et al [53] developed a standardized and reliable assessment tool for suicide attempts, which may yield more accurate and consistent data across studies. Future studies should consider using more standard tools to capture the complexity of suicidal behaviors fully.

Conclusion

This study found that adolescents experiencing internet addiction and overuse were at a higher risk for stress, anxiety, and depression. Furthermore, internet addiction was associated with an increased risk of suicide attempts among adolescents in China. Given the considerable impact of suicide on society, the results of this study underscore the importance of addressing internet addiction among Chinese adolescents as part of suicide prevention and management efforts.

Acknowledgments

We would like to express our gratitude to all the participants in this project, as well as the school personnel, who have offered invaluable support.

This work was supported by the Scientific Research Launch Project for New Employees of the Second Xiangya Hospital of Central South University, National Natural Science Foundation of China (82201703), and Hunan Provincial Natural Science Foundation of China (2023JJ60085). The authors would also like to acnowledge the following funding sources: The STI2030-Major Projects-2021ZD0200700； The National Natural Science Foundation of China (82071543, 82471568); and The Key Research

and Development Program of Hunan Province (2023SK2028). No generative artificial intelligence was used in the manuscript writing.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JZ, YS, SL, XJ, and TF designed the study. SL, LS, JZ, and YS were responsible for the integrity of the data and the accuracy of data analysis. JZ, YS, and SL prepared the manuscript. SL, XJ, and TF edited and revised the manuscript. JZ, YS, and SL were responsible for the critical revision of the manuscript. All authors have contributed to and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The mental health crisis among college students intensified amid the COVID-19 pandemic, suggesting an urgent need for innovative solutions to support them. Previous efforts to address mental health concerns have been constrained, often due to the underuse or shortage of services. Mobile health (mHealth) technology holds significant potential for providing resilience-building support and enhancing access to mental health care.

Objective: This study aimed to examine the trends in mental health and well-being outcomes over 3 years among college students, with an exploratory aim to assess the potential impact of the Roadmap mHealth app on these outcomes.

Methods: A fully automated longitudinal observational study was conducted remotely from a large public academic institution in the Midwestern United States, evaluating mental health and well-being outcomes among college students using the Roadmap mHealth app over 3 fall semesters from 2020 to 2022. The study enrolled 2164 college students in Year I, with 1128 and 1033 students returning in Years II and III, respectively. Participants completed various self-reported measures, including the Patient Health Questionnaire-9 for depression, Generalized Anxiety Disorder-7 for anxiety, and additional metrics for coping, flourishing, and loneliness.

Results: The findings indicated an evolving trajectory in students' mental health. In Year I, depression and anxiety levels were higher compared with levels reported between 2014 and 2019, remaining stable into Year II. However, significant decreases were noted by Year III for both depression (Year I mean 7.78, SD 5.65 vs Year III mean 6.21, SD 4.68; t_{108}=–2.90; P=.01) and anxiety (Year I mean 6.61, SD 4.91 vs Year III mean 5.62, SD 4.58; t_{116}=–2.02; P=.046). Problem-focused coping decreased initially from Year I (mean 2.46, SD 0.58) to Year II (mean 2.36, SD 0.60; t_{1073}=–5.87; P<.001), then increased by Year III (mean 2.40,

XSL•FO
RenderX

SD 0.63; t_{706}=2.26; *P*=.02). Emotion-focused (Year I mean 2.33, SD 0.41 vs Year III mean 2.22, SD 0.47; t_{994}=–7.47; *P*<.001) and avoidant coping (Year I mean 1.76, SD 0.37 vs Year III mean 1.65, SD 0.38; t_{997}=–8.53; *P*=.02) consistently decreased. Loneliness significantly decreased from Year I (mean 5.79, SD 1.74) to Year III (mean 5.17, SD 1.78; t_{1013}=–10.74; *P*<.001), accompanied by an increase in flourishing from Year I (mean 63.78, SD 14.76) to Year III (mean 66.98, SD 15.06; t_{994}=7.22; *P*<.001). Analysis of app usage indicated that the positive piggy bank and gratitude journal were the favored activities. Greater engagement with the app was positively correlated with enhanced flourishing, even after adjusting for demographic and sociobehavioral factors (β=.04, SE .016; t_{3974}=2.17; *P*=.03).

