Several reviews related to telementoring in health care have been previously published; however, they did not focus on applications for surgery in specific [15,24]. Other reviews covering surgical applications of telemedicine and telementoring have been presented [1,11,25-30]. These articles largely covered implementations of telementoring systems where video feed from the mentee is sent for audio feedback from the remote mentor. Some of them did not focus on MIS and explored applications in open surgery as well [11,29,30]. Additional review articles focused on specific use of telementoring for certain specialties such as head and neck [31], robotic [32], and urology [33]. With respect to MIS, Nickel et al [23] provided a concise clinical summary, whereas others reported on the use of audio and static AR cues [16,17,19,34,35]. While these reviews offer a comprehensive understanding of telementoring during MIS, they do not highlight the developments in the use of dynamic AR cues. To the best of our knowledge, there has not yet been a systematic examination specifically on the use of dynamic AR cues used by remote mentors during telementoring in MIS. Such a synthesis providing an overview of the different types of dynamic AR cues as well as the surgical procedures, clinical settings, and factors used for testing is needed. This will help guide future research and developments on telementoring in MIS and ensure that they are relevant and practical.

Through this scoping review we aim to provide a comprehensive summary of dynamic AR cues used for telementoring during MIS. A survey of the various types of surgeries, participants, dynamic AR cues, and evaluation of the telementoring technology is presented to guide future developments on

XSL•FO
RenderX

telementoring during MIS. We aim to address the following research questions (RQs), which are yet to be answered by review articles published in the field:

- RQ1: What are the MIS specialties and procedures where dynamic AR cues have been used for telementoring? What are the clinical trials or settings they were tested on?
- RQ2: What are the different types of dynamic AR cues used for MIS telementoring? What information does the mentor convey to the mentee using these cues?
- RQ3: What factors are used to evaluate the use of dynamic AR cues during MIS telementoring? What are the common outcomes reported?

Methods

Overview

The review was conducted based on the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) guidelines [36].

Eligibility Criteria

To be considered eligible for the review, articles must satisfy the following criteria (Textbox 1).

Textbox 1. Eligibility criteria for scoping review.

Inclusion criteria

- Original article.
- Reporting telementoring technologies using dynamic augmented reality cue.
- Reporting telementoring technologies during minimally invasive surgeries (including, endoscopic, laparoscopic, and robot-assisted).
- Published in English.

Exclusion criteria

- Articles on nonsurgical applications.
- Open surgery (ie, not minimally invasive surgeries).
- Microsurgery.
- Studies without telementoring technologies.
- Reports of telementoring without the use of augmented reality.
- Telementoring using static augmented reality cues (annotations) only.
- Articles without enough information (such as editorials and comments).
- Review articles.

Search

A thorough search of scientific databases including PubMed, Web of Science, and Scopus was conducted. Other databases such as “IEEE *Xplore*” and “ACM Digital Library” covering technical fields were also included. The search terms comprised of, but were not restricted to, “telementoring,” “teleproctoring,” “augmented reality,” “overlay,” and “minimally invasive surgery.” There were no restrictions imposed on the year of publication. The latest search was conducted on March 11, 2024. The strategy used for searching in PubMed is provided in Multimedia Appendix 1. Additional records were found through citation searches and scanning review articles.

Study Selection

Through the searches, a total of 460 scientific records were identified. Duplicate removal, title and abstract and full-text screening were done using the Rayyan web app [37]. Two reviewers [HH] and [NN] were independently responsible for title and abstract and full-text screening process. Resolution of disagreements on eligibility of an article was done through consensus and discussion with a third reviewer [OA] when necessary.

Data Extraction

Data items extracted from the articles included year of publication, type of surgery, surgical specialty and procedure, phase of clinical trial, number of participants and their experience level, telementoring technology, type of dynamic AR cue, comparator (if applicable), factor measured, and outcome of the study. The data extraction form with the variables to be extracted from each eligible article were jointly developed by 2 reviewers [HH] and [NN] for this scoping review. The reviewers were independently responsible for extracting the data from each study. Resolution of disagreements on results of the data extraction was achieved through discussion with a third reviewer [OA] when necessary.

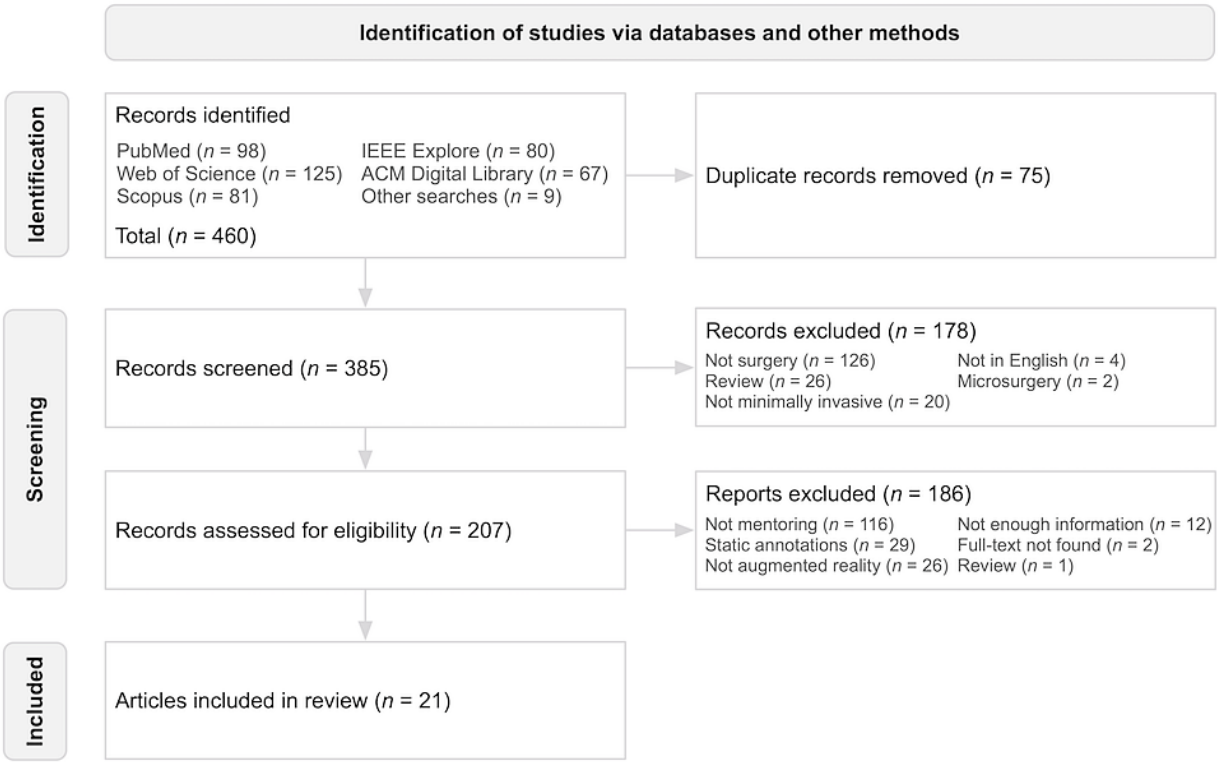
Quality Assessment

Methodological quality assessment of the included studies was conducted based on the Medical Education Research Study Quality Instrument (MERSQI) [38]. The tool is designed to appraise the quality of medical education research, which was found to be appropriate for the topic addressed by this scoping review. The quality assessment tool was not used as an exclusion criterion, but instead, it was used after the screening process to gauge the quality and reliability of the articles reporting the use of dynamic AR cues during minimally invasive surgical

XSL•FO
RenderX

telementoring [39]. Each article was assessed according to study design, type of data obtained, evaluation instrument used, analysis of the data, and outcomes measured to give a score out of 18. A higher score given to an article indicates a superior study design. Similar to the study selection and data extraction process, 2 reviewers [HH] and [NN] were responsible for quality assessment of the included studies, while disagreements were resolved through discussions with a third reviewer [OA] when necessary.

Data Synthesis



The data extracted from the articles were presented using a descriptive table with information on surgery, participants (performing the procedure), dynamic AR cues, comparator, outcomes measured, and primary findings of the study. Study characteristics such as surgical procedure, clinical trial, type of dynamic AR cue, and publication year were visually summarized as counts. A meta-analysis was not conducted since a wide variety of outcomes measured, clinical setting, and type of participants was observed.

Results

Overview

A total of 21 articles reporting on the use of dynamic AR cues during telementoring in MIS were included in the review (Figure 1). An average MERSQI score of 12.9 was observed in the included articles. Table 1 presents a summary of the included articles. The table elements are described in detail in the following sections. They include details about the MIS procedures, the various dynamic AR cues used for telementoring, and evaluation of the technologies and their outcomes.

Figure 1. Flowchart depicting identification, screening, and inclusion of articles on the use of dynamic augmented reality cues during minimally invasive surgical telementoring.

MIS (Research Question 1)

Article on MIS included 2 categories, namely, manual or conventional laparoscopic (n=16 articles) and robot-assisted (n=6). These were subdivided based on surgical specialties, which consisted of general, gynecology, neurosurgery, urology, and nonspecific specialties. Figure 2 depicts the surgical procedures and the corresponding clinical settings under which the telementoring technologies were tested. Each vertical block represents an article using dynamic augmented reality cues. Articles using multiple dynamic cues are represented as segmented vertical blocks. The surgical procedures identified included cholecystectomy [6,13,18,40,47,49,50], salpingectomy [20], ventriculostomy [52], aquablation [46], and prostatectomy [41,45]. Nonspecific procedures consisted of basic tasks (such as cutting, knot tying, ligation, peg transfer, and tool motion) [18,21,22,41,44,51,53] as well as suturing [21,41-44,48,51,54]. The procedures were conducted under four different clinical settings: virtual simulator, synthetic phantom, animal (cadaver or live), or human (live). Virtual simulators present highly realistic computer-generated surgical procedures. However, they often have limited haptic feedback providing tactile sensation [55]. Synthetic phantoms consist of low or high-fidelity tissue models. Depending on the material it is made of, it may even provide realistic tissue interaction [56]. Animal models include euthanized cadavers or anesthetized live animals, while surgeries on real patients were categorized as human (live). All the 4 clinical settings were used for telementoring during cholecystectomy procedures. Maximum number of articles covered laparoscopic suturing on synthetic phantoms (n=6). A range of dynamic AR cues were used in articles covering robot-assisted basic tasks performed on animal models.

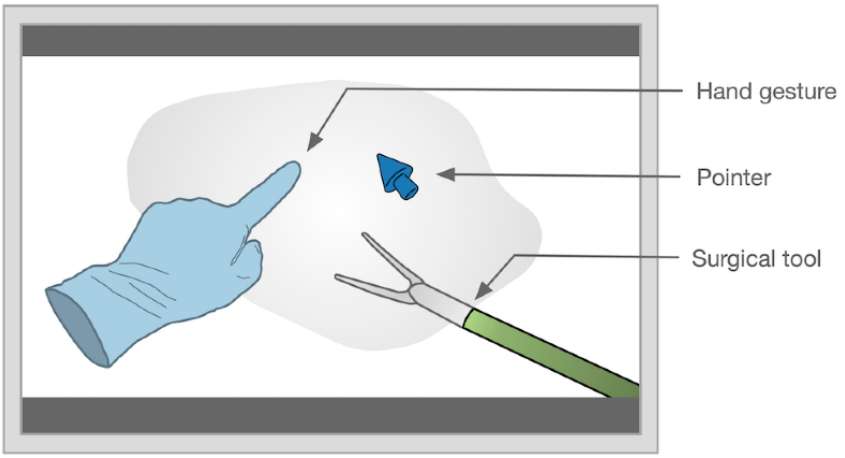

Figure 2. Depiction of surgical procedures and the corresponding clinical settings under which the telementoring technologies were tested.

Telementoring Technology (Research Question 2)

The mentors used various forms of dynamic AR cues that were overlaid on the mentee's view of the operating field (Figure 3). These visual cues were divided into 3 types, hand gesture (displaying mentor's hand position and orientation), pointer (in the form of dynamic annotations), and surgical tool (showing the type of tool, position, or required motion). As depicted in Figure 4 [6,13,18,20-22,41-46,48,51-54], most of the articles covered hand gestures and surgical tools (n=10 articles on each cue). The telementoring system developed by Jarc et al [21,53] used all the 3 types of dynamic AR cues. Some of the pros and cons of each cue are summarized in Table 2. The following paragraphs provide a detailed description of the three dynamic AR cues.

Figure 3. Various dynamic augmented reality cues overlayed on the mentee's operative field.

XSL•FO
RenderX

Figure 4. Number of articles reporting telementoring systems using dynamic augmented reality cues, specifically, hand gestures, pointers, and surgical tools [6,13,18,20-22,40-48,51-54]. ART: augmented reality telementoring; MVR: merged virtual reality; VIPAR: virtual interactive presence and augmented reality.

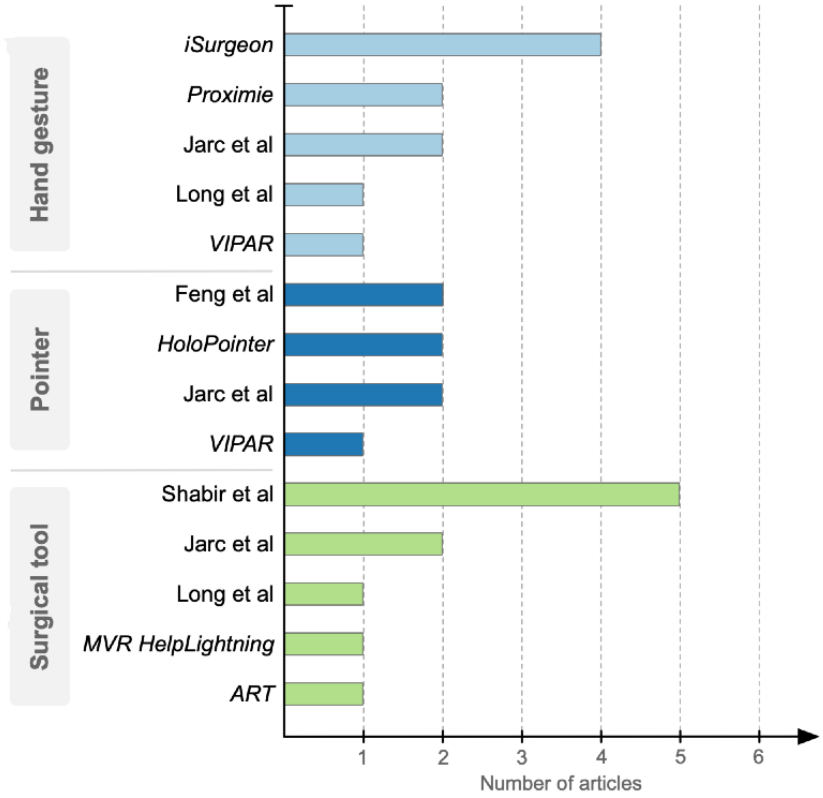

Table 2. Summary of common pros and cons of each dynamic augmented reality cue.

Dynamic augmented reality cue	Pros	Cons
Hand gesture	• Natural and intuitive mode of communication [18]. • Orientation and position can be conveyed [21]. • Grasping tool actions can be mimicked using open and close gestures with fingers [53].	• Mentee's view of the operative field may get obstructed [43]. • Complex tool tip movements may not be conveyed [48].
Pointer	• Critical anatomical structures and dissection plane can be indicated [52]. • Mentors can use hands-free interaction when pointing is enabled through head tracking [47].	• Tool tip orientation may not be conveyed [48]. • Complex instructions such as grasping and other tool movements may not be replicated [48]. • Verbal clarification of the instruction may be required [53].
Surgical tool	• Exact tool to be used, tool tip orientation, and position can be conveyed [44,54]. • Required motion and open and close gestures of the tool can be conveyed [53]. • Decreases the need for takeover of the surgery by the mentor [54].	• Mentee's view of the operative field may get obstructed [43]. • Implementation of the technology may be challenging [22].

Hand Gesture

Hand gesture was one of the most used dynamic AR cues among the included articles. It enhances the mentoring experience with the ability to point at critical anatomical structures, demonstration of grasping gestures by opening and closing fingers, and depiction of orientation through hand rotation movements [13,53]. In the iSurgeon system, the mentor's hand gestures were captured using an overhead depth video camera, which was then projected on to the mentee's view of the operative field [6,13,18,51]. In this way, the mentor was able to support the mentee by communicating the dissection plain, target anatomy, and indicating the next steps of the procedures [6]. Similarly, the hand gesture overlays were also used in telementoring systems such as Proximie and Virtual Interactive Presence and Augmented Reality (VIPAR) [46,52]. In the VIPAR system, the video camera on iPad tablet devices were used to capture the mentee's operative view as well as the mentor's hand gestures. Both the video feeds were then combined allowing a transparent overlay of the mentor's hand

XSL•FO
RenderX

to appear in the mentee's view [52]. The telementoring system developed by Jarc et al [21,53] integrated custom wireless input devices and commercial game controllers allowing the mentor to manipulate the orientation and position of a virtual hand appearing in the mentee's operative view. The mentor was also able to indicate grasping gestures (open and close) using the input device. In this way, the mentee was able to understand and translate the hand gestures to orient, position, and manipulate the surgical tool accordingly. Consequently, the use of virtual hands for telementoring was rated as highly effective by both the mentors and mentees [53]. As reflected by its frequent usage observed in the included articles, hand gestures provide a natural and intuitive mode of communication for the mentor making it easier for the mentee to interpret and follow the instructions.

Pointer

The virtual pointer was used to indicate critical anatomy or a specific region in the mentee's operative view. Frequency of its use as dynamic AR cue during telementoring was relatively lower compared with hand gestures and surgical tools among the included articles. Nevertheless, the use of pointers showed significant improvement in quality of instructions compared with verbal feedback alone [50]. The HoloPointer system used an AR HMD device (Microsoft HoloLens) to track head movements [40]. In doing so, the mentor was able to point at various regions of the operating field view in a hands-free manner [47]. In other studies, the mentors used hand movements, which were captured by a motion sensing device (Microsoft Kinect) to control the virtual pointer as described by Feng et al [49,50]. The VIPAR system, similar to its implementation for hand gestures, used an iPad tablet device to capture the pointing device used by the mentor and combine it with the mentee's operative view [52]. The 3D pointers appearing on the mentee's view were manipulated by the mentor using game controllers in the system presented by Jarc et al [21,53]. However, the use of 3D pointers received low ratings from the mentors. Overall, virtual pointers allowed the mentors to clarify verbal instructions by directing the mentee's attention to a particular region of interest. However, it was not used as frequently, since the mentor is not able to convey precise instructions, such as tool tip orientation and motion.

Surgical Tool

Virtual surgical tools provided a close-to-reality visual cue during telementoring. It enhances the realism of the mentee's training environment as the mentor can accurately convey the precise tool to be used, orientation and position of the tool tip, as well as the necessary movements (such as open and close gestures). Hence, the surgical tool as a dynamic AR cue was frequently used among the included studies. This was primarily done in 2 ways, by superimposing live video feed with real surgical tool from the mentor's side on to the mentee's view or by displaying 3D models of the surgical tool, which the mentor manipulates using various input devices. One of the earliest implementations, the augmented reality telementoring (ART) system, used a laparoscopic box simulator with an embedded camera at the remote mentor's side. As the mentor maneuvered the real surgical tool, the live video feed was superimposed on the mentee's view of the operative field. This resulted in improved understanding of instructions and quicker skills acquisition. The mentees also reported that the cue did not obstruct the operative view [54]. With respect to the use of 3D surgical tool models, Shabir et al [43,48] reported a telementoring system where the mentor did not use real tools and instead controlled the virtual tools appearing on the mentee's view using a haptic device (Touch, 3D Systems). Similarly, Long et al [41] used an AR HMD device that tracked the mentor's hand movements. These movements were then translated to manipulate the virtual tool instructing the mentee. Following the approaches for hand gestures and virtual pointers, Jarc et al [21,53] enabled the mentors to manipulate the ghost tools using custom input devices and game controllers. The virtual surgical tool models enabled the mentor to convey intricate tool wrist orientation information. Overall, surgical tools enhance the instructional experience by replicating complex motions during different surgery phases and overcoming communication barriers between the remote mentor and mentee. Despite the considerable benefits, the use of surgical tools as dynamic AR cues for telementoring in MIS is still in the early stages of clinical trial.

Evaluation of Technology (Research Question 3)

The telementoring technologies using dynamic AR cues were evaluated with participants having varying expertise in MIS. Majority of the studies had experienced surgeons as mentors [13,21,41,45,47,51-53], whereas medical students [6,13,18,21,44,54] and surgical trainees [40,47,50,53] frequently formed the mentee group. The evaluation studies were identified as having either descriptive or analytical study designs. The descriptive studies (n=7 articles) presented the usability or feasibility of the proposed dynamic AR cue, whereas analytical studies (n=15 articles) used comparators to measure effectiveness. Such analytical studies compared outcomes of telementoring using dynamic AR cue against performance with no cue (independent performance without mentoring), prerecorded visual cue (video guidance), in-person guidance, audio cue, or static AR cue (2D telestration). Audio cue [6,13,18,40,47,49,50] and in-person guidance [20,42-44,46,54] were the most frequently used comparators.

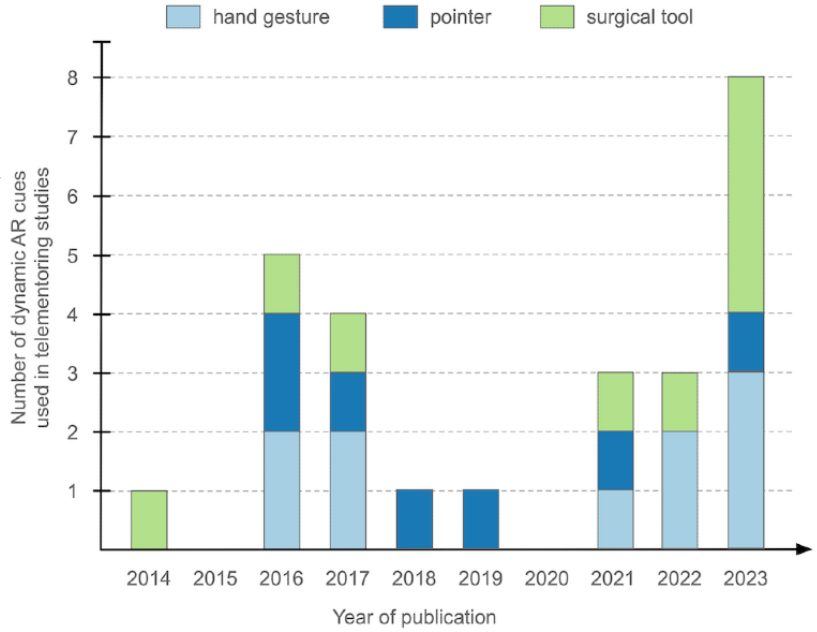
The telementoring studies assessed the effectiveness of dynamic AR cues using a range of outcome measures. These were categorized broadly into factors based on technical evaluation and some of the items specified under the MERSQI outcomes domain [38]. Accordingly, the factors measured included technical, perceptions, skills, and patient outcomes. Technical factors (n=4 articles) included assessment of information latency between mentor and mentee locations [22,41,48,52]. Perceptions (n=5 articles) consisted of preferences, subjective performance assessment, user ratings, and workload measured using NASA (National Aeronautics and Space Administration) Task Load Index (NASA-TLX) [13,21,40,45,53]. Skills (n=13 articles) encompassed Critical View of Safety (CVS), economy of movement, fundamentals of laparoscopic surgery (FLS), gaze behavior, Global Operative Assessment of Laparoscopic Skills (GOALS), number of errors, operating time, Objective Structured Assessment of Technical Skills (OSATS), and turn frequency measuring communication skills

XSL•FO
RenderX

[6,13,18,20,40,42-44,47,49-51,54]. Patient outcomes (n=1 article) included hemoglobin level, urinary retention, complications, and anesthesia use in a real surgery setting [46].

Discussion

One of the aims of the scoping review was to present a comprehensive summary of the use of dynamic AR cues for telementoring during MIS. Through systematic searches of the scientific literature, it was observed that dynamic AR cues for telementoring were more frequently implemented for laparoscopic surgeries (as compared with robot-assisted surgeries). It was mainly used for teaching suturing skills on synthetic phantoms and remote mentoring during simulated cholecystectomy procedures. The mentors primarily consisted of expert surgeons, while medical students and surgical trainees dominated the mentee group. The use of hand gestures and surgical tools as dynamic AR cues were more frequent as compared with virtual pointers. Hand gestures and surgical tools allowed the mentor to convey information such as position, orientation, and tool tip motions to the mentee. To display the dynamic AR cues to the mentee, a small proportion of the studies used iPad tablets (n=1, 5%) Microsoft HoloLens (n=3, 14%), and the surgeon's console with stereoscopic vision for robot-assisted surgery (n=4, 19%). However, most of the articles used a standard visualization screen (n=13, 62%) through which the mentee was able to see the AR cues. Among the included articles, at least 14 (67%) of them had a study design where the use of dynamic AR cue was compared with different modes of instruction with the most common comparators being audio cues and in-person guidance. The key factor used for evaluation was skills. The most frequently reported outcome measures were time taken for task completion and number of errors.



In general, the results of the included papers suggest that participants subjected to telementoring with dynamic AR cues experienced considerable beneficial effects when compared with groups receiving no cue, prerecorded visual cue, in-person guidance, audio cue, or static AR cue. More specifically, dynamic AR cues resulted in significant improvement of FLS score when compared with no cue [44] and lowered error count (P<.05) when compared with prerecorded visual cues [43]. While comparing against in-person guidance, some studies reported longer operating time [42], increased anesthesia use, and cauterization [46] with the use of dynamic AR cues. At the same time, few others noted a reduced complication percentage [20], lower operating time (P=.01), steeper learning curve, and fewer failed attempts [54]. Furthermore, several other studies found no significant difference in performance [42,44], number of errors [54], operating time [43,46], and clinical outcomes [46]. This indicates that telementoring using dynamic AR cues was similar to in-person guidance. While comparing with audio cues, some studies reported no significant difference in CVS, GOALS score [40], number of errors [50], and operating time [6,40,50]. However, the majority of studies demonstrated significant advantages of dynamic AR cues over audio cues. These were in terms of subjective performance [40,47,50], user ratings [40], NASA-TLX score (P<.022) [13], economy of movement [47,50], error rates [13,18,47], gaze behavior (P<.01) [18], GOALS score [6,13], operating time (P<.001) [13], OSATS score (P<.01) [6,13,18], turn frequency (P<.0001) [49], and complications [6,13]. These results show that dynamic AR cues were comparable, and significantly superior to telementoring with audio cues alone. In addition, a study by Jarc et al [53] noted that users preferred dynamic AR cues over static 2D telestrations. Overall, dynamic AR cues resulted in superior outcomes, and in some cases, they were considered on par with conventional methods such as in-person guidance and audio cues.

The extent to which the above-mentioned findings may be used to determine the benefits of the technology is limited. This is because majority of the analytical studies with a comparator were conducted on synthetic phantoms, mostly assessing suturing [42-44,54]. Only 2 of the analytical studies were conducted in real patient settings comparing dynamic AR cue with audio during cholecystectomy [40] and in-person guidance during aquablation [46]. In addition, the outcome measures used to assess the different dynamic AR cues were not consistently used across the studies. The effectiveness of hand gestures was primarily assessed through OSATS, pointers through subjective performance, and surgical tools through latency and operating time. As a result, it is difficult to objectively compare between the different dynamic AR cues and determine the optimal one. Nevertheless, the articles published in the past few years reveal an upward trend in the use of hand gestures and surgical tools (Figure 5). This strongly indicates a rising interest in the use of dynamic AR cues for telementoring in MIS as well as the relevance of using hand gestures and surgical tools.

The implementation of telementoring using dynamic AR cues requires consideration of several technical factors. The Society of American Gastrointestinal and Endoscopic Surgeons (SAGES) issued a set of guidelines that telementoring systems are recommended to comply with. SAGES recommends that a minimum bandwidth of 40 megabits per second must be maintained. In addition, the latency (delay in sending mentee's operative view to the remote mentor) must fall below 450 milliseconds [57]. One of the methods used to reduce latency is by encoding the video frames at the mentee's location and decoding it at the mentor's side. However, during this process, there is a risk of lowered video quality experienced by the mentor. To measure the extent of visual degradation experienced by the mentor, metrics such as structural similarity index measure (SSIM), peak signal-to-noise ratio (PSNR), and mean square error (MSE) are often used [58,59]. SSIM is considered more effective since it is more closely related to the visual quality perceived by the human eye, as compared with PSNR and MSE [22]. The delay experienced by the mentee in receiving mentor's instructions can be reduced when point cloud data (depicting hand gestures or surgical tool) is used instead of video data. Harnessing 5G and future 6G capabilities that provide extremely low latencies can ensure little to no disruption [23]. While several studies included in the review reported information latency between mentor and mentee, they were mostly conducted on synthetic phantoms [22,41,48]. Further research presenting technical results during actual live MIS is imperative.

XSL•FO
RenderX

Figure 5. Number of articles using dynamic augmented reality cues in minimally invasive surgical telementoring.

Ethical, safety, and legal concerns must be addressed while implementing telementoring systems. Informed patient consent must be ensured [23]. Every effort should be made to minimize cybersecurity risks and ensure compliance with guidelines on telemedicine issued by HIPAA (Health Insurance Portability and Accountability Act) [31]. The computer systems at both the mentor and mentee locations must be secure with monitoring schemes in place to detect and prevent potential breaches of sensitive patient data. To protect the data while being transferred between the mentor and mentee, appropriate data encryption and virtual private networks must be used [57]. In addition, a clearly outlined process for licensure and credentialing of surgeons is also required for remotely located mentors [8]. Generally, the mentee (who will be a competent operating surgeon) holds primary medical responsibility and is legally liable. Nonetheless, the SAGES states that during telementoring, the remote mentor retains shared responsibility for the patient [60]. Consequently, the mentor must hold the necessary medical license and surgical privileges in the region where the surgery is taking place. This becomes a barrier to adopting telementoring nationally in places like the United States and Canada as licensing is usually at the state or provincial level. However, this would not be a problem in the European Union (EU) where surgeons licensed under one EU member state can practice in other EU states as well [22]. Furthermore, licensing requirements would not be an issue when dynamic AR cues are used to enhance in-person guidance.

Telementoring using dynamic AR cues addresses the need for efficient ways to remotely guide an operating surgeon. This can be potentially replaced with telesurgery where the remote surgeon performs the surgery through robot-assisted surgical systems. While successful telesurgery cases were reported since the early 2000s, significant progress was made only in the recent years owing to the advances in surgical robot systems as well as telecommunication technologies [61]. However, several factors prevent widespread adoption of telesurgery. Although 5G networks are available, 3G or 4G is the standard in most countries leading to major concerns about latency. In addition, more research is needed to assess the cost-effectiveness of telesurgical services. A long-term sustainable approach must be explored for implementation and maintenance. Nonetheless, several cases of telesurgery for surgical specialties such as general, urology, and neurosurgery have been reported [62]. This provides hope for using remote technologies to reduce the global burden of death and disease that can be prevented or treated through surgical care.

This review is limited by the inclusion of articles published in English only, making it less comprehensive. A risk of bias assessment of the included studies was not carried out. A comparative analysis between the different dynamic AR cues was not conducted due to the variety in outcome measures reported. Instead, overall summary potentially guiding future research on dynamic AR cues used for MIS telementoring is presented.

Although further research is needed to establish its benefits over conventional mentoring, the use of dynamic AR cues in MIS telementoring proves to be promising. Future developments may focus on evaluating the technology through multi-institutional randomized controlled trials. In addition to measures of perceptions and skills, objective clinical outcomes that reliably assess the effectiveness of telementoring should also be evaluated.

Abstract

Background: The advancement of information and communication technologies has spurred a growing interest in and increased applications of patient-generated health data (PGHD). In particular, PGHD may be promising for older adults with cancer who have increased survival rates and experience a variety of symptoms.

Objective: This scoping review aimed to identify the characteristics of research on PGHD as applied to older adults with cancer and to assess the current use of PGHD.

Methods: Guided by Arksey and O'Malley as well as the JBI (Joanna Briggs Institute) methodology for scoping reviews, 6 electronic databases were searched: PubMed, Embase, CINAHL, Cochrane Library, Scopus, and Web of Science. In addition, the reference lists of the selected studies were screened to identify gray literature. The researchers independently screened the literature according to the predefined eligibility criteria. Data from the selected studies were extracted, capturing study, participant, and PGHD characteristics.

Results: Of the 1090 identified studies, 88 were selected. The publication trend gradually increased, with a majority of studies published since 2017 (69/88, 78%). Almost half of the studies were conducted in North America (38/88, 43%), followed by Europe (30/88, 34%). The most common setting in which the studies were conducted was the participant's home (69/88, 78%). The treatment status varied; the median sample size was 50 (IQR 33.8-84.0). The devices that were used to measure the PGHD were classified as research-grade wearable devices (57/113, 50.4%), consumer-grade wearable devices (28/113, 24.8%), or smartphones or tablet PCs for mobile apps (23/113, 20.4%). More than half of the studies measured physical activity (69/123, 56.1%), followed by patient-reported outcomes (23/123, 18.7%), vital signs (13/123, 10.6%), and sleep (12/123, 9.8%). The PGHD were mainly collected passively (63/88, 72%), and active collection methods were used from 2015 onward (20/88, 23%). In this review, the stages of PGHD use were classified as follows: (1) identification, monitoring, review, and analysis (88/88, 100%); (2) feedback and reporting (32/88, 39%); (3) motivation (30/88, 34%); and (4) education and coaching (19/88, 22%).

Conclusions: This scoping review provides a comprehensive summary of the overall characteristics and use stages of PGHD in older adults with various types and stages of cancer. Future research should emphasize the use of PGHD, which interacts with patients to provide patient-centered care through patient engagement. By enhancing symptom monitoring, enabling timely interventions, and promoting patient involvement, PGHD have the potential to improve the well-being of older adults with cancer,

XSL•FO
RenderX

contributing to better health management and quality of life. Therefore, our findings may provide valuable insights into PGHD that health care providers and researchers can use for geriatric cancer care.

Introduction

Background

Advancements in early detection and treatment modalities have led to a consistent increase in the survival rates of patients diagnosed with cancer. In the United States, the number of survivors of cancer reached 18.1 million in 2022, and this figure is projected to increase to 26 million by 2040 [1]. With rising cancer survival rates, there is a notable trend of aging among survivors of cancer. In 2022, over two-thirds (67%) of US survivors of cancer were aged 65 years or older [1].

Older adults often experience multiple chronic health conditions, and survivors of cancer show an even higher prevalence of these issues compared to those without cancer [2]. Common co-occurring conditions in older patients with cancer include musculoskeletal conditions, such as osteoarthritis and sciatica; mental health disorders, such as depression and anxiety; and cardiovascular diseases, such as hypertension and coronary artery disease [2,3]. These conditions may exacerbate susceptibility to functional decline, with older survivors of cancer facing an accelerated deterioration in grip strength, gait speed, and overall physical performance compared to their peers without cancer [4]. Moreover, the presence of multiple chronic conditions and functional limitations in older survivors of cancer are associated with a reduced quality of life, increased risk of early mortality, and significant economic burden [5,6].

Given the challenges associated with both cancer and aging, innovative approaches to monitoring and managing the health of older survivors of cancer are essential for improving their health and well-being outcomes. The collection and sharing of pertinent health data can offer survivors of cancer and their health care providers an opportunity to enhance their health [7]. The rise of consumer technologies, such as smartphone apps and wearable devices, has paved the way for the creation and use of tools that enable individuals to gather their own health-related data [8]. These data are related to their physical behavior (eg, step count or sleep patterns), physiological parameters (eg, heart rate or blood pressure), biochemical markers (eg, blood glucose levels), and environmental factors (eg, air quality or temperature) in which they are present.

With the advancement of information and communication technologies, the interest in and the applications of patient-generated health data (PGHD) are growing. PGHD refer to “health-related data—including health history, symptoms, biometric data, treatment history, lifestyle choices, and other information—created, recorded, gathered, or inferred by or from patients or their designees (ie, care partners or those who assist them)” [9]. PGHD are distinct from data sourced from clinical environments or interactions with health care providers. The primary distinction is that PGHD are recorded by patients and not providers, and their sharing is directed by the patients [9]. Patients can collect these data either passively or actively through mobile health apps, wearable devices (eg, fitness bands), medical devices (eg, blood glucose monitors), or survey instruments on mobile devices [7]. Passive data collection occurs when data are gathered automatically with minimal patient input, typically using automated systems or sensors. By contrast, active data collection requires patients to be actively involved, typically by responding to surveys.

PGHD enable the consistent, long-term monitoring of diverse health-related information that can be easily exchanged between patients and health care providers [10]. These data can complement the information that health care systems typically gather through providers, offering individualized baseline indicators. With PGHD, both patients and health care providers can quickly discern changes in the health status, allowing for more appropriate and prompt interventions [11].

PGHD have found applications in monitoring and managing various long-term health conditions. For instance, PGHD can be used to identify undiagnosed obesity and diabetes, assess the risk of these conditions, and predict glycemic events in patients with diabetes [12]. In the context of HIV care, PGHD help alleviate financial and temporal pressures by reducing the need for frequent in-person consultations [11]. Continuous monitoring through PGHD enhances medication adherence and increases patients’ understanding of their health status [11]. For survivors of cancer, who face higher posttreatment health risks, PGHD enable real-time tracking of health parameters such as activity levels, symptom progression, and medication adherence, facilitating early detection of issues and more personalized interventions [7]. Beyond individual care, PGHD can also benefit larger survivors of cancer communities by contributing to population-level insights, informing public health strategies, enhancing survivorship guidelines, and supporting research on cancer survivorship.

While there is the potential for using PGHD in older adults with cancer, few review studies have focused on PGHD in these patients. A comprehensive understanding of the characteristics and use of PGHD in older adults with cancer will help improve patient engagement in health care and enable researchers to apply PGHD in geriatric cancer care. This will ultimately lead to the effective application of PGHD in enhancing the health and well-being of older adults with cancer.

RenderX

Objectives

This scoping review aimed to identify the characteristics of research on PGHD as applied to older adults with cancer and to assess the current use of PGHD. The main research question for the scoping review was "What is the present landscape of research concerning PGHD in older adults with cancer?"

The specific research questions were as follows: (1) What are the characteristics of the studies conducted on PGHD in older adults with cancer? (2) What are the characteristics of older adults with cancer who have been the subject of PGHD-related research? and (3) What are the characteristics of PGHD that have been gathered from older adults with cancer?

Methods

Design

This scoping review was conducted following the guidelines of Arksey and O'Malley [13] and the JBI (Joanna Briggs Institute) methodology for scoping reviews [14]. This scoping review was also performed according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Review) guidelines Multimedia Appendix 1 [15]. The population, concept, and context for this scoping review were as follows: (1) population—older adults with cancer, (2) concept—PGHD, which were collected using devices; and (3) context—no limitation for setting. The protocol of the scoping review was registered in the Open Science Framework Registry.

Search Strategy

In this study, 6 electronic databases—PubMed, Embase, CINAHL, Cochrane Library, Scopus, and Web of Science—were searched for relevant literature. Considering the population, concept, and context of this scoping review, the search strategy was developed by combining keywords and index terms from each database (Multimedia Appendix 2). PGHD as a concept was introduced as a Medical Subject Headings (MeSH) term by PubMed in 2018. To retrieve relevant literature before the introduction of PGHD as a MeSH term, we further constructed PGHD-specific search terms by combining the keywords "patient-generated" and "devices." In addition, the search was limited to the index terms included in the titles and abstracts of the studies to ensure proper identification of the literature. An experienced librarian at the researcher's university confirmed this search strategy. A literature search was conducted using a confirmed search strategy on October 21, 2022. After the literature search, the reference lists of the selected studies were screened to identify the gray literature.