Conclusions: In this study, students' mental health and well-being improved, with notable reductions in depression, anxiety, and loneliness, associated with an increase in flourishing. The app did not appear to worsen students' mental health. Based on the usage pattern, it is possible the app enhanced positive psychology-based practices. Future research should explore the efficacy of mHealth interventions through randomized controlled trials to further understand their impact on college students' mental health outcomes.

Introduction

Nearly 20 million students are enrolled in colleges across the United States [1]. During this time, students undergo crucial psychological and social development [2]. Mental health issues are prevalent in college student populations, with the peak onset of mental illness occurring before age 25 [3]. However, early detection of emerging mental illness before significant symptoms develop remains limited [4]. Without adequate attention, at-risk young adults with mental health issues are more likely to struggle academically (ie, receive lower grand point averages), drop out of college, or be unemployed compared with their peers [5-7]. These outcomes may consequently correlate with increased substance abuse, self-injury, or suicidality [8-11].

The long-simmering mental health crisis in college students was further exacerbated by the COVID-19 pandemic, which saw higher levels of depression and anxiety than ever previously reported [12,13]. Even before the pandemic, the demand for mental health services was rising [14,15]. Thus, while the current mental health crisis among college students remains a major public health problem, it also presents a unique opportunity to develop and test novel interventions for providing psychosocial support to this population. Psychosocial support refers to interventions aimed at addressing both psychological and social aspects of mental health, helping individuals cope with stress, improve their emotional well-being, and develop supportive social connections [16].

The increase in psychopathology across college campuses has led to expanded counseling and mental health services [17,18]. However, students who stopped attending college due to mental health concerns reported not seeking help or experiencing long wait times [19]. Alarmingly, 80% of students who die by suicide never contact their campus mental health services [20]. Both the underuse and shortage of mental health services are significant issues [21,22]. Mobile health (mHealth) technology offers a novel approach to overcoming barriers associated with mental health care delivery [23]. Evidence suggests that mHealth interventions can support various mental health problems, such as mood disorders, stress, and substance use [24,25]. Focusing on resilience-building aligns with recent recommendations that mental health-related mHealth apps should support well-being, enhance mood, and foster self-care skills rather than address specific mental health problems [26]. Mobile health technology has been shown to be convenient, anonymous, and easy to use [27].

Our interdisciplinary team developed a positive psychology-based mHealth app, Roadmap, initially for use in patients with cancer and their family caregivers. It was initially designed to provide information, education, and skills-based training. Over time, it was iteratively enhanced to provide psychosocial support, that is, the physical, mental, and social health-related quality of life (HRQOL), for any user and to aggregate their step counts and sleep, collected through wearable sensors (Fitbits) [28]. The app incorporated principles based on positive psychology, which emphasizes enhancing individuals' strengths, cultivating gratitude, fostering resilience, and promoting overall well-being through evidence-based interventions [29,30]. Based on initial observations from our earlier deployment of the Roadmap app, we observed specific patterns in user engagement and feedback regarding the types and frequencies of self-reported measures that were most useful. This informed our strategic selection of validated measures (eg, Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7 (GAD-7), coping, flourishing, loneliness), as well as the intervals at which these were administered across the 4-month study design. This approach aimed to optimize the app's utility in monitoring and assessing their health outcomes with app use without excessive burden.