Eligibility Criteria and Study Selection

To assess the eligibility of studies on PGHD in older adults with cancer, the inclusion criteria were as follows: (1) studies that included older adults with a mean or median age of 65 years or older; (2) studies that included older adults with cancer, regardless of the type of cancer or treatment status; and (3) studies that applied PGHD, including wearable devices that measure patients' physical activity or physiological features or mobile phones that measure patient-reported outcomes (PROs). The exclusion criteria were as follows: (1) studies in which PGHD were selectively used in some of the participants; (2) studies comparing results using PGHD for validation of other tools; (3) publications other than original studies, such as editorials, letters, or protocols; (4) publications that were not peer reviewed, such as abstracts, conference proceedings, dissertations, or theses; and (5) studies written in languages other than English or Korean.

The studies identified in the literature search were exported to the reference management software program (EndNote X9; Clarivate Analytics). After deleting duplicate results using EndNote, the results were extracted with a Microsoft Excel program (Microsoft Corp) for literature screening. Two researchers (Yesol K and GK) independently selected studies based on the inclusion and exclusion criteria. The titles and abstracts were initially reviewed; subsequently, the full texts were reviewed to select studies for final inclusion. If the two researchers did not agree on a particular study, a consensus was reached through discussion and the participation of a third researcher (MC).

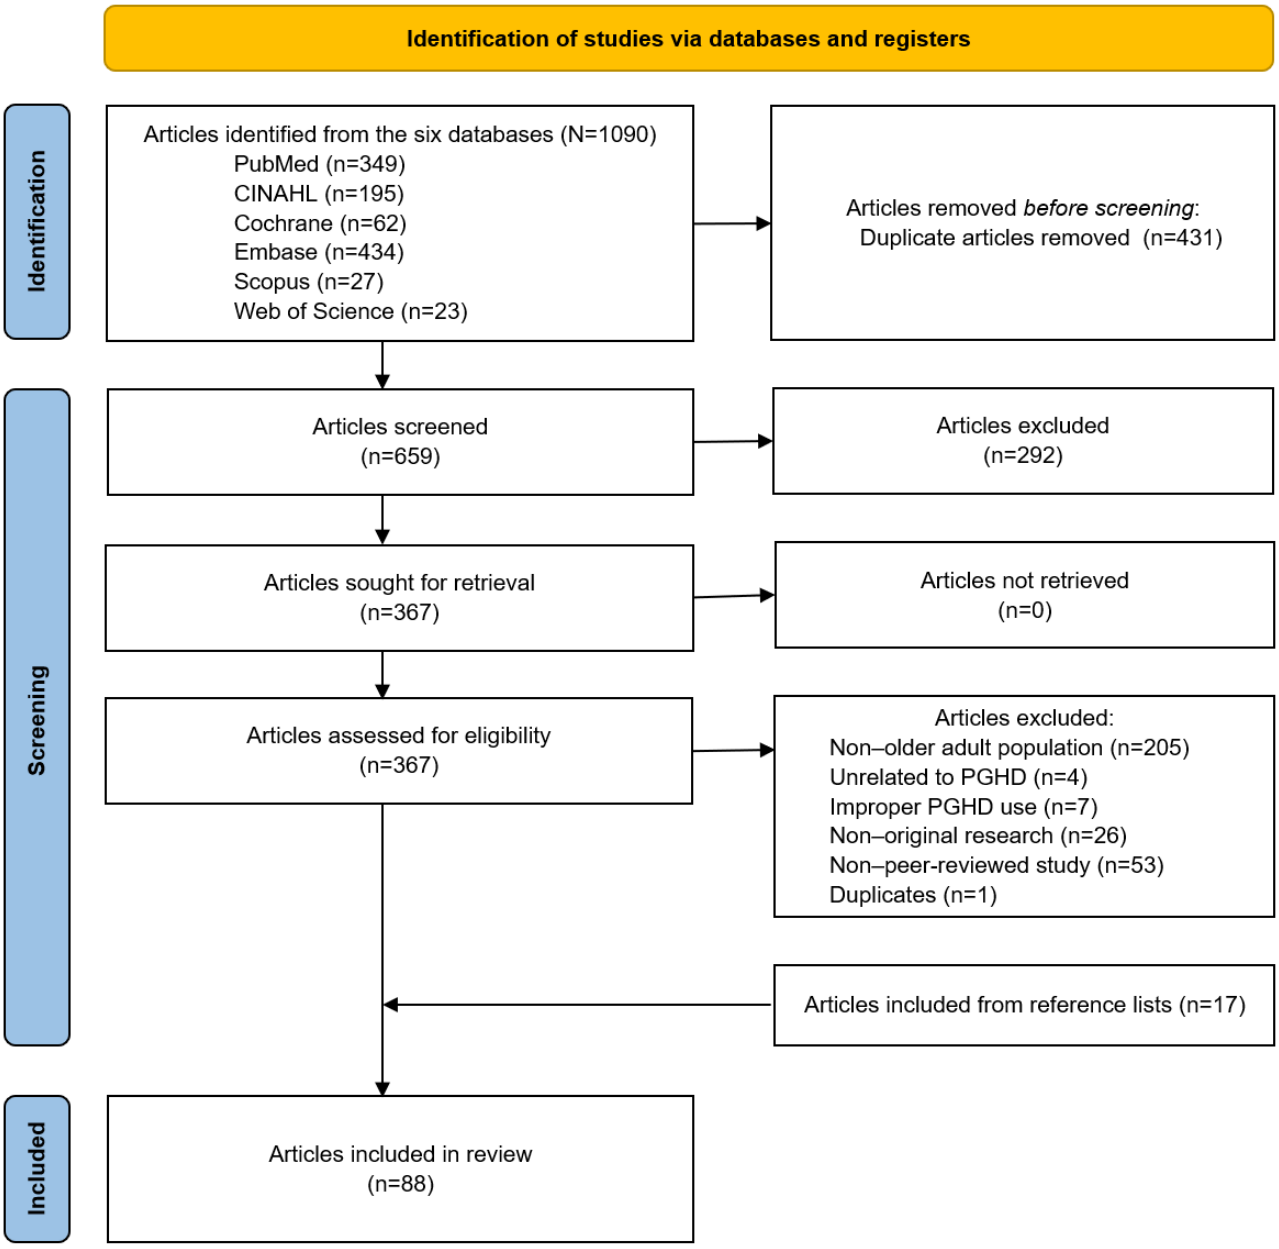
Data Extraction

Data from the selected studies were extracted using Microsoft Excel in a structured data charting format, which was constructed by the researchers. It comprised the study, participant, and PGHD characteristics. First, the study characteristics included published year, country, continent, study design, and dataset. Second, the participant characteristics included the study setting, type of cancer, treatment status, and sample size. Lastly, the PGHD characteristics included the type of device that was used to measure PGHD, type of assessment by PGHD, on-body locations of the wearable devices that measure PGHD, duration of wear of the devices that measure PGHD, type of PGHD collection, and type of PGHD use. The types of PGHD collection were categorized as passive (using sensor-based devices that automatically acquire and transfer PGHD from patients), active (requiring active patient engagement to collect PGHD that are not easily collected automatically), and combined methods [16]. The types of PGHD use were categorized into the following four categories: (1) identification, monitoring, review, and analysis; (2) feedback and reporting; (3) motivation; and (4) education and coaching [16]. Two researchers (Yesol K and GK) independently extracted the data, and disagreements, if any, were resolved by consensus through discussion and the participation of a third researcher (MC).

Data Analysis

The data extracted from this scoping review are summarized and presented using descriptive statistics. The results were mapped and are presented in the form of tables, charts, or figures according to the purpose and research questions of this scoping review.

Results



Study Selection

The literature selection process is illustrated in Figure 1 as a PRISMA (Preferred Reporting Items for Systematic Reviews

XSL•FO
RenderX

and Meta-Analyses) flow diagram. A total of 1090 articles were retrieved from 6 database searches. After the elimination of duplicates, the titles and abstracts of 659 (60.5%) articles were reviewed. Subsequently, the full texts of 367 (33.7%) articles were reviewed to determine eligibility for this review. The reasons for the exclusion of articles from the full-text review are listed in Figure 1. After the screening, 71 (6.5%) articles were selected. A review of the references of the 71 selected articles led to the additional selection of 17 articles, resulting in a selection of a total of 88 articles for the review [17-104].

Figure 1. PRISMA flow diagram of this study. PGHD: patient-generated health data; PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Study Characteristics

The studies included in this scoping review were published between 2006 and 2022 (Multimedia Appendix 3). There has been a discernible upward trend in publication volume, with more than 70% of the articles published since 2017 (69/88, 78%) [36-104]. Geographically, North America emerged as the leading contributor to the body of research, accounting for 43% (38/88) of the studies. The study designs were categorized into nonexperimental and experimental designs. Among studies with nonexperimental designs, a survey-based study design was most frequently adopted (39/88, 44%). Among studies with experimental designs, a pre-experimental design was most frequently adopted (28/88, 32%). Data derived from original research constituted the basis for more than 60% of the studies (59/88, 67%; Table 1).

Participant Characteristics

The participant characteristics are presented in Table 2. Most studies were conducted at the participants' homes (69/88, 78%). Among the included studies, none focused solely on older adults living alone. Only 15 (17%) of the 88 studies distinguished participant characteristics based on whether they lived alone or with others, and most participants in these studies lived with others. Of the 88 studies, 64 (73%) specified the selection criteria for study participants according to cancer type. These studies included 76 cases of various types of cancer, the most common of which was prostate cancer (22/76, 29%). Regarding gender proportions, 66 (75%) of the 88 studies had a higher proportion of men, while 20 (23%) studies had a higher proportion of women. Of these, 18 (20%) studies focused exclusively on men, all involving patients with prostate cancer. In contrast, 3 (3%) studies focused exclusively on women, all involving patients with breast cancer. Half of the studies were conducted on patients who received active treatment (29/88, 33%) or surgery (15/88, 17%); a quarter were conducted on survivors of cancer (22/88, 25%). In this review, survivors of cancer are defined as individuals who have completed their primary cancer treatments—such as surgery, chemotherapy, or radiation therapy—and are in the posttreatment phase. The median sample size was 50 (IQR 33.8-84.0), and more than 40% of the studies included fewer than 50 (39/88, 44%) participants. In the studies included in this review, the mean age of participants ranged from 65 (SD 7) to 76.9 (SD 10.5) years.

[a]There were a total number of 76 cases of various types of cancer among 64 studies.

PGHD Characteristics

The characteristics of the PGHD identified in each study are summarized in Table 3. In this review, research-grade wearable devices were used in more than half of the cases (57/113, 50.4%): these included the ActivPal Monitor (PAL Technologies Ltd), Stepwatch Activity Monitor (Modus Health), and ActiGraph GT3x Activity Monitor. Consumer-grade wearable devices were used in 28 (24.8%) cases: these included Fitbit, Apple Watch, Garmin band, Microsoft Band, Samsung Gear, and Xiaomi MiBand. Smartphones, tablet PCs, and computers were used to collect data using mobile apps or web-based surveys in 25 (22.1%) cases. Other devices, including smart mattresses and an instant camera, were used in 3 (2.7%) cases.

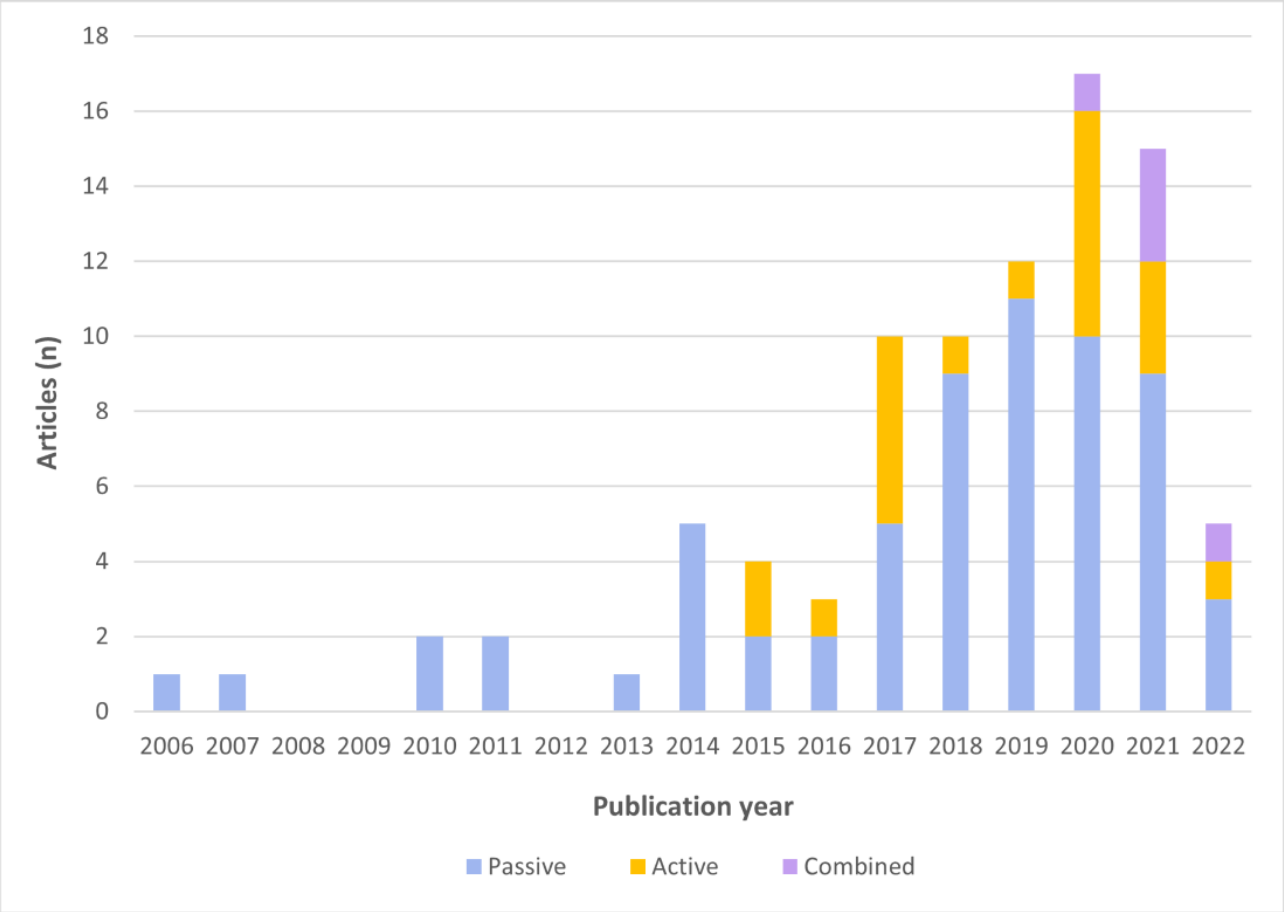
[a]The total number is 113 due to multiple categories.

[b]The total number is 123 due to multiple categories.

[c]The total number is 117 due to multiple categories.

Regarding the type of assessment by PGHD, more than half of the assessments (69/123, 56.1%) focused on physical activity measured through step count, moderate-to-vigorous physical activity, and sedentary behavior. Sleep, including the sleep-wake cycle, circadian rhythm, and movement in bed, were measured in 12 (9.8%) cases. There were 23 (18.7%) cases of PROs, including symptoms and quality of life, and 6 (4.9%) cases of other assessments, such as body weight and exposure to light intensity.



Regarding the on-body locations of wearable devices that measure PGHD, approximately one-third were worn on the wrist (35/116, 30.2%). Additionally, mobile apps or cameras were used without attaching them to the body in 25.9% (30/116) of cases. Regarding the wearing period of the device, the device was worn for ≤1 week in 47 (41.6%) cases and for >12 weeks (3 months) in 16 (14.2%) cases.

PGHD were collected in various ways, including passive, active, and combined collection (Table 3 and Figure 2). PGHD were primarily passively collected from participants (63/88, 72%),

XSL•FO
RenderX

constituting most of the included studies published between 2006 and 2022. Furthermore, in 20 (22%) studies, PGHD were actively collected from participants from 2015 onward. However, few studies combined passive and active collection methods for PGHD (5/88, 6%), which have been used in research since 2020.

Figure 2. Type of patient-generated health data collection by year.

In detail, 25 studies actively collected PGHD, including combined collection methods. Among these, smartphones, tablet PCs, or computers were the predominant devices for active data collection through mobile apps or surveys (23/25, 92%). Except for 1 study that used computers, of the 22 studies using smartphones and tablet PCs, 6 (27%) used the Android (Google LLC) operating system, 5 (23%) used iOS (Apple Inc), 3 (14%) used both, and 8 (36%) did not specify the operating system. Regarding device ownership, 10 (45%) studies provided devices to participants, 3 (14%) studies relied on participants' own devices, 4 (18%) studies used both approaches, and 5 (23%) studies did not report on this aspect.

Among the studies included in this review, approximately a quarter (21/88, 24%) had a sample size of over 100 participants. The PGHD monitoring period varied from 1 day to 24 weeks, with over 60% (13/21) of studies reporting a duration of 1 week or less. Additionally, more than three-quarters of these studies (16/21) collected PGHD passively, primarily using wearables, including both research-grade and consumer-grade devices. Of the 88 studies, 67 (76%) reported on participants' adherence to PGHD collection, with adherence rates ranging from 36% to 100%. More than half of these studies (36/67, 54%) reported an adherence rate above 80%. In addition, the dropout rates reported in 57 longitudinal studies ranged from 0% to 72.4%. Approximately one-fifth of these studies (13/57, 23%) completed PGHD collection with full participant retention.

In this review, health care providers supported PGHD collection from participants in only 20 (23%) studies. Health care providers assisted with the synchronization of the devices, troubleshooting of technical issues, and so forth (10/20, 50%) [42,44,74,86,87,89,98,101,103,104]. They also provided reminders to participants, encouraging PGHD collection (9/20, 45%) [32,36,40,43,58,83,92,97,101]. In addition, health care providers directly assisted with data collection (1/20, 5%) [47] and requested additional information if participants did not respond appropriately (1/20, 5%) [90]. In the case of support methods, phone calls (11/20, 55%) [40,42,43,47,83,86,87,89,90,92,97], text messages (1/20, 5%) [86], app push notifications (4/20, 20%) [32,40,43,58], emails (1/20, 5%) [83], and in-person contact (2/20, 10%) [44,47] were identified.

In this study, the stages of PGHD use were classified as follows: (1) identification, monitoring, review, and analysis; (2) feedback and reporting; (3) motivation; and (4) education and coaching (Multimedia Appendix 4). Identification, monitoring, review, and analysis of PGHD were implemented across all studies (88/88, 100%). Other stages were implemented by interacting with the participants and health care providers. Feedback and

XSL•FO
RenderX

reporting were applied in 34 (39%) studies by using PGHD to aid participants in checking their data and receiving technical advice [24,26,32,33,38,40,42,43,52-54,56,58,60,63,69-72,74,75,79,82,83,86-90,92,93,98,101,104]. PGHD was used as a motivator for participants in approximately one-third of the studies (30/88, 34%) [24,32,33,40,42,43,53,54,56,58,60,63,65,70,71,74,75,77,79,82,86-88,92,93,96,98,100,101,103]. It included directly encouraging participants to generate data, reminding them, setting goals, and supporting them in the process of generating PGHD. Approximately one-fifth of the studies (19/88, 22%) provided education and coaching using PGHD, enhancing the attainment of additional information, knowledge, and skills [25,32,40,53,56,58,70-72,75,77,79,82,87,88,92,93,100,104].

Discussion

Principal Findings

This scoping review presents a broad overview and summary of the studies on PGHD use among older adults with cancer. Following are the key findings of this scoping review, which included a total of 88 studies published between 2006 and 2022. A variety of devices were used to collect PGHD, including research-grade wearable devices, consumer-grade wearable devices, and smartphones or tablet PCs. These devices assessed different PGHD in older adults with cancer, including physical activity, sleep, vital signs, and PROs. In most studies, PGHD were collected passively, requiring no additional effort from the patient, other than wearing the device. Active and mixed PGHD collection methods have recently been applied to research. In most studies, there was no support from health care providers when PGHD were collected from older adults with cancer. PGHD were used for the identification, monitoring, review, and analysis in all studies included in the review. However, fewer than half of the studies identified advanced use of PGHD, such as feedback and reporting, motivation, and education and coaching.

Study Characteristics

Since 2017, an increasing number of studies have been published on the applications of PGHD in older adults with cancer. This may be attributed to the fact that the MeSH term for PGHD was introduced in PubMed in 2018. Given the current publication trend, this can be considered an early stage of use of PGHD-related research in older adults with cancer, indicating that there is a need for further research. Approximately one-third of the included studies used secondary sources for PGHD; most were original, while 5 used cohort data. These 5 studies used the following cohort data: the Baltimore Longitudinal Study of Aging [55] and the National Health and Nutrition Examination Survey [19,22,23,62] from the United States, which measured the participants' physical activity. The advantage of using data from a cohort is that PGHD can be collected from a relatively large number of people and can be used by many researchers simultaneously, which can have a positive impact on patient health care. Therefore, it is recommended to consider including PGHD when constructing a large cohort study.

Participants Characteristics

Approximately 80% (69/88) of the studies reviewed in this analysis focused on the application of PGHD in home settings, underscoring its well-established use outside of hospital environments. Our findings indicate that it is valuable to provide health care providers with continuously collected data on health status at home through PGHD [105]. PGHD can offer patients valuable insights into their health by allowing them to monitor their health at home between hospital visits or during self-care [106]. Moreover, the application of PGHD eliminates time and location constraints, thereby enhancing patient accessibility and participation in their health care [107].

In this review, the cancer treatment statuses of the participants differed. Notably, the cancer survivorship phase, which constituted a quarter of this review, often lacked ongoing health care beyond periodic hospital follow-up visits. Multiple studies have highlighted the unmet need of survivors of cancer for continued care postactive treatment [108,109]. However, PGHD offers several benefits for survivors of cancer. Petersen [7] indicated that it is beneficial for survivors of cancer to apply for PGHD to improve and promote their health. For instance, the collection of PGHD at home, encompassing various health aspects, such as symptoms, can assist health care providers in identifying and managing health issues effectively [7]. In other words, PGHD have the potential to improve patient engagement among survivors who do not frequently receive hospital care and allow health care providers to access patients in a clinical setting. This makes it a promising tool for enhancing the quality of life and health outcomes of survivors of cancer, thereby encouraging future studies to actively use PGHD in their management.

PGHD Characteristics

We found that wearable devices were used to collect approximately three-quarters of the PGHD. These wearable devices have expanded the scope of research beyond the confines of electronic health records by enabling integrated data acquisition from patients [110]. Previous reviews reporting on the use of wearable devices across various health domains indicated that approximately 86% data were collected using consumer-grade wearable devices, including Fitbits, whereas approximately 14% were from research-grade devices [111]. In contrast, in this study, research-grade wearable devices were used in approximately half of the cases and consumer-grade in approximately a quarter. This difference can be attributed to the perceived suitability and higher measurement accuracy of research-grade wearable devices in research settings, particularly among older adults with cancer, which is the target population of this review [112]. Despite this, recent clinical studies have shown an increase in the use of consumer-grade wearable devices, and their reliability and validity have been established [113]. Given their relative affordability and lower burden of wear, consumer-grade wearable devices, which enable continuous usage, are considered to have a high potential for widespread use [114]. Therefore, rather than distinguishing between the types of wearable devices, the focus should be on the selection of the most appropriate device for collecting

XSL•FO
RenderX

PGHD, considering the specific circumstances and environments of older adults with cancer.

In this review, more than half of the collected PGHD items focused on physical activity. Previous studies have shown that older adults with cancer tend to engage in less physical activity compared to middle-aged patients [115]. Moreover, physical activity has been demonstrated to enhance physical function and overall quality of life in older adults with cancer [116,117]. This underscores the importance of prioritizing increased physical activity as a critical factor in improving the health of this population. PGHD can increase health awareness and patient engagement, leading to positive effects on physical activity [107]. Essentially, it can help older adults with cancer in making health behavior changes that enhance physical activity while supporting their autonomy [7]. Moreover, self-monitoring of physical activity using PGHD can motivate individuals to engage in these activities [118]. Therefore, future research using PGHD to monitor and encourage physical activity among older adults with cancer may improve their health outcomes.

This review identified PGHD that measure PROs, including symptoms, in older adults with cancer, which is crucial for enhancing treatment and health outcomes [119]. While visiting a hospital in person and objectively measuring their condition is challenging for patients with cancer, self-reporting conditions, including symptoms, can be more beneficial [120]. Patients were able to report the symptoms they experienced in real time from their homes through PGHD, and contrary to expectations, they did not find it burdensome to report daily [40]. PGHD offer a means for patients with cancer to communicate their condition directly to health care providers, thereby eliminating time and distance constraints and benefiting both the patients and providers [7]. Especially, older patients with cancer are at a higher risk of reporting more severe symptoms [121]. Therefore, enabling older patients with cancer to assess their condition, including symptoms, through PGHD without time and distance limitations can facilitate the early detection of deterioration and personalized care [119]. However, none of the studies included in this review actively involved older adults with cancer in selecting the PGHD to be collected. Therefore, future studies should consider selecting and collecting PGHD items based on participants' needs to enhance engagement.

In addition, based on the data collected through the PROs, reports or alerts about symptoms were provided to patients, and health care providers offered advice or interventions for symptom management [32,42,79]. This indicates that patients, even when not in the hospital, can experience gratitude and psychological comfort, knowing that they are connected to and receiving care from health care providers and are managing their health issues [40]. PGHD enabled patients to gain confidence in self-management of their symptoms, suggesting a positive impact on their health management.

This review categorizes PGHD collection into passive, active, and combined methods, with the passive collection being predominantly used (63/88, 72%). This differs from a prior review of PGHD for disease prevention and health promotion, in which active or partially active methods were more common in healthy populations [16]. Passive methods that use wearable devices for objective data collection without an added burden have been in use since 2006. Given the focus on older adults with cancer in this review, simpler passive methods have been widely adopted. In addition, health care providers tend to view passively collected PGHD as more reliable and more challenging to manipulate, as indicated in previous studies [122].

In contrast, approximately one-fifth of the studies used the active collection method, which showed a gradual increase over time. This method, which involves direct and active participation of the patients in data collection, allows patients to report their subjective states, contributing to enhanced patient engagement [123]. However, a previous review identified conflicting characteristics between passive and active collection [16]. Passive approaches were found to be less burdensome for patients, but may reduce their participation, whereas active approaches require voluntary effort, but motivate patient involvement [16]. Considering these characteristics, a combined collection approach may be ideal for PGHD. In this review, only approximately 6% (5/88) of the studies used a combined collection method, which started to appear in 2020. For example, in the study by Low et al [91], passive data collection using wearable and smartphone sensors for PGHD, combined with active data collection of patient-reported symptoms, facilitated personalized and adaptive symptom assessments to enable early detection of adverse events. This approach may ultimately enhance patient well-being by enabling timely interventions throughout long-term cancer treatment and recovery. Thus, future research should consider using a combined data collection approach to comprehensively assess the health status of older adults with cancer.

An adequate level of digital literacy is essential for patients to generate PGHD, comprehend their significance, and receive motivation for behavioral changes to enhance adherence. However, concerns have arisen about the potential disparities among those unable to collect or use PGHD for various reasons. Age is a contributing factor, as older adults may struggle to adopt new technologies owing to their unfamiliarity [124]. Moreover, patients with cancer often experience higher physical and psychological symptom burdens than do those without cancer, potentially reducing their inclination to use digital health technologies [125]. Therefore, future studies may require additional strategies to identify and enhance digital literacy among older adults with cancer. A tailored approach that integrates demographic factors (eg, age or gender), geographic factors (eg, place of residence), socioeconomic factors (eg, education level), behavioral factors (eg, information-seeking behavior), and social factors (eg, social support) could promote more effective use of wearable devices and mobile apps for PGHD collection and use [126].

Regarding the PGHD use stages, all studies used PGHD at the first stage, primarily collecting and analyzing PGHD, to identify and monitor the health status of older adults with cancer for research purposes. This aligns with a previous review of disease prevention and health promotion, in which many studies reviewed and analyzed PGHD [16]. However, the first stage of PGHD use can be considered as merely using the gathered information for analysis. To facilitate bidirectional rather than unidirectional communication through PGHD, patients must be

XSL•FO
RenderX

able to check or access their generated data. The studies included in this review initially identified and analyzed PGHD, and then PGHD were used for advanced use depending on the purpose of the study. In only approximately one-third of the studies, the patients were provided with information and feedback on PGHD to help them understand their condition; PGHD motivated patients to achieve health-related goals and was used for education or coaching interventions. Therefore, offering actionable recommendations based on PGHD is expected to increase patient engagement in health behaviors, especially among older adults. This implies that the use of PGHD should not be limited to the generation of data through wearable devices but should extend to accessing this data and receiving feedback that motivates behavior change. Similarly, when collecting PROs including symptoms via mobile apps, a bidirectional structure is necessary in which patients receive advice or guidance in addition to reporting their information.

To promote the widespread use of PGHD in research involving older adults with cancer, it is crucial to increase adherence to digital devices for PGHD measurements. This necessitates identifying the needs, barriers, and facilitators for older adults with cancer regarding PGHD, and providing education where there are gaps to encourage adherence. In particular, patients with lower digital literacy encounter greater barriers to using PGHD [16,127]; this can negatively impact the collection and use of PGHD, emphasizing the need for initiatives to improve digital literacy.

Cultural considerations are also essential for adopting PGHD among older adults with cancer. A survey conducted across four European countries revealed that over half of the participants recognized the usefulness of PGHD and expressed willingness to share it with health care providers to improve their own health [128]. In contrast, for community-dwelling older adults in urban areas of South Korea, family or peer influence was reported as both a facilitator and a barrier to adopting digital technologies [129]. Considering the unique cultural attitudes and behavioral intentions that influence technology adoption is crucial for effectively collecting and using PGHD among older adults with cancer [130].

Moreover, the quality of PGHD is a significant concern, influenced by user-related factors, device and technology, and data governance [110]. Researchers should not only focus on collecting PGHD but also on enhancing data quality for effective use. Additionally, the establishment of standards or frameworks for assessing the quality, reliability, and accuracy of PGHD from various devices is essential. Meeting these requirements will enable the sharing and integration of PGHD with health care providers for use in patient care and health management in clinical settings. Ultimately, future research should aim to integrate PGHD from nonhospital settings into health care systems, such as electronic health records or research registries, to ensure continuity of care.

Limitations

This scoping review endeavored to apply a rigorous methodology; however, it has a few limitations. First, the PubMed MeSH term for PGHD has only been included since 2018, indicating that some studies, corresponding to PGHD, may not have been searched. To compensate for this, search terms corresponding to PGHD such as wearable devices and patient report were included. Furthermore, even if PGHD were not explicitly stated, studies deemed to be PGHD through discussions among researchers were included in the review. Additionally, the references of the selected studies were reviewed to ensure that there were no omissions. Second, this review did not include gray literature in the literature selection process. By excluding theses and conference papers, and focusing only on peer-reviewed studies, it is possible that recent literature containing the latest information on PGHD was excluded. Third, this study included older patients with various types of cancer at different treatment stages, suggesting a need for caution regarding the heterogeneity related to cancer in the application of PGHD. Therefore, careful interpretation of the results of this review is warranted, and future research should focus on understanding the use of PGHD according to the specific types of cancer and treatment stages. Finally, although the inclusion criteria of this review focused on studies with a mean or median age of 65 years or older, some studies may have included participants younger than 65 years. This could affect the generalizability of the findings to the geriatric population, as the presence of younger participants may not fully reflect the health characteristics and challenges faced by older adults.

Conclusions

This scoping review investigated and summarized the overall characteristics and use stages of PGHD among older adults with various types and stages of cancer. Research involving PGHD in older adults with cancer is gradually increasing and is primarily conducted at home through wearable devices or mobile apps. PGHD encompass a collection of physiological variables, such as physical activity, sleep, and vital signs, along with PROs, using both passive and active methods, and have been used in various aspects of research. However, while PGHD collected from older adults with cancer were universally used for analysis within the studies, their use for providing feedback, motivation, and interventions that could impact patients and researchers was limited. These findings suggest that future research should emphasize the use of PGHD, which interact with patients to provide patient-centered care through patient engagement. Furthermore, health care, especially in areas such as physical activity and symptom management, is critical for older adults with cancer, and PGHD can positively influence their active participation in health care. Therefore, our findings may provide insights into PGHD that can be used by health care providers and researchers in future research in the context of geriatric cancer care.

Abstract

Background: Virtual reality (VR) technology has shown significant potential in improving the social skills of children and adolescents with autism spectrum disorder (ASD).

Objective: This study aimed to systematically review the evidence supporting the effectiveness of VR technology in improving the social skills of children and adolescents with ASD.

Methods: The search for eligible studies encompassed 4 databases: PubMed, Web of Science, IEEE, and Scopus. Two (XY and JW) researchers independently assessed the extracted studies according to predefined criteria for inclusion and exclusion. These researchers also independently extracted information regarding gathered data on the sources, samples, measurement methods, primary results, and data related to the main results of the studies that met the inclusion criteria. The quality of the studies was further evaluated using the Physiotherapy Evidence Database scale.

Results: This review analyzed 14 studies on using VR technology interventions to improve social skills in children and adolescents with ASD. Our findings indicate that VR interventions have a positive effect on improving social skills in children and adolescents with ASD. Compared with individuals with low-functioning autism (LFA), those with high-functioning autism (HFA) benefited more from the intervention. The duration and frequency of the intervention may also influence its effectiveness. In addition, immersive VR is more suitable for training complex skills in individuals with HFA. At the same time, nonimmersive VR stands out in terms of lower cost and flexibility, making it more appropriate for basic skill interventions for people with LFA. Finally, while VR technology positively enhances social skills, some studies have reported potential adverse side effects. According to the quality assessment using the Physiotherapy Evidence Database scale, of the 14 studies, 6 (43%) were classified as high quality, 4 (29%) as moderate quality, and 4 (29%) as low quality.

Conclusions: This systematic review found that VR technology interventions positively impact social skills in children and adolescents with ASD, with particularly significant effects on the enhancement of complex social skills in individuals with HFA. For children and adolescents with LFA, progress was mainly observed in basic skills. Immersive VR interventions are more suitable for the development of complex skills. At the same time, nonimmersive VR, due to its lower cost and greater flexibility, also holds potential for application in specific contexts. However, the use of VR technology may lead to side effects such as dizziness, eye fatigue, and sensory overload, particularly in immersive settings. These potential issues should be carefully addressed

in intervention designs to ensure user comfort and safety. Future research should focus on optimizing individualized interventions and further exploring the long-term effects of VR interventions.

Introduction

Background

Autism spectrum disorder (ASD) is a neurodevelopmental condition marked by challenges in social interaction and communication, as well as by the presence of repetitive and stereotyped interests and behaviors [1]. The precise etiology of ASD remains elusive; however, studies indicate that a combination of genetic, environmental, and neurodevelopmental factors may contribute to its development [2]. Statistics from the US Centers for Disease Control and Prevention have shown a marked rise in the prevalence of ASD diagnoses in recent decades, with 1 in 77 children currently being diagnosed [3]. Social impairment is often characterized by difficulty interpreting social cues, including changes in facial expressions, body language, and tone of voice. This can lead to children and adolescents with ASD displaying a reduced interest in, or maladaptive responses to, social situations [4]. Currently, early intervention is an effective way to improve the social skills of children and adolescents with ASD [5,6].

Individuals with ASD experience significant deficits in social skills. These deficits manifest as difficulties in understanding others' emotions and intentions, establishing and maintaining social relationships, and lacking flexibility in social interactions [7]. Such challenges often lead to increased social isolation and a decreased quality of life for those with ASD [8]. The severity of ASD symptoms varies; individuals with high-functioning autism (HFA) usually experience milder social impairments, while those with low-functioning autism (LFA) face more severe communication challenges [9]. Various interventions have been developed to address social skill deficits in individuals with ASD, achieving varying levels of success. For example, applied behavior analysis (ABA) is a therapeutic approach designed to improve social skill acquisition and enhance social motivation among individuals with ASD. Research by Roane et al [10] suggests that individualized, ABA-based interventions can significantly improve developmental outcomes for individuals with ASD, leading to progressive enhancements in social skills [11]. In addition, speech therapy offers personalized language and communication support, helping individuals gradually improve social communication skills. In the Social Communication Intervention Project (SCIP) led by Adams et al [12], it was found that speech therapy could enhance expressive language and comprehension, enabling individuals to gradually improve social skills by practicing conversations, learning communication techniques, and using assistive tools [13]. Cognitive behavioral therapy (CBT) is also widely used to address critical symptoms and socio-emotional challenges in children and adolescents with ASD. A meta-analysis by Wang et al [14] revealed significant improvements in both autistic symptoms and socio-emotional issues following CBT. Despite the considerable benefits of these traditional interventions, they have certain limitations. The high costs and the need for specific therapeutic environments and specialized therapists make these services inaccessible for many families, limiting their reach and frequency [15,16]. In addition, the lack of personalization in traditional methods may impact their effectiveness, especially for individuals with varying needs and responses [17]. These limitations underscore the importance of exploring alternative, more adaptable, individualized, and cost-effective intervention strategies.

Virtual reality (VR) technology, as a promising tool for promoting health, has gradually been applied in various fields, including gaming, education, health care, and psychotherapy. In gaming and entertainment, VR technology provides users with a highly immersive experience, allowing them to be fully immersed in a virtual world, which enhances interactivity and engagement [18,19]. VR simulates laboratories and historical scenes in education, enabling students to engage in hands-on learning within a safe virtual environment, thereby promoting deeper understanding and knowledge retention [20]. VR has been widely used in health care for rehabilitation, pain management, and psychotherapy [21,22]. Research by Rizzo and Koenig [23] suggests that VR technology provides a highly personalized interactive environment for psychotherapy and cognitive rehabilitation, helping patients better engage in treatment. Moreover, VR aids motor rehabilitation, particularly for patients with Parkinson disease and children with balance disorders, significantly enhancing recovery outcomes [24]. VR interventions can be categorized into immersive and nonimmersive types, depending on the realism of the simulated scenes [25]. Immersive VR typically uses head-mounted displays to fully engage the user's senses, offering a highly realistic experience, thus making it particularly suitable for interventions requiring deep involvement [26]. In contrast, nonimmersive VR is experienced through traditional computer displays, offering greater flexibility and accessibility, thus making it more appropriate for everyday educational settings [27]. For ASD interventions, Parsons and Cobb [28] conducted an in-depth study on the application of VR technology, noting that VR can provide a safe virtual environment for children with ASD to practice social skills without real-world pressures. Therefore, VR technology holds significant potential as an innovative and adaptable intervention for addressing social skill deficits in children and adolescents with ASD.

XSL•FO
RenderX

Objective

Although VR technology has shown great potential in the fields of education and therapy, especially in improving social skills in children and adolescents with ASD, empirical research remains limited. Therefore, this systematic review aims to evaluate the effects of VR interventions in ASD treatment and address the following key research questions: (1) What are the differences in the positive effects of VR interventions on the social skills of children and adolescents with HFA versus LFA? (2) How do different types of VR interventions impact the social skills of children and adolescents with ASD? and (3) Are there potential adverse effects of VR interventions on children and adolescents with ASD?

To answer these questions, this study aims to achieve the following objectives: (1) to compare the positive effects of VR interventions on the social skills of children and adolescents with HFA and LFA, (2) to analyze the impact of different types of VR interventions on the social skills of children and adolescents with ASD, and (3) to evaluate the potential adverse effects of VR interventions on children and adolescents with ASD.

Methods

Recruitment

Our research protocol was registered in the International Platform of Registered Systematic Review and Meta-analysis Protocols (ID: INPLASY202420079U1). This study followed the PRISMA (Preferred Reporting Items for Systematic Evaluation) guidelines to ensure transparency in the research process [29,30].

Search Strategy

A comprehensive search was conducted across 4 electronic databases: PubMed, Web of Science, IEEE, and Scopus, as of April 11, 2024, to systematically identify pertinent studies concerning the impact of VR technology on improving the social abilities of children and adolescents with ASD. The search focused explicitly on peer-reviewed articles published in English. The search strategy incorporated keywords such as VR, ASD, social skills, communication skills, children, and adolescents. Multimedia Appendix 1 provides detailed information about the search terms used. Previous reviews have described the selection of search terms for VR interventions, social skills, and children and adolescents with ASD [31]. In addition, researchers manually searched the included studies' reference lists to identify relevant articles.

Eligibility Criteria

The criteria for inclusion in the study were developed using the PICOS (Population, Intervention, Comparison, Outcomes, and Study design) principles [32], as follows:

- Population: The participants were children and adolescents aged 3-18 years, diagnosed by a physician or by a reliable ASD assessment tool. Mixed studies on children and adolescents with attention deficit/hyperactivity disorder, Down syndrome, or other neurodevelopmental disorders were excluded.
- Intervention: This study investigated the implementation of VR technology as an intervention in clinical settings or clinical trials.
- Comparison: No restrictions were placed on the control group.
- Outcomes: All studies used a validated tool or methodology to assess the social competence of children and adolescents with ASD.
- Study design: There were no restrictions on trial design, including randomized and nonrandomized controlled trials.

Study Selection and Data Extraction

Two researchers independently conducted a multistep search and assessed the studies based on the titles, abstracts, and full texts. To evaluate the risk of bias in the included studies, we used the Cochrane Risk of Bias tool [33]. This tool evaluates bias across several domains, including random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective reporting, and other sources of bias. Two (XY and JW) researchers independently assessed each study, resolving disagreements through discussion or consulting a third researcher [34].

The team created a data extraction form to collect information about each study's characteristics, including details of the literature (authors and year), participant characteristics (sample size and age range), intervention components (location, intervention design, frequency, and duration), measurement instruments, and data related to primary outcomes. To increase transparency, we have included the PRISMA checklist in the Multimedia Appendix 2. This checklist provides a comprehensive overview of the methodology followed throughout the study, ensuring all relevant criteria are addressed and documented. This addition will allow readers to understand our research process better and replicate it.

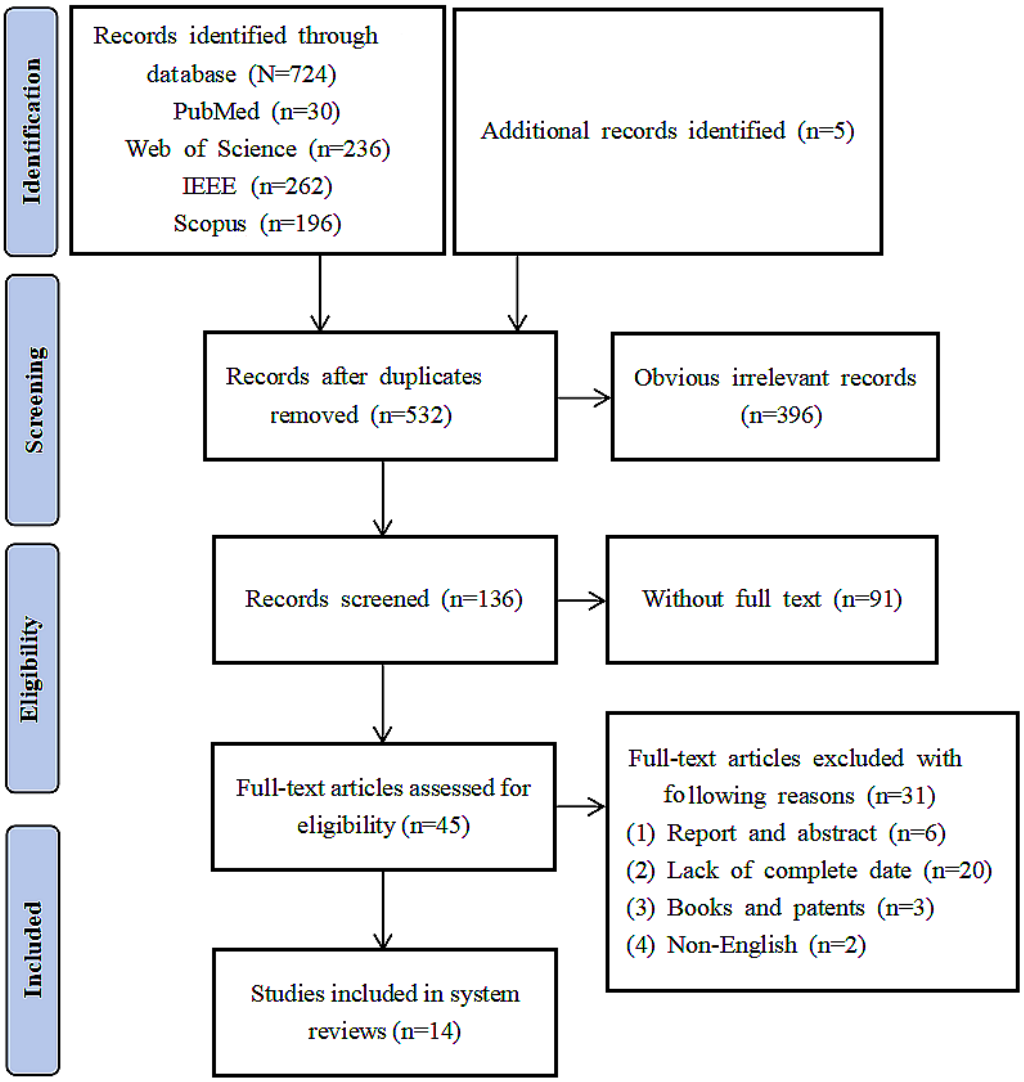
Quality Assessment

The methodological quality of each included study was independently assessed by 2 researchers according to the Physiotherapy Evidence Database (PEDro) scale [35]. The decision to use the PEDro scale was based on its widespread use and recognition in assessing the quality of clinical trials, particularly in physiotherapy and rehabilitation [35]. Despite the challenges posed by VR studies, the PEDro scale remains a valuable tool due to its comprehensive assessment of key methodological aspects, such as randomization and allocation concealment, which are critical for reducing bias in clinical research [36].

The PEDro scale consists of 11 scoring criteria: eligibility criteria (not scored), random allocation, concealed allocation, baseline comparability, blinding of subjects, blinding of therapists, blinding of assessors, sufficient follow-up, intention-to-treat analysis, between-group comparisons, and point estimates with variability [36]. PEDro scores ranged from 0 to 10, with a median score of 5. However, scoring individuals and therapists participating in VR technology trials can be challenging, and blinding participants or therapists in VR studies is often not feasible due to the nature of the technology, as both

XSL•FO
RenderX

parties are usually aware of the ongoing intervention [37]. Therefore, considering the limitations of using VR technology, the scoring system can be categorized into 3 categories: high quality ≥6, appropriate quality=4-5, and low quality ≤3 [38]. In total, 2 (XY and JW) researchers independently assessed the methodological quality of the included studies according to the 11 PEDro criteria and calculated a total score to determine the quality of the study [39].



Disagreements regarding quality ratings should be deliberated until a consensus is achieved; if consensus proves elusive, a third researcher makes the final decision following a mutual discussion.

Results

Search Results

Figure 1 illustrates the specific search process, during which we initially retrieved 724 relevant studies: 30 from PubMed, 236 from Web of Science, 262 from IEEE, 196 from Scopus, and 5 additional studies (manual screening of reference lists and consultations with experts in the field). After excluding duplicates, 532 studies were included in the final analysis. First, 396 irrelevant studies were excluded based on title and abstract screening. The researchers removed 91 incomplete studies, leaving 45 studies for analysis. The final exclusion of reports and abstracts, studies lacking trial data, books, patents, and non-English language studies resulted in the inclusion of 14 studies.

Figure 1. The flow chart of literature screening.

Research Characteristics

A total of 14 relevant studies were included in this review [40-53], with detailed characteristics of each study presented in Tables 1 and 2.

The 14 studies included 279 children and adolescents with ASD aged 3-18 years [40-53]. Six studies used the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) to diagnose children and adolescents with ASD [46,47,49,50,52,53], while 8 studies had clinical diagnoses made by physicians (Table 1) [40,45,48,51].

Of these 14 studies, 5 were from the United States [43,48,49,51,53]; 1 from Hong Kong [42]; 1 from Iran [47]; 1 from Cyprus [40]; 1 from Indonesia [44]; 3 from Taiwan, China [41,45,46]; 1 from Italy [50]; and 1 from China [52]. In terms of the trial design, 1 study used a single case trial [44,50]; 4 used a randomized controlled trial [42,46,50,52]; and 9 used a single-group, before-and-after controlled trial [40,41,43,45,46,48,49,51,53] (Table 1).

Regarding trial sites, 9 studies were conducted in institutions or clinics [40,44,46,47,49-53], and 5 were conducted in homes or schools (Table 1) [41-43,45,48].

XSL•FO
RenderX

In terms of intervention modalities, 3 studies used a cave automatic virtual environment [40-42,46], 1 study used a 3D Immersive Virtual Environment System to Enhance Social Understanding [41], 4 studies used VR Social Skills Training [45,48,51,53], 1 study used VR SAFE Course [49], 1 study used a 3D projection of primary emotions [50], and 5 studies did not report the specific VR technology and content used (Table 2) [43,44,47,50,52].

The 14 studies had a minimum intervention period of 1 day [49] and a maximum of 15 weeks [51]. Notably, 3 studies did not report detailed information on the duration of the intervention (Table 2) [40,43,44].

To assess social competence, 2 studies used the Psychoeducational Profile (Third Edition) [42,52], 2 used the Simulator Sickness Questionnaire [51,53], 1 used the Social Events Card and Social Behaviors Scale [41], 1 used the Vineland Adaptive Behaviour Scale [47], and 1 used the Jaccard Index scores [48]. One study used image testing [50], 1 study used the Social Communication Questionnaire [51], 1 study used Social Skills Training scales and the Likert Scale [46], 1 study used speech data mining [53], 1 study used Social Skills Performance Evaluation Sheet [45], and 4 studies used behavioral observation and analysis (Table 2) [40,43,44,49].

Quality Evaluation

Details of the quality assessments of the included studies are presented in Table 3. The 14 studies had an average PEDro quality (overall study quality) score of 5.21, of which 6 had an overall study quality score of ≥7. All 14 studies met the eligibility criteria and point measures criteria, reflecting a general consistency in study design and a general focus on outcome assessment. Random allocation, concealed allocation, and between-group comparison were implemented in 6 studies each. In contrast, a similar-at-baseline comparison was implemented in 10 studies, demonstrating that a proportion of the studies attempted to adopt the methodological criteria of randomization and control in their design to enhance the validity and credibility of the findings.

No studies implemented subject blinding, therapist blinding, or assessor blinding simultaneously, suggesting that the use of blinding was very limited in these studies, which may be due to the specific design and implementation settings of the studies. Most studies (n=11) reported a participant attrition dropout rate. Still, they did not perform intention-to-treat analyses, which may have affected the interpretation and generalization of the findings.

Main Findings

Impact of VR Interventions on the Social Skills of Children and Adolescents With ASD

Among the 14 studies included [40-53], 71% (n=10) of the participants were individuals with HFA [40-43,45,46,48,50,51,53], 21% (n=3) included both participants with HFA and LFA [47,49,52], and 7% (1) involved only participants with LFA (Table 1) [44]. We found that VR interventions significantly improved the social skills of children and adolescents with HFA, while the improvements for participants with LFA were more limited (Table 4).

XSL•FO

Studies focusing on HFA consistently demonstrated that VR social skills training systems significantly improved the social skills of children and adolescents with HFA [40-43,45-53]. Some studies also found that VR training effectively enhanced eye contact and the quality of social interactions in individuals with HFA [49]. Other research indicated that VR training helped HFA children and adolescents improve cognitive flexibility, social initiative, and conflict resolution skills [45,49,53]. In comparison, the effects of VR interventions on children and adolescents with LFA were less pronounced [40-53]. While VR-based shopping skills training was found to help individuals with LFA improve basic life skills to some extent, the overall progress was slower, and the degree of improvement was not as significant as in individuals with HFA [44]. Although some studies found that LFA participants did not perform as well as participants with HFA in VR settings, others still reported that VR interventions helped them progress in self-care skills [47,52]. Furthermore, the research emphasized that continuous improvements in adaptive prompts and personalized training could offer more support for individuals with LFA [52].

Impact of Different VR Intervention Approaches on the Social Skills of Children and Adolescents With ASD

Of the included studies, 64% (9/14) were conducted in institutional or clinical settings [40,44,46,47,49-53], while 36% (5/14) were conducted in-home or school environments (Table 1) [41-43,45,48]. We found that interventions conducted in institutional or clinical settings generally had greater control and professional oversight (Table 4) [40,44,46,47,49-53]. These settings often had specialized equipment and supervision by therapists, resulting in more significant intervention effects, which were better suited for highly customized interventions for children and adolescents with ASD [40,44,46]. However, the primary advantages of home- or school-based interventions were their convenience and real-world applicability [42,45]. Although these interventions had relatively less control, they still demonstrated benefits in terms of flexibility and cost-effectiveness [41-43,45,48].

Regarding intervention duration and frequency, 79% (11/14) of the studies reported this information [41,42,45-53], while 21% (3/14) did not [40,43,44]. The intervention duration ranged from as short as 1 day to as long as 15 weeks (Table 2) [49,51]. Compared to short-term interventions, we found that long-term interventions led to more significant improvements in social skills and cognitive flexibility (Table 4) [42,45-53]. In addition, higher-frequency interventions generally produced more noticeable improvements, while lower-frequency interventions, although beneficial, did not yield results as strong as high-frequency ones [52,53]. Lower-frequency interventions may not sufficiently reinforce the skills being taught, leading to weaker transfer effects [45]. Overall, the most effective intervention duration was found to be 6 to 15 weeks, with a frequency of at least 2-3 sessions per week [42,45-53]. This high-frequency, long-term intervention model provided participants ample opportunities to practice, ensuring effective social skills development and long-term retention [42,45-53].

Of the studies, 50% (7/14) used immersive VR technology [40-43,46,49,50], while 50% (7/14) used nonimmersive VR

XSL•FO
RenderX

systems (Table 2) [44,45,47,48,51-53]. We found that immersive VR was more effective for complex social skills training, especially in participants with HFA (Table 4) [40-43,46,49,50]. Immersive VR technology, by providing rich multisensory stimulation, allowed participants to better grasp emotional expression and social interaction skills within simulated environments [40]. In more complex school scenarios, immersive VR better supports participants in practicing and transferring learned skills to real-life situations [42]. Finally, immersive VR training experiences received positive feedback, and no instances of motion sickness were reported [43]. While nonimmersive VR systems, such as desktop-based VR, did not offer fully immersive experiences, they still demonstrated advantages in terms of flexibility, cost, and adaptability [44,45,47,48,51-53].

Adverse Effects of VR Interventions on Children and Adolescents With ASD

Although VR technology significantly improved social skills, 6 studies reported adverse side effects associated with its use (Table 4) [40,42-44,46,51]. One study found that some children and adolescents with HFA experienced dizziness and nausea while using the cave automatic virtual environment system [40]. Another study reported that 71% (10/14) of children and adolescents with LFA experienced anxiety and fear when using head-mounted displays for the first time, and most participants felt fatigued after using VR devices [44]. In addition, 2 other studies also reported anxiety-related issues [46,51]. While overall, the use of VR technology for social skills training was positive, some children reported discomfort, although no cases of motion sickness were observed [43]. Another study indicated that children and adolescents with HFA experienced headaches and eye fatigue, particularly after prolonged use of VR devices [42].

Discussion

Principal Findings

This systematic review analyzed the effects of VR interventions on the social skills of children and adolescents with ASD. The results showed that VR interventions significantly impacted individuals with HFA, while the effects on those with LFA were more limited. The study also indicated that the duration and frequency of the interventions had a notable impact on their effectiveness. Moreover, immersive VR was found to be more suitable for training complex skills in individuals with HFA. At the same time, nonimmersive VR excelled in cost and flexibility, making it more appropriate for basic skill interventions in individuals with LFA. Finally, although VR interventions showed positive outcomes in improving social skills, some studies reported potential side effects, highlighting the need to account for individual differences when designing intervention programs and implementing measures to reduce adverse effects.

Impact of VR Interventions on the Social Skills of Children and Adolescents With ASD

The differences in the effectiveness of VR interventions for children and adolescents with HFA and LFA can be attributed to variations in cognitive, social, and sensory processing skills [40-43,45,46,48,50,51,53]. Individuals with HFA generally have higher cognitive abilities and language skills, enabling them to understand better and adapt to complex social situations within VR environments [54]. This finding aligns with earlier studies that highlighted the need for more personalized intervention strategies based on ASD symptom severity [9-11]. These previous studies suggested that traditional interventions like ABA and CBT were more effective for high-functioning individuals due to their adaptability and cognitive skills, which is similarly observed in VR settings [9-11]. The advantages demonstrated by children and adolescents with HFA in VR interventions are partly due to their stronger abstract thinking skills and higher sensory tolerance [55]. Multisensory stimuli, such as the combination of visual, auditory, and tactile inputs, activate key brain regions, including the mirror neuron system and the prefrontal cortex, further enhancing social interaction and emotional understanding [56]. In addition, individuals with HFA are better at handling contextual changes within VR environments, adapting to feedback mechanisms in virtual scenarios, allowing them to quickly learn and transfer skills to real-life situations [42]. This adaptability explains why children with HFA generally exhibit faster progress in VR interventions. In contrast, individuals with LFA's slower cognitive and language development hinders their progress in VR interventions [44,47,49,52]. This limitation reflects findings from traditional interventions, where children with LFA often progressed more in structured, basic tasks than in complex social or emotional skills [12,13,49]. Children with LFA often struggle with processing multisensory stimuli in virtual environments, making them prone to discomfort, such as sensory overload or anxiety reactions [44,57]. This sensory sensitivity confuses complex social scenarios, making it difficult for them to keep pace with the intervention [58]. Moreover, for individuals with LFA, cognitive and social difficulties limit their ability to master complex emotional expression or social interaction skills [49]. They tend to show progress in more structured, more straightforward tasks, such as life skills training or behavior management [44,52]. These limitations suggest that individuals with LFA require specialized support and simplified task designs to ensure gradual improvement in controlled settings.

Future interventions should be more personalized to bridge the gap in VR intervention outcomes between individuals with HFA and LFA [59]. For individuals with HFA, continued focus on complex social scenario training is essential. For individuals with LFA, interventions should emphasize managing sensory stimuli, reducing the risk of sensory overload, simplifying social interaction tasks, and offering more structured and incremental training content. The effectiveness of VR interventions is also significantly influenced by the setting in which they are conducted. Institutional and clinical environments generally offer specialized equipment and supervision by therapists, providing participants with highly customized support and real-time feedback [40,44,46,47,49-53]. These settings help ensure the quality and consistency of interventions, especially in emotional regulation and complex social skills training [60]. However, the limitations of institutional and clinical environments include high costs and limited scalability [40,47]. In contrast, home and school environments, although lacking

XSL•FO
RenderX

immediate professional supervision, offer convenience and real-world applicability advantages, making them more suitable for skill transfer to everyday activities [41-43,45,48]. In addition, home and school settings reduce participants' anxiety, as children are more relaxed and receptive to interventions in familiar environments [61]. The flexibility and accessibility of these environments make them suitable for long-term interventions, though they may compromise the depth and complexity of the intervention [61]. Future research should explore how to incorporate more professional support into home and school environments to ensure the effectiveness of interventions is not compromised.

Impact of Different VR Intervention Approaches on the Social Skills of Children and Adolescents With ASD

The duration and frequency of interventions significantly impact the effectiveness of VR interventions. Longer intervention durations and higher frequencies generally have more significant and lasting effects, particularly in social skills and emotional regulation [41,46-48]. This observation is consistent with the findings in traditional therapies, where prolonged and frequent sessions in interventions like ABA and CBT have been linked to more sustainable outcomes in social skills improvement [11,14]. Shorter intervention durations or lower frequencies may not be sufficient to consolidate the skills learned, limiting the maintenance of intervention effects [42,45,49-53]. Long-term, high-frequency interventions provide more practice opportunities, helping participants gradually master and transfer these skills [62]. However, high-frequency and long-term interventions may also lead to fatigue, particularly in individuals with LFA who are more sensitive to sensory overload [44]. Therefore, future intervention designs should balance the duration and frequency of interventions, ensuring sufficient practice opportunities while avoiding sensory fatigue and overstimulation in participants. Further research should explore the combination of optimal intervention duration and frequency to ensure both effectiveness and sustainability.

The differences in the effectiveness of immersive and nonimmersive VR interventions stem from their varying levels of sensory stimulation and interaction methods [63]. Immersive VR, with its multisensory stimulation and highly realistic virtual environments, is particularly effective for children with HFA, enhancing their adaptability in complex social interactions [40-43,46,49,50]. However, its intense sensory input may pose challenges for individuals with LFA, potentially causing anxiety or sensory overload [44,45,47,48,51-53]. As a lower-stimulus alternative, nonimmersive VR supports adaptive training for children with LFA, focusing on basic skills and behavior management [64]. Its ease of use and scalability make it suitable for broader and long-term applications, particularly in educational settings where lower-stimulus environments are often preferable [15,17]. Future research should prioritize integrating the strengths of immersive and nonimmersive VR to balance engagement and usability, ensuring interventions can address the diverse needs of individuals with ASD effectively.

Practical Implications and Adverse Effects

VR technology interventions hold significant potential for clinical and educational applications in children and adolescents with ASD [65]. In clinical practice, VR can serve as a complementary tool to traditional interventions, providing therapists with a flexible and engaging means to meet the diverse needs of individuals with ASD [66]. For instance, the benefits of VR as an adjunct to speech therapy align with findings from the SCIP intervention in traditional therapy, where tailored approaches proved beneficial for improving social communication skills in children with ASD [12]. For instance, traditional speech therapy interventions, such as SCIP, have been shown to effectively improve social communication skills in children with ASD [12]. Integrating VR into these interventions could enhance the effects of traditional speech therapy, offering more engaging and personalized treatment sessions [67]. In addition, a meta-analysis of CBT's effectiveness in addressing social-emotional challenges in children with ASD has shown significant improvements in core symptoms following CBT [14]. By incorporating VR into CBT, children can practice coping strategies in simulated real-life emotional and social scenarios, potentially enhancing outcomes [68]. Finally, VR could be combined with ABA to create personalized social scenarios, allowing therapists to offer more dynamic and adaptable intervention plans while children practice social behaviors in realistic but controlled environments [11,69].

Despite the many advantages of VR interventions, there are challenges to its widespread application, particularly regarding accessibility, cost, and the training required for educators and therapists to implement these technologies [70,71] effectively. Previous studies on traditional therapy have also highlighted these issues, where high costs and professional training needs limit scalability [15,16]. Adequate training for therapists and educators is crucial to maximizing the potential of VR interventions [72]. Research has highlighted that while immersive VR offers powerful therapeutic effects, there are challenges related to user comfort and sensory overload, especially for children with ASD. It is essential to carefully manage symptoms such as dizziness, nausea, and sensory overload, emphasizing the importance of gradual exposure in VR-based interventions [73]. In addition, studies have reported adverse effects such as eye fatigue, headaches, anxiety, and disorientation during VR use [40,42-44,46,51]. These reactions are particularly concerning for children with ASD, who may exhibit heightened sensitivity to sensory stimuli [74]. For instance, immersive VR systems with complex visual and auditory elements have been found to increase the risk of dizziness and nausea in approximately 15% of users [75]. Such adverse effects may reduce engagement and limit VR interventions' scalability [76]. To address these challenges, intervention designs must incorporate strategies to minimize adverse effects. These include shortening session durations, integrating regular breaks, and adapting VR content to reduce sensory overload [77]. For example, designing environments with simpler visual elements or offering less immersive options for highly sensitive children could significantly mitigate these effects [78]. Furthermore, providing psychological support during interventions, such as teaching coping mechanisms for

XSL•FO
RenderX

anxiety, may enhance user comfort and overall feasibility [79]. Future research should also systematically evaluate the prevalence and impact of these adverse effects, offering data-driven recommendations for optimizing VR-based interventions.

Moving forward, research should focus on improving the affordability and user-friendliness of VR interventions, ensuring that they are not limited to professional settings but can be widely applied in both clinical and educational environments [80].

Limitations

Despite the many strengths of this study, several limitations require further discussion. The sample size of this systematic review is relatively small, including only 14 studies, which may limit the generalizability of the findings. The included studies used various scales and tools to assess the social skills of children and adolescents with ASD, and this diversity in assessment tools may have led to inconsistencies in the pooled results. Due to differences in evaluation tools and reported data types, this study could not provide a quantitative summary. There was significant heterogeneity in intervention protocols, including variations in VR content, session length, and frequency. This lack of standardization limits comparisons between studies and highlights the need for uniform intervention protocols in future research. Many of the included studies had small sample sizes, which reduced statistical power and increased the likelihood of underestimating the effects of VR interventions. Future research should recruit larger and more diverse samples to enhance the reliability and generalizability of findings. Finally, some studies lacked detailed reporting of key methodological elements, such as randomization and blinding, which increases the potential for bias. Adopting rigorous designs and transparent reporting practices, guided by frameworks such as PRISMA or CONSORT (Consolidated Standards of Reporting Trials), will help strengthen the evidence base for future studies. By addressing these limitations, this study underscores the importance of more robust and standardized research to advance the field of VR interventions for ASD.

Conclusion

This systematic review highlights the significant potential of VR technology interventions in enhancing social skills for children and adolescents with ASD (Textbox 1).

In conclusion, long-term, high-frequency VR interventions (especially those lasting 6 to 15 weeks with 2-3 sessions per week) demonstrate the most effectiveness. Future research should focus on optimizing VR interventions to meet the personalized needs of different subgroups of patients with ASD and conduct large-scale longitudinal studies to validate their long-term impact.

Textbox 1. Key insights on virtual reality (VR) interventions for children and adolescents with autism spectrum disorder (ASD).

- Differences in VR intervention effects for individuals with high-functioning autism (HFA) and low-functioning autism (LFA): VR interventions show considerable improvements in complex emotional regulation and social interaction skills for children and adolescents with HFA. In contrast, improvements for individuals with LFA have been relatively limited, primarily supporting basic life skills. This suggests the need for more tailored VR approaches for different ASD subgroups.
- Impact of different VR intervention types: Immersive VR proves more effective for enhancing complex social skills, particularly in children with HFA, as it provides a deeply engaging experience. Meanwhile, due to its flexibility and lower cost, nonimmersive VR offers valuable benefits in specific contexts, particularly in home or school settings. Institutional and clinical settings have shown more specialized and effective results, whereas interventions in home or school environments provide greater adaptability.
- Potential adverse effects of VR interventions: Although VR technology holds promise, adverse effects such as dizziness and fatigue may arise, especially during immersive VR sessions. These potential issues should be carefully addressed in the design of VR-based interventions.
- Practical recommendations for stakeholders: Therapists, educators, and developers should collaborate to optimize VR interventions for children with ASD. Therapists can integrate VR as a complementary tool to traditional therapies, tailoring interventions and gradually increasing exposure to reduce sensory overload. Educators can use VR for social skills training in controlled environments with proper training. Developers should focus on creating cost-effective, user-friendly VR platforms with customizable features to ensure accessibility in clinical and educational settings. These efforts will enhance the scalability and impact of VR interventions.

Acknowledgments

This research was supported by the Special Funding for Key Areas in Biomedicine and Health of Ordinary Colleges and Universities in Guangdong Province (2022ZDZX2086; 2024ZDZX2108) and the Humanities and Social Sciences Project of the Chinese Ministry of Education (24YJAZH106). Meanwhile, we express our sincere gratitude to Dr Zhongtang Wu, who serves in the College of Physical Education at Shenzhen University, for his invaluable technical expertise and assistance, which was paramount to the success of our research.

Data Availability

All data generated or analyzed during this study are included in this published paper (and Multimedia Appendices 1 and 2).

Authors' Contributions

ZR was responsible for the research protocol and critically redrafted the paper. XY and JW performed literature searches. XY and JW performed study identification and screening. XY, JW, YM, and YT extracted and analyzed the data from the included journals. XY and JW wrote the first draft of the paper. JY, HC, AZ, and RF, contributed to refining the ideas, carrying out additional analyses, and finalizing this paper. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Alzheimer disease (AD) is a progressive condition characterized by cognitive decline and memory loss. Vision transformers (ViTs) are emerging as promising deep learning models in medical imaging, with potential applications in the detection and diagnosis of AD.

Objective: This review systematically examines recent studies on the application of ViTs in detecting AD, evaluating the diagnostic accuracy and impact of network architecture on model performance.

Methods: We conducted a systematic search across major medical databases, including China National Knowledge Infrastructure, CENTRAL (Cochrane Central Register of Controlled Trials), ScienceDirect, PubMed, Web of Science, and Scopus, covering publications from January 1, 2020, to March 1, 2024. A manual search was also performed to include relevant gray literature. The included papers used ViT models for AD detection versus healthy controls based on neuroimaging data, and the included studies used magnetic resonance imaging and positron emission tomography. Pooled diagnostic accuracy estimates, including sensitivity, specificity, likelihood ratios, and diagnostic odds ratios, were derived using random-effects models. Subgroup analyses comparing the diagnostic performance of different ViT network architectures were performed.

Results: The meta-analysis, encompassing 11 studies with 95% CIs and *P* values, demonstrated pooled diagnostic accuracy: sensitivity 0.925 (95% CI 0.892-0.959; *P*<.01), specificity 0.957 (95% CI 0.932-0.981; *P*<.01), positive likelihood ratio 21.84 (95% CI 12.26-38.91; *P*<.01), and negative likelihood ratio 0.08 (95% CI 0.05-0.14; *P*<.01). The area under the curve was notably high at 0.924. The findings highlight the potential of ViTs as effective tools for early and accurate AD diagnosis, offering insights for future neuroimaging-based diagnostic approaches.

Conclusions: This systematic review provides valuable evidence for the utility of ViT models in distinguishing patients with AD from healthy controls, thereby contributing to advancements in neuroimaging-based diagnostic methodologies.

Introduction

Alzheimer disease (AD) is a progressive neurodegenerative disorder characterized by deterioration in cognitive function and memory impairment. As the global population ages, AD is emerging as a significant public health concern, affecting millions of individuals worldwide [1]. AD poses a mounting socioeconomic burden due to the escalating costs associated with medical care and long-term support for patients with these diseases and their caregivers. Consequently, there is an urgent need to develop accurate and early diagnostic methods to facilitate timely intervention and management of this debilitating condition [2].

The early and accurate detection of AD is imperative for initiating timely therapeutic interventions and proper care planning before irreversible neurological damage occurs. However, a definitive diagnosis of AD can only be established postmortem through the identification of amyloid plaques and neurofibrillary tangles in the brain tissue. Consequently, researchers have turned their attention to leveraging novel imaging techniques, such as magnetic resonance imaging (MRI) and 18-fluorodeoxyglucose and positron emission tomography, by the use of advanced computational techniques like machine learning (ML) and deep learning (DL) approaches to facilitate the earlier identification of AD. These advanced neuroimaging modalities and computational methods hold the potential to aid in the presymptomatic detection and monitoring of AD progression, which enables more effective disease management strategies [3]. DL and ML approaches have been widely applied to various diagnostic tasks, although the diagnostic accuracy of DL remains uncertain in some areas. To address this gap, meta-analysis methods have been proposed [4] to provide a more comprehensive understanding. For example, studies have estimated the diagnostic accuracy of DL models for COVID-19 detection [5] and evaluated ML models for osteoporosis diagnosis in the hip bone [6]. Similarly, both ML and DL techniques have been extensively used for the detection and diagnostic evaluation of AD. Odusami et al [7] undertook a systematic review and meta-analysis. They used ML models alongside multimodal neuroimaging data to classify various stages of AD progression. The findings from their investigation were highly encouraging, demonstrating pooled estimates for sensitivity of 94.6% and specificity of 93.5% in classifying patients with AD from healthy controls. This study demonstrates the considerable promise of ML algorithms when combined with multimodal neuroimaging biomarkers for differentiating patients with AD from cognitively normal (CN) individuals. This capability holds potential advantages for enabling early diagnosis and disease monitoring, essential for effective management and treatment. The application of ML in AD diagnosis opens a new chapter for research with the capacity to significantly impact patient care and management. The extensive meta-analysis conducted by Wang et al [8] explored the concept of deep neural networks and heat map visualizations on multimodal neuroimaging data, encompassing structural MRI and functional imaging, to unravel patterns linked with AD. Through the application of deep neural networks and heat map visualizations, the study successfully pinpointed and emphasized the particular brain regions mostly impacted by the disease. This outcome provides valuable insights into the fundamental mechanisms underlying AD. Qu et al [9] conducted a comprehensive review and meta-analysis comparing the diagnostic efficacy of generative adversarial network (GAN)–based and non-GAN DL approaches in AD diagnosis. Their findings revealed that GAN-based DL models are more superior and effective than the non-GAN models in distinguishing individuals with AD from those with just CN individuals. This superiority was demonstrated through significant enhancements in accuracy, sensitivity, specificity, and the area under the curve of the summary receiver operating characteristic. However, when differentiating between progressive mild cognitive impairment (MCI) and stable MCI, the GAN method did not demonstrate a notable improvement in either the accuracy or the sensitivity. Despite this, it displayed marginally better specificity and area under the curve of the summary receiver operating characteristic curve compared with the non-GAN method. These results highlight the potential of GAN-based DL techniques to enhance AD diagnosis. Nonetheless, their applicability may be constrained in certain diagnostic contexts. Vision transformers (ViTs) are a novel type of DL model that has been effectively used in various types of computer vision tasks due to their ability to learn long-range connections within the images [10]. The ViTs process image data using the self-attention mechanism, which allows the model to connect sensitive regions of the image, which ultimately improves computing efficiency and contextual comprehension. Dosovitskiy et al [11] proposed a novel approach in computer vision, demonstrating the efficacy of ViT for image recognition tasks. Deviating from conventional methods that rely on convolutional neural networks (CNN), ViTs directly apply transformer architecture to sequences of image patches. By leveraging pretraining on extensive data sets, ViTs achieve competitive performance on various image classification benchmarks with lesser computational complexity. This pioneering study emphasizes the potential of transformer-based models in revolutionizing image recognition tasks, with scalable and promising results. Thereafter, various novel ViT models were developed, with enhancements aimed at reducing their computational cost and extending them to additional vision tasks, such as object detection [12] and image segmentation [13]. ViTs are well-designed to serve as the fundamental models for computer vision tasks in the medical field. Therefore, many studies have been published recently focusing on this area of research [14-17].

CNN models process images as pixel arrays, whereas ViT splits the input images into visual tokens. The visual transformer breaks an image into fixed-size patches, embeds each one appropriately, and incorporates positional embeddings as input

XSL•FO
RenderX

for the transformer encoder. In addition, ViT models offer nearly four times the computational efficiency and accuracy compared with CNNs [18]. The self-attention layer in ViT enables the model to embed information globally across the entire image. It also learns from the training data to encode the relative positions of image patches, allowing it to reconstruct the image's structure effectively.

Despite the promising outcomes documented in the scientific literature regarding the utilization of ViTs for AD image classification and analysis, a comprehensive meta-analysis examining the advantages and performance of these ViTs is notably absent. This research gap underscores the necessity for a systematic review and meta-analysis to consolidate existing evidence systematically; this systematic review with meta-analysis of ViT network architecture aims to address this evidence gap. The goal of this review and meta-analysis is to evaluate and summarize all available evidence to quantitatively assess the diagnostic test accuracy (DTA) of ViTs for detecting AD using MRI and positron emission tomography (PET) brain images, also providing critical insights that can inform future research directions and clinical practice in the field of AD diagnosis and management.

Methods

Data Sources and Literature Query

In this systematic review and meta-analysis, relevant studies on AD and ViT-based models were systematically gathered from multiple databases known for extensive research on these topics. These databases included CENTRAL (Cochrane Central Register of Controlled Trials), China National Knowledge Infrastructure, PubMed, Scopus, ScienceDirect, and Web of Science. In addition, we searched other sources like Google Scholar for gray literature and conducted citation searches. In total, 24,693 records were identified. The selected literature encompassed publications from January 1, 2020, to March 1, 2024, specifically focusing on studies using ViTs for AD prediction with neuroimaging data. The selected studies used MRI and PET as imaging data. The search strategy used MeSH terms and other selected keywords across different databases. Search strings can be found in Multimedia Appendix 1. A comprehensive outline of the search methodology, adhering to the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guideline of reporting systematic reviews [19], can be found in Multimedia Appendix 2.

Eligibility Criteria

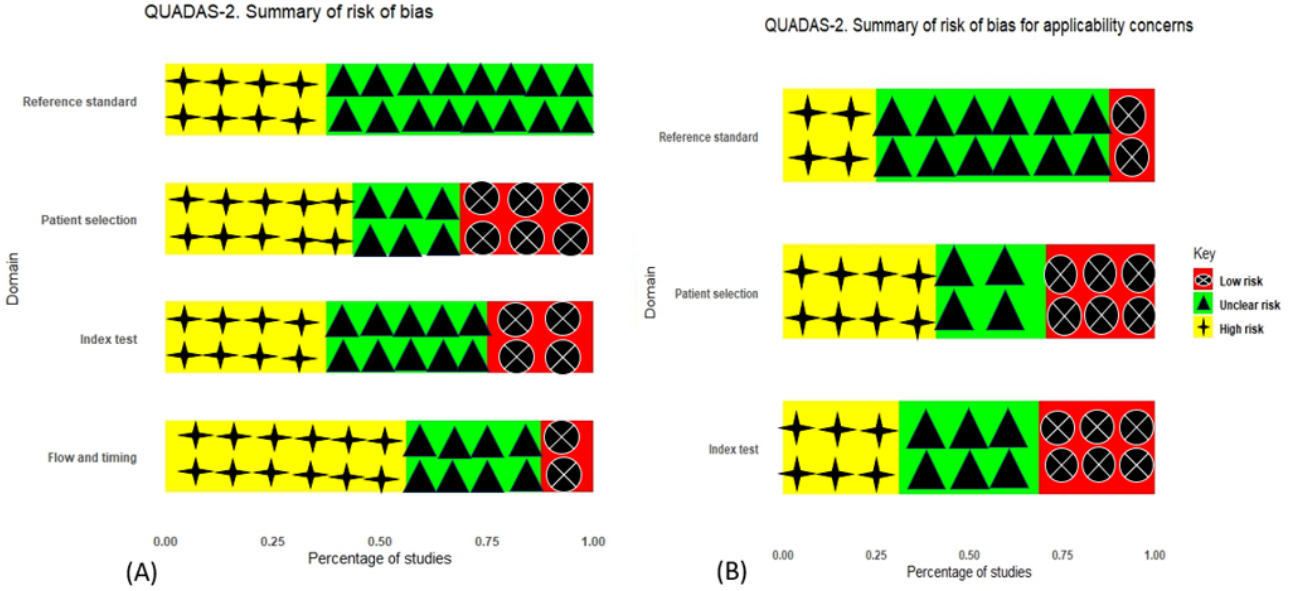
In this systematic review and meta-analysis, we considered studies using ViTs for AD image classification, specifically those published since their inception in 2020 [11]. These studies were required to report detailed performance metrics, including sensitivity, specificity, and a 2×2 confusion matrix, for ViT models used either independently or in hybrid models with other DL architectures. The MRI and PET image data sets used in the studies could be either unimodal or multimodal. Studies were excluded based on the following criteria: (1) conference abstracts, (2) duplicate studies, (3) incomplete papers lacking full text, (4) studies lacking classification results for AD and normal control (NC), (5) studies not using ViT models for AD detection, (6) literature reviews, and (7) studies not adopting neuroimaging for AD and NC prediction. Studies included in this review showcased the application of ViT models for AD image classification and provided comprehensive performance metrics.

Selection of Involved Studies

Two teams of reviewers (VM and TEK and HY and NW) independently conducted the screening process. Using Rayyan (Rayyan Systems Inc) [20], a freely available software, duplicates were removed based on titles or abstracts, streamlining the screening process. The initial review involved titles and abstracts, followed by a thorough examination of full texts for further screening. Eligible studies were included in the final analysis. In instances where the 2 review teams were unable to reach an agreement, the disagreement was resolved by consulting a more experienced third reviewer (LZ), who facilitated consensus.