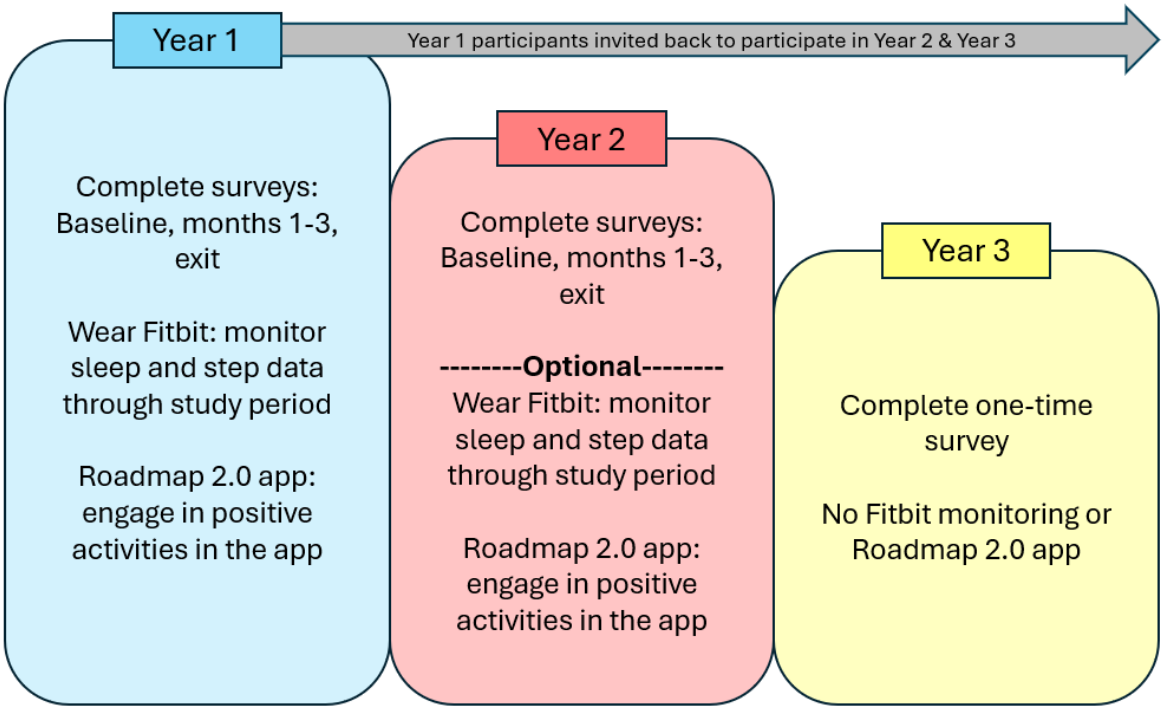
Positive psychology emphasizes enhancing individuals' strengths, cultivating gratitude, fostering resilience, and promoting overall well-being. Such a framework is particularly suitable for college students, as it aligns with crucial developmental goals during this life stage, such as building resilience, self-efficacy, and effective coping strategies. College students are often navigating significant life changes and stressors, making them an ideal population to benefit from interventions that focus on positive psychology principles. Interventions based on these principles have been developed to improve health (eg, physical, mental, social) and well-being through well-studied constructions (eg, positive daily reflection [29,30], gratitude [31-34], and savoring [35]). Simple strategies aimed at enhancing positive thoughts, emotions, and behaviors have been shown to be effective and highly scalable [36-39]. These strategies have been used in students to support engagement, learning, and well-being. In fact, an economic evaluation of positive psychology strategies that sought to foster positive emotions, stimulate positive functioning, and reduce depressive symptoms found that cost-effectiveness was increased in individuals randomized to the positive psychology intervention arm compared with the waitlisted usual care group [40]. Thus, the strong evidence base for a positive psychology framework to enhance resilience or positive adaptations despite high-risk or chronic stress provides support for their use in college students.

In the fall semester of 2020, we leveraged the Roadmap app to explore HRQOL outcomes among college students [41]. Approximately one-third of students had a mental health disorder and—given the strict lockdown restrictions in the fall semester of 2020—students recorded low physical activity levels (through Fitbits). In addition, we found significant associations of COVID-19 positivity with the use of marijuana and alcohol and with lower belief in public health measures [42]. With consent, the same students were invited to participate in the Roadmap study and report their HRQOL in the following fall semesters of 2021 and 2022. Based on our initial observations [41] and the emerging literature on college student mental health during the pandemic [43], we posited that our participants would report changes in their HRQOL as the pandemic progressed, specifically across the 3-year study period. We also explored whether the Roadmap app, a positive psychology-based mHealth app, might be associated with changes in these HRQOL outcomes. By examining both the trajectory of HRQOL and the role of the Roadmap app, our work contributes to understanding the broader effects of the pandemic on student mental health and highlights the potential of a mHealth app in supporting psychological well-being. The primary aim of this study was to examine the trends in mental health and well-being outcomes over 3 years among college students, with an exploratory aim to assess the potential impact of the Roadmap mHealth app on these outcomes.



Methods

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki (as revised in 2013). The study was approved by the institutional review board (IRB) of the University of Michigan Medical School and was registered on ClinicalTrials.gov (NCT04766788). Study participants completed an IRB-approved informed consent through the SignNow platform [44]. The authors are accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. There were no deviations from the registered study on ClinialTrials.gov NCT04766788. In addition, there were no deviations from the published protocol manuscript [41]. Of note, the study was originally intended to last 1 year (Year I); however, it was expanded to follow the study participants over several years, continuing the following 2 years, designated as Year II and Year III. This was not originally described in the published protocol manuscript [41]. Please refer to the study schema in Figure 1.