Data Collection Process

Two researchers (VM and TEK) independently adopted a self-developed data extraction form to meticulously extract specific parameters regarding network architecture. These include the country of study, network model type, data type, methods, number of training epochs, batch sizes, and other relevant information. In addition, we diligently extracted the (2×2) confusion matrix, consisting of true positive, false negative, true negative, and false positive. These data formed the foundation for computing various DTA metrics, including sensitivity, specificity, diagnostic odds ratios (DORs), recall, precision, F_1-score, and positive and negative likelihood ratios (LR+ and LR–). This rigorous approach ensures a comprehensive analysis of ViT performance in AD detection using neuroimages. These metrics were used to assess the performance of models used in studies. The formulas for estimating some of these parameters are presented in Equations 1-4.



Risk of Bias and Quality Assessment

The quality assessment of the included studies was conducted using the Quality Assessment of Diagnostic Accuracy Studies-2 tool [21], a validated instrument designed to rigorously evaluate both the methodological integrity and reporting quality of diagnostic accuracy studies. This tool systematically appraises key domains, including patient selection, index test, reference standard, and flow and timing, thereby offering a structured framework for a comprehensive assessment of study quality. About 31% of the outcomes in the included studies lacked details on patient selection, leading to a high risk of bias, whereas the rest were considered low risk. In addition, 37% of

XSL•FO
RenderX

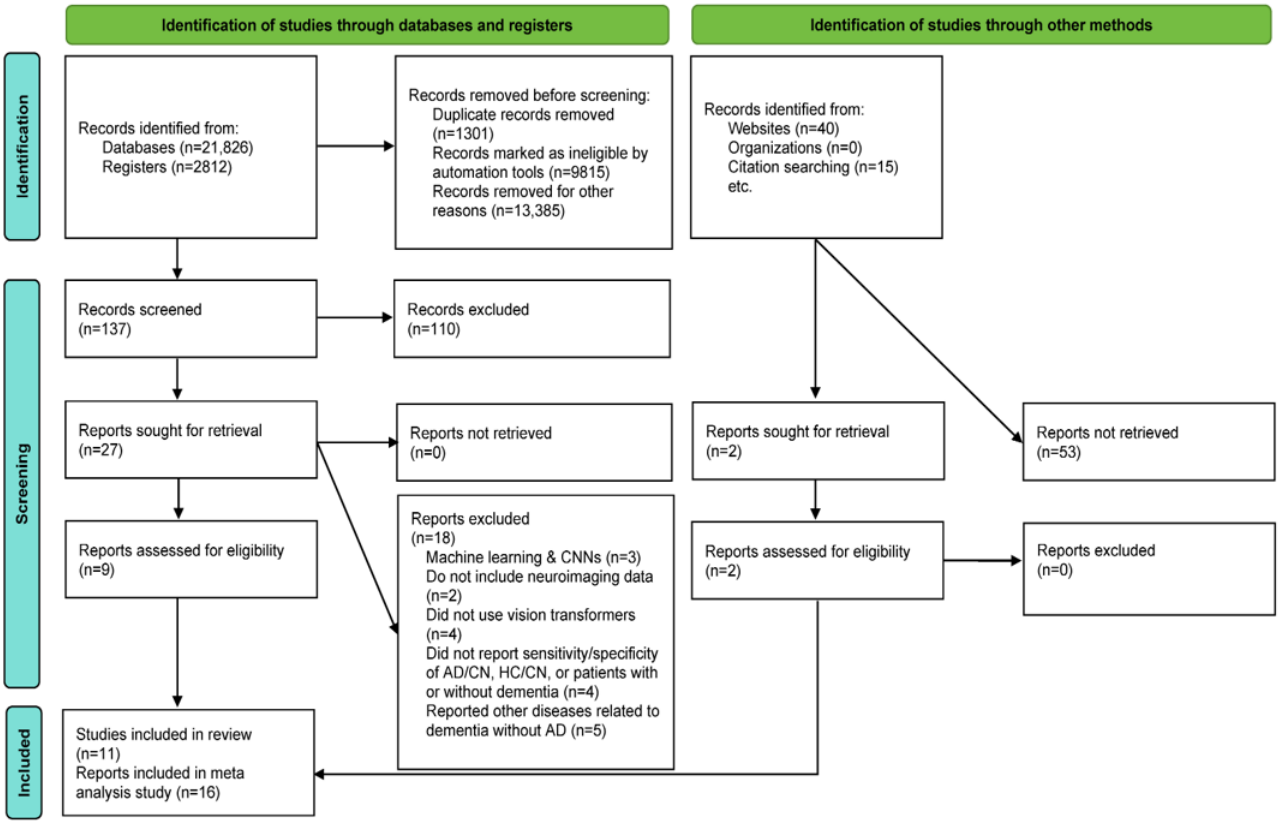
the outcomes had unclear information on how the index test was performed, resulting in an unclear risk of bias for the test. Since the studies focused on AD, there was a mismatch between the review question and the index test. Furthermore, about 31% of the outcomes from all included studies did not clarify if the review question matched the targeted condition, raising concerns about the applicability of the index test. About 31% of the outcomes lacked clear information on the interval between the index test and reference standard, as well as on their execution, leading to unclear bias regarding flow and timing. The remaining studies were considered low risk for these factors. Figure 2 shows the overall study of the risk of bias evaluation.

Figure 2. Summary of QUADAS-2 plots across the 16 included studies in the domain. (A) Risk of bias plot. (B) Risk of bias for applicability concerns. QUADAS-2: Quality Assessment of Diagnostic Accuracy Studies-2.

Statistical Analysis

The analysis combining data from multiple studies was conducted independently for sensitivity and specificity to consolidate the diagnostic accuracy findings of each network model. In this study, we used a random-effects model [22] to analyze the diagnostic performance of various ML models for medical diagnosis.

The primary outcomes are sensitivity, specificity, and the summary receiver operating characteristic curve, to provide a comprehensive assessment of diagnostic performance across studies. We computed point estimates and their corresponding 95% CIs for sensitivity and specificity to ensure consistency and comparability. Secondary outcomes, such as positive and negative likelihood ratios, were also explored. To assess statistical heterogeneity, the Cochran Q test and the I^2 statistic were used. For the Q statistic, values ranging from 0% to 40% imply insignificant heterogeneity, 30% to 60% connote moderate heterogeneity, and 75% to 100% mean considerable heterogeneity. Publication bias was assessed using funnel plots, with significance set at $P<.05$ for 2-sided tests. Furthermore, we conducted subgroup analyses by stratifying studies based on the training approach, distinguishing between those using the ViT model alone and hybrid models. This meticulous approach allowed for a robust evaluation of the effectiveness and potential biases within the literature.



Results

General Overview of All Included Studies

The initial search across databases yielded a total of 24,693 publications. After removing duplicates and screening the titles and abstracts, 11 papers [23-33] met the eligibility criteria, and 16 reports were included for qualitative synthesis and meta-analysis [23-33]. In addition, 4 of these papers [24,26,30,32] reported more than one study, resulting in a total of 16 outcomes that were used in the analysis as shown in Figure 1.

XSL•FO
RenderX

Figure 1. PRISMA flowchart for search strategy. Records were identified from CENTRAL, China National Knowledge Infrastructure, PubMed, Scopus, ScienceDirect, and Web of Science. AD: Alzheimer disease; CN: cognitively normal; CNN: convolutional neural network; HC: healthy controls; PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

The ViT-based network architectures were classified into 2 categories. Among the reported studies, 7 of 16 outcomes (64%) used ViT models alone during the training and testing phases, whereas the remaining studies used hybrid models that integrated ViT with other DL architectures for training and testing. Various public data sets were used for training and evaluating the models, including the Alzheimer's Disease Neuroimaging Initiative; Alzheimer's Disease Neuroimaging Initiative Grand Opportunity Study; UK Biobank; Australian Imaging, Biomarkers, and Lifestyle Study; and others. The neuroimaging modalities used in these studies encompassed functional MRI, structural MRI, and PET, specifically fluorodeoxyglucose-PET.

The characteristics of the included studies are summarized in Table 1. The studies originated from China, representing 36% (4/11) of the total. The United States is the second most frequent at 27% (3/11). Lithuania and Korea are tied for third at 9% (1/11) each, whereas Colombia and Thailand each account for 9% (1/11). The most common objective across these studies was the diagnosis of AD versus NCs. Some studies used different datasets, and in such cases, we included each study separately. In addition, certain studies reported on multiple network architectures.

Table 1. Comprehensive summary of the characteristics of all the studies included in this systematic review.

Study	Country of study	Network architecture model (ViT[a]/hybrid)	Data (imaging method), MRI[b]/PET[c]	Training epochs/batch size	Type of task	Significance and the limitations of the study	Brief study summary
Alejandro et al 2023 [23]	Colombia	ViT	MRI	250/NA[d]	Classification	Significance: new image preprocessing techniques and spatial data augmentation. Limitations: small data set	This study uses deep learning to analyze MRI scans and detect AD[e] with up to 89% accuracy in early stages.
Odusam et al 2023_1 [24][f]; Odusam et al 2023_2 [24][f]	Lithuania	ViT	MRI+PET	NA/1024	Detection	Significance: using transfer learning, which improves the performance of the proposed model; an image fusion technique has been proposed to fuse multimodal images for AD diagnosis. Limitations: limited data set (ADNI[g] only used), the fusion parameters in the study were not optimized to their full potential.	Multimodal MRI+PET fusion for improved AD.
Zhu et al 2022 [25]	China	ViT	MRI	16/NA	Detection	Significance: integrates representation learning, feature distilling, and classifier modeling into a unified framework. Limitations: the fixed 5×3×5 size of the feature extraction patch is less suitable because brain disease-related structural changes vary in size, so a dynamic patch size would be more appropriate.	BraInf, a novel model, uses long-term connections in brain scans to detect AD with near-perfect accuracy.
Tang et al 2023_1[f] [26]; Tang et al 2023_2 [26][f]; Tang et al 2023_3[f] [26]	China	Hybrid	MRI+PET	128/300	Detection or classification	Significance: in the study CsAGP[h] a dual-branch vision transformer using cross-attention and graph pooling for multilevel feature interaction and representation was introduced to learn a shared feature representation by interacting with features at multiple levels. Limitations: the proposed CsAGP is slice-based and considers only axial view slices. Since 2D images cannot include all the information from a full brain scan. Also, this study has not conducted a time processing comparison.	A dual-branch vision transformer model using cross-attention and graph pooling for AD detection from multimodal images, achieving high classification accuracy rates through extensive experiments on the ADNI database.

RenderX

Study	Country of study	Network architecture model (ViT[a]/hybrid)	Data (imaging method), MRI[b]/PET[c]	Training epochs/batch size	Type of task	Significance and the limitations of the study	Brief study summary
Liu et al 2023 [27]	China	Hybrid	MRI	50/NA	Classification	Significance: a multimodal method used to handle missing data in various clinical settings. Limitations: reliance on a GPU[i] may pose challenges in clinical environments where access to GPUs is limited.	This work introduces a cascaded multimodal mixing transformer (3MT) model for AD classification that effectively handles incomplete data, leveraging cross-attention and a novel modality dropout mechanism for robust and state-of-the-art performance on multimodal data sets.
Dhinagar et al 2023 [28]	United States	ViT	MRI	16/NA	Classification	Significance: variants of the ViT architecture used, 3D MRI images. Limitations: small data set used.	Application of ViTs on structural MRI scans for AD detection, achieving high classification accuracy.
Pan et al 2022 [29]	China	Hybrid	MRI	NA/NA	Classification	Significance: GAN[j] and transformer architecture used in AD detection. Limitations: one dataset used.	A Cross-Modal Transformer GAN (CT-GAN) framework that effectively fuses structural and functional brain imaging data to enhance AD prediction was introduced.
Khatri et al 2024_1 [30][f]; Khatri et al 2024_2 [30][f]	Korea	ViT; hybrid	PET	32/NA	Classification	Significance: ViT architecture by pretraining the feature extractor using the self-distillation with no labels (DINO) and extreme learning machine (ELM) as classifier models was introduced. Limitation: training process is complex.	RMTnet, a deep learning model combining recurrent neural networks (RNNs) and transformers for AD diagnosis using FDG-PET, was introduced.
Khan et al 2024 [31]	Thailand	Hybrid	MRI+PET	100/32	Detection	Significance: a novel model of mixed-transformer with furthered U-Net architecture. Limitations: lack of model interpretability.	The model combines MRI and PET scans with mixed-transformer and semantic segmentation techniques, achieving superior performance metrics compared with existing models.
Aghdam et al 2024_1 [32][f]; Aghdam et al 2024_2 [32][f]	United States	ViT; hybrid	MRI	20/NA	Detection	Significance: diagnosis of AD on white matter of T1-weighted structural data. Limitations: small data sets.	PVTAD[k], a new method for AD diagnosis that applies the Pyramid Vision Transformer to the white matter of T1-weighted structural MRI data, was introduced.

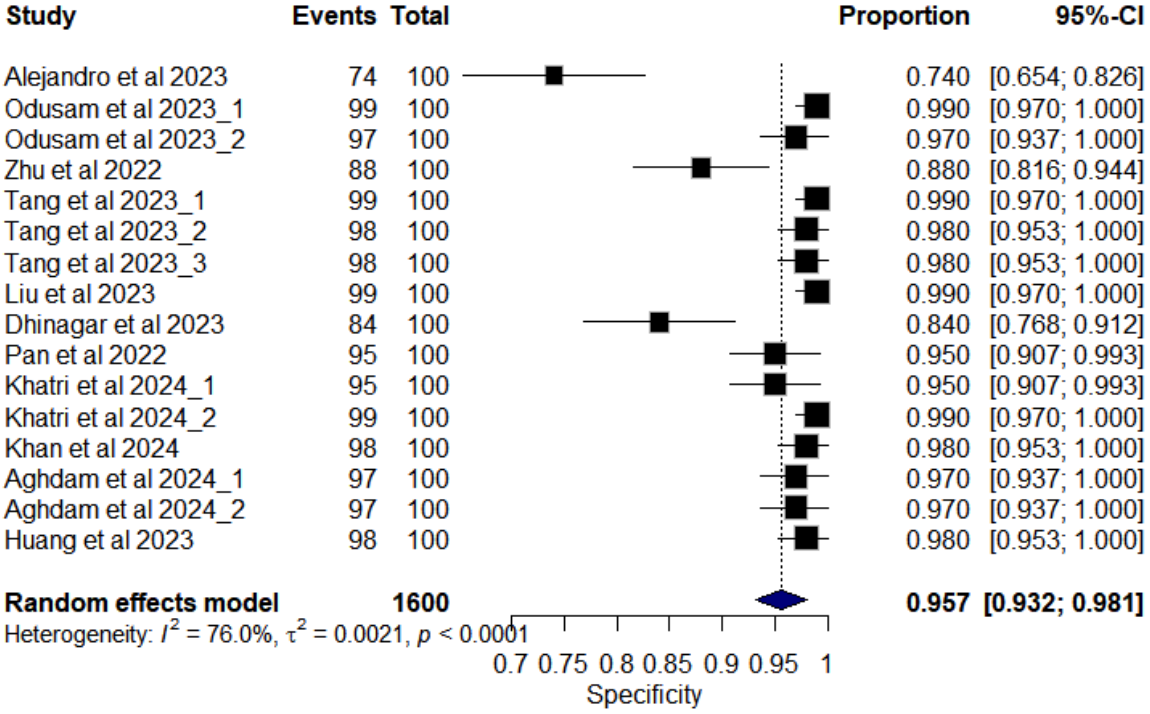
The Overall Diagnostic Test Accuracy



The overall DTA for all included studies is presented in Figure 3; the pooled sensitivity of univariate analysis of 11 studies [23-33] with 16 outcomes was 0.925 (95% CI 0.892-0.959, I^2=84.2% for 16 outcomes). The pooled specificity of univariate analysis was 0.957 (95% CI 0.932-0.981, I^2=76% for 16 outcomes), as shown in Figure 4.

Figure 3. Forest plot of pooled sensitivity from 11 studies [23-33] with 16 outcomes using a meta-analysis of the proportion random-effect model.

RenderX

Figure 4. Forest plot of pooled specificity from 11 studies [23-33] with 16 outcomes using a meta-analysis of the proportion random-effect model.

As depicted in Figure 5, the positive likelihood ratio (LR+) showed a pooled value of 21.84 (95% CI 12.26-38.91, I^2=64.9% for 16 outcomes). Similarly, the negative likelihood ratio (LR–) showed a pooled value of 0.084 (95% CI 0.054-0.133, I^2=40.2% for 16 outcomes), as shown in Figure 6. The summary receiver operating characteristic curve of the bivariate model has an AUC of 0.924 (Figure 7), indicating excellent overall diagnostic performance.

Figure 5. Forest plot of pooled positive likelihood ratio (LR) from 11 studies [23-33] with 16 outcomes. The risk ratio (RR) with 95% CI for each outcome is presented alongside the corresponding study weight.

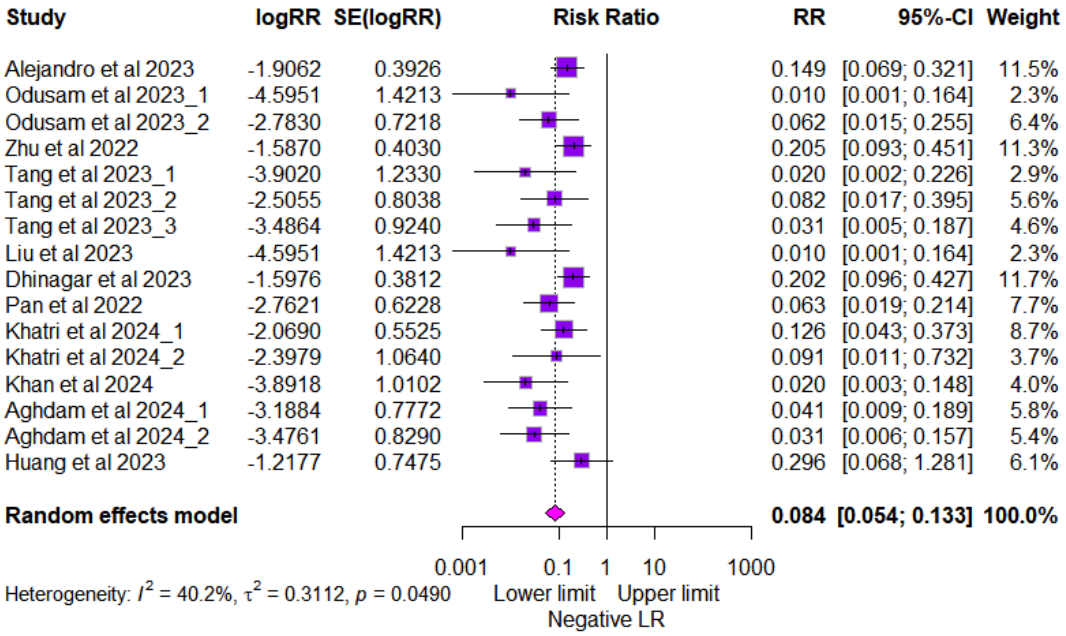
RenderX

Figure 6. Forest plot of pooled negative likelihood ratio (LR) from 11 studies [23-33] with 16 outcomes. The risk ratio (RR) with 95% CI for each outcome is presented alongside the corresponding study weight.



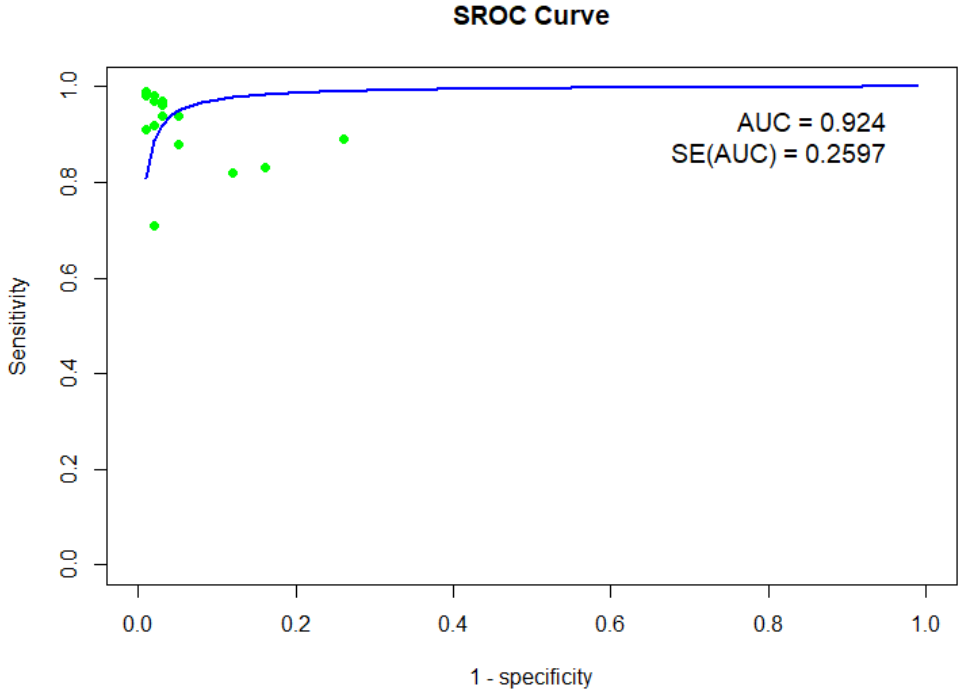


Figure 7. A plot of bivariate SROC for the diagnosis of AD using the ViT model. Green points represent individual studies included in the analysis, while the blue curve represents the fitted SROC curve based on the bivariate model. AD: Alzheimer disease; AUC: area under the curve; ViT: vision transformer; SROC: summary receiver operating characteristic curve; SE(AUC): standard error of the area under the curve.

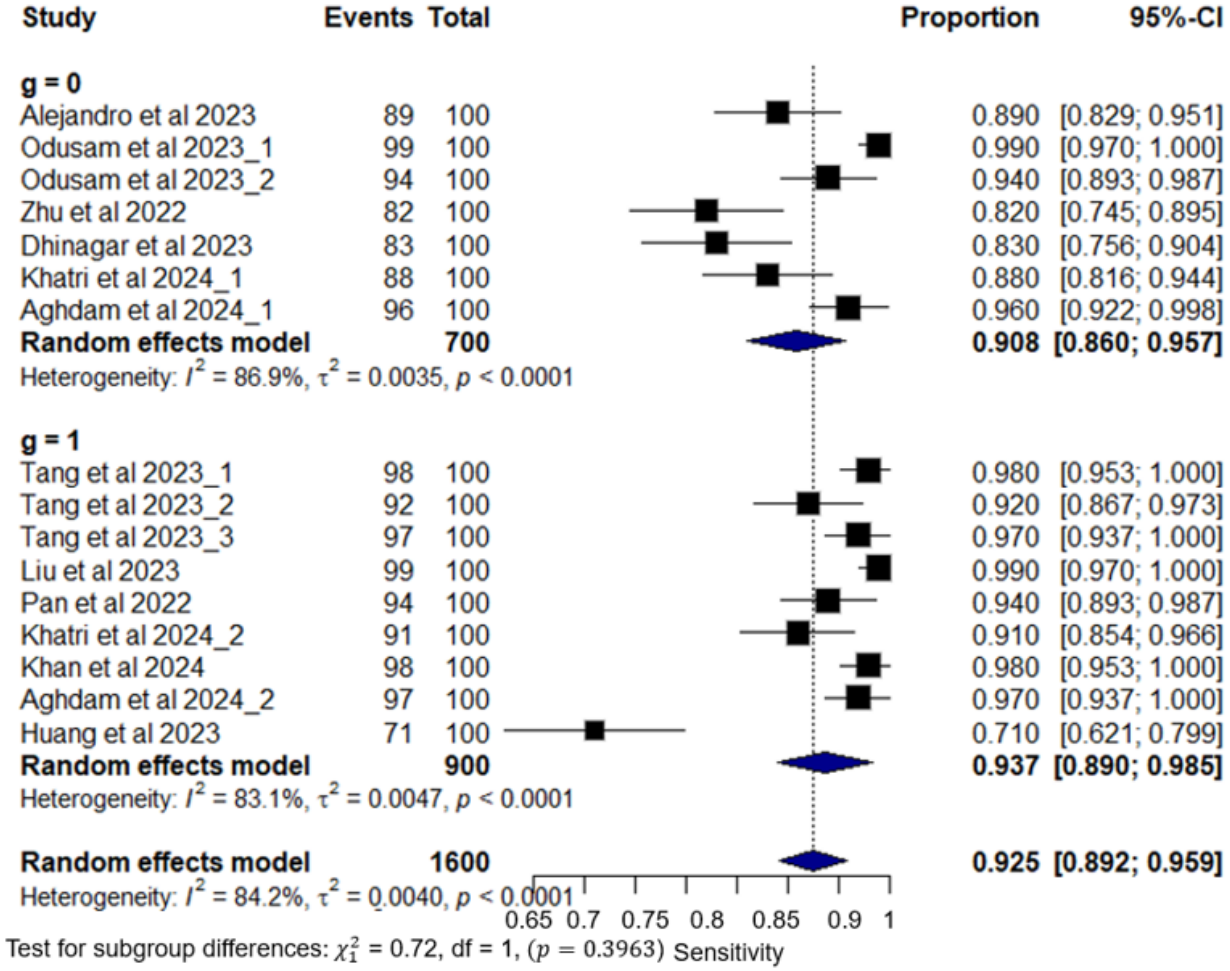
DTA for the Subgroup Analysis Based on Network Architecture



Based on the network architecture, the model was divided into 2 models: ViT models and hybrid networks that incorporate the ViT model with other DL models. The ViT model alone has a sensitivity of 0.908 (95% CI 0.860-0.957, I^2=86.9% for 7 of 16 outcomes), whereas the hybrid models have a sensitivity of 0.937 (95% CI 0.890-0.985, I^2=83.1% for 9 of 16 outcomes). The pooled sensitivity values indicate that there is no significant difference between the 2 subgroups of the network model, with a P value of .40, as shown in Figure 8. The pooled specificity of the ViT model alone exhibits a pooled specificity of 0.912 (95% CI 0.849-0.976, I^2=88.4% across 7 of 16 outcomes). In contrast, the hybrid model demonstrates superior pooled specificity at 0.984 (95% CI 0.975-0.992, I^2=0% across 9 of 16 outcomes). These results reveal that there is a statistically

XSL•FO
RenderX

significant difference in the specificity of the 2 categories of network models with a *P* value of .03 as shown in Figure S1 in Multimedia Appendix 3.

In the subgroup analysis comparing the ViT model and the hybrid model in our meta-analysis, the pooled DOR for the ViT model was 152.681 (95% CI 34.969-666.632, I^2=87.4% for 7 of 16 outcomes), whereas for the hybrid model, it was notably higher at 880.203 (95% CI 337.53-2052.12, I^2=50% for 9 of 16 outcomes). In addition, the *P* value for the subgroup difference was found to be .04, indicating a statistically significant difference between the 2 models. Given the substantially higher pooled DOR for the hybrid model and the significant subgroup difference, it shows that the hybrid model appears to be more effective in diagnosing AD based on our meta-analysis findings (Figure S2 in Multimedia Appendix 3).

Figure 8. Subgroup analysis plot of pooled sensitivity based on the network architecture category. NB: Model 0 represents the ViT model alone, whereas Model 1 adapts the ViT model with other deep learning (DL) models.

Assessment of Study Quality

Assessment of the review domains on risk of bias and applicability concerns was performed after reviewing studies. The review domains included patient selection, index test, reference standard, and flow and timing.

Patient Selection

There were 4 of 16 outcomes from 3 studies [28,30,33] (25%) that raised low concerns for patient selection bias and 5 of 16 outcomes from 2 studies [26,32] (31.25%) with high concerns, whereas 7 of 16 outcomes from 6 studies [23-25,27,29,31] (43.75%) were unclear, due to the studies not providing the detailed information about dataset used during training, testing, and validation.

Index Test

There were 6 of 16 outcomes from 4 studies [26,28,29,33] (38%) that raised low concerns, 4 of 16 outcomes from 3 studies [25,27,32] (25%) with high concerns, and 6 of 16 outcomes from 4 studies [23,24,30,31] (38%) that were unclear, primarily due to inadequate reporting of methodological details.

Reference Standard

There were 10 of 16 outcomes (62%) from 7 studies [25,26,28,29,31-33] with low concerns and 6 of 16 outcomes (38%) from 4 studies [23,24,27,30] that were unclear.

Flow and Timing

We conducted applicability concerns based on the interval between the index test and reference standard, whether all patients were included in the analysis, and whether the same data set used in studies received the same reference standard.

XSL•FO
RenderX

The results showed 7 of 16 outcomes from 4 studies [28,30,31,33] (43.75%) raise low concerns for patient selection bias, 3 of 16 outcomes from 2 studies [26,32] (18.75%) raise high concerns, and 6 of 16 outcomes from 5 studies [23-25,27,29] (38%) were unclear; for the index test, 4 of 16 outcomes from 4 studies [26,28,29,33] (25%) raise low concerns, 5 of 16 outcomes from 4 studies [25,27,31,32] (31.25%) raise high concerns, and 5 of 16 outcomes from 3 studies [23,24,30] (31.25%) were unclear; for reference standard, 10 of 16 outcomes from 7 studies [25,26,28,29,31-33] (62%) raise low concerns, 1 of 16 outcomes from 1 study [30] (6%) raises high concerns, and 4 of 16 outcomes from 3 studies [23,24,27] (25%) were unclear, which can be found in Multimedia Appendix 4.

Discussion

Principal Findings

In the current systematic review and meta-analysis, the DTA of the vision transformer (ViT) in detecting AD was evaluated. The pooled DTA metrics across 11 studies revealed robust performance in detecting AD. The pooled sensitivity was 0.925 (95% CI 0.892-0.959), indicating the model's ability to correctly identify individuals with AD, whereas the specificity was 0.957 (95% CI 0.932-0.981), demonstrating its capacity to accurately classify individuals without AD. In addition, the positive likelihood ratio was 21.84 (95% CI 12.26-38.91), showing the strength of a positive test result, whereas the negative likelihood ratio was 0.08 (95% CI 0.05-0.13), indicating the robustness of a negative test result. The area under the curve was 0.924, further confirming the model's overall diagnostic accuracy. Comparatively, the study conducted by Odusami et al [7] also assessed diagnostic performance in AD detection using ML and DL models. Their meta-analysis reported pooled sensitivity and specificity estimates of 94.60% (95% CI 90.76-96.89) and 93.49% (95% CI 91.60-94.90), respectively, for differentiating AD from CN individuals. Notably, while our specificity estimate was slightly higher than that reported by Odusami et al [7], both studies demonstrate high accuracy in AD detection.

The comparison suggests that both approaches achieve strong diagnostic performance, with minimal variations in specificity estimates. These differences may originate from variations in sample characteristics, imaging protocols, or model architectures used across studies. Overall, the findings corroborate the effectiveness of ML and DL approaches in AD detection, providing valuable insights for clinical practice and future research directions.

Qu et al (2022) [9] conducted a meta-analysis on AD versus CN classification across 11 studies, revealing GAN-based DL with a pooled sensitivity of 0.88, specificity of 0.93, and an AUC of 0.96. In our study, using the ViT-based models for AD detection, we observed promising results with a pooled sensitivity of 0.940, specificity of 0.962, and an impressive AUC of 0.9874. Our findings suggest that ViT models offer high diagnostic accuracy in distinguishing patients with AD from healthy controls, potentially enabling early and accurate diagnosis. Notably, our results further indicate slightly superior sensitivity and specificity compared with GAN-based approaches, indicating the potential superiority of ViT models in AD detection.

Hu et al [34] conducted a meta-analysis assessing the diagnostic performance of MRI-based ML in AD detection. Their findings revealed a DOR of 43.34 (95% CI 26.89-69.84), suggesting strong discriminatory power, as the odds of a positive result were 43.34 times higher in patients with AD compared with those without AD. Comparatively, our analysis indicates that ViT-based models outperformed other types of DL models. Hu et al [30] reported an LR+ of 7.15 (95% CI 5.40-9.47) and an LR– of 0.17 (95% CI 0.12-0.22). These likelihood ratios imply that a positive result is associated with a higher likelihood of AD, whereas a negative result suggests a lower likelihood. In contrast, our estimated results for ViT models yielded a pooled LR+ of 26.02 and LR– of 0.07. This indicates that a positive ViT model result is 26.02 times more likely in individuals with AD compared with those without, whereas a negative result is more likely in patients without AD. Overall, the findings highlight the superior diagnostic accuracy of ViT models in AD detection compared with other types of DL models.

The meta-analysis revealed substantial heterogeneity across the studies due to differences in countries, ViT-based architectures, and data types. This heterogeneity could be a potential source of bias and highlights the need for more studies to obtain more consistent results in AD detection. The high sensitivity and specificity of the ViT-based models imply that ViT models can be a valuable tool in clinical scenarios to aid radiologists and neurologists in interpreting neuroimages for AD, potentially reducing the number of false negatives and false positives. The use of ViT, which captures direct relationships between image areas, may offer advantages in analyzing the complex network of the brain. Based on a search of academic literature databases, this is the first systematic review and meta-analysis that focuses on the diagnosis of AD using ViT-based models. Therefore, this review serves to highlight the potential of ViT and neuroimaging in enhancing the precision and productivity of AD diagnosis, providing a plethora of innovative solutions to address the challenges inherent in early detection and classification. However, this study faced some limitations. First, the pioneering nature of this systematic review presents a challenge for comparative analysis with other DL models. This is because, to the best of our knowledge, there have been no previous systematic and meta-analysis studies that focus specifically on ViT in the context of AD. The pioneering nature of this study means that there is a lack of existing literature to draw comparisons and establish a benchmark for the diagnostic accuracy of ViT-based models. The study acknowledges this issue and recognizes the need for further research to fill this gap. In the future, more studies are needed; specifically, there is a need to establish a more comprehensive understanding of ViTs diagnostic accuracy and their performance relative to other DL models in diagnosing AD.

Second, the reliance on public datasets for the included studies means that the diagnostic performance of ViT methods is based on data that may not fully represent the complexity and variability of real-world AD cases. The use of such datasets, although useful for initial research, does not account for the potential subtleties and specificities of patient data obtained

XSL•FO
RenderX

from hospitals. This limitation is further compounded by the challenges associated with patient privacy and the complexities of preprocessing hospital data, which can hinder the validation of ViT methods in a real-world context. The study emphasizes the need for future research to address these challenges and validate the findings on more representative and diverse datasets. Researchers should also conduct further evaluations of ViTs using hospital data to better align with real-world applications [35].

Third, the limited number of studies available has restricted the research to binary classification tasks, which differentiate patients with AD from CN individuals. This focus does not capture the full spectrum of AD's progression, including the various stages and the transition from MCI to late MCI and stable MCI [15]. The study acknowledges the need for a broader application of ViT-based DL methods to detect and track the various stages of AD, which is crucial for a more comprehensive understanding of the disease and its progression. In addition, there is a notable gap in studies that use multimodal data to predict the progression of AD.

Furthermore, the study highlights a significant gap in the current models' ability to provide expert-level interpretations [36]. The absence of a reference standard in the form of expert diagnosis makes it difficult to conclusively determine the superiority of ViT-based models in real-world health care settings. This limitation underscores the importance of future research efforts that should focus on enhancing the transparency and explainability of ViT-based models. In addition, there is a need to explore the integration of these models with expert opinions to improve the accuracy of AD detection and diagnosis. By doing so, the research can move toward a more collaborative approach that combines the strengths of both artificial intelligence and human expertise.

Third, most ViTs require the use of GPUs for training, which may not be readily available in many hospitals. Therefore, there is a need to develop smaller models that can be trained in more affordable and accessible environments.

Finally, the findings of this study have important implications for clinical practice. ViT models show high diagnostic accuracy in AD detection, offering the potential for early diagnosis and personalized treatment. However, several barriers may hinder their implementation in routine clinical settings. These include the need for large, well-labeled datasets, the risk of overfitting, and the challenges of integrating ViT models into existing clinical workflows. In addition, the computational resources required for training, such as GPUs, may not be readily available in many hospitals. Addressing these challenges is essential to realize the full potential of ViTs in clinical applications.

Conclusion

The systematic review and meta-analysis highlight the strong diagnostic capability of ViT-based models in detecting AD from MRI and PET brain images. Although there are limitations, such as the lack of comparative analysis with other DL models, ViT models demonstrate high sensitivity and specificity. ViTs have the potential to significantly enhance image analysis in AD diagnosis by improving feature extraction, enabling early detection of subtle brain changes, supporting personalized diagnoses, and facilitating the integration of additional data for more accurate diagnoses. However, the effective application of ViT models comes with challenges, including the need for large datasets, the risk of overfitting, and the integration of these models into clinical workflows. To fully harness their potential in clinical settings, continued research is essential, particularly to improve model transparency and incorporate expert opinions. This study highlights the promising role of ViTs in advancing early AD detection and classification, paving the way for innovative solutions in neuroimaging analysis.

Abstract

Background: Medication-related harm, including adverse drug events (ADEs) and medication errors, represents a significant iatrogenic burden in clinical care. Digital health technology (DHT) interventions can significantly enhance medication safety outcomes. Although the clinical effectiveness of DHT for medication safety has been relatively well studied, much less is known about the cost-effectiveness of these interventions.

Objective: This study aimed to systematically review the economic impact of DHT interventions on medication safety and examine methodological challenges to inform future research directions.

Methods: A systematic search was conducted across 3 major electronic databases (ie, PubMed, Scopus, and EBSCOhost). The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines were followed for this systematic review. Two independent investigators conducted a full-text review after screening preliminary titles and abstracts. We adopted recommendations from the Panel on Cost-Effectiveness in Health and Medicine for data extraction. A narrative analysis was conducted to synthesize clinical and economic outcomes. The quality of reporting for the included studies was assessed using the CHEERS (Consolidated Health Economic Evaluation Reporting Standards) guidelines.

Results: We included 13 studies that assessed the cost-effectiveness (n=9, 69.2%), cost-benefit (n=3, 23.1%), and cost-utility (n=1, 7.7%) of DHT for medication safety. Of the included studies, more than half (n=7, 53.9%) evaluated a clinical decision support system (CDSS)/computerized provider order entry (CPOE), 4 (30.8%) examined automated medication-dispensing systems, and 2 (15.4%) focused on pharmacist-led outreach programs targeting health care professionals. In 12 (92.3%) studies, DHT was either cost-effective or cost beneficial compared to standard care. On average, DHT interventions reduced ADEs by 37.12% (range 8.2%-66.5%) and medication errors by 54.38% (range 24%-83%). The key drivers of cost-effectiveness included reductions in outcomes, the proportion of errors resulting in ADEs, and implementation costs. Despite a significant upfront cost, DHT showed a return on investment within 3-4.25 years due to lower cost related with ADE treatment and improved workflow efficiency. In terms of reporting quality, the studies were classified as good (n=10, 76.9%) and moderate (n=3, 23.1%). Key methodological challenges included short follow-up periods, the absence of alert compliance tracking, the lack of ADE and error severity categorization, and omission of indirect costs.

Conclusions: DHT interventions are economically viable to improve medication safety, with a substantial reduction in ADEs and medication errors. Future studies should prioritize incorporating alert compliance tracking, ADE and error severity classification, and evaluation of indirect costs, thereby increasing clinical benefits and economic viability.

KEYWORDS

digital health technology; drug safety; adverse drug events; medication errors; patient safety

Introduction

Medication-related harm, including adverse drug events (ADEs) and medication errors, represents a significant burden in clinical care [1]. A previous systematic review showed that 3% of patients in various health care settings experience preventable medication-related harm worldwide, with a quarter classified as severe or potentially life threatening [2]. Unsafe medication practices can occur at various stages of the medication process, including prescribing errors, where nearly 50% of medication errors occur (eg, inappropriate drugs for age and condition, incorrect dosage, contraindication, and drug-drug interactions (DDIs) overlooked) [3,4]; dispensing errors; administration errors; and inadequate monitoring (eg, hypokalemia due to inadequate renal and electrolyte monitoring among diuretic users) [5,6]. Additional costs associated with medication errors have been estimated at US $42 billion annually, indicating a significant burden of unsafe medication practices for patients and the health system [7].

Digital health technology (DHT) applies information and communication technology to enhance health care outcomes [8]. DHT interventions range from a clinical decision support system (CDSS)/computerized provider order entry (CPOE) or electronic prescribing, automated medication-dispensing systems, telemedicine, and mobile health (mHealth) apps to telephone or text message reminders [9-12]. DHT may assist in supporting clinical decisions and enhancing the monitoring of medication use [13,14]. Several studies have shown that DHT may confer benefits by reducing ADEs and medication errors in both hospital and community settings [15-17]. Previous systematic reviews have examined the clinical impact of DHT interventions (ie, CPOE) to improve medication safety [18,19], but none have examined the economic impact of such interventions.

Given the increasing application of DHT, there is an urgent need to determine the economic benefits of DHT to allow clinicians to decide whether to implement DHT strategies [20]. Although DHT interventions can potentially improve clinical outcomes, their additional expense for infrastructure, implementation, and maintenance may hinder their adoption compared to standard care [21,22]. This study aimed to systematically review the economic impact of DHT interventions on medication safety and examine the methodological challenges in these interventions. Such understanding can better inform resource allocation and policy decisions for strengthening health system capacity [23].

Methods

Search Strategy

This systematic review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guideline. A systematic search was performed across 3 major electronic databases (PubMed, Scopus, and EBSCOhost) to identify studies investigating economic evaluations of DHT to improve medication safety outcomes (ie, reduction in ADEs and medication errors). The search strategies included 3 categories of terms related to:

- DHT interventions, defined as strategies that use information and communication technology to enhance health outcomes (ie, reduction in ADEs and medication errors). To ensure comprehensive coverage of all available evidence, we included a broad range of DHT interventions, including a CDSS/CPOE, electronic prescribing, telemedicine, telepharmacy, automated medication-dispensing systems, mHealth apps, and telephone or text message reminders. Comparators included paper-based prescribing, traditional floor stock storage, and standard pharmaceutical care.
- Medication safety outcomes (ie, changes in the ADE and medication error rate). An ADE is defined as “an injury resulting from the use of a drug,” which includes harm resulting from either errors or medication-inherent effects [24]. The term “medication error” refers to “any error in the process of prescribing, dispensing, or administering a drug, which may or may not result in harm” [25]. A previous study showed that although medication errors are common, only around 1% result in actual harm or ADEs, which might be because these errors have little potential for injury or they are intercepted before an adverse outcome occurs [24,26].
- Economic evaluations (ie, cost-benefit analysis [CBA], cost-effectiveness analysis [CEA], cost-utility analysis [CUA], and cost minimization analysis [CMA]).

Full details of the search strategy are provided in Table 1. An additional search of reference lists of relevant reviews and included studies was performed.

[a]DHT: digital health technology.

[b]MeSH: Medical Subject Headings.

Inclusion and Exclusion Criteria

We included studies that reported health economic evaluations of DHT to improve medication safety outcomes (ie, ADEs and medication errors) compared to standard care. Detailed information related to inclusion criteria is provided in Table 2. We excluded studies where the intervention did not include DHT, studies that did not report medication safety outcomes, studies without full economic evaluation, non-English studies, conference abstracts, and editorials.

XSL•FO

Table 2. PICO[a] framework and inclusion criteria of the study.

Framework item	Inclusion criteria
Population/problem	Patients receiving medication at any point of care, including in hospital and community settings
Intervention	Any DHT[b] intervention, including: • CDSS[c]/CPOE[d] • Automated medication-dispensing system • Telepharmacy, telemedicine • mHealth[e] app • Other
Comparator	Standard care (eg, paper-based prescribing, traditional floor stock storage)
Outcome	Reduction in ADEs[f] and medication errors
Study type	A full economic evaluation of DHT to improve medication safety categorized as CBA[g], CEA[h], CUA[i], and CMA[j]

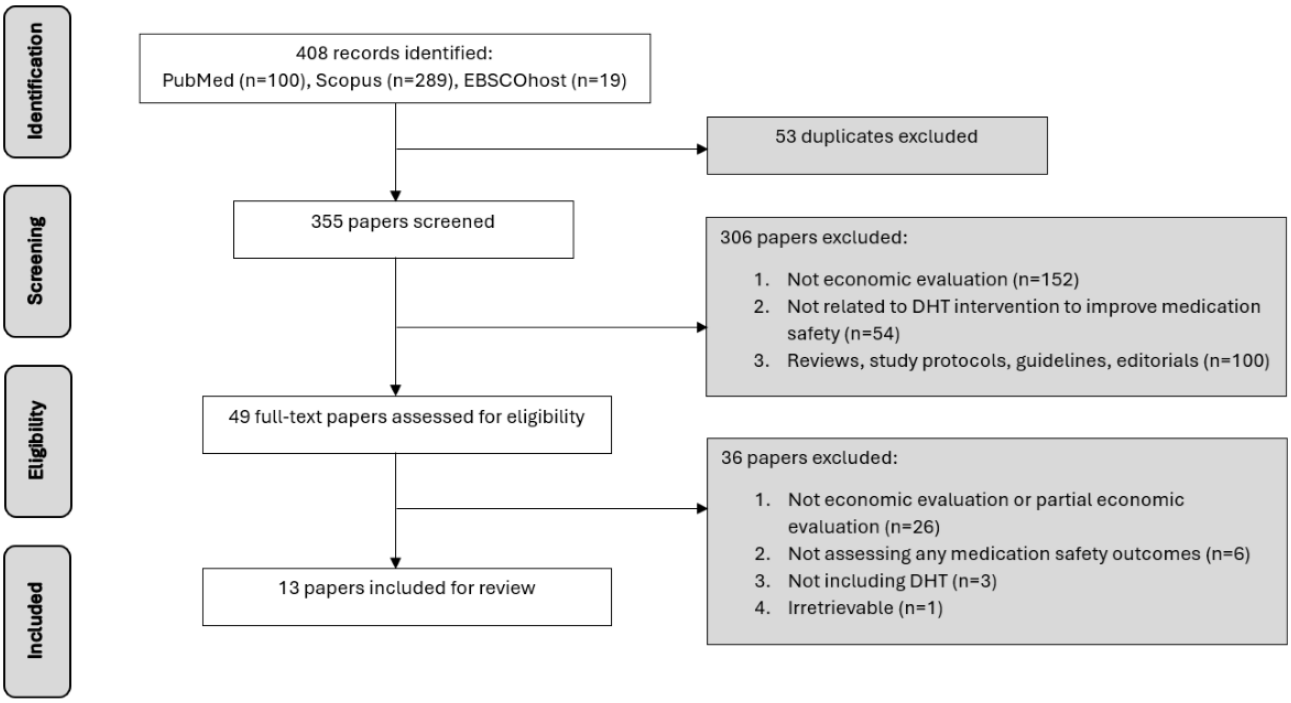
[a]PICO: population/problem, intervention, comparator, outcome.
[b]DHT: digital health technology.
[c]CDSS: clinical decision support system.
[d]CPOE: computerized provider order entry.
[e]mHealth: mobile health.
[f]ADE: adverse drug event.
[g]CBA: cost-benefit analysis.
[h]CEA: cost-effectiveness analysis.
[i]CUA: cost-utility analysis.
[j]CMA: cost minimization analysis.

Screening and Data Extraction

The database-screening results were exported to the Mendeley reference manager library and examined for duplicates. Two investigators (authors WNI and NZ) independently conducted a full-text review after screening the preliminary titles and abstracts. Any discrepancies between the 2 reviewers were resolved through discussion. We adopted recommendations from the Panel on Cost-Effectiveness in Health and Medicine for data extraction. Data extracted included (1) study characteristics; (2) clinical and economic outcomes, including the incremental cost-effectiveness ratio (ICER), the cost-benefit ratio (CBR), and the return on investment (ROI); (3) cost components; (4) methodological challenges; and (5) quality of reporting. All monetary values were converted to 2024 US dollar values using the Campbell and Cochrane Economics Methods Group–Evidence for Policy & Practice Information Centre Cost Converter [27].

Quality of Reporting

Reporting quality was assessed using the CHEERS (Consolidated Health Economic Evaluation Reporting Standards) 2022 checklist. The checklist included 28 items, classified into 6 categories: (1) title and abstract, (2) introduction, (3) methods (including choice of model, health outcomes, and measurement of effectiveness), (4) results, (5) discussion, and (6) others. Based on the reporting quality, the included studies were categorized as excellent (score 100%), good (score 75%-99%), moderate (score 50%-74%), and low (score ≤49%) [28].



Results

Study Selection

A total of 408 citations were retrieved from the electronic databases. After removing duplicates, 355 (87%) papers remained for evaluation based on titles and abstracts, yielding 49 (13.8%) records eligible for full-text assessment. A total of 13 (26.5%) economic evaluation studies [10,12,15,17,29-37] were finally included in this systematic review. Most of the studies included CEA (n=9, 69.2%) [12,15,17,29-34], followed by CBA (n=3, 23.1%) [10,35,36], and CUA (n=1, 7.7%) [37]. The included studies were predominantly conducted in hospital inpatient settings (n=10, 76.9%) [10,12,17,30-36]. The study selection flowchart based on PRISMA guidelines is provided in Figure 1.

XSL•FO
RenderX

Figure 1. PRISMA flowchart of study selection. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Overview of Key Characteristics

The most frequently implemented DHT intervention was the CDSS/CPOE or electronic medication record system. This intervention typically replaced traditional paper-based prescribing, with a safety alerts feature to assist clinicians in making informed decisions during the prescribing process [12,17,29,30,33-35]. A wide range of features were used in the included studies, ranging from basic DDI to the addition of medication administration tracking and various alerts, including pregnancy contraindications, allergy checks, dosage checks, therapeutic duplications, and potentially inappropriate medication (PIM) usage in vulnerable populations at increased risk of ADEs [12,17,29,30,33-35]. One study [30] compared a structured pharmacist medication review supported by a CDSS with a review conducted without CDSS support for older hospitalized patients. The intervention included medication reconciliation and personalized pharmaceutical care (Table 3).

Of the 13 studies, 4 (30.8%) [10,31,32,36] showed that the implementation of automated medication-dispensing systems has been increasingly used to reduce dispensing and administration errors, enhance workflow efficiency, and improve stock inventory tracking. These systems typically incorporated automated individual unit-dose dispensing, which ensured precise medication packaging tailored to patient-specific prescriptions, unlike manual systems where nurses prepare doses manually [31,32,36]. The systems were often integrated with barcode scanning technology, either at the hospital pharmacy or at the patient bedside level, enabling verification of both the medication and the patient's identity to prevent administration errors [31,32]. Additional functionalities included structured drug storage and controlled access (eg, automated dispensing cabinets [ADCs] and medicine carousel systems with rotating shelves or bins to minimize the time spent searching for medications and medication selection errors) [10,32,36]. One intervention also improved inventory management by providing automated real-time stock monitoring [10]. Furthermore, some systems were linked with electronic medication administration records and other CDSS tools, allowing better coordination between dispensing and prescribing processes [31,32,36].

[e]CBA: cost-benefit analysis.

[f]CUA: cost-utility analysis.

[g]Number of acute care hospitals in the United States.

[h]Total number of doses.

A technology-based pharmacist outreach was implemented in 2 (15.4%) studies [15,37], involving pharmacists engaging directly with other health care professionals to target specific high-risk prescribing errors, such as prescribing nonsteroidal anti-inflammatory drugs (NSAIDs) without proton pump inhibitors (PPIs) for patients with a history of peptic ulcers, beta-blockers for patients with asthma, and angiotensin-converting enzyme (ACE) inhibitors or diuretics without proper monitoring of renal function and electrolytes. The interventions involved a CDSS-supported feedback system and pharmacist educational outreach for general practice staff. This intervention model extended beyond simple error reporting by providing pharmacist-intensive support and guidance to other health care professionals.

Clinical Effectiveness Estimates

The DHT interventions were effective in reducing ADEs, with an average reported effectiveness of 37.12% (range 8.2%-66.5%) across the included studies (Multimedia Appendix 2 and Table 4) [12,17,29,30,34,35]. Medication errors reduced by an average of 54.38% (range 24%-83%) [10,12,15,17,29,31-33,36]. The variability in the effectiveness of DHT in reducing ADEs and medication errors can be influenced by differences in DHT features and the target population. A comprehensive CDSS/CPOE with both prescription entry and administration tracking resulted in greater reduction in ADEs compared to a CDSS/CPOE with only basic alerts [12,34]. Nevertheless, none of the studies provided data on alert compliance tracking by health care professionals. Higher effectiveness was also observed in DHT interventions targeting high-risk populations, such as older and pediatric hospitalized patients. These populations are more prone to ADEs and medication errors resulting from comorbidities, concomitant medications, and differences in physiological characteristics. Consequently, interventions targeting these populations showed greater absolute reductions in ADEs and medication errors compared to interventions targeting lower-risk populations, as the elevated baseline risk provides more room for improvement [29,30].

XSL•FO
RenderX

Table 4. Examples of ADEs[a] and medication errors assessed in the included studies.

Safety outcomes	Examples	Reduction (%), mean (range)
ADEs	• Dyspepsia associated with NSAIDs[b], antiplatelets, and corticosteroids use • Severe hypotension resulting from ACE[c] inhibitors in patients with volume depletion • Acute kidney injury caused by NSAIDs prescribed without proper renal monitoring • Hyperkalemia due to the concurrent use of ACE inhibitors and potassium-sparing diuretics • Bleeding complications caused by an inappropriate dose of anticoagulants • Hypoglycemia resulting from insulin overdose • Bradycardia from incorrect beta-blocker dispensing • Falls and fractures caused by benzodiazepine use in older patients • Renal toxicity from aminoglycosides prescribed without dose adjustment for kidney function • Hypotension and syncope caused by inappropriate antihypertensive drug combinations • Cardiac arrhythmia caused by QT-prolonging drug combinations • Severe allergic reactions from failure to recognize and document allergies	37.12 (8.20-66.50)
Medication errors	• Incorrect drug dosing due to incorrect weight-based calculation and transcription error • Failure to adjust medication doses for patients with renal impairment • NSAIDs without PPIs[d] in patients with ulcer history • Beta-blockers prescribed to patients with asthma • Dispensing the incorrect medication, strength, or dosage form • Errors related to supply failure or expired drugs • Monitoring errors, such as patients on ACE inhibitors or diuretics without renal and electrolyte monitoring in the past 15 months, patients on warfarin without a recorded International Normalized Ratio (INR) check in the past 12 weeks, patients on methotrexate without a full blood count or liver function test in the past 3 months	54.38 (24.00-83.00)

[a]ADE: adverse drug event.

[b]NSAID: nonsteroidal anti-inflammatory drug.

[c]ACE: angiotensin-converting enzyme.

[d]PPI: proton pump inhibitor.

Cost-Effectiveness Estimates

CDSS/CPOE Intervention

Implementation of a CDSS/CPOE to replace paper-based prescribing was associated with an average cost ranging from US $25.64 to $81.36 per patient, depending on the complexity and features of the system. The key cost components for a CDSS/CPOE included initial investments in hardware and software, licensing fees, staff training, ongoing system maintenance, and periodic updates to ensure compatibility with clinical workflows (Table 5) [12,17,29,30,33-35]. The implementation cost of a CDSS/CPOE depends on the hospital size, influenced by the need for more extensive hardware infrastructure and software to support a higher number of workstations, higher provider and patient volume, and more comprehensive clinical decision support rules to support various specialties [17]. Most studies evaluating a CDSS/CPOE reported the interventions as cost-effective from perspectives of societal, hospital, and health care systems, with 3 (23.1%) studies [12,17,33] identifying cost-saving results. Only 1 (7.7%) study showed an exceptionally high ICER per ADE prevented without stating a willingness-to-pay (WTP) threshold, highlighting that more data on the effectiveness of CPOE in reducing ADEs are needed [34]. This study was conducted in 2006; therefore, the data on effectiveness may not reflect the most current findings, as presented in more recent studies [12,29,30,33,37]. Although the development of an electronic medical record system with a CDSS requires an initial high investment, 1 (7.7%) study [35] showed that it yields a positive cost-benefit ratio of 1.45, indicating that every US $1 spent generates US $1.45 in benefits, with the ROI achieved within 3 years, driven by a 40% reduction in ADEs as additional treatments and hospitalizations due to ADEs reduced and efficiency improved from transitioning to electronic systems [35].

Table 5. Cost components associated with the DHT[a] interventions included in this review.

Author	DHT type	Currency, year	Cost components	Discount rate (%)
Vermeulen et al [12]	CDSS[b]/CPOE[c]	Euro, 2009	• Software, hardware, and maintenance specific to the CDSS/CPOE • Costs for personnel involved in setting up and maintaining the system • Maintenance and operational costs: ongoing expenses for system updates and operational requirements	Not reported (follow-up period did not exceed 1 year)
Westbrook et al [33]	CDSS/CPOE	AU $, 2012-2013	• Software license fees, infrastructure upgrades, and equipment specific to the electronic medication management system • Personnel training and configuration • Ongoing operating costs: annual software licensing fees, routine system maintenance, and regular training sessions for personnel	5
Wu et al [34]	CDSS/CPOE	US $, 2007	• Software and hardware setup • System configuration and testing • Training sessions for doctors, nurses, and support staff on using the new electronic system • Ongoing operational and maintenance costs: software updates and maintenance, licensing fees, and periodic staff training • Workload costs (considered in sensitivity analysis)	5
Avery et al [15]	IT-based pharmacist outreach	UK pound sterling, 2012	• Report generation • Pharmacist training • Error management activities, including review of patient medical records, consultations with general practitioners, patient follow-up (eg, patient counselling and medication adjustment, if needed), and training for general practice staff by pharmacists	Not reported (follow-up period did not exceed 1 year)
Berdot et al [10]	Automated medication-dispensing system	Euro, 2015	• Purchase of dispensing units, including software and licenses • Immobilized drug stock • Annual maintenance • Labor costs: pharmacy technician wages for ADC[d]-related tasks	Not reported
Forrester et al [29]	CDSS/CPOE	US $, 2010	• Hardware, software, and system setup • Administrative costs: prescription processing, including chart pulls and queuing • Incentives: financial incentives related to meaningful use and pay-for-performance criteria • Maintenance costs • Personnel costs for implementation, training, and support	3
Elliot et al [37]	IT-based pharmacist outreach	UK pound sterling, 2012	• Report generation • Pharmacist training • Error management activities, including review of patient medical records, consultations with general practitioners, patient follow-up (eg, patient counselling and medication adjustment, if needed0, and training for general practice staff by pharmacists	3.5
Gallagher et al [30]	CDSS and pharmacist review	Euro, 2012	• Pharmacist time and training: cost of pharmacists applying structured medication reviews and the CDSS • Health care staff review time: physician and nurse time for reviewing care plans • Hospital inpatient day: cost of inpatient care per day • Software and training costs	Not reported (follow-up period did not exceed 1 year)
Li et al [35]	CDSS/CPOE	US $, 2009	• Hardware and software costs • Implementation costs: workflow setup, training, and transition • Maintenance costs: ongoing system support and utilities	10
Maviglia et al [36]	Barcode-dispensing system	US $, 2009	• Planning cost: workflow redesign and stakeholder engagement • Software development: linking the barcode system with the existing CPOE system, medication inventory, dose verification tracking, interface design, etc • Equipment purchase and infrastructure changes • Training cost	3

XSL•FO
RenderX

Author	DHT type	Currency, year	Cost components	Discount rate (%)
Nuckols et al [17]	CDSS/CPOE	US $, 2012	• Implementation cost: hardware, software, training, and technical support • Provider workflow cost	3
Risor et al [31]	Automated medication-dispensing system	Euro, 2017	• System integration: development of interfaces between electronic medication administration records, scanners, and the barcode-scanning system • Equipment purchase: automated medication-dispensing machine and barcode-scanning devices • Operational costs: cost of dose packaging, pharmaceutical services for prescription checks, and additional labor costs • Training cost: training for nurses and pharmacy staff on AMS[e] processes	Not reported (follow-up period did not exceed one year)
Risor et al [32]	Automated medication-dispensing system	Euro, 2018	• System implementation: establishment of electronic medication administration records tailored to AMS types • Equipment purchase: automated medication-dispensing machines, scanners, and ADCs (complex automated medication system [CAMS] only) • Operational costs: maintenance costs, dose bag handling, and additional pharmacy labor for prescription checks (only for patient-specific automated medication system [PSAMS] and CAMS) • Training cost: education programs tailored to the AMS complexity used in each ward	Not reported (follow-up period did not exceed one year)

[a]DHT: digital health technology.

[b]CDSS: clinical decision support system.

[c]CPOE: computerized provider order entry.

[d]ADC: automated dispensing cabinet.

[e]AMS: automated medication system.

Automated Medication-Dispensing System

Implementation of automated medication-dispensing systems to replace traditional floor stock systems was cost-effective and beneficial, with the ICER ranging from US $0.33 to $62.00 per medication error avoided [10,31,32,36]. Key cost components for an automated medication-dispensing system included purchase of dispensing cabinets or medicine carousel systems with rotating shelves or bins, equipment for the repackaging center, software development, a barcode scanner, labor for restocking and packaging, training expenses, and system integration with the existing CPOE and pharmacy system. A reported net benefit of US $5,379,938.17 was achieved over 5 years, with the ROI attained within 4.25 years after initiation [10,36]. The key drivers of the cost-effectiveness included handling costs and differences in the rates and types of medication errors [31,32,36]. Different types of dispensing errors have varying cost consequences; for example, the administration of an incorrect drug, dosage, or strength can have more severe consequences than procedural or administrative errors, which may potentially but not necessarily result in actual harm [32].

IT-Based Pharmacist Outreach

The implementation of a pharmacist-led DHT intervention was cost-effective in reducing clinically significant prescribing and monitoring errors in primary care, with an ICER of US $129.8 per medication error prevented and US $7788 per quality-adjusted life year (QALY) per practice [15,37]. In addition, this intervention not only improved health outcomes (ie, additional QALYs) but also reduced overall costs compared to usual care, indicating its potential for cost savings [37]. Key cost components included pharmacist training, the time spent reviewing patient records and consulting with general practitioners (GPs), report generation from the CDSS, facilitation of practice meetings, patient follow-up, and system integration with the existing IT infrastructure. The number of patients per general practice was a key driver of cost-effectiveness in this intervention. In larger practices, intervention costs (eg, pharmacist training and CDSS report generation) are distributed across a broader patient base. In addition, the targeted nature of this intervention, which addressed specific prescribing errors (ie, NSAIDs without PPIs, beta-blockers for asthma, and monitoring errors) increased the efficiency and impact of pharmacists' and GPs' time in practices with higher patient volumes due to economies of scale [15,37,38].

Methodological Characteristics and Challenges in the Included Studies

Of the 13 studies 6 (46.2%) [10,12,17,31,32,35] used a quasi-experimental design (ie, before-after and interrupted-time-series approaches, with multiple data points tracking ADEs and medication errors before and after DHT initiation). A decision analytic model was used in 3 (23.1%) studies [29,33,35], focusing on short-term, event-specific analysis, while a Markov model was used in 1 (7.7%) study [37]. Randomized controlled trial (RCT)–based evaluation was used in 2 (15.4%) studies [15,30]. Challenges related to methodological aspects of evaluating DHT interventions for medication safety are presented in Table 6. Methodological challenges included short follow-up times, the absence of CDSS alert compliance tracking, a lack of ADE severity classification, and the omission of indirect costs (eg, productivity loss and caregiver time).

XSL•FO
RenderX

Table 6. Methodological challenges in DHT[a] intervention evaluation for medication safety.

DHT type and methodological issues	Description
CDSS[b] /CPOE[c]	
Study design	• The short-term duration of the study (hospital stay until discharge or 10-day follow-up) did not capture the medium- or long-term impact of the intervention [12,30]. • Studies were not able to track whether or how many CDSS alerts were acknowledged and acted upon by health care professionals, limiting accurate assessment of DHT's effectiveness [12,17,29,30,33-35]. • There was no standard care comparator. Before-after designs may not fully account for external factors influencing the observed trend [12,33,35]. The use of a parallel control group for direct comparison could help mitigate confounding effects.
Cost data	• Studies included a societal perspective but lacked data on indirect patient costs (eg, productivity loss, caregiver time) [17].
Clinical data	• There was a lack of detailed ADE[d] severity classification, which may introduce variability in assessing ADE consequences and the benefits of the intervention [33]. • Few studies assessed direct patient-centered outcomes (eg, hospital readmissions, QALY[e]) [17].
Automated medication-dispensing system	
Study design	• Studies did not analyze whether identified dispensing errors were tracked or immediately corrected (real-time monitoring), relying on retrospective analysis [10,31,32,36]. • Studies were conducted only in hospital settings, limiting generalizability to different settings.
Cost data	• Studies did not explore how saved handling time could be reallocated to other productive tasks (ie, opportunity cost).
Clinical data	• Studies focused on refill errors and urgent deliveries but did not systematically track errors or discrepancies between prescription and dispensing records [10].
Pharmacist-led IT intervention	
Study design	• Studies focused on specific high-risk prescribing and monitoring errors but did not directly assess the proportion of errors leading to ADEs [15,37].

[a]DHT: digital health technology.

[b]CDSS: clinical decision support system.

[c]CPOE: computerized provider order entry.

[d]ADE: adverse drug event.

[e]QALY: quality-adjusted life year.

Quality of Reporting

Based on the quality assessment using the CHEERS checklist, most of the included studies (n=10, 76.92%) [12,15,17,29-33,36,37] were rated as good, and the remaining 3 (23.1%) studies [10,34,35] were rated as moderate. Adherence to the checklist items varied across the section. Most studies did not report any approach to engagement with patients in the study design and results, except for the RCT-based study [30]. The rationale for selecting the model was inadequately reported in over a third of the studies, indicating issues in validating the selected methodology [10,30,31,34,36]. All studies reported how to measure ADEs and medication errors; however, the valuation of these safety outcomes was not reported in some studies [10,12,33]. The components of the outcomes included costs related to additional treatments and hospital stays due to the occurrence of ADEs and medication errors. Although most studies conducted sensitivity analysis to assess the robustness of the findings, only 1 (7.7%) study [32] assessed the heterogeneity of the outcomes based on different types of automated medication-dispensing systems. Most studies only focused on aggregated data without exploring subgroup differences, such as variations within patient populations, hospital wards, or intervention types.

Discussion

Principal Findings

This is the first systematic review that assessed the economic evaluations of DHT interventions to improve medication safety outcomes. More than half of the studies (n=7, 53.9%) focused on a CDSS/CPOE, less than a third (n=4, 30.8%) on automated medication-dispensing systems, and the remaining (n=2, 15.4%) on pharmacist-led outreach programs targeting health care professionals. On average, DHT interventions reduced ADEs by 37.12% and medication errors by 54.38%. In 92.3% (12/13) of the included studies, the DHT was either cost-effective or cost beneficial compared to standard care. Despite a significant upfront cost, DHT showed an ROI within 3-4.25 years. Key methodological challenges included short follow-up periods, a

XSL•FO
RenderX

lack of ADE severity categorization, the absence of alert compliance tracking, and the omission of indirect costs.

A CDSS/CPOE has been increasingly used to support clinicians in making informed decisions by providing recommendations based on patient data and clinical guidelines [39]. Nevertheless, the effectiveness of a CDSS is often compromised by alert fatigue, which occurs when clinicians override a large number of potentially irrelevant drug safety alerts (eg, drug interactions that are not clinically significant, flagging dosages outside the standard guideline when the prescribed dosage is appropriate for the patient condition) [40-42]. A previous study showed that alert fatigue might be reduced by using a CDSS/CPOE with interactive features, such as incorporating tiered safety alerts with varying priority levels, offering action plans for clinicians (eg, dose reduction), and requiring clinicians to justify overriding an alert [41]. In our review, none of the studies tracked CDSS/CPOE alert compliance, which may influence their effectiveness. A previous study showed drug allergy alerts had the highest compliance [43]. Further DHT evaluation studies should investigate how alert compliance affects the outcomes to ensure optimal utility of DHT.

In addition, tailoring clinical roles within a CDSS can also enhance alert acceptance [44-46]. A pharmacist-mediated CDSS has improved prescriber acceptance by filtering irrelevant advice and providing actionable drug safety recommendations [44]. This approach leverages pharmacists' expertise related to medication to support the decision-making process and reduce alert fatigue among prescribers [47-49]. Several included studies combined a CDSS with pharmacist-led interventions, such as structured medication review and targeted training for health care professionals for error correction, highlighting the central role of pharmacists in medication safety [15,30,37].

Advancements in CDSSs/CPOE have significantly reduced prescribing errors, but administration errors, such as administering the wrong dose, using the incorrect route of administration, and failing to administer a scheduled dose, still present substantial room for improvement [50]. This review found that a CDSS/CPOE with integrated prescription entry and administration tracking that address prescribing errors, while also monitoring and mitigating administration errors, achieves a greater reduction in ADEs compared to systems with basic features [12,34]. The development and implementation of more comprehensive systems that target all stages of medication management, including administration, are essential to reduce medication errors and ADEs.

Different types of automated medication-dispensing systems were used in the included studies. Several factors need to be considered when selecting an automated medication-dispensing system, including the volume of prescriptions and types of medication the device can handle (eg, oral tablets, liquid medications, injectables), integration with the existing information technology system, and the presence of an error-checking mechanism [51,52]. Almaki et al [53] and Tsao et al [54] showed that integration with existing digital infrastructure is key to supporting a seamless workflow process to ensure all components of medication management (ie, prescribing, dispensing, and inventory control) are interconnected, enhancing efficiency and medication error prevention.

All the included studies focused on hospital-based automated medication-dispensing systems, with limited investigation in outpatient settings [10,31,32,36]. Williams et al [52] demonstrated that automated medication-dispensing systems for chronic medication regimens, such as antiretroviral therapy, enable efficient one-time password (OTP)–based medication collection and reduced waiting times, benefiting high-volume, resource-limited outpatient clinics. Further studies may adopt this system for less complex medication regimens to improve patient satisfaction and reduce the staff burden, enabling health care providers to focus on other critical tasks, such as optimization of drug therapy [54,55].

Targeting medication errors with a substantial clinical impact was a key strategy in the technology-based pharmacist-led outreach [15,37]. As around 1% of medication errors lead to actual harm, prioritizing interventions is essential [24]. The National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP) developed an index to standardize the classification of medication errors based on severity (ie, no error, error-no harm, error-harm, and error-death), which has been adopted in the hospital setting [56,57]. An initiative to standardize the interception of medication errors using this severity classification index has proven effective to prevent clinically significant patient harm and provide substantial cost savings to the health system [58].

Various economic models were used in the included studies (eg, quasi-experimental design, RCT, decision analytic model), indicating the complexity and multifaceted nature of DHT for medication safety. Sculpher et al [59] emphasized the importance of placing an RCT within a broader framework of evidence synthesis and decision analysis in economic evaluation studies to balance internal validity and broader applicability. Quasi-experimental design can be practical for assessing real-world effectiveness and scalability. However, the assessment of confounders that might affect the observed trend and the lack of guidance in conducting economic evaluations alongside quasi-experimental trials necessitate careful interpretation of the findings [60].

Strengths and Limitations

This study is the first systematic review investigating economic evaluations of DHT interventions to improve medication safety outcomes. We conducted a rigorous literature search with a comprehensive strategy encompassing a wide range of DHT intervention types to provide a thorough review of different strategies to improve medication safety. We also included evaluations on methodological challenges in DHT intervention assessment to inform future research direction.

Nevertheless, our review has several potential limitations. First, the generalizability of findings may be restricted to high-income settings, as most included studies were conducted in such contexts. Second, heterogeneity in health care settings, study designs, and economic evaluation methods may hinder direct comparisons across studies. Despite this, a narrative synthesis was developed to integrate and interpret the findings. Third, the

XSL•FO
RenderX

exclusion of non-English studies may have limited the comprehensiveness of the evidence base. Finally, there was a lack of medication error and ADE severity classification among the included studies. Since different medication errors and ADEs have varying cost implications, this variability makes the interpretation of overall cost-effectiveness less straightforward.

Conclusion

DHT interventions are economically viable to improve medication safety, with substantial reduction in ADEs and medication errors. On average, DHT interventions reduced ADEs by 37.12% and medication errors by 54.38%. In 92.3% of the included studies, DHT was either cost-effective or cost beneficial compared to standard care. Despite a significant upfront cost, DHT showed an ROI within 3-4.25 years. The key drivers of cost-effectiveness include reductions in outcomes, the proportion of errors resulting in ADEs, and implementation costs. Key methodological challenges included short follow-up periods, the absence of compliance tracking, the lack of ADE severity categorization, and the omission of indirect costs. Future studies should prioritize incorporating alert compliance tracking, ADE and medication error severity classification, and the evaluation of indirect costs, thereby increasing clinical benefits and economic viability.

Abstract

Background: The integration of artificial intelligence (AI) systems for automating medical history taking and triage can significantly enhance patient flow in health care systems. Despite the promising performance of numerous AI studies, only a limited number of these systems have been successfully integrated into routine health care practice. To elucidate how AI systems can create value in this context, it is crucial to identify the current state of knowledge, including the readiness of these systems, the facilitators of and barriers to their implementation, and the perspectives of various stakeholders involved in their development and deployment.

Objective: This study aims to map and summarize empirical research on AI systems designed for automating medical history taking and triage in health care settings.

Methods: The study was conducted following the framework proposed by Arksey and O'Malley and adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) guidelines. A comprehensive search of 5 databases—PubMed, CINAHL, PsycINFO, Scopus, and Web of Science—was performed. A detailed protocol was established before the review to ensure methodological rigor.

Results: A total of 1248 research publications were identified and screened. Of these, 86 (6.89%) met the eligibility criteria. Notably, most (n=63, 73%) studies were published between 2020 and 2022, with a significant concentration on emergency care (n=32, 37%). Other clinical contexts included radiology (n=12, 14%) and primary care (n=6, 7%). Many (n=15, 17%) studies did not specify a clinical context. Most (n=31, 36%) studies used retrospective designs, while others (n=34, 40%) did not specify their methodologies. The predominant type of AI system identified was the hybrid model (n=68, 79%), with forecasting (n=40, 47%) and recognition (n=36, 42%) being the most common tasks performed. While most (n=70, 81%) studies included patient populations, only 1 (1%) study investigated patients' views on AI-based medical history taking and triage, and 2 (2%) studies considered health care professionals' perspectives. Furthermore, only 6 (7%) studies validated or demonstrated AI systems in relevant clinical settings through real-time model testing, workflow implementation, clinical outcome evaluation, or integration into practice. Most (n=76, 88%) studies were concerned with the prototyping, development, or validation of AI systems. In total, 4 (5%) studies were reviews of several empirical studies conducted in different clinical settings. The facilitators and barriers to AI system implementation were categorized into 4 themes: technical aspects, contextual and cultural considerations, end-user engagement, and evaluation processes.

Conclusions: This review highlights current trends, stakeholder perspectives, stages of innovation development, and key influencing factors related to implementing AI systems in health care. The identified literature gaps regarding stakeholder perspectives and the limited research on AI systems for automating medical history taking and triage indicate significant opportunities for further investigation and development in this evolving field.

Introduction

Background

In health care, efficient management of the flow of patients through the health care system is important to ensure that care is accessible and appropriate, given the needs of patients [1]. With the introduction of artificial intelligence (AI) systems, there has been growing interest in using these technologies to improve patient flow [2]. Research in this area remains in its early stages, constituting a disjointed field [3]. In addition, AI systems hold great promise to make patient flows more efficient at the admission of patients by improving triage [4,5].

Traditionally, triage involves a health care professional taking the patient's medical history to systematically decide the optimal prioritization and assess the appropriate treatment for the patient. There are different types of triage, each with its distinctive elements, such as inpatient triage, emergency department triage, incident triage, military triage, and mass casualty triage, all of which possess the aforementioned characteristics [6]. AI systems could potentially increase the efficiency of triage processes by replacing health care professionals in taking the patient's medical history and directing patients to the most appropriate treatment. This could effectively reduce health care professionals' workload and allow for a more optimal allocation of their time [4,5]. Despite the high hopes and AI systems showing good performance in studies, only a small number have been implemented in operational health care systems [7,8].

To fully understand how AI systems for automating medical history taking and triage could be used to create value in the health care context, it is important to understand the entire development and implementation process, including data collection, algorithm development, model validation, and real-world implementation [9]. Each of these steps presents unique challenges and considerations that must be carefully addressed to ensure successful integration into health care. It is essential to determine at which stage of the innovation development process the AI systems are halted or hindered before they are integrated into health care practices [7,8]. Many technical and nontechnical factors affect the implementation process. Technical challenges, such as data quality and interoperability, algorithm accuracy, and system reliability, must be carefully evaluated and addressed [9-11]. In addition, ethical considerations, regulatory frameworks, organizational barriers, and patient acceptance play critical roles in the implementation and use of these technologies [10]. By studying these factors, we can identify the barriers that hinder the effective implementation of AI systems and facilitate strategies to overcome them.

However, it is equally important to recognize that the successful implementation of AI systems in health care extends beyond the technical and regulatory aspects. The perspectives of a wide range of stakeholders must be considered as they can offer valuable insights and contribute to the overall effectiveness and acceptance of these systems [12,13]. Stakeholders include health care providers, patients, decision makers, regulatory bodies, administrators, and other context-based relevant actors. Each stakeholder group brings unique perspectives, priorities, and concerns, which must be integrated into the development and deployment of AI systems for medical history taking and triage [12,13]. By incorporating such diverse perspectives, we can ensure that these technologies align with the needs, values, and expectations of the stakeholders they seek to serve.

In light of these considerations, it is crucial to conduct a scoping review to map and summarize empirical research on AI systems for automating medical history taking and triage. By systematically reviewing the literature, we can identify the current state of knowledge across various stages of the innovation development process, gain insights into the hindering and facilitating factors affecting the implementation and use of AI systems, and consider the perspectives of different stakeholders. Such a comprehensive review will not only help identify gaps in knowledge but also guide future research efforts and inform evidence-based practice for integrating AI systems for automating medical history taking and triage in health care settings.

Aim and Research Questions

The aim of the scoping review was to map and summarize empirical research on AI systems for automating medical history taking and triage. The following research questions (RQs) guided this review:

1. What are the characteristics of research publications on AI systems for automated medical history taking and triage in health care?
2. Whose perspective (researcher, health care professional, or patient) of the AI systems is described?
3. At which stage of the innovation development process are the AI systems studied?
4. What facilitating factors and barriers are considered in relation to the introduction of the AI systems?

Methods

Study Design

The scoping review was designed according to the framework of Arksey and O'Malley [14], which has been widely used to explore, summarize, and draw conclusions about the overall state of research on new technology and health care (refer to the studies by Sharma et al [15], Gama et al [16], and Wikström et al [17]). The characteristics of included research publications (RQ1) and whose perspective is described in the publications (RQ2) are questions commonly addressed in scoping reviews. To investigate at which stages of the innovation development process the AI systems in the research publications were studied (RQ3), we adopted the Technology Readiness Level (TRL) scale for clinical readiness by Fleuren et al [7]. The scale is based on the original TRL scale developed by the National Aeronautics and Space Administration to evaluate technological maturity. It measures the clinical applicability of AI (ie, machine learning) systems on a scale of 1 to 9 (1 being the least mature and 9 being the most mature) [7,18]. To identify and report patterns in facilitating factors and barriers to the introduction of AI systems (RQ4), we used techniques from thematic analysis (ie, we coded the data and generated themes) [19]. The scoping review was reported according to the PRISMA-ScR (Preferred

XSL•FO
RenderX

Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) guidelines [20] (Multimedia Appendix 1), and a scoping review protocol was established before conducting the review.

Search Strategy

To cover any literature relevant to the scope of the review, we used 4 key terms: *health care*, *AI systems*, *medical history-taking*, and *triage* (Textbox 1). To systematically capture literature related to the key terms and synonyms, they were searched using both index terms (ie, subject headings) and free text, as outlined in Multimedia Appendix 2. To generate an extensive coverage of relevant studies, as recommended in scoping reviews [14], 5 major databases for health care–related research were searched: PubMed, CINAHL, PsycINFO, Scopus, and Web of Science Core Collection. The search was conducted in October 2022. All the databases were searched for studies published between January 2000 and September 2022. The search strings were first piloted in one of the databases (PubMed) and then further developed with the support of a research librarian before systematically searching all 5 databases. Textbox 2 provides an illustration of one of the search strings.

Textbox 1. Key terms used in search and their definitions.

- Healthcare: "...all the organizations, institutions and resources that are devoted to producing health actions" [21]
- Artificial intelligence (AI) systems: "...a machine-based system that can, for a given set of human-defined objectives, make predictions, recommendations, or decisions influencing real or virtual environments. AI systems are designed to operate with varying levels of autonomy." [22]
- Medical history-taking: The process of acquiring information from a patient on medical conditions and past treatment [23,24]
- Triage: The process upon which the optimal prioritization and assessment of the appropriate next step for the patient can be decided [6]

Textbox 2. Search string used for the PubMed database (publications were filtered for publication date from January 1, 2000, to September 30, 2022).

((“neural networks, computer”[MeSH Terms:noexp] OR “artificial intelligence”[MeSH Terms:noexp] OR “deep learning”[MeSH Terms] OR “supervised machine learning”[MeSH Terms] OR “artificial intelligence”[Title/Abstract] OR “deep learning”[Title/Abstract] OR “supervised machine learning”[Title/Abstract]) AND (“delivery of health care”[MeSH Terms] OR “health care”[Title/Abstract] OR “healthcare”[Title/Abstract] OR “medical”[Title/Abstract] OR “clinical”[Title/Abstract])) AND (“Medical History Taking”[MeSH Terms] OR “anamnes*”[All Fields] OR “Triage”[MeSH Terms])

Eligibility Criteria

The eligibility criteria were set to identify research publications that presented empirical studies or systematically conducted reviews of empirical studies that focused on AI systems for automating medical history taking and triage in health care. A retrieved study was eligible for inclusion if it (1) contained a title and abstract; (2) was written in English; (3) was published between January 1, 2000, and September 30, 2022; (4) was peer reviewed; (5) analyzed empirical data or systematically reviewed empirical data; and focused on (6) health care, (7) AI, and (8) medical history taking or triage (Textbox 3). Before using the eligibility criteria for study selection in all databases, we piloted the criteria for the studies retrieved from one of the databases (PubMed). The criteria were not altered after piloting.

XSL•FO
RenderX

Textbox 3. Eligibility criteria.

Inclusion criteria
Contained title and abstract: Yes
English language: Yes
Publication date: January 1, 2000, to September 30, 2022
Peer reviewed: Yes
Empirical study: Analyzed empirical data or systematically reviewed articles with empirical data
Focused on health care: Yes
Focused on artificial intelligence: Yes
Focused on medical history taking or triage: Yes
Exclusion criteria
Contained title and abstract: No
English language: No
Publication date: Before December 31, 1999
Peer reviewed: No
Empirical study: Analyzed based on theoretical or hypothetical reasoning
Focused on health care: No
Focused on artificial intelligence: No
Focused on medical history taking or triage: No

Study Selection

First, studies identified through the search strategy were imported into Endnote software (version 20; Clarivate) and exported to the Rayyan web application (Rayyan Systems, Inc) [25] for controlled removal of duplicates. After the removal of duplicates, 2 of the authors (ES and HJ) independently screened the retrieved titles and abstracts for checking their eligibility for inclusion. When screening studies for inclusion, the authors checked the retrieved studies for inclusion according to the inclusion criteria in chronological order, that is, if criterion 1 was met, the authors checked if the retrieved study met inclusion criterion 2, and so on. Conference proceedings were excluded because they are often preliminary and based on limited analyses [26]. Editorials, commentaries, viewpoints, discussion and opinion papers, and book chapters were excluded because they often do not undergo a rigorous and impartial peer-review process. Narrative and integrative reviews were excluded because they did not systematically analyze or review empirical data. Any disagreements during the screening of titles and abstracts were discussed with a third author (JN) until a consensus was reached. Full texts of the studies that met the inclusion criteria after screening titles and abstracts were assessed for eligibility. ES and HJ independently screened the full texts of the studies. Disagreements concerning the full-text screening were discussed among all the authors until a consensus was reached.

Data Extraction

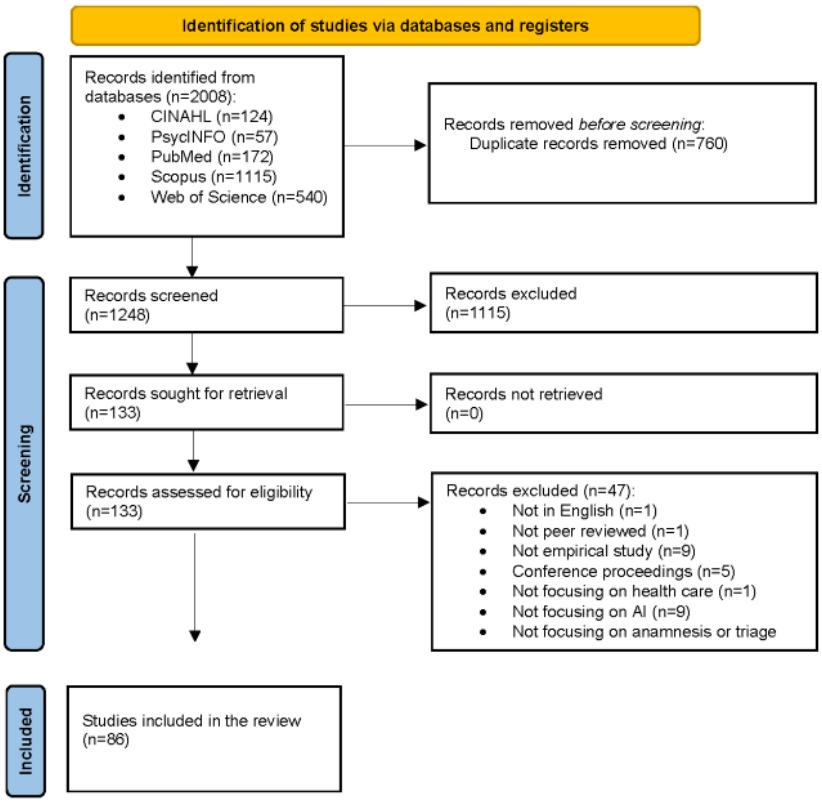
A data extraction template was developed by one of the authors (ES) based on the RQs. The template was piloted with 5 studies before extracting the data from all included research publications. The template was not altered after piloting. To extract data relevant to the RQs, the template contained columns for information on the characteristics of the research publications (RQ1; authors, publication year, country, clinical setting, sample population, study aim, study design, type of AI system, and main task performed by AI system), the perspective described in the research publications (RQ2; ie, the researchers', health care professionals', or patients' perspectives), the TRLs (1-9) of the AI systems in the research (RQ3), and facilitators and barriers to the introduction of the AI systems (RQ4). To identify the type of AI system and the main task performed by the AI system (RQ1), we adopted the operational terms presented in the Organisation for Economic Co-operation and Development Framework for the Classification of AI systems [27].

We extracted data in relation to RQs 1 to 3 from all included studies, whereas data in relation to RQ4 were extracted only from the studies deemed to have TRLs equal to 6 or higher (ie, they reported a demonstration of an AI system in a real health care environment) and for literature reviews. In total, 2 (3%) of the 77 studies with TRLs ≥6 [28,29] and 2 (33%) of the 6 literature reviews did not report the introduction of AI systems in real health care environments [30,31]. Consequently, data from these studies did not address RQ4.

Data on the characteristics of the research publications (RQ1) were extracted from the entire article; data on the perspective described in the research publications (RQ2) and the TRLs (RQ3) were extracted from the methods, results, and discussion sections of the articles. Finally, data on facilitators and barriers to the introduction of the AI systems (RQ4) were extracted from the results, discussion, and conclusions sections of the research publications.

XSL•FO
RenderX

Data Analysis



Following the framework proposed by Arksey and O'Malley [14], we began the analysis with a basic numerical analysis of the extracted data and produced tables to report the distribution of the characteristics of the studies (RQ1), the perspective described in the studies (RQ2), and their TRLs (RQ3). Thereafter, to provide a narrative account of the facilitating factors and barriers to the introduction of the AI systems (RQ4), we coded and organized the extracted data thematically [19] This involved an inductive iterative process in which we coded the extracted text on the facilitating factors and barriers and collated the codes into potential themes, which we then revised and refined. ES and HJ independently coded the data, compiled all the codes, and developed the final themes. The thematic analysis was finalized through a group discussion among all 3 authors.

Results

Overview

A total of 2008 records were retrieved from the electronic databases. After removing duplicates (n=760, 37.85%), 1248 records remained and were included in the screening. Of these, 133 (10.66%) records were assessed for eligibility in full text, and 86 (64.7%) were deemed eligible for inclusion. The PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) flow diagram gives the details on the identification and screening of studies (Figure 1) [32].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. AI: artificial intelligence.

RQ1: Characteristics of the Research Publications

The included studies were published between 2000 and 2022, but most (63/86, 73%) of the studies were published between 2020 and 2022. The remaining studies (16/86, 19%) were published predominantly between 2018 and 2019. Only a small number of studies (7/86, 8%) were published between 2000 and 2017. Most of the studies were from Asia (26/86, 30%), particularly China (8/86, 9%); North America (25/86, 29%), predominantly the United States (23/86, 27%); and Europe (22/86, 26%), primarily the United Kingdom (9/86, 10%). A small number of studies (13/86, 15%) were from Africa (1/86, 1%), Oceania (5/86, 6%), and South America (4/86, 5%) or did not specify the country of origin (3/86, 3%). The most common clinical contexts in focus in the included studies were emergency care (32/86, 37%), followed by radiology (12/86, 14%) and primary care (6/86, 7%). In addition, a large number of studies (15/86, 17%) did not specify the clinical context in focus. The sample population in most studies consisted of patients (70/86, 81%), which included datasets of different types of patient records. In the remaining studies, the sample population was health care professionals (9/86, 10%), citizens (2/86, 2%), or unspecified (5/86, 6%). In these studies, the sample size was small, and there was a higher degree of involvement of the participants in the study. Regarding study design, a large number of studies were retrospective studies (31/86, 36%) or did not specify any specific design (29/86, 34%). Other study designs were, for example, prospective studies (7/86, 8%), different types of pilot studies (4/86, 5%), or reviews (4/86, 5%). The most common type of AI system was hybrid models (68/86, 79%), that is, they combined statistical and symbolic approaches. Most (40/86, 47%) of the AI systems studied were used for forecasting, that is, they predicted future outcomes based on past and present behavior or recognition (36/86, 42%), which

XSL•FO
RenderX

involved identifying and categorizing data into specific classifications or performing image segmentation and object recognition. Definitions of the types of AI systems and their main tasks used in this review can be found in the Organisation for Economic Co-operation and Development Framework for the Classification of AI systems [27]. Multimedia Appendix 3 provides an overview of the characteristics of all the 86 included studies [28-31,33-114].

RQ2: Perspectives Described in the Publications (Among Researchers, Health Care Professionals, or Patients)

Although the sample population in a large number of the included studies consisted of patients, these studies did not portray their perspectives. In most (83/86, 97%) of the included studies, researchers' perspectives were portrayed (ie, researchers' description and interpretation of the AI system and the results of the particular study. Only 1 (1%) study reflected the patients' perspectives [87]. It described patient ratings of the usability and interface of an AI system for medical history taking in an emergency department. The same study also portrayed physicians' and 10 nurses' ratings for the same AI system. Overall, patients, physicians, and nurses were strongly positive about the AI system as a support for patient-clinician communication [87]. Another study described health care professionals' perspectives [63]. More specifically, it explored how emergency triage nurses understood, contextualized, and incorporated an AI-based decision support system into their work on triaging patients. Initially, nurses expressed apprehension that the AI system lacked the cultural and contextual understanding necessary for patient triage. However, they later discovered that the system helped them provide safe care [63]. In total, 2% (2/86) of the studies presented health care professionals' perspectives [63,87]. Additional studies were conducted using health care professionals as the sample population. However, these studies focused solely on health are professionals' decision-making performance in relation to triage with AI systems, without providing insights into their perspectives [40,44,49,59,77,80,95]. In addition, 1% (1/86) of the studies portrayed citizens' (ie, men and women aged 18-80 y) perspectives on an AI system with a conversational user interface for self-guided medical history taking [46]. The citizens completed a usability test and questionnaire concerning the usability, design, and functionality of the AI system. Overall, the citizens stated that they felt comfortable with the system; however, the authors noted that the level of technical competencies and educational levels were high among the participants, limiting the generalization to patient groups [46].

RQ3: Stages of the Innovation Development Process (TRLs)

Most (76/86, 88%) of the included studies did not demonstrate or validate AI systems for medical history taking and triage in clinical environments (ie, they were concerned with clinical problem identification; proposal of a model or solution; or model prototyping, development, or validation. These studies scored ≤5 on the TRL scale for clinical readiness [7]. A few (6/86, 7%) studies scored ≥6 on the TRL scale (ie, they described real-time testing of AI models, workflow implementation, evaluation of clinical outcomes, or model integration). In total, 5% (4/86) of the studies, which were reviews of several different empirical studies, were not considered applicable to the TRL scale [30,31,52,57]. An overview of the included studies and their TRL scores is presented in Table 1.

Table 1. Technology Readiness Level (TRL) by Fleuren et al [7] of the included studies (n=82).

TRLs	Clinical definitions	Studies, n (%)
1	Clinical problem identification	0 (0)
2	Proposal of model or solution	0 (0)
3	Model prototyping	8 (9)
4	Model development	50 (58)
5	Model validation	18 (21)
6	Real-time model testing	1 (1)
7	Workflow implementation	2 (2)
8	Clinical outcome evaluation	1 (1)
9	Model integration	2 (2)

No studies were classified as TRL 1 or 2. A small number (8/86, 9%) of studies achieved TRL 3, indicating prototyping or model development of an AI system [46,82,86,93,98,103,105,108]. Examples of studies in this category include an AI-based field triage tool [82], triage of medical referrals [105], and a self-diagnosis system for emergency dental care [93]. A substantial number (50/86, 58%) of studies achieved TRL 4, that is, they demonstrated the potential of AI systems or optimized and validated these using clinical data. Examples of these studies include triage of adult chest radiographs [36], triage using digitalized patient histories in primary care [49], and triage of patients with COVID-19 under limited health care resources [69]. Several (18/86, 21%) studies were categorized as TRL 5. This means that they validated AI models using realistic datasets other than the population used to train or test the AI model. This particular type of validation data was either retrospective [48] or prospective [40]. One study attained a TRL of 6; it investigated the testing of an AI model in real time, specifically, an algorithm for automated diabetic retinopathy screening [28]. In addition, 2% (2/86) of the studies examined AI models integrated into clinical workflows and assessed their outcomes, resulting in an assessment of TRL 7 [29,87]. The

XSL•FO
RenderX

studies had a common theme of emergency care and focused on a symptom-taking tool [87] and a rapid and laboratory-free COVID-19 triage [29], respectively. One study achieved a score of 8 on the TRL scale, that is, it evaluated the clinical outcomes of an implemented AI model. This study examined a medical history–taking system that generated differential diagnoses in an outpatient department [65]. In total, 2% (2/86) of the studies focused on the postimplementation phase of AI systems and thus achieved the TRL 9 [63,81]. One study focused on the impact of cultural embeddedness when implementing an AI system for emergency care triage [63]. Another study investigated the user demographics and levels of triage acuity of a symptom checker chatbot used within a large integrated health system [81].

RQ4: Facilitating Factors and Barriers to the Introduction of the AI Systems

From the 6 retrieved studies that reported the introduction of AI systems for automating medical history taking and triage in health care, we identified 4 themes relating to facilitating factors and barriers to their introduction [52,57,63,65,81,87]. The themes were related to technical aspects, contextual and cultural factors, end users, and evaluation (Table 2). The theme denoted as *technical aspects* pertained to the AI systems' design, integration, requirements, and performance. The theme of *contextual and cultural* factors was associated with the organization and patient populations in which the AI systems were introduced. The theme *end users* encompassed the viewpoints and experiences of patients and health care professionals with regard to AI systems. The theme *evaluation and regulation* covered various aspects of evaluating, regulating, and setting guidelines for AI systems.

Table 2. Facilitating factors and barriers to the introduction of artificial intelligence (AI) systems.

	Facilitating factors	Barriers
Technical aspects	• Flexible design of AI system [52] • Integration with existing technical systems [87]	• Requirements of AI system [52] • Insufficient performance of AI systems [63,65,87] • Lack of integration with existing technical systems [57]
Context and culture	• Understanding of a setting's organizational context, clinical workload, and cultural competence [63]	• Delays in the start-up of AI systems [57] • Highly mixed patient populations, which was a challenge for the AI system [87]
End users	• Consideration of patient's perspectives [57] • Adequate training and the possibility to understand the AI system [52,63,81] • Innovative methods for promoting use among health care professionals [57] • Communication of benefits of using the AI system [52,63]	• Lack the acceptance of diagnosis provided by the AI system [65] • Negative receptivity among health care professionals [63] • Health care professionals' lack of time [65] • Low comprehensiveness among specific patient groups [87] • Lack of eHealth literacy among patients [57,87] • Insufficient language skills among patients [87] • Low number of users [57] • Lack of opportunities for patients to learn how to use the system [87]
Evaluation	• Formulation of evaluation guidelines and regulations [57] • Initial and ingoing and evaluation [57] • User-focused evaluation [87]	• Lack of regulation and guidelines for evaluation [57] • Lack of external validation [52]

Of the 6 studies, 5 (80%) reported factors related to technical aspects of the introduction of AI systems for automating medical history taking and triage that either facilitated or hindered its introduction into clinical settings [52,57,63,65,87]. Technical facilitators included a flexible design that allows the AI system to be implemented in different geographical areas [52]. Furthermore, doctors and nurses perceived that integrating AI systems with electronic health records would enhance their usefulness [87]. Technical barriers involved the amount of information required by AI systems, which might not be possible to collect in the short time required for the triage process in emergency departments [52]. An additional issue to consider was the inadequate performance of AI systems. This was due to their lack of cultural understanding of the context and the patient population they served [63], limited accuracy, particularly when dealing with patients with complex presentations, such as older adults [65], and the absence of optimization for certain patient groups, such as those with neurological symptoms [87]. The lack of integration with established health care systems constituted an additional barrier associated with the technical attributes of the AI systems [57].

A total of 3 (50%) of the 6 studies reported facilitating barriers related to context and culture [57,63,87]. Facilitating factors included greater integration of the AI system into the clinical workflow, as nurses and physicians believed this would enhance its usefulness [87]. In addition, the knowledge of the organizational context, clinical workload and culture, skills, and recognized behavior change techniques should be considered

XSL•FO
RenderX

when implementing AI systems. Contextual and cultural barriers included delays in the start-up of AI systems due to strategic decision-making processes [57] and the use of these systems in settings with highly mixed patient populations, such as emergency departments. This posed a challenge for AI systems, as reported by physicians, ultimately impacting their usefulness [87].

Of the 6 studies, 5 (80%) reported facilitating factors and barriers in relation to end users [52,57,63,81,87]. The consideration of patients' perspectives in adapting the AI system for accessibility and usefulness as well as innovative approaches to promote use among health care professionals, such as having superusers [57], were identified as facilitating factors. Other factors that facilitated the introduction of AI systems for automating medical history taking and triage included providing adequate training for health care professionals, as this is crucial given the systems' dependence on their users, and enabling them to effectively use the system [52,63,81] while also supporting patients through familiar health delivery mechanisms [81]. In addition, effective communication regarding the potential benefits of AI systems in enhancing patient care, resource use [52], and patient outcomes [63] was found to facilitate their adoption. Notably, the significance of the latter aspect was emphasized for its widespread uptake [63]. End-user barriers to the uptake of the AI system included physicians' nonacceptance of AI-generated diagnosis [65], negative receptivity toward rapid implementation [63], and health care professionals constrained by limited time to use the AI system [87]. In addition, a lack of comprehension among certain patient groups (such as those with neurological symptoms), inadequate eHealth literacy [57,87], linguistic deficiencies in patients (specifically, in expressing complaints in a way that the AI system can understand) [87], and limited opportunities for patients to acquire the necessary skills to use AI tools, due to limited occasions for using it [57,87], were additional barriers linked to end users.

Facilitating factors and barriers related to evaluation were reported in 50% (3/6) of the studies [52,57,87]. Factors suggested to facilitate the introduction of AI systems were the formulation and implementation of evaluation guidelines and regulations to ease the development and use of AI systems [57]. Initial and ongoing assessments of AI systems and evaluations focused on users were facilitating factors for assessing the safety and effectiveness of introducing AI systems in complex environments [87]. Barriers related to evaluation included the current lack of evaluation regulations and guidelines [57] as well as the validation of AI systems [52].

Discussion

Principal Findings

The goal of this study was to analyze and compile existing empirical studies on AI systems used for automating medical history taking and triage in health care. This review shows that research on AI systems to automate medical history taking and triage in clinical settings is still at an early stage, articulating a large gap to be bridged between model development and the bedside, similar to what has been highlighted in previous research on AI in health care [7,15,16,115,116]. There is a paucity of studies demonstrating AI systems to automate medical history taking and triage in clinical settings, representing the perspectives of patients or health care professionals, and providing information on facilitators and barriers to the introduction of these AI systems. The findings on the state of research in this area should be understood in light of some of the characteristics of the included research studies, indicating that research on AI systems to automate medical history taking and triage in health care remains relatively new and underdeveloped, and is mainly conducted in a nonclinical research environment of prototyping, development, and validation. While it is crucial to establish a solid research foundation that tests and validates AI systems before their implementation in clinical settings, which could potentially impact care quality, safety, clinical outcomes, and working conditions for health care professionals, it is also essential to conduct research that puts these systems into practical use to showcase their potential [117]. However, the current level of research on AI systems for automating medical history taking and triage remains inadequate.

Characteristics of the Research Publications

The study revealed a notable surge in research on AI systems for automating medical history taking and triage over the past 3 years, indicating a growing interest in leveraging AI technologies in relation to managing patient flows in health care settings. Geographically, research was predominantly concentrated in Asia, North America, and Europe, aligning with regions known for both advanced health care infrastructure and research capabilities. The prevalence of studies focusing on emergency and primary care underscores the potential of AI systems to automate medical history taking and triage in first-line care, which globally faces challenges in meeting the needs of the people it is intended to serve [118,119]. Many (12/86, 14%) studies also focused on radiology, illustrating the potential of AI systems to assist radiologists in image triage, a finding that is not surprising, given the progress of AI in image recognition tasks [120]. However, a significant (15/86, 17%) proportion of studies did not specify the clinical context, suggesting the need for more context-specific investigations to better understand the applicability of AI systems for medical history taking and triage. A large number (31/86, 36%) of studies also had a retrospective design, which, together with the large group of non-context–specific studies, may indicate a trend toward horizontal research rather than toward the implementation of AI systems for automating medical history taking and triage in clinical settings. As previous studies have suggested, this type of research and development may be partly due to the challenges of conducting studies that actually implement AI in real clinical settings [116]. The most common type of AI system was hybrid models that performed tasks related to forecasting or recognition. These findings resonate with previous research on the ways in which machine learning has been used to predict the flow of patients through health care systems [3]. Most (70/86, 81%) studies used patient datasets as their sample population, comprising patient records that were used to test, validate, and prototype AI models. This also meant that they focused on the technical capabilities of AI systems to

XSL•FO
RenderX

automate medical history taking and triage based on a specific set of patient records, rather than their usability for health care professionals or patients.

Perspectives Described in the Publications (Among Researchers, Health Care Professionals, or Patients)

While the promise of AI systems for automating medical history taking and triage to transform health care is well recognized, this study highlights an imbalance in stakeholder perspectives in the current research. Researchers' viewpoints overwhelmingly dominated the literature. Despite providing insights into the description and interpretation of AI systems designed for medical history taking and triage, there has been limited exploration of the critical viewpoints stemming from patients and health care professionals regarding their practical application in clinical settings. Previous research has argued that the imbalance between different stakeholder groups' perspectives in research on AI in health care should be addressed to meet the distinct needs of different groups [121]. Furthermore, the importance of the acceptability of interventions in routine health care practice is widely recognized in the fields of intervention, innovation, implementation, and improvement science [117]. Therefore, it is essential to consider the views of patients and health care professionals regarding the use of AI systems to automate medical history taking and triage. This will help to ensure the successful implementation of these systems. The positive feedback from patients on usability and support in patient-clinician communication from AI systems for automating medical history taking and triage emphasizes the potential benefits of involving patients in the design and evaluation of such systems. Previous research investigating a rule-based, automated medical history–taking app [122] even deemed patient involvement in the development process of these types of tools necessary. One additional study delved into health care professionals' perspectives, focusing on concerns and adjustments when integrating AI systems for automating medical history taking and triage into the triaging processes. The study found that nurses were uneasy with the AI system's acontextual nature [63]. To increase trust in AI systems, researchers suggest that focusing solely on technical aspects, such as objectivity, efficiency, and accuracy, is insufficient. AI systems must also be aligned with the values and principles of the clinical environment in which they are used. This is crucial because people are more inclined to trust and embrace AI systems when they perceive them as aligning with the inherent value, significance, and utility of the context in which they are deployed [123].

Stages of the Innovation Development Process: TRLs

The application of the TRL framework [7] provided a structured understanding of AI systems for automating medical history taking and triage development stages. Most (76/86, 88%) studies focused on lower TRLs, which aligns with the prevalence of studies that emphasize developmental work and potential demonstrations in the broader field of applying AI in health care [15]. This disparity underscores a critical gap in our understanding. This highlights the pressing need for more comprehensive investigations into the practical implementation and validation of AI systems in real health care settings. These higher TRL evaluations are pivotal in ensuring that AI technologies not only show promise in controlled environments but also prove their effectiveness and reliability when deployed in complex and dynamic safety-critical settings in health care practice [124]. Such research can contribute significantly to building trust and confidence in AI systems within the medical domain and promoting their implementation and use in practice.

Facilitating Factors and Barriers to the Introduction of AI Systems

The introduction of AI systems for automating medical history taking and triage is a complex process influenced by several factors, both hindering and facilitating its implementation. One set of barriers described lies in technical aspects, encompassing system performance and integration. The effectiveness and seamless integration of these AI systems into existing health care workflows will significantly impact their adoption and use. In addition to the technical issues, contextual and cultural factors are also important. The organizational context within health care settings as well as the diversity of patient populations shaped adoption. Different health care institutions, stakeholder roles, and patient perspectives may have unique requirements and expectations regarding AI integration in health care [9,125]. Recognizing the importance of stakeholder and patient perspectives highlights the need for tailoring AI systems to cater to context- and situation-specific needs and concerns [9,126,127]. Regulatory and evaluative considerations add another layer of complexity to the integration process. The development of guidelines and user-focused evaluations is essential to ensure the safety, efficacy, and ethical use of AI systems in health care [128-130]. These considerations underscore the need for a well-structured and carefully monitored approach to the implementation of AI in medical history taking and triage.

Limitations

The study's strengths include a thorough review of records with rigorous screening. The search strategy covered 5 electronic databases, ensuring comprehensiveness. However, it missed the opportunity to explore gray literature, which could have revealed additional cases that may present ongoing or completed work not yet in the research literature. We decided not to include conference proceedings in this review due to their often preliminary nature and limited analysis [26]. Upon examining the conference papers identified in the search, it became evident that they represented a diverse array of formats and scopes and varied significantly in how they were quality assessed and made accessible. This heterogeneity posed a challenge for their integration into a pooled analysis alongside more uniform and rigorously peer-reviewed papers. Nevertheless, in instances where the evidence is limited or contradictory, which is often the case in research on AI, the incorporation of conference proceedings can prove advantageous for systematic reviews [26]. Therefore, it is recommended that future reviews in this domain of research consider the incorporation of high-quality conference proceedings. We did not manually search the reference lists of the included studies to add more content to the search because an as stringent as possible review of the current literature was sought. Identifying studies focusing on

XSL•FO
RenderX

AI systems can be a complex task due to the lack of consensus on their definition. To ensure clarity for the reader, we have aimed to be transparent about how we define AI systems in this review. To maintain clarity, we based our inclusion on how the original authors described their systems as AI, relying on their accuracy. Because AI definitions vary, this introduces subjectivity, potentially affecting the consistency and comparability of the included articles. We suggest that future research consider this challenge in greater depth. We used a search strategy similar to that used in previous scoping reviews to identify AI systems [15,16]. The studies reviewed in this study concentrate on medical history taking and triage, both crucial processes for managing patient flow by assessing a patient's condition and referring them to the appropriate care. However, it is important to note that this approach may have some limitations. Therefore, we recommend that future research conduct separate literature reviews for each of these patient flow management processes. The eligibility criteria for study publication dates were set to identify any early studies on the topic of this review, despite AI applications in health care being a more recent phenomenon [131]. To ensure consistency, all full-text screening decisions were confirmed in pairs and discussed at biweekly meetings. This approach encouraged open discussions to address doubts, exclusion criteria, and differing interpretations. Conflicting interpretations and uncertainties were resolved through discussion.

Conclusions

This scoping review contributes to the understanding of AI system implementation in health care by providing insights into current trends, stakeholder perspectives, innovation development stages, and influencing factors. It highlights gaps in patient perspectives and the underrepresentation of higher TRLs, indicating opportunities for further research. To realize the full potential of AI systems for automating medical history taking and triage in health care settings, it is crucial to integrate patients' voices into AI development, enhance real-world validation, and address the multifaceted challenges highlighted by end users and regulations. As health care systems evolve, embracing AI technologies while ensuring alignment with clinical and patient needs remains a key challenge for future research and implementation efforts. These multifaceted factors collectively shape the landscape of AI system adoption in the context of automating medical history taking and triage. Therefore, a holistic and inclusive approach is necessary to ensure the effectiveness and ethical use of these types of AI systems.

Abstract

Background: Patients are increasingly being provided with access to their electronic health records. However, in mental health care contexts, concerns have been raised due to a perception that such access would pose risks to patients, third parties, and the therapeutic relationship. These perceived risks may affect the information practices of health care professionals (HCPs) and patients, such as how they document, share, and use information in mental health care services with a patient-accessible electronic health record (PAEHR). Although there is growing research interest in PAEHRs, no study has specifically examined how they impact information practices. Understanding the impacts on information practices may help explain other outcomes of implementing PAEHRs and inform their design.

Objective: This scoping review aimed to explore the research on PAEHRs in mental health care contexts and how PAEHRs affect information practices of HCPs and patients in this context.

Methods: A scoping review was considered the most appropriate method due to the relatively recent adoption of PAEHRs in mental health care contexts and the heterogeneous nature of the evidence base. A comprehensive search of electronic databases was conducted for original empirical studies that described the use of PAEHRs or associated systems in mental health care contexts. One author reviewed all full texts, with 3 other authors reviewing a subset of studies. The study characteristics and findings were documented, and a thematic synthesis and textual narrative analysis were used to develop descriptive and analytical themes that addressed the research questions.

Results: A total of 66 studies were considered eligible and included in the analysis. The impact of PAEHRs on information practices in mental health care contexts included the following: (1) they may change how HCPs document patient information, including a reduction in detail and a focus on information perceived by HCPs as objective rather than subjective; (2) they may negatively impact workflows due to changes in documentation practices and limited guidance for HCPs on how to use PAEHRs; and (3) they may contribute to improved communication between HCPs and patients, including constructive disagreements regarding what is documented in the health record. The changes to HCP information practices were influenced by a concern for the therapeutic relationship and patient safety. Furthermore, PAEHRs supported new information practices for patients, such as using their PAEHR to prepare for clinical encounters.

Conclusions: We have identified several ways in which PAEHRs shape the information practices of HCPs and patients in the mental health context. These findings can inform the design of PAEHRs to promote information practices that contribute to improving the quality of mental health care. Further research is necessary to understand how changes in information practices due to the implementation of PAEHRs impact clinical outcomes and patient experiences of care.

patient-accessible electronic health records; patient portals; psychiatry; mental health; health informatics; mental illness; scoping review

Introduction

Background

Patients in many high-income countries, such as Australia, the United States, the United Kingdom, France, and the Netherlands, have a legal right to request access to their health records [1,2]. Traditionally, patients have had to apply for a copy of their paper-based health records, which can hinder easy access and efficient use of their health information [3]. There is a growing movement to make it easier for patients to access their health information by providing electronic access to their health records. This shift toward online access has been enabled by the widespread adoption of electronic health records (EHRs) [2,4].

Providing patients with access to their health records can improve their disease management, self-care, and understanding of their health conditions [5], while facilitating more productive discussions between health care professional (HCPs) and patients [5-7]. Mental health care contexts have been slower to adopt patient-accessible EHRs (PAEHRs), and in some cases limitations have been placed on patients with mental health conditions accessing their PAEHR [8-12]. There are various concerns regarding the use of PAEHRs in mental health care contexts, including the impact on third parties, such as relatives whose information may be documented in the record and the risk that patients will experience distress from reading their PAEHR [11,13].

The digitalization of patient health records has impacted the information practices of HCPs and patients, changing the way they seek, document, and share information [14]. We use the concept of information practices to capture how information activities, such as documentation, are situated in and shaped by specific contexts [15]. Østensen et al [16] defined information practice as "a socially constructed practice that determines how information is produced, organized, disseminated, distributed, reproduced and circulated in the community, and which specific types of information are legitimized." The concept of information practice is used in this study because it encourages consideration of factors unique to mental health care contexts, such as stigma and risk management, which may shape HCPs' and patients' information activities [17,18].

Several technologies are available to provide patients with access to parts or all of their health record, including electronic personal health records (ePHRs) and patient portals. A range of initiatives, such as OpenNotes and Blue Button, implemented predominantly in the United States and across several Nordic countries, have promoted immediate patient access to their EHRs via patient portals [19-21]. Both personal EHRs (pEHRs) and patient portals can be defined in comparison to EHRs, which are the digital clinical records held by a health service and accessible only by HCPs [22,23]. Patient portals provide patients with access to some parts of the EHR and a range of other functions, such as booking appointments [24]. In comparison, pEHRs are health records controlled by the patient, which may be linked to an EHR or stand-alone entities [25]. pEHRs may include a range of functions, such as capturing patient-generated data, such as biometric data from wearable devices, and providing access to educational material [26,27]. Beyond these simple definitions, there is substantial heterogeneity in the types, functions, architecture, and content of pEHRs and patient portals [26,28]. In this paper, because the focus is on patients' online access to their health records, we use the term PAEHRs. This term captures the range of technologies that give people complete or partial access to the information contained in their EHR. Other terms may be mentioned in this paper when referring to results from specific studies.

Several recent reviews have explored the use of PAEHRs [29-32], with 2 specifically in mental health contexts [9,24]. However, these studies have not considered the impact of PAEHRs on information practices and have usually focused solely on patient portals. Zhang et al [24] found that the factors for successful implementation and adoption of patient portals in mental health care contexts include education for patients, the perceived value of the portal by patients, how easy it was for patients to use the portal, attitudes of HCPs toward using the portal, and adequate staffing and staff training to support the use of the portal. Schwarz et al [9] found that patients reported various positive experiences of using patient portals, such as increased empowerment and trust in clinicians, while negative experiences were related to inaccuracies in their records or disrespectful language. HCPs reported more concerns than benefits, including increased documentation burden and possible harm from patients reading their records. These studies reflect the growing prevalence and interest in PAEHRs in mental health care contexts. However, research is needed to consider the impact of PAEHRs on information practices because changes to information practices, such as HCPs documenting less information, may impact the quality and safety of care provided in mental health care settings.

This paper builds on our previous scoping review where we found that EHRs promote standardized and formalized documentation practices that often conflict with the prevalent use of narrative free-text information in mental health care settings [15]. The review also found that HCPs had concerns about documenting sensitive information in EHRs due to the increased ease of access by other HCPs [15]. The previous scoping review suggests that changing what is documented, how it is documented, and who can access information in the health record may alter clinicians' information practices. Other studies have found that adopting EHRs affects patients' intention to disclose certain information [33,34]. Thus, it could be assumed that the introduction of PAEHRs may impact HCPs' and patients' information practices.

This review has the following objectives and research questions:

1. How do PAEHRs change the information practices of patients and HCPs in mental health care contexts?

XSL•FO
RenderX

2. What effects do changes in information practices have on other aspects of care, including the therapeutic relationship, risk management, information sharing, and patient experience?

A Note on Language

In this study, we used the term *patient* when referring to people accessing and using mental health services. We chose this over other terms, such as client or service user, mainly because many of the PAEHR technologies reference "patients" in their name (eg, patient portal), and we wanted to avoid causing confusion by using another term. We acknowledge that the term *patient* can be considered disempowering and that the terminology in this space is not settled.

The title of this paper refers to *mental health care contexts*, which is used to capture the broad range of clinical and nonclinical services people may access when experiencing mental health issues [35].

Methods

Overview

Scoping reviews facilitate consideration of a broad range of evidence, methods, and study types in relatively new or heterogeneous research fields [36]. Because PAEHRs in mental health care contexts are relatively new and information practices have received limited consideration in the literature, we considered a scoping review an appropriate method to address the research objectives [37,38]. We were informed by the framework for scoping reviews by Arksey and O'Malley [36] and the relevant criteria outlined in the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Multimedia Appendix 1) [39]. No protocol was published for this review.

Study Selection

The inclusion and exclusion criteria are outlined in Textbox 1. We chose to include soon-to-be-implemented PAEHRs, which we defined as systems that had been announced or were planned for implementation, for 3 reasons. First, if we were to publish an updated review, it would provide us with the opportunity to compare pre- and postimplementation studies. Second, perceptions of a PAEHR may influence practices as much as using a PAEHR [40,41]. Third, in our initial reading of the literature, we noticed that often PAEHRs had low use by HCPs or had only been recently implemented. Thus, there may be little difference between perceptions in the lead-up to implementation and perceptions after implementation if the PAEHR has not been widely used.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Articles describing original empirical research
- Research conducted in a mental health care context (eg, psychiatric hospital) or with participants who have a lived experience of mental illness (eg, patients in a primary health care context with a diagnosis of depression)
- Studies published up to September 2023
- Studies focused on the implementation of a system for allowing patients with mental health conditions to access their health record or about the perception of an imminent implementation of such a system or studies that sought input from people with involvement in the design, adoption, use, or evaluations of patient-accessible electronic health records

Exclusion criteria

- Studies with no methodology
- Studies with no full text in English
- Protocol papers, commentaries, or posters
- Studies exploring health care professionals' or patients' general perceptions about access to online mental health records
- Studies where the participants are children or adolescents, or the study is conducted in the youth mental health system
- Studies conducted in forensic mental health care settings
- Scoping reviews or systematic reviews

Search Strategy

We searched Scopus, Embase, Web of Science, MEDLINE via PubMed, PsycINFO, and CINAHL using a combination of key terms summarized in Textbox 2. A search was also conducted on Google and ResearchGate. The search strategy was developed iteratively alongside further identification of key terms in the literature and hand searching reference lists of relevant studies. The initial search was undertaken in late 2018 and updated in December 2022, with new papers continually identified until September 2023, when the final draft was completed.

XSL•FO
RenderX

Textbox 2. Example search strategy used in Scopus.

(TITLE-ABS-KEY (“patient portal” OR “open*notes” OR “personal electronic record” OR “personal electronic health record” OR “personal electronic medical record” OR “personal medical record” OR “personal health record” OR “pEHR” OR “pEMR” OR “patient*controlled personal health records” OR “shared medical record” OR “patient controlled record” OR “patient*held medical record” OR “patient*controlled journal” OR “patient*controlled electronic health record” OR “blue button” OR “health record portal” OR “consumer portal” OR “patient access to health record” OR “PHR” OR “ePHR” OR “patient accessible record” OR “patient*shared record” OR “patient*carried record” OR “patient*held record” OR “patient internet portal” OR “patient accessible electronic health record” OR “patient access to record”) AND TITLE-ABS-KEY (“psychiatr*” OR “mental illness” OR “mental health” OR “mental health services” OR “behavioral health*” OR “mental healthcare” OR “mental health care” OR “mental health nurs*” OR “schizophrenia” OR “bipolar” OR “depression” OR “anxiety” OR “personality disorder” OR “psychosocial”))

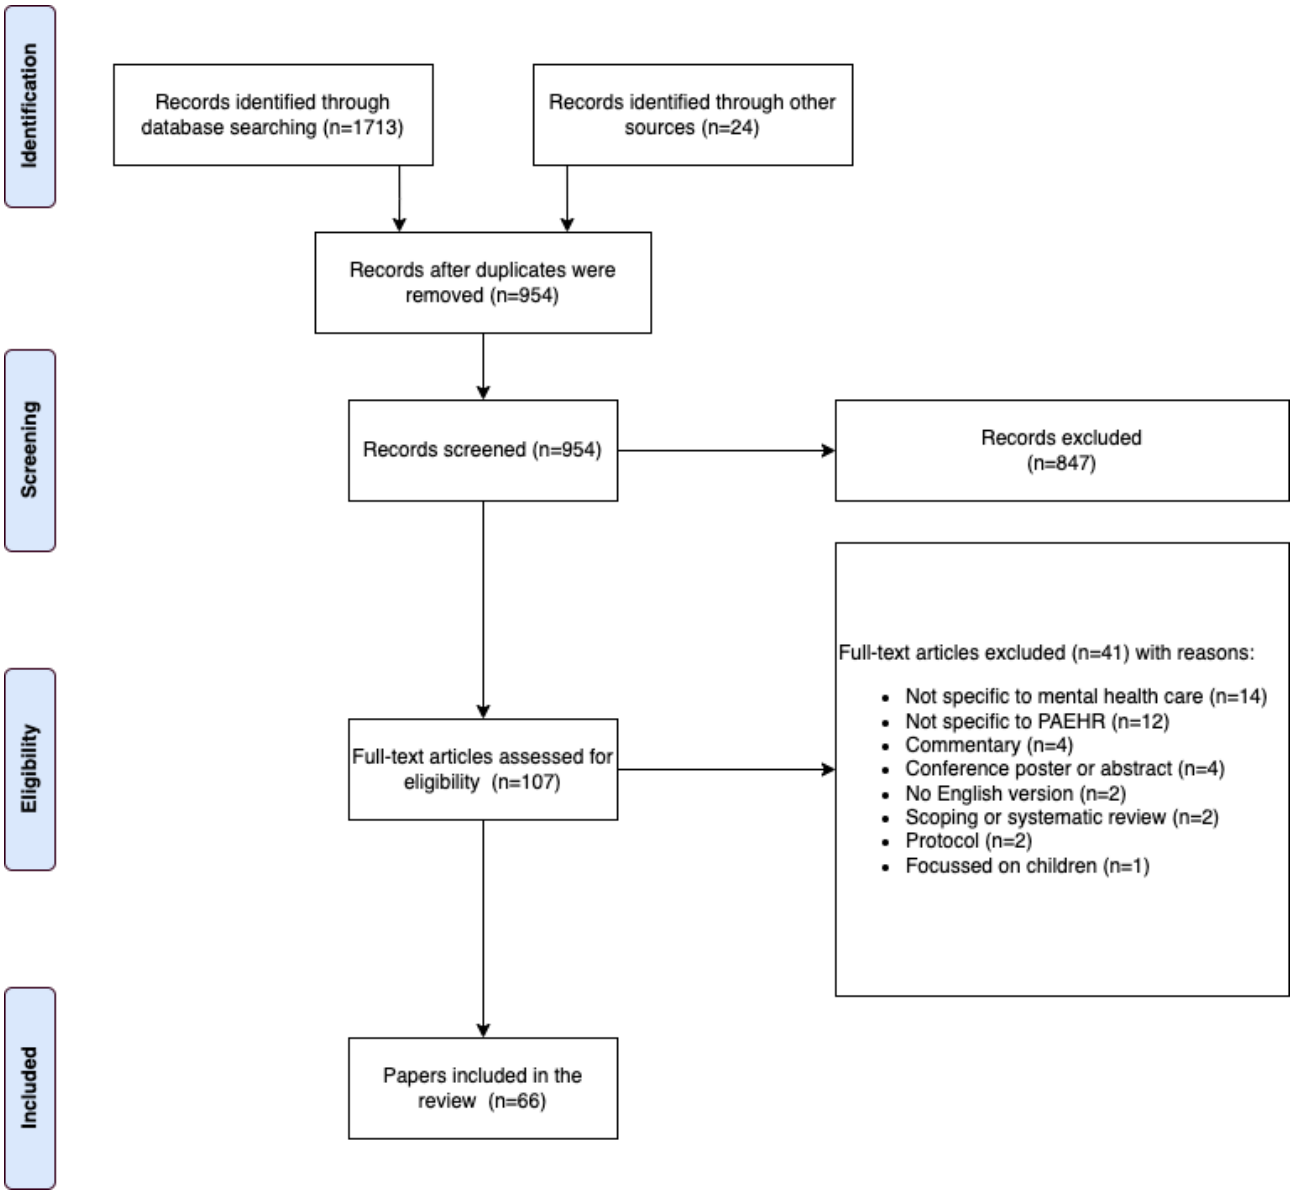
Screening Process

After removing duplicates, TK screened the titles and abstracts against the inclusion criteria to identify relevant studies for full-text screening. TK reviewed all full-text articles using the inclusion and exclusion criteria. TK identified 23% (15/66) of the studies for which it was unclear whether they met the inclusion criteria. The other 3 authors (MP, KG, and SC) each reviewed one-third (5/15, 33%) of these studies to determine whether they should be included. The authors worked together to resolve disagreements and determine the final articles for inclusion in the review. There were a few disagreements regarding studies in which the use of the PAEHR was minimal, as it was part of a larger study or intervention. Furthermore, 23% (15/66) of the studies that did not clearly meet the inclusion criteria were included after a discussion between the authors.

Analysis of Included Studies

Due to the breadth of the study designs and objectives, covering a range of qualitative and quantitative methods, we adopted a textual narrative and thematic synthesis approach, as has been done in similar studies [15,42,43]. The textual analysis involved tabulating study findings alongside study characteristics and conclusions in a spreadsheet. The study characteristics we planned to document included the country where the study took place, year of publication, study design and method, participant characteristics, research focus, type of PAEHR, implementation status, and functions of the PAEHR. TK extracted these data from each paper into a spreadsheet, which was discussed with the research team to ensure its completeness.

Using the thematic synthesis approach described by Thomas and Harden [44], we developed descriptive themes by coding both direct participant quotes and researcher interpretations from the qualitative studies into a mind map. Our research questions framed this coding process, in that we coded findings related to how HCPs and patients used the PAEHR to manage information, how the PAEHR changed how HCPs and patients managed information, and findings related to issues raised in the Introduction section of this paper. Related codes were clustered together to develop descriptive themes. We intended these descriptive themes to stay as close to the original findings as possible. We integrated the quantitative data extracted during the textual synthesis into the descriptive themes. Finally, using our review questions, we developed analytical themes that sought to consider the impact of the PAEHRs on the information practices of HCPs and patients. This process is necessarily subjective and relied on the researchers’ judgment and insights [44,45]. To ensure the validity of the themes, TK undertook the initial descriptive analysis before seeking feedback from the research team to ensure the themes aligned with their understanding of the included studies and research questions. Similarly, TK developed the analytical themes before seeking feedback from the research team.



Results

Overview

The search strategy identified 1713 studies. Another 24 studies were identified through hand searching and other sources, including Google and ResearchGate. After removing duplicates, of the 1737 studies, 54.92% (n=954) were identified for screening. After screening the titles and abstracts, of the 954 studies, 11.2% (n=107) met the inclusion criteria. Of the 107 articles reviewed in the full text, 38.3% (n=41) were excluded, and 61.7% (n=66) were included (Figure 1). Details of the included studies are outlined in Multimedia Appendix 2.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram. PAEHR: patient-accessible electronic health record.

Study Characteristics

The following sections report on the characteristics of the included studies that were identified in the textual synthesis.

Country

The top 3 countries where the studies were conducted were the United States (29/66, 44%), Canada (13/66, 20%), and Sweden (9/66, 14%). Table 1 provides a more detailed breakdown of the countries where the included studies were conducted. The main difference across countries was whether there was a national patient portal system, such as in Sweden, compared to a patient portal implemented across a specific service or set of services, such as the US Veterans Affairs My HealtheVet.

XSL•FO
RenderX

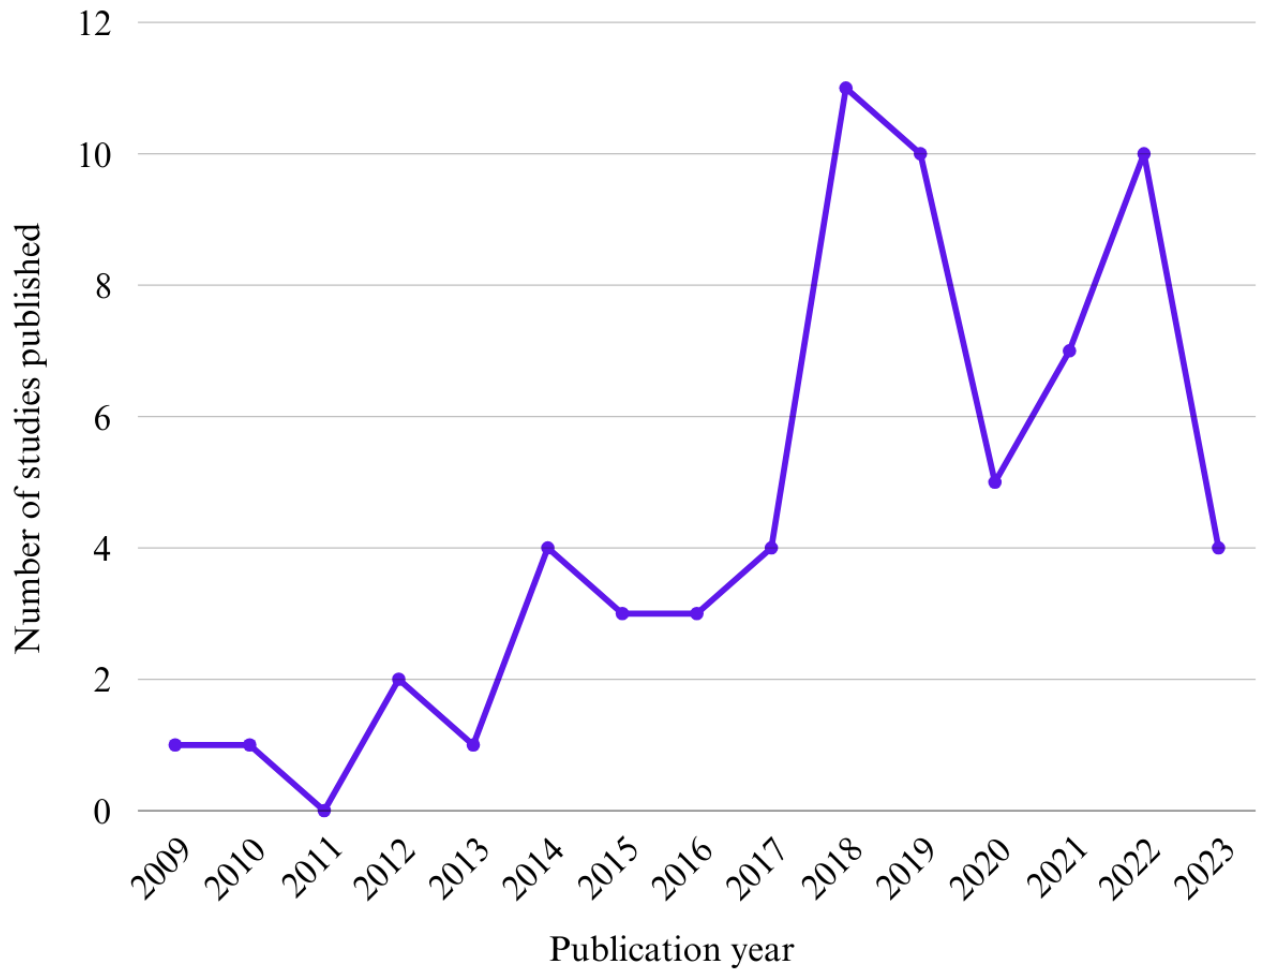

Table 1. Countries where the studies were conducted (N=66).

Countries	Studies, n (%)
United States	29 (44)
Canada	13 (20)
Sweden	9 (14)
Norway	4 (6)
The Netherlands	2 (3)
United Kingdom	3 (5)
Germany	2 (3)
New Zealand	1 (2)
Multiple countries	3 (5)

Year of Publication

The included studies were published in the period from 2009 to 2023 (the cutoff year for inclusion). The highest number of studies was published in 2018 (11/66, 17%), followed by 2019 (10/66, 15%) and 2022 (10/66, 15%). There is an overall upward trend of studies published on PAEHRs in mental health care contexts since 2009, with some fluctuations in recent years, as illustrated in Figure 2. Due to the varied level of detail reported in the included studies on the functions and technical features of the PAEHRs, we did not evaluate how PAEHRs have changed over time.

Figure 2. Increasing trend in publications on patient-accessible electronic health records in mental health care contexts.

Study Design and Method

There was a mix of quantitative (29/66, 44%), qualitative (22/66, 33%), and mixed methods (15/66, 23%) approaches used in the included studies (Table 2). The main methods used were surveys (27/66, 41%), interviews (18/66, 27%), and interventions or trials involving a PAEHR (13/66, 20%).

[c]We did not report the specific methods of intervention studies; instead, we just categorized them as interventions.

Participants

Most studies (37/66, 56%) included only patients as participants, while 27% (18/66) of the studies included only HCPs, and 15% (10/66) of the studies included both patients and HCPs. Table 3 provides a more detailed breakdown of participants. Nurses were the most represented HCPs, followed by social workers, psychologists, psychiatrists, and physicians. Family members, carers, and peer workers were rarely involved as participants in the included studies.

Table 3. Participants in the included studies (N=66).

Participants	Studies, n (%)
Study sample (high level)	
HCPs[a]	18 (27)
Patients	37 (56)
Both HCPs and patients	10 (15)
Other or not specified	1 (2)
Study sample (detailed)	
Patients	48 (73)
Family and carers	3 (5)
Peer workers	3 (5)
Social workers	17 (26)
Psychiatrists	14 (21)
Psychologists	16 (24)
Mental health nurses, nurse practitioners, nurses, and nurse assistants	19 (29)
Physicians, doctors, general practitioners, and family physicians	14 (21)
Allied health—not including psychologists (occupational therapists, counselors, and physiotherapists)	5 (8)
Administrative staff	7 (11)

Research Focus

We compared the aims of the included studies and grouped them according to similar topic areas, as outlined in Table 4. Most studies focused on the general experiences and perceptions of HCPs (18/66, 27%) and patients (13/66, 20%) toward a PAEHR. Several studies also explored specific clinical interventions or models of care using a PAEHR (12/66, 18%) and adoption and use rates across different demographic groups (11/66, 17%).

Patients' experience and perspectives of PAEHR	13 (20)
Interventions using a PAEHR	12 (18)
Adoption and use of PAEHR by different patient groups	11 (17)
Design and usability of PAEHR for patients	7 (11)
Barriers and facilitators to patients using PAEHR	4 (6)
HCP or patient perspectives of the impact of PAEHR on therapeutic relationships	5 (8)
Exploring how education or training can support the use of PAEHR by an HCP or patient	3 (5)
Describing policies related to PAEHR	2 (3)
Exploring the impact of PAEHRs on transparency in the clinical encounter	2 (3)
Perceived benefits, harms, or risks of PAEHRs	2 (3)
Other (exploring errors in PAEHR, changing HCP practices, family or carer perceptions, reasons patients do not adopt PAEHR, perspectives on the needs of patients and clinicians when using OpenNotes, and impact of PAEHR on medication adherence)	6 (9)

[a]Some studies included multiple research aims and thus were counted twice.

[b]HCP: health care professional.

[c]PAEHR: patient-accessible electronic health record.

PAEHR System Used

There were several challenges in defining the PAEHR system used in each study. Most studies (26/66, 40%) discussed patient portals or OpenNotes generally without specifying a specific product or whether the system was a patient portal of ePHR (Table 5). Some studies discussed systems that appeared to be implemented at the national or health system level, although it was difficult to discern across studies if the same system was being discussed.

Table 5. Patient-accessible electronic health record (PAEHR) systems reported in the included studies (N=66).

Type of PAEHR	Patient portal or ePHR[a] (categorized by author)	Studies, n (%)
Lawson Smart Record	ePHR	4 (6)
Veterans Affairs My HealtheVet	Patient portal	13 (20)
Patient Portal—general (including OpenNotes)	Patient portal	26 (40)
Swedish Journalen	Patient portal	8 (12)
Helsenorge.no [46-49]	Patient portal	4 (6)
ePHR—general	ePHR	6 (9)

Implementation Status

Most studies (51/66, 77%) reported on a PAEHR that had been implemented (Table 6).

XSL•FO
RenderX

Table 6. Implementation status of patient-accessible electronic health record (PAEHR; N=66).

Implementation status of PAEHR	Studies, n (%)
Implemented PAEHR	51 (77)
Soon-to-be-implemented PAEHR	5 (8)
PAEHR being designed as part of the study	3 (5)
Not applicable (expert perspective)	2 (3)
Partial implementation, including if some participants were using or had access to the PAEHR	3 (5)
Pre-post implementation	1 (2)
Unclear	1 (2)

Functionality of PAEHR

The included studies did not provide enough information for a thorough analysis of the functions available across the different PAEHRs. Therefore, we only address specific elements of functionality related to the themes discussed in the results of the thematic synthesis discussed in the Thematic Results section.

Study Quality

Due to the heterogeneity of the included studies and the lack of evaluation instruments that could be applied systematically across these studies, a quality evaluation was not deemed appropriate for this scoping review. It is optional for scoping reviews to evaluate the quality of the included studies [50]. One quality issue we identified during the review of the included studies was a lack of detail regarding the functionality and technical specifications of the PAEHRs, which Talmon et al [51] recommend should be reported in health informatics studies. We identified a lack of reporting on functionality and technical specifications in our previous scoping review of EHRs [15].

During the peer-review process, a reviewer identified that 4 articles were published in journals that they considered predatory. We concluded that publishing in a predatory journal is not necessarily an indication of the quality of the study, and thus, we decided to include these studies in the review.

Thematic Results

Overview

In the following sections, we report on the findings of the thematic synthesis of the 66 included studies. The analysis led to the development of 8 themes and 12 subthemes. The themes are outlined in Table 7. Illustrative quotes for each theme are provided in Multimedia Appendix 3.

XSL•FO
RenderX

Table 7. Summary of themes.

Themes	Subthemes
Theme 1: patient-accessible electronic health records (PAEHRs) change the purpose of the health record	—[a]
Theme 2: health care professionals (HCPs) change their information practices to protect the therapeutic relationship and patient safety	• Subtheme 2.1: PAEHRs introduce risks to the therapeutic relationship • Subtheme 2.2: PAEHRs introduce risks to patient safety • Subtheme 2.3: trust, transparency, and accuracy of information can mitigate the risks posed by the PAEHRs to the therapeutic relationship and patient safety • Subtheme 2.4: PAEHRs offer opportunities to enhance accountability and communication between HCPs and patients regarding the documentation of information
Theme 3: PAEHRs disrupt HCPs' documentation practices	• Subtheme 3.1: HCPs document less detailed information in PAEHRs, particularly relating to sensitive information • Subtheme 3.2: PAEHRs require HCPs to document information that patients will understand • Subtheme 3.3: PAEHRs require HCPs to take a person-centered approach when documenting potentially subjective information • Subtheme 3.4: HCPs limit the documentation of uncertain information in PAEHRs • Subtheme 3.5: HCPs may omit content or restrict access to PAEHRs
Theme 4: PAEHRs introduce changes to HCPs' information workflows	—
Theme 5: HCPs require tailored training, education, and guidelines on documenting information in a PAEHR	—
Theme 6: patients are empowered with new information practices if they are supported to use their PAEHR	• Subtheme 6.1: patients need support to use their PAEHR • Subtheme 6.2: PAEHRs must be easy for patients to navigate, access, and understand
Theme 7: PAEHRs raise new concerns about information privacy and security for HCPs, patients, and third parties	• Subtheme 7.1: PAEHRs pose challenges to managing third-party data • Subtheme 7.2: PAEHRs pose challenges to managing third-party access to patient information

[a]No subthemes.

Theme 1: PAEHRs Change the Purpose of the Health Record

HCPs perceived that the introduction of a PAEHR changed the purpose of the health record, with HCPs concerned by the increasing array of audiences they had to consider when documenting information [49,52-54]. This change was framed as a culture shift [55], with one HCP in the study by Denneson et al [53] describing it as "antithetical to the way that many of us have been, literally, trained and learned to think about our field." HCPs thought the way information was documented previously, which assumed that only other HCPs would access it, was inappropriate for patients and would pose risks such as worry, offense, or distress for patients [47,49,52,56]. Conversely, there was a perception that writing only for the patients may reduce the clinical value of the EHR [57]. HCPs in several studies also perceived a shift in control over the health records due to the ability of patients to access their health records in real time via their PAEHR [49,56,57]. Although patients may have previously been able to request access to their records, clinicians described having had more control over what was released and when it was released [49,53]. HCPs also felt they had less control over what patients might do with the information in their PAEHR, such as sharing it with third parties [58].

Theme 2: HCPs Change Their Information Practices to Protect the Therapeutic Relationship and Patient Safety

Overview

HCPs were concerned that PAEHRs would damage the therapeutic relationship because patients may not understand what is documented in their PAEHR or experience distress from reading their PAEHR. Some HCPs and patients recognized that PAEHRs could enhance the therapeutic relationship through improved transparency and communication about what was documented. However, the perceived risks appeared to be significant enough to change HCPs' information practices. These perceived risks are part of a broader perception, outlined in theme 1, that the purpose of the record changes when patients have access to it via a PAEHR and that this puts into question previous practices around what is documented, for whom, and for what purpose.

XSL•FO
RenderX

Subtheme 2.1: PAEHRs Introduce Risks to the Therapeutic Relationship

HCPs across several studies reported concerns that PAEHRs would negatively impact the therapeutic relationship due to patients not understanding what was written in their record or perceiving something written in their record to be a negative judgment about them [53,58-61]. This risk shaped many of the documentation changes described in theme 3. HCPs described a risk that patients might see a disconnect between what was written in their record and their in-person clinical experience [53]. For example, what HCPs document is not always the same information they would share with patients, such as clinical formulations [53]. HCPs in the study by van Rijt et al [58] perceived a risk that patients might feel "insulted, misinterpret the information given, or feel unheard," which in turn may negatively impact a patient's trust in the HCP. In comparison, patients in the included studies focused more on the benefits of the PAEHR for the therapeutic relationship, as considered in subthemes 2.3 and 2.4.

Subtheme 2.2: PAEHRs Introduce Risks to Patient Safety

HCPs across several studies reported a concern for patient safety, specifically that patients might find the PAEHR overwhelming and distressing or be triggered by reading their records [49,53,55,57-59,62]. For example, Turvey et al [62] reported that 55% (16/29) of HCPs in their study reported having patients who experienced significant distress after reading their records, while 29% (8/29) and 21% (6/29) of HCPs reported experiences of patients terminating treatment after accessing their records or reporting having engaged in "negative and/or self-destructive behavior toward themselves or others," respectively. These results do not specify how many patients had negative experiences of reading their PAEHR. Rather these results suggest that HCPs are coming across examples of patients' having negative experiences, which is shaping their perception of PAEHRs. These concerns could be considered through the lens of HCPs' ethical need to keep patients safe, with HCPs in the study by Jonnergård et al [63] identifying "patient safety" as the most important issue to be addressed in implementing OpenNotes. In addition, there were some concerns that PAEHRs might lead to increased violent behavior by patients. However, studies that explored these concerns did not find evidence of increased violent behavior from the adoption of PAEHRs in mental health contexts [64,65].

Patients were concerned about the risk of being upset by access to their PAEHR or experiencing anxiety when thinking about what might be written in their PAEHR [57,66]. For example, 11% (4/37) of patients reported "sometimes experiencing significant distress" after reading their record in the study by Turvey et al [62]. Denneson et al [67] found in patient survey that 26.4% (47/178) of patients sometimes, and 8.4% (15/178) often or always, "experienced stress or worry after reading their record," while 18% (32/178) of patients sometimes, and 8.4% (15/178) often or always, reported "feeling upset." A common reason reported for patients feeling upset after accessing their PAEHR was because they made the patients' problems seem smaller than they were [67]. Some patients in the study by Schwarz et al [68] also reported a fear of reading their records because of how confronting it may be to revisit the experiences they had shared with their HCPs during clinical sessions. Alternatively, accessing information in the PAEHR between appointments could reduce the anxiety of waiting to see the HCP [37]. Interestingly, the 1 study that compared patients with mental health diagnoses to patients without mental health diagnoses found no difference in perceptions, including the likelihood to report worry, toward viewing their records [69].

Subtheme 2.3: Trust, Transparency, and Accuracy of Information Can Mitigate the Risks Posed by the PAEHRs to the Therapeutic Relationship and Patient Safety

Trust and transparency mediated the potential negative impact of PAEHRs on the therapeutic relationship. Several studies found that PAEHRs could support the therapeutic relationship through improved transparency and trust [37,38,52,54,57,68], particularly when information in the PAEHR aligned with what was discussed in the clinical encounter [38,66,67]. For example, the study by Cromer et al [38] reported a negative impact on patients' trust in HCPs when they perceived low transparency about what was documented and when there was outdated information, mistakes, details that did not align with their recollection, or missing information. Similarly, patients in the study by Pisciotta et al [61] reported that the quality of information documented in their PAEHR was important to patients, including accurate notes that were not copied and pasted from previous sessions. Schwarz et al [68] described this as a "trust, but verify" situation, where patients valued the opportunity to confirm that HCPs understood them and their needs. Accuracy was also important, as patients were worried that inaccurate records could negatively affect their future treatment [38].

Subtheme 2.4: PAEHRs Offer Opportunities to Enhance Accountability and Communication Between HCPs and Patients About What Is Documented

Communication between HCPs and patients about the PAEHR and what was being documented was identified as important for building trust and strengthening the therapeutic relationship [38,50,52,53,57,66,67,70]. HCPs in the study by Denneson et al [53] discussed the role of communication, disagreements, and listening as important to consider when documenting in the PAEHR. In the study by Cromer et al [38], patients spoke of trust being built when HCPs listened to them, approached the relationship as an equal, and focused on the patient's strengths. Several studies suggested that communication about what was documented, even disagreements, could positively contribute to the therapeutic relationship [38,53,58,62]. Interestingly, Pisciotta et al [61] found that patients and HCPs avoided discussing health records for different reasons. HCPs were worried about patients challenging their records or requesting changes, and patients were worried about appearing difficult or offending the HCP. However, both HCPs and patients agreed that having a conversation about information before it is documented in the PAEHR is beneficial [61].

Although both HCPs and patients fear disagreements over what is documented in the PAEHR, disagreements could also provide an opportunity to improve accountability and communication [37,46,49,58,68,71]. Disagreements may come about due to legitimate errors in what was documented, a misunderstanding

XSL•FO
RenderX

of what was discussed and documented, or an actual disagreement between the HCP and patient as to what they understood was true [46,49,52,53,62]. However, these disagreements could improve the PAEHR by addressing errors or misunderstandings and providing opportunities to discuss issues that were previously left unspoken [46,54,58,71]. Patients commonly identified errors in their PAEHR; in a national Swedish survey by Bärkås et al [72], half of the respondents (1586/3131, 50.56%) from mental health care contexts reported finding an error, while a third (1089/3131, 34.78%) reported finding an omission. In addition, Bärkås et al [72] found that patients in mental health care settings were more likely to identify errors and rate them as serious than patients in other health care settings. Some HCPs saw the PAEHR as a way to increase accountability by having a feedback loop where patients could review their health record and report inaccuracies, errors, or misinterpretations [53,54]. Knowing that patients may disagree with what is written in the PAEHR may motivate clinicians to proactively discuss what they are documenting with patients and consider patients' needs when documenting information [53,61,62].

Although HCPs were concerned that some patients may try to dictate what should be written in their PAEHR and the care they receive [54], there was limited evidence of this occurring. For example, only 15.4% (~51/332) of HCPs in the study by Johansen et al [47] reported receiving patient feedback. However, this may be due to patients' low awareness of the PAEHR, as outlined in theme 6.

Theme 3: PAEHRs Disrupt HCPs' Documentation Practices

Overview

HCPs reported that giving patients access to their mental health records would lead to or had led to changes in how they documented information [47,49,53,57,58,61,65,73,74]. These changes were usually framed as an attempt to protect the therapeutic relationship from potential misunderstandings or to protect patients from distress caused by reading their health record. As outlined in theme 2, HCPs appear to take a risk-averse approach to PAEHRs due to a perception that patients may react negatively or experience distress from reading their PAEHR. However, HCPs also seem to recognize that certain ways of framing information about patients may trigger a negative reaction, disagreement, or distress. There was a lack of guidance, support, or training for HCPs on managing these risks when documenting information in a PAEHR [53,54,56,75].

Subtheme 3.1: HCPs Document Less Detailed Information in PAEHRs, Particularly Relating to Sensitive Information

Clinicians addressed perceived risks posed by the PAEHR by omitting or "watering down" information that the patient might perceive negatively [53,57-59,65,70,76]. Petersson et al [65], in exploring the adoption of OpenNotes in Swedish Psychiatric Care settings, found that 22% (147/667) and 17.7% (117/662) of HCPs surveyed were less candid in their documentation and took more time to edit notes, respectively. Similarly, 63% (127/~208) of HCPs in the study by Dobscha et al [59] reported that they are or plan to be less detailed in their documentation. One reason reported for including less detail was a perception that more detailed notes increased the potential for misinterpretation and disagreements [61]. An HCP in the study by Zanaboni et al [49] described it as not writing "things that you can keep to yourself," such as longer hypotheses. However, some HCPs considered that the benefit of documenting complete information outweighed the risks and that any harm could be repaired through discussions with the patient [49]. Patients preferred detailed notes that provided a complete picture of their appointment and mental health, as they perceived the health record to be a reflection of the HCPs' understanding of them [61].

HCPs and patients agreed that sensitive information required careful management in how it was documented in PAEHRs [54,58,61,65,71,74-78]. Sensitive information was defined broadly, including information that patients may not want to be shared beyond the clinical encounter, information that may be triggering or distressing for the patient, information that might be stigmatizing, and information related to the risk of self-harm or suicide [54,58,71,75,78,79]. It was common for studies to refer to mental health information generally as sensitive information. Some clinicians reported excluding specific details from the PAEHR that could be triggering, traumatic, or cause harm to patients [58,71,76]. For example, participants in the study by Kassam et al [54] discussed not documenting specific instances of physical abuse reported by patients experiencing domestic violence. Instead, the HCPs may imply domestic violence in the record by focusing on the safety planning they had discussed with the patient. There was agreement across HCPs and patients in the study by Pisciotta et al [61] that traumatic information should not be recorded in detail in the PAEHR.

HCPs identified various risks to documenting less detailed information, including that it might impact the clinical value of the EHR, particularly if the information is not detailed enough for other HCPs [54,58,62]. HCPs in the study by van Rijt et al [58] considered that they are responsible for what is documented and for what is not documented, as well as the impacts these documentation choices have on the patient. Patients may also rely on their health record to access certain services or support, which may require detailed information [61,67].

Subtheme 3.2: PAEHRs Require HCPs to Document Information That Patients Will Understand

One way that HCPs changed their documentation was to reduce or reframe the use of medical terminology or jargon that patients might not understand [54,55,61,71,80]. This change was something that both HCPs reported doing [49,54,61,66,71] and that patients wanted HCPs to do [61,66,68]. In one of the few reported examples of HCPs receiving guidelines for using a PAEHR, the guidelines recommended that HCPs limit the use of abbreviations, medical language, or euphemisms, even if they may be commonly used in the medical profession [81]. However, medical terminology may also be used by HCPs to communicate with other health HCPs or to disguise information from the patient [49,56]. Another approach to managing medical terminology was proactively discussing it with the patients to manage any potential confusion the terms might cause [54].

XSL•FO
RenderX

Subtheme 3.3: PAEHRs Require HCPs to Take a Person-Centered Approach When Documenting Potentially Subjective Information

HCPs reported that they changed their documentation to be more objective and less open for interpretation in the presence of a PAEHR [58,71,76]. For some HCPs, this change was related to a concern that information in the record may offend patients [47,52]. For example, HCPs discussed the challenge of documenting a patient's behavioral or physical presentation, which the patient could perceive as a subjective judgment [54]. Participants in the study by Blease et al [71] recommended that clinicians avoid demeaning, embarrassing, or stigmatizing terms such as "patient complains of." HCPs were conscious of medical terms that had stigmatized social meanings, such as "psychotic," that could lead to misunderstandings with patients [62,76]. This concern meant that HCPs might not document information related to the clinician-patient relationship, the patient's personality, or certain symptoms such as paranoia and may instead provide less detailed objective information [54,70]. However, it was recognized that some mental health assessments require subjective input from the HCP and that not including this information in the EHR might impact future episodes of care and cause confusion among the care team [54].

HCPs across several studies acknowledged that PAEHRs encourage them to write more person-centered and empathetic information [53,54,61]. In the study by Kassam et al [54], HCPs reported that the PAEHR made them conscious of language that "may be perceived as judgmental and demoralizing." Recognizing that a negative tone could come across as judgmental, some clinicians sought to write in a tone that conveyed empathy [61]. This need formed part of a broader consideration that HCPs should not just highlight the deficits and issues in the record but also the strengths and unique attributes of the patient [61]. Some HCPs sought to document more information on patients' strengths and recovery when using a PAEHR [54,61]. Patients have reported wanting HCPs to include such information in their record [61]. There was an acknowledgment by HCPs that while some information may be perceived as offensive, other information was explicitly disrespectful, and PAEHRs might help minimize such language [70].

It was important to patients that that the information documented in their PAEHR was respectful and empathetic. Participants in the studies by Cromer et al [38] and Fagerlund et al [46] wanted their health record to reflect them as a whole person rather than just containing "surface level observations." Patients thought that HCPs could show respect by being mindful of their tone and words that may appear as judging or labeling [61]. In the study by Bärkås et al [72], a third of patients in a national survey reported feeling offended by something written in their PAEHR.

Subtheme 3.4: HCPs Limit the Documentation of Uncertain Information in PAEHRs

HCPs discussed the challenge of documenting uncertain or unfinalized information in the PAEHR, such as diagnostic hypotheses or information that had not been confirmed with the patient [49,56-58,71,78]. For example, HCP might avoid documenting the assessment process leading to a final diagnosis or treatment plan because a patient might read those initial notes without knowing that it is not a final decision [49,53,56]. HCPs may withhold documenting suspected diagnoses due to the risk of upsetting or alarming the patient [54] or wait to discuss the diagnosis face-to-face with the patient before documenting it [49]. Some studies reported cases of patients discovering a diagnosis in their record that had not been discussed with them previously [38,61]. However, documenting uncertain information could play an important role in collaborative care arrangements and handovers, where multiple HCPs contribute to an assessment and need access to this information [56]. This information may also form an important part of the clinician's work to assess a patient and formulate a diagnosis or treatment plan [57].

Subtheme 3.5: HCPs May Omit Content or Restrict Access to PAEHRs

HCPs discussed various scenarios where information might be withheld from patients or omitted from the PAEHR [47,49,52,56,58,59,62,70,78]. These scenarios included where patients were experiencing delusions or suicidal thoughts that could be exacerbated by access to their records [54] or where a patient's knowledge of a treatment plan in advance, particularly involutory treatment, may hinder the provision of that treatment [58]. This practice may occur either through actively omitting information from the PAEHR, maintaining information in a separate informal record not sanctioned by the health service, or recording the information in a section of the PAEHR that patients cannot access. Some PAEHRs offered functionality to restrict or hide information from patients [47,53,60]. Some PAEHRs provided functionality to limit patient access to information, including allowing for a delay to be implemented before patients could view information [49,78,82], allowing only "signed" notes that an HCP had validated to be viewed by patients [47,52,78,82], or providing specific templates where HCPs could document sensitive information that patients could not view [65,74,82]. Some HCPs in the study by Zanaboni et al [49] mentioned keeping a physical folder with information that had not yet been included in the EHR. The risk of such unsanctioned records is that the information may be lost if not entered into the EHR or inaccessible by other HCPs [56]. HCPs discussed the need for discretion in determining when to withhold information from patients, particularly when there is a justified reason for doing so [54]. Other HCPs thought that patients should have access to all their health information and that all patients should have equal access to their PAEHR [53], a view also held by some patients [83]. Limiting patient access to information, particularly mental health information, could perpetuate stigma and distrust of services [54].

HCPs across several studies identified certain patients that they considered at increased risk of negative outcomes from accessing their PAEHR [47,49,59,65,71,76]. The groups reported were those with psychosis, paranoia, high levels of suspicion, or personality disorders [49,65,71]. In a pilot study of OpenNotes by Peck et al [76], where HCPs could choose which patients to enroll, HCPs reported choosing patients based on the severity of their illness, length of time in treatment, and psychiatric diagnosis. Similarly, in the study by Zanaboni et al

XSL•FO
RenderX

[49], HCPs in an outpatient setting discussed how they do not treat "the most challenging patients." HCPs in the study by Kassam et al [54] reported that their documentation practices may change with specific patients in mind, including their diagnosis and clinical program. HCPs may also consider the context, such as whether patient access during a crisis may negatively shape their engagement with mental health care services, particularly planned involuntary treatment [58]. Although HCPs across several studies believed that a certain subgroup of patients, either due to diagnosis or current symptoms, may be at greater risk of harm from accessing their health record, there seemed to be a lack of guidance or support for making these decisions. Thus, it may be that the available evidence does not accurately reflect the experiences of certain groups of patients if HCPs are actively not encouraging certain patients to use their PAEHR, or because studies are not being undertaken in settings with patients who have more complex conditions. This finding that HCPs may avoid involving certain patients in using their PAEHR may also explain why, in some studies, patients with certain diagnoses had lower odds of being registered for a PAEHR [84-87].

Theme 4: PAEHRs Introduce Changes to HCPs' Information Workflows

HCPs across several studies reported that PAEHRs would or had increased their workload due to changes in documenting information, answering patient questions, and reassuring patients [10,47,49,52,55,58,59,65,68,80]. However, in other studies, HCPs did not report any change to their workflow or workload [49,52,59,65,71] or suggested that changes in documentation may only require more work initially to adapt their documentation style [54]. For example, only 14.5% (86/594) of HCPs in the study by Petersson et al [65] reported that appointments took longer, and 18% (106/588) reported spending more time answering patient questions. The variation in the impact of PAEHRs on HCP workflows may be related to how the PAEHR was implemented and the level of support provided to HCPs and patients. One workflow change reported was the order of communication and documentation of information [49]. As previously discussed in subtheme 3.5, HCPs across several studies had previously used the health record to document preliminary information. The adoption of a PAEHR led HCPs to document this preliminary information elsewhere or not at all or to have earlier discussions with the patient about this information [49,56-58,71,78]. Another workflow issue raised by HCPs in the study by van Rijt et al [58] was the time required to explain what is written in the PAEHR and update the PAEHR if a patient disagreed with what was documented. In some cases, workflow issues were related to technical issues with the PAEHR, such as slow sign-in or troubleshooting technical issues for patients [88]. Interestingly, patients in the study by Schwarz et al [68] were concerned that the PAEHR might undermine the trust established with their HCP partly due to an increased HCP workload.

Theme 5: HCPs Require Tailored Training, Education, and Guidelines Documenting Information in a PAEHR

There was a clear lack of support and guidelines for HCPs across the included studies [49,53,75]. As outlined in theme 1, PAEHRs were viewed by HCPs as contrary to how they were trained. Several studies discussed the need for HCPs to receive training and support in using and promoting PAEHRs, such as how to write notes appropriately for patients [53,61,73,75,89,90]. Some of the issues identified as requiring guidance included describing sensitive matters and writing information "that may potentially be perceived in a negative light in a way that is clinically appropriate and respectful" [71]. When guidance was unavailable, HCPs took a risk-averse approach by adopting the information practices outlined in theme 3, such as reducing the level of detail documented about patients.

The few studies that included training for HCPs found mixed results regarding its effectiveness. Dobscha et al [73], reporting on a study of web-based education programs for HCPs using OpenNotes, found that after training, clinicians were better able to communicate, educate, and advise patients on accessing and reading their notes. The training also reduced HCPs' concerns regarding the potential negative outcomes of OpenNotes. However, HCPs in the study by Zanaboni et al [49] who also completed internet-based learning modules discussed how they would like more formal training in using the PAEHR, as their memories of the online training were vague. HCPs in the study by Jonnergård et al [63] identified that HCPs preferred to receive information about OpenNotes via channels that allowed for dialogue and rich information, such as workplace meetings.

Theme 6: Patients Are Empowered With New Information Practices if They Are Supported to Use Their PAEHR

Overview

Many studies reported improvements in patient empowerment or the perception of improved empowerment with the adoption of PAEHRs. Empowerment included improvements in self-monitoring; medication management and self-management of conditions; increased engagement with health care providers, health screening, and care plans; improved understanding of and insight into one's mental health; and feeling more prepared to engage with HCPs [37,50,52,54,57,59,67,68,73,76,77,90-95]. For example, patients in the study by Shin et al [66] reported that seeing their health record made them feel involved in the health care process, which was empowering. HCPs in the study by Kassam et al [54] thought PAEHRs helped dismantle power imbalances between patients and HCPs, fostering patient empowerment. Many of these studies were patients' self-reports or clinicians' perceptions of increased empowerment. However, Kipping et al [92] found that, when comparing patient portal users with nonusers, those who used the portal had increased appointment attendance, self-reported autonomy, and patient activation. Furthermore, in a randomized control trial, Druss et al [96,97] found that personal health record users had increased engagement with preventative health services.

PAEHRs could also support patients' engagement with information by acting as a reference tool, supporting their preparation for and engagement in clinical encounters, reminding them of previous discussions with HCPs, and helping them keep track of their treatment [37,49,52,54,57-59,66,68,70,98]. PAEHRs may also improve

XSL•FO
RenderX

patients' knowledge of their health status, treatment, and medications [47,55,58,67,95]; increase the number of contacts with HCPs and the completion of follow-up assessments [94]; encourage patients to ask more questions about their treatment [62]; and help prepare them to discuss their treatment with an HCP [37,50,58]. The transparency promoted by the PAEHR, as discussed in subtheme 2.3, can also help patients track how their care is progressing [83]. Patients may also use the PAEHR to validate communications from their HCP and clarify information after a clinical encounter [52,66]. However, some patients were concerned that PAEHRs would replace face-to-face conversations with their HCPs [66].

In most studies that explored the rates of PAEHR adoption, the engagement of patients was low [84,85,92,99,100]. Connolly et al [101] found in a study of veterans with depression that only 21.9% (~669/3053) were registered for their My HealtheVet platform. HCPs across several studies also reported low PAEHR adoption and patient engagement with their PAEHR [49,52,57,93]. There were mixed findings on the demographic groups that were more likely to access their PAEHR. Connolly et al [101] found that patients with more severe symptoms were more likely to register for and download information from their patient portal. Some studies suggest that people with mental health conditions may be more likely to use a PAEHR [72,102], but this was not consistent across all studies [103]. PAEHR use may increase over time, with Onyeaka et al [12] finding in a national survey in the United States of people with depression and anxiety that patient portal use had increased from approximately a third to a half of respondents over 3 years. There were variable results regarding whether people with different diagnoses were more likely to use a PAEHR. Etingen et al [84] suggested that differences in use across diagnoses may be due to some diagnoses being more likely to be associated with other comorbidities, which may encourage or facilitate engagement with the PAEHR.

Interestingly, in studies that explored the functions of PAEHRs used by patients, viewing their health records is not always the primary use [12,84,101]. In many cases, other functions, such as medication refills and booking and viewing appointments, are used most [84]. Robotham [90] and Forchuk et al [98] also found that patients value visual representations of, and the ability to track changes in, their health information.

Only a few studies discussed patients documenting information in their PAEHR [37,55,66]. Patient-documented information is not a feature of all PAEHR systems, but some patients saw value in this functionality. For example, patients in the study by Shin et al [66] discussed how being able to report information in the PAEHR might help HCPs better understand their needs. In the study by Durocher et al [37], 1 participant thought it would be valuable if they could flag notes in the PAEHR and provide their interpretations of certain events.

Subtheme 6.1: Patients Need Support to Use Their PAEHR

Patients were more likely to access their PAEHR when HCPs spoke to them about accessing their PAEHR and when they understood its purpose [87]. However, in several studies, HCPs took a passive approach by letting patients figure out how to access and read their health record themselves [47,52,59,65]. In some studies, it appeared that not all HCPs had discussed the PAEHR with their patients; for example, 40% (82/205) of participants in the study by Dobscha et al [59] had not discussed it with their patients, and only a few participants reported having multiple conversations with patients about it. Similarly, in the study by Johansen et al [47], 50.8% (~169/332) of the HCPs surveyed reported that they informed patients that they could read their own EHR. In the study by Petersson et al [65] study, only 26.8% (180/671) of the HCPs encouraged patients to read their PAEHR, while 15.6% (105/671) initiated a discussion with patients about something in their PAEHR, and only 10% (67/670) used the PAEHR actively in treatment. This issue was also reflected in the study by Fagerlund [46], where patients could not recall being informed about the PAEHR and instead had heard about it through advertisements or media coverage. In addition, Leung et al [104] found that 50% (~51/103) of patients surveyed were aware that they could access their health records, while Bärkås et al [72] found that 64.77% (2028/3131) of patients in a national survey in Sweden had not been encouraged by anyone to read their PAEHR.

It is unclear why HCPs are not discussing the PAEHR with patients. Earlier themes might suggest that this finding is related to the perceived risks of PAEHR to patients or the lack of support for HCPs [53,59]. Some HCPs in the study by Zanaboni et al [49] suggested that the PAEHR is the patient's tool, and therefore, the patient had to take the lead in using the PAEHR, rather than it being driven by the HCP. This perception of the PAEHR not being the HCP's responsibility may be supported by a lack of training or information for HCPs [49].

Several studies implemented a PAEHR as part of an intervention or model of care, which appeared to lead to increased use by patients. For example, Weisner et al [105] found that patients in an intervention that involved six 45-minute sessions with a psychologist focused on patient education and activation had greater log-ins to a patient portal and checking of information in the portal than those not involved in the intervention. Kelly et al [93] found in a randomized controlled trial that patients were more likely to access a PAEHR when it was implemented alongside support from a peer navigator. Druss et al [97] also found that peer specialist involvement might contribute to higher PAEHR use.

Providing educational resources and support may help patients engage with their PAEHR. Kelly et al [93], when comparing low engagement in their study with higher engagement in the study by Druss et al [96], noted that the latter provided more intense resources and support to patients. Denneson et al [106] found in implementing a web-based education program for patients who accessed their health record on the internet that the training improved patients' interactions and communication with HCPs and their own "activation." The web-based program included information on what is included in their health record and how to use and communicate with clinicians about them.

Subtheme 6.2: PAEHRs Must Be Easy for Patients to Navigate, Access, and Understand

Several studies explored design requirements for PAEHRs and identified issues and opportunities to make it easier for patients to use their PAEHR [12,61,73,75,89,90,98,107,108]. Several

XSL•FO
RenderX

studies identified login and account setup processes as an issue for patients, with recommendations that the process should be simplified, including addressing issues such as remembering passwords [12,75,83,89,98,109]. Patients also raised basic accessibility issues such as font size and colors [89,98,107] and navigation issues, including the number of links that patients had to navigate [79,107]. For example, in the study by van den Heuvel [91], patients who had dropped out of using an ePHR cited issues with the user friendliness as the main reason, along with the ePHR requiring too much work and effort. HCPs may need to support patients in navigating and understanding their PAEHRs, particularly patients with low health literacy or digital literacy, cognitive issues, and memory issues [68,71,107,108]. For HCPs to support patients, they need to be aware of what patients see in the record and how it functions for patients [58]. A lack of technology skills could be a barrier to patients engaging with their PAEHR [12,68], while some patients may also lack access to technology or the internet needed to use their PAEHR [12]. There is a risk that the benefits of PAEHRs may primarily benefit patients who are literate, educated, and affluent [10].

Theme 7: PAEHRs Raise New Concerns About Information Privacy and Security for HCPs, Patients, and Third Parties

Overview

Both patients and HCPs shared general concerns about privacy and security threats introduced by the PAEHR [49,52,57,62,68,76,104,107]. Some of these concerns were related more broadly to EHRs that multiple HCPs could access rather than the PAEHR itself [52,76]. For example, some patients in the studies by O'Neill et al [13] and Peck et al [76] raised concerns about their health record being available to other HCPs without their explicit consent. General concerns were also expressed about data hacking and breaches, but no participants reported experiences of these issues [10,62,68,76,77,79,104,107]. The most specific privacy threats identified were managing third-party data in the PAEHR and third-party access to the PAEHR, as outlined in the subsequent sections.

Subtheme 7.1: PAEHRs Pose Challenges to Managing Third-Party Data

An issue reported by HCPs was how to protect the privacy of third parties, such as family members, when documenting information they had provided in the health record information [49]. For example, HCPs might gather information about a patient from their family, which, when recorded in the PAEHR, would become visible to the patient. This risk might lead to HCPs reporting less information from family members or carers in the health record, which, as 1 participant in the study by Erlingsdóttir et al [57] said, will be a "big problem because it is important information that otherwise falls out of the system." Another approach reported by participants in the study by Zanaboni et al [49] was to deidentify information provided by third parties.

Subtheme 7.2: PAEHRs Pose Challenges to Managing Third-Party Access to Patient Information

Both HCPs and patients raised concerns that PAEHRs could lead to third parties, such as family members, inappropriately accessing a patient's health record [49,57,68,71]. Participants in the study by van Rijt et al [58] outlined the risk that patients could be influenced to share copies of their records or login details with family members who they may not want to have access to this information. There was also the broader issue of whether HCPs should record information assuming that the patient might give a third-party access to their PAEHR. For example, 1 participant in the study by Denneson et al [53] stated the following:

> *...someone said, "I smoked meth for 40 years and my wife doesn't know." And I was like, gosh, do I put this in the note? Because I don't know if he is going to give his wife access to his notes and then see something that was delivered in confidence...*

Such concerns might prompt HCPs to deny access altogether to certain information in the PAEHR to manage the risk of third-party access [49].

A few studies explored the potential benefits and issues with family members or carers being given access to PAEHRs [54,68,77,91,98,104]. One of the few studies that involved family and carers found that they thought it would be helpful to support the patient if they had access to the PAEHR [104]. Similarly, in the study by Leung et al [77], some patients reported that family or carer access could also be beneficial if it helped their family members or carers to better understand their health issues. However, in the same study, 43.7% (~43/103) of patients were interested in family members having access. The study by Schwarz et al [68] found that family access could enhance the exchange of information about the patient's illness and help family members participate in the patient's care. Van den Heuvel et al [91] reported that 23.1% (~9/39) of patients preferred informal caregivers to have access compared to 25.6% (10/39) finding it adverse. Similarly, Leung et al [104] found, in interviewing patients about a patient portal, that less than half of those interviewed were interested in family members having access to their records. There may also be scenarios where family members support the patient in using the PAEHR [110], which raises questions about how to ensure that the patient has the option to maintain privacy in those situations.

Discussion

Principal Findings

This scoping review explored how PAEHRs implemented in mental health care contexts change the information practices of HCPs and patients. We found that HCPs change their documentation practices in the presence of a PAEHR, including reducing the level of detail they document. HCPs changed their information practices because they were concerned that the PAEHR would negatively impact the therapeutic relationship and patient safety, and there was a lack of guidelines as to how these risks should be managed. There were clear benefits for patients who could use the PAEHR to understand and manage

XSL•FO
RenderX

their care. However, patients may struggle to use the PAEHR without support and consideration of its ease of use.

The findings of this review suggest that HCPs perceive that PAEHRs change the purpose of the health record by requiring them to write with consideration of the patient as an audience rather than solely a clinical audience. It is a long-running issue that in an increasingly connected health care system, while technical interoperability between EHRs may increase, information is not necessarily written for multiple audiences [111]. The findings of this review suggest that digital health technologies that allow records created or updated by HCPs to be indiscriminately accessed by multiple types of users risk HCPs adopting information practices outside formal systems and processes, such as by creating separate records that are not officially recognized by the health service [49,112]. Omitting information from a patient's health record not only fragments the record but also poses a risk to future care if information is lost or unavailable when needed. Potential technical advances, such as natural language processing and generative artificial intelligence, may solve this issue by supporting HCPs in translating their notes for different audiences [113-115].

HCPs in the included studies were concerned that PAEHRs would negatively impact the therapeutic relationship. The concern for the therapeutic relationship is not surprising, given it is a strong predictor of outcomes in mental health care [116]. HCPs and patients also thought that the PAEHR could strengthen the therapeutic relationship by contributing to transparency, communication, and trust. This finding aligns with evidence that mutual trust, demonstration of mutual respect, and shared decision-making were key components of a beneficial therapeutic relationship [117]. This finding may also explain why HCPs and patients saw benefits in the PAEHR facilitating communication about disagreements, as it helps build mutual trust [118]. However, both HCPs and patients expressed concerns that discussing what is documented in the PAEHR may add to workloads. A lack of time available for HCPs and patients to actively review and discuss the PAEHR may limit its use in strengthening the therapeutic relationship.

Risk to patient safety due to patients experiencing distress from reading their PAEHR was a key concern for both HCPs and patients. One of the key strategies used by HCPs to manage risk was to not document or limit the documentation of information that they perceived may be distressing for patients. This focus on risk is expected, given risk management has a prominent role in mental health care, as HCPs must consider and manage risks posed by patients to themselves or others [119]. One way HCPs manage risk is by avoiding situations that may involve heightened risks [119,120]. In this review, HCPs avoided risk by not documenting information they perceived could pose a risk to patients. This approach to avoiding risk may have been reinforced by a lack of guidelines for managing risk. HCPs are usually required to take a systematic approach to risk assessment, informed by organizational policies [121], which appeared to be lacking in relation to PAEHR adoption in the included studies. Evidence also suggests that there is value in involving patients in identifying and managing risks [122]. However, patient involvement in HCPs' decisions to limit the documentation of information in the PAEHR appeared to be limited.

Patients wanted a greater breadth of information documented in their PAEHR, including strength-based and recovery-focused information. In contrast, HCPs managed the perceived risks of PAEHRs by reducing the depth of information they documented. These findings align with the growing literature on person-centered documentation, which seeks to consider the role patients can play in information documentation practices. Lyadhl et al [123] reflects that health record documentation practices are embedded in a biomedical model of care that prioritizes certain types of information to support communication between HCPs, rather than communication with patients. Person-centered documentation requires consideration of the patient's goals, needs, resources, and narrative. "Collaborative documentation" is a model that supports HCPs and patients in working together to determine what should be documented during the clinical encounter [124,125]. It is a form of shared decision-making that seeks to improve the transparency of what is documented in the patient's EHR [124]. Adopting a model such as collaborative documentation may address some of the concerns that PAEHRs will lead to disagreements about what is documented in the PAEHR.

PAEHRs can support new patient information practices, but there are barriers to patients using their PAEHR. PAEHR use by patients was low in the included studies, which is concerning given that recent studies in other health care settings have found generally high use rates [126,127]. The lower rates of PAEHR use in mental health care contexts may be partly explained by the slower adoption of PAEHRs in mental health care contexts, as the use of PAEHRs tends to increases over time [12,128]. It is also worth noting that many of the studies that considered use rates were conducted before the COVID-19 pandemic. The pandemic may have accelerated the adoption and use of PAEHRs due to the limits on in-person contact and the rapid adoption of telehealth [129].

Patient uptake of PAEHRs also relies on endorsement from HCPs [130]. However, our findings suggest that the lack of guidance for HCPs paired with the perceived risks to the therapeutic relationship and patient safety may act as a barrier to HCPs actively engaging patients in using their PAEHR. It was also identified that HCPs may not proactively engage certain groups of patients whom they perceive as at greater risk of negative outcomes from using their PAEHR. This finding may partly explain why, in some studies, patients with certain diagnoses were less likely to use their PAEHR. There is value in considering which patients may experience a negative response to a accessing their PAEHR, noting that some patients in the included studies did have negative experiences. Patient readiness measures, which have been found to be valid in measuring the likelihood of patients using health information technology [131,132], could form part of guidelines for HCPs to identify patients who need further support to use their PAEHR.

The time and resource pressures on HCPs are well documented, as are the impacts of these pressures on HCPs' ability to engage with new digital health technologies [133,134]. In some mental

XSL•FO
RenderX

health care services, other professionals could support patients to use their PAEHR, if HCPs are not provided with the time and resources to do this role. For example, peer workers are increasingly involved in mental health care services [135] and could play a role in supporting patients to use their PAEHR, as well as role-modeling how can be integrated into [136]. Similarly, care workers or "health care navigators" who in some health care systems support patients to move between health care services [137] may be well positioned to support patients in using their PAEHR. However, in all these cases, consideration will need to be given to how confidentiality of patient information is managed.

Managing third-party access to the PAEHR, particularly coercive access, was a key issue for HCPs but was not raised as a key issue by patients. It may be that patients at risk of having third parties inappropriately access their records were not participants in the included studies. The few studies that asked patients about family access found that they were uncomfortable with family members having access to their PAEHR. The issue of third-party access could be addressed through initiatives such as dynamic consent, where patients are given real-time control over managing their data through a personalized digital interface [138]. Australia's national PAEHR, My Health Record, presents another approach for patients to manage third-party access by allowing them to nominate a trusted person to access their record and determine the level of access available to them [139]. Health care services could also provide kiosks for patients to access their PAEHR in the health care clinic if at-home access poses a risk of unauthorized third-party access. However, these approaches do not necessarily address the issue of third parties who may coerce patients into providing access to their PAEHR.

The findings of this review also raise questions as to how inequalities in patients' resources and digital literacy may shape their interactions with a PAEHR. In the mental health care context, patients can experience socioeconomic disadvantages, which may limit their access to technology, meaning they may rely on smartphones or public computers [96,107,140]. PAEHRs should be designed to maintain privacy and accessibility, regardless of the location or type of device patients use to access them. There is a risk that the benefits of PAEHRs may disproportionately favor patients with more resources, rather than those facing the greatest health challenges [141,142]. These issues pose a more serious question about what the health system expects of patients when a PAEHR is available. Wynia and Dunn [143] outline 2 assumptions underlying PAEHRs: that more information for patients equals better decision-making and that patients should take greater responsibility for their health care. Lucivero [144] posits that PAEHRs may enroll patients into providing free labor for the health system where they act as intermediaries between HCPs by using their PAEHR to fill gaps in information. However, this role may be undermined if HCPs do not support patients to use their PAEHR, such as if HCPs are unwilling to act on information patients share with them, or if patients do not have the resources to fulfill this role.

Comparison With Prior Work

The findings of this review align and extend the findings of recent reviews by Zhang et al [24] and Schwarz et al [9] in mental health care contexts. Some of the factors for successful implementation of patient portals identified by Zhang et al [24], such as training and resourcing, are also issues that we identified as contributing to some of the changes to HCPs' information practices. Similar to the findings of Schwarz et al [9], we found that HCPs were more likely to express concerns about PAEHRs compared to patients. Our study extends the research into PAEHRs in mental health care contexts by framing the perceived risks of PAEHRs to the therapeutic relationship and patient safety as key factors in HCPs changing their information practice, further fueled by a lack of guidance and training. Several recent reviews of PAEHRs in other health care contexts also support the findings of this study. In a systematic review, Tapuria et al [31] found that patient portals had a range of benefits, such as reassuring patients and reducing anxiety, improving the physician-patient relationship, and improving patient outcomes. However, they also identified concerns regarding security, privacy and confidentiality, and patients experiencing anxiety with access to their records. In a recent systematic review of facilitators and barriers to electronic portal use, Powell [145] found that HCP encouragement is a key factor in both the initial and continued use of the PAEHR by patients. The findings of our review suggest that PAEHRs in mental health care contexts raise similar issues to their use in other health care contexts. However, we also found that that in mental health care contexts, HCPs still harbor significant concerns about how to protect the therapeutic relationship and patient safety—2 issues that have distinctive implications in the mental health care context.

What Do the Findings Mean for Future Research?

Future research should consider how changes to HCP and patient information practices after the adoption of a PAEHR impacts clinical and patient experience outcomes. This study found that the use of PAEHRs led to changes in what is documented in the EHR and a potential "watering down" of information. Future research should explore the impact of these changes on collaborative care and clinical outcomes in the presence of a PAEHR. If these changes to information practices significantly impact the ability of other HCPs to provide appropriate care, it will strengthen the case for increased training, support, and guidance for how HCPs should document information in the presence of a PAEHR. It would also be valuable for more studies to explore the implementation and use of PAEHRs in practice and how HCP and patient use change over time, particularly given that use of PAEHRs tends to increase over time. There are very few studies that involved HCPs and patients in the process of designing a PAEHR. Given the findings of this review, there is a clear need for more studies that actively involve HCPs and patients in decisions about how PAEHRs are designed and implemented.

Limitations

This review is limited in part due to the heterogeneity of the field, particularly the lack of common definitions of PAEHRs, which means that there may be studies that were missed in the

XSL•FO
RenderX

search strategy. Furthermore, our search strategy did not include gray literature, meaning evaluations of some PAEHR systems that have not been published in academic journals may have been missed. This review was also limited by having only 1 author screen all the studies and extract the data for analysis. A pragmatic approach to screening was used, where only studies with unclear eligibility for inclusion were screened by a second author.

Conclusions

This scoping review explored the impact of PAEHRs on information practices in mental health contexts. HCPs reported making various changes to their documentation practices to minimize the risk of PAEHRs harming the therapeutic relationship and patient safety. However, PAEHRs could also promote communication between HCPs and patients about what was being documented. PAEHRs also introduced new information practices for patients that allowed them to manage their health better and engage with health care services. PAEHRs are still considerably new in mental health care contexts, and patient adoption and use of established PAEHRs remain relatively low. Research is required on the impact of documentation changes on clinical outcomes and patient experience as well as approaches to improve adoption and use rates of PAEHRs. The findings of this study point to a lack of guidelines and support for HCPs and patients in the implementation of PAEHRs.

Abstract

Background: The consistency and quality of care in modern primary care are supported by various clinical reminders (CRs), which include “alerts” describing the consequences of certain decisions and “prompts” that remind users to perform tasks promoting desirable clinical behaviors. However, not all CRs are acted upon, and many are disregarded by general practitioners (GPs), a chronic issue commonly referred to as “alert fatigue.” This phenomenon has significant implications for the safety and quality of care, GP burnout, and broader medicolegal consequences. Research on mitigating alert fatigue and optimizing the use of CRs remains limited. This review offers much-needed insight into GP attitudes toward the deployment, design, and overall effectiveness of CRs.

Objective: This systematic review aims to synthesize current qualitative research on GPs’ attitudes toward CRs, enabling an exploration of the interacting influences on the occurrence of alert fatigue in GPs, including the deployment, design, and perceived efficacy of CRs.

Methods: A systematic literature search was conducted across the Health Technology Assessment database, MEDLINE, MEDLINE In-Process, Embase, CINAHL, Conference Proceedings Citation Index, PsycINFO, and OpenGrey. The search focused on primary qualitative and mixed methods research conducted in general or family practice, specifically exploring GPs’ experiences with CRs. All databases were searched from inception to December 31, 2023. To ensure structured and practicable findings, we used a directed content analysis of the data, guided by the 7 domains of the Non-adoption, Abandonment, Scale-up, Spread, and Sustainability (NASSS) framework, including domains related to Technology, Adopter attitudes, and Organization.

Results: A total of 9 studies were included, and the findings were organized within the 7 domains. Regarding Condition and Value Proposition, GPs viewed CRs as an effective way to maintain or improve the safety and quality of care they provide. When considering the attributes of the Technology, the efficacy of CRs was linked to their frequency, presentation, and the accuracy of their content. Within Adopters, concerns were raised about the accuracy of CRs and the risk that their use could diminish the value of GP experience and contextual understanding. From an Organization perspective, the need for training on the use and benefits of CRs was highlighted. Finally, in the context of the Wider system and their Embedding Over Time, suggestions included sharing best practices for CR use and involving GPs in their design.

Conclusions: While GPs acknowledged that CRs, when used optimally, can enhance patient safety and quality of care, several concerns emerged regarding their design, content accuracy, and lack of contextual nuance. Suggestions to improve CR adherence included providing coherent training, enhancing their design, and incorporating more personalized content.

Introduction

Primary care is facing unprecedented pressure across the globe, caught between growing patient demand, issues of workforce recruitment and retention, and increasingly complex options for treatment [1,2]. To improve the consistency and quality of care in this dynamic and highly pressured environment, health systems worldwide have introduced guidelines for care informed by the latest clinical evidence [3,4]. These guidelines are promoted and supported in high-income countries through a range of clinical reminders (CRs) that are presented to general practitioners (GPs) via their clinical management systems and consist of "alerts" that remind them of the consequences of making a certain decision, and "prompts" that remind the user to perform a task that promotes desirable clinical behaviors [5-10]. These alerts can relate to potential diagnoses, drug-drug interactions, and allergies, and prompts linked to patient-specific needs, further information, and recommendations for high-quality care (see Figure 1; see also [11]).

Figure 1. Types of clinical reminders and alerts used in clinical management systems in primary care (Cecil et al [11]).

The growing sophistication of medical knowledge and the electronic systems that manage patient data and inform clinical decision-making have led to a steady increase in the activation of CRs at the point of care and the cognitive load placed on GPs [12-15]. Not all CRs are acted upon, and some may justifiably be considered irrelevant or inapplicable [16,17], but increasingly GPs are disregarding pertinent or urgent CRs [18-20], a chronic negligence commonly referred to as "alert fatigue" [21].

Despite the implications of alert fatigue for the safety and quality of care, GP burnout, and the medico-legal consequences for individuals and their organizations, the proliferation of CRs in primary care is reliant on evidence limited to their effects on a specific condition [22,23]. What remains underexplored is how their use might be optimized in the context of the cumulative effect of multiple CRs on a single health care provider [19,20,22,24]. There is then a need to better understand GP attitudes toward the deployment, design, and overall effectiveness of CRs, as well as broader implications for their impact on patient-clinician communication [22,25]. The systematic review presented here aims to address this by synthesizing current qualitative research on GPs' attitudes toward CRs describing the findings within the Non-adoption, Abandonment, Scale-up, Spread, and Sustainability (NASSS) framework [26]. This framework was designed to study unfolding digital health technology programs and so provides the opportunity for offering structured insight into the future design, use, and positioning of CRs in primary care.

Methods

Applying the NASSS Framework to Digital Health Implementation

The review used best practices in systematic review methodology and directed content analysis [27,28]. We describe the results through the lens of the NASSS framework developed to support, guide, and monitor the implementation of digital technologies in health and social care [26,29,30]. The framework uses 7 domains to describe various aspects of the technology, end users, organizational structure, and broader policy-driven context [26]. The domains are defined alongside their potential impact on implementation in Table 1.

XSL•FO
RenderX

Table 1. The NASSS[a] framework: domains, definitions, and influences on implementation (adapted from [26,29-31]).

Domain	Definition	Influences on implementation
Condition	The condition(s) for which the innovation or technology has been designed. These can be physical, mental, or psychosocial in nature.	• The complexity of the condition. • Its metabolic volatility, association with comorbidities, and impact on cognitive function [32].
Technology	The technology/ies or other innovation that is/are being introduced. Include(s) both hardware and software and can include a novel protocol or pathway—or some combination of these.	• Its material properties, functionality, dependability, and speed [33]. • The knowledge needed to use them [34]. • The knowledge generated by the technology [35]. • The supply model and the relationship with the care provider [36]. • The ownership of intellectual property [37].
Value Proposition	The value (financial or otherwise) that the new technology and care model generates. This includes, for commercial stakeholders, the return on investment; for patients, improvements in comfort or quality of life; for health care organizations, improvements in quality, safety, inclusivity, and efficiency of the care delivered.	• Provision of value to a range of stakeholders, suppliers, patients, the health care system, and taxpayers or insurers. • Formulating a credible business plan where efficacy or cost-effectiveness studies are unavailable or contested [38,39].
Adopters	The intended users of the technology or other innovation. This includes patients/laypersons, professionals, administrative, and support staff.	• Acceptability to service users and their families/carers [40]. • Attitudes toward new and emerging technologies [41]. • Influence of sociocultural factors such as poverty or social exclusion [42]. • Acceptability to staff. • Impact on roles, professional traditions, and codes of conduct [26].
Organizations	The cultural and organizational characteristics of the organizations involved. This includes structure, capacity, and capability to adopt new ways of working, as well as resources of staff and infrastructure.	• The organization's general capacity to innovate [43]. • Readiness for this particular technology [26]. • The decisions around funding the intervention (including the presence of interorganizational agreements or speculative cross-system savings in the funding decision [44]). • The extent of the change needed, including the potential disruption to existing routines [45]. • The work required in implementation, including staff engagement, fidelity of implementation, and evaluation [46].
Wider System	The national and local context for the introduction of the technology or program	• The impact of national and local policies and objectives [47]. • The support of regulatory or professional bodies [48]. • Sociocultural factors including public perceptions of the technology [49]. • The presence of interorganizational networking and collaborative initiatives in supporting implementation [50].
Embedding Over Time	The key changes and uncertainties expected to affect the integration of the technology over the next 3-5 years.	• The ability of the technology to adapt to changing contexts [51]. • The resilience and cultural stability of the organizations involved [52].

[a]NASSS: Non-adoption, Abandonment, Scale-up, Spread, and Sustainability.

Search Strategy

The databases searched were the Health Technology Assessment Database, MEDLINE, MEDLINE in Process, Embase, CINAHL, Conference Proceedings Citation Index, PsycINFO, and OpenGrey, from January 1, 1960, to December 31, 2023, a date range chosen to reflect the introduction of electronic or digitally supported health care. The search was conducted by the author IG in March 2024 and no language or location limits were applied. Medical Subject Headings (MeSH) terms and free-text words were used against the Sample, Phenomenon of Interest, Design, Evaluation, Research type framework [53] to

XSL•FO
RenderX

collect relevant studies from the perspective of GPs in a primary care setting (see Multimedia Appendix 1). The search strategy is described in the PROSPERO registration and the previously published protocol [54]. The EndNote (Clarivate Plc) bibliographic software was used to organize all retrieved studies and remove any duplicates.

Eligibility Criteria

Studies included were primary qualitative research conducted in primary care settings and published in English. The research had to have a focus on general or family practice and be qualitative in nature because we were specifically interested in GPs' experience with and perspectives of CRs (see Multimedia Appendix 2 for detailed eligibility criteria).

Study Selection and Data Extraction

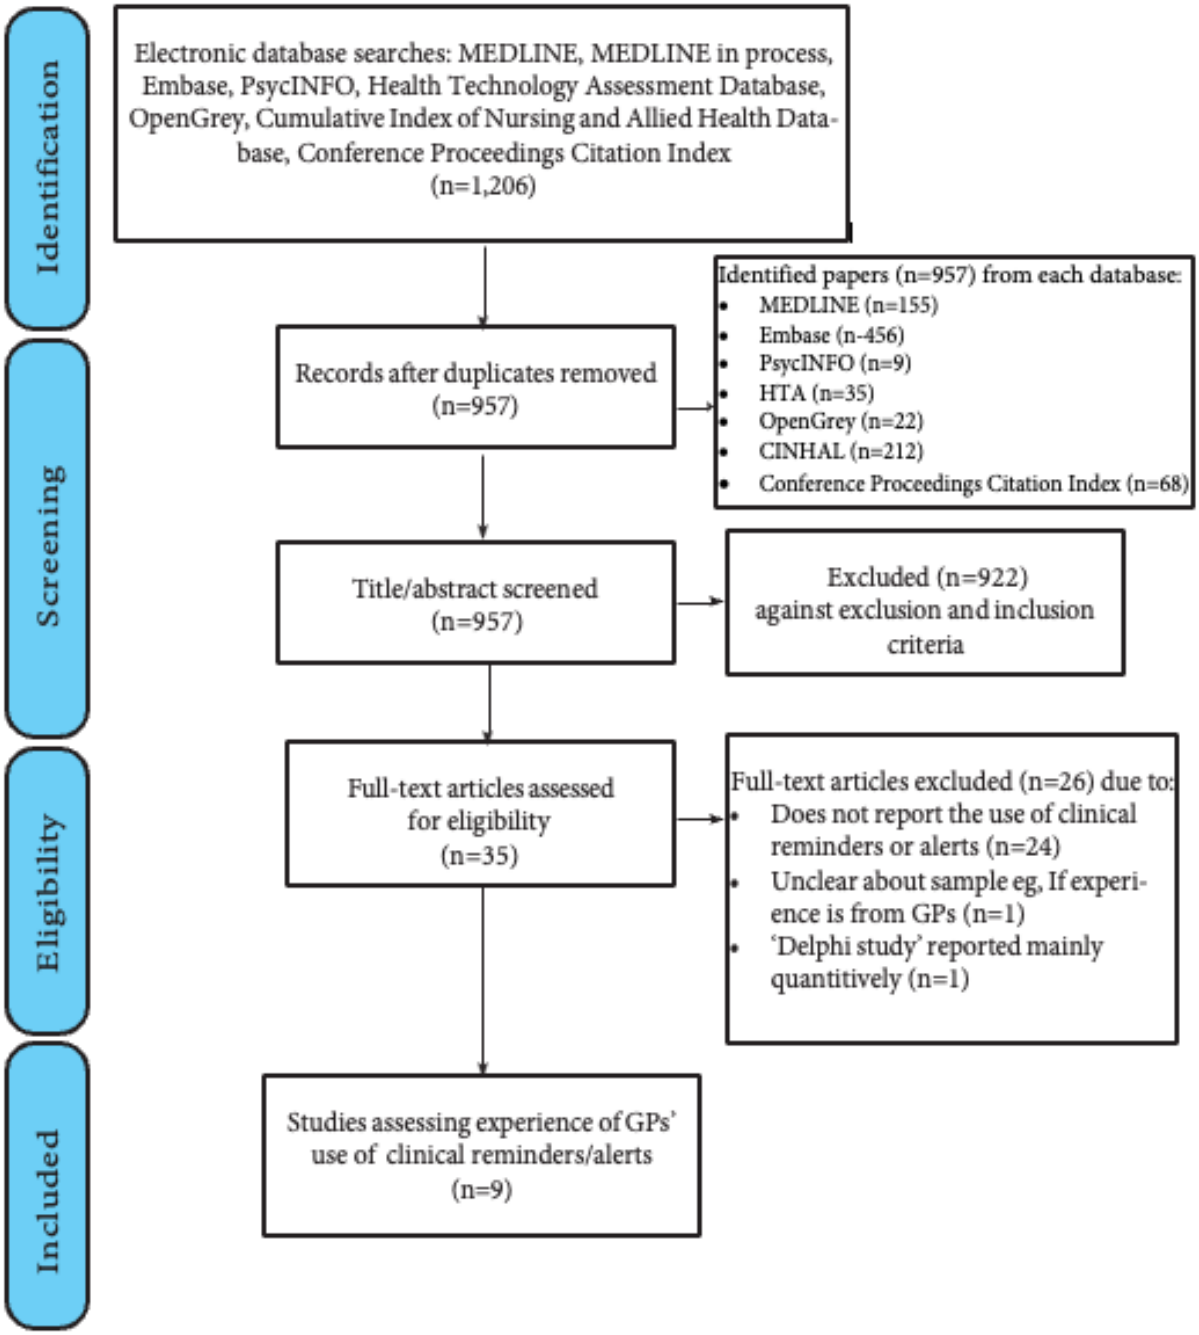
We used the recommended full dual review approach, that is, 2 independent reviewers (IG and AP) screened the title, abstract, and then the full texts, as this has been shown to increase the number of eligible papers identified and more broadly minimize error in the selection process. The data were managed using an Excel spreadsheet (Microsoft Corporation), with any disagreements on the inclusion of a study consensually resolved through discussion with a third reviewer (IL). A data extraction form was designed to summarize study characteristics. The data extracted included information on study outcomes, study design, participants, and key findings.

Quality Appraisal

The quality and bias of included papers were determined by the Critical Appraisal Skills Programme checklist for qualitative studies and the Mixed Methods Appraisal Tool for mixed method studies [55]. Although the Mixed Methods Appraisal Tool cautions against the approach of labeling studies at low, medium, and high risk of bias, we used a scoring system to determine this labeling, for ease of interpretation between the 2 different tools. The quality appraisal was undertaken independently by 2 authors (IL and IG) who between them agreed on the final value.

Data Synthesis

The data were coded and managed via NVivo12 (Lumivero, LLC). We used a directed content analysis to populate the NASSS framework, based on the unconstrained matrix approach. This allowed the development and inclusion of constructs directly relevant to emergent themes within the established framework [56,57]. The analysis was conducted by IG and IL who both independently analyzed a sample of the same 3 papers. They then met to discuss their analysis and any discrepancies in the allocation of data before IL analyzed the remainder of the studies, with the final analysis and data allocation consensually agreed upon by all authors. In completing the analysis, we merged the domains of "Wider system" and "Embedding over time" due to the concurrence that arose in the data.



Results

Study Characteristics

The screening and study selection are outlined in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 2; also see Multimedia Appendix 3). The study selection and data extraction templates can be found in Multimedia Appendix 4. Full-text studies were excluded because of duplication, or lack of detail on the care provider, setting, or digital tool (see Multimedia Appendix 5 for a detailed description). A total of 9 studies were included, 5 from the United Kingdom [58-62] and 1 each from Australia [63], Belgium [64], the Netherlands [65], and Norway [66]. Seven of these were considered high quality [58-62,65,66], 1 medium [64], and 1 low [63]. The papers were published between 2003 and 2021. The key characteristics of included studies and findings are summarized in Table 2. This includes the quality assessment (see Multimedia Appendix 6 for a detailed description). The directed content analysis enabled the mapping of the data within the NASSS framework. Within each domain, we determined a series of emergent constructs relevant to the implementation of CRs in primary care. These findings are summarized in Table 3 and presented below within each domain of the framework alongside exemplar quotes taken from the studies identified.

Table 2. Key characteristics and findings of identified studies.

Reference	Country of study	Study outcomes	Study design (quality of study)	Purpose of CR[a,b]	Participants/setting	Key findings
Ahearn and Kerr [63]	Australia	To determine GPs'[c] perceptions of strengths and weaknesses of prescription systems	Focus groups (low)	Medication	14 GPs; 1 focus group in a rural area and 2 focus groups in an urban area	• CRs affected prescribing behavior. • GPs recognized the need for training. • Considered helpful features of clinical decision support systems.
Bindels et al [65]	The Netherlands	To investigate the experiences of GPs with the "GRIF system" (automated test ordering combined with a feedback system)	Group discussion and interview (high)	Diagnosis	24 GPs; mean age 49 (SD 4.9) years, mean experience 19 (SD 7) years; males comprised 75%	• The system increased attention to and promotion of guidelines.
Christensen and Grimsmo [66]	Norway	To study primary care physicians' experiences of electronic prescription reminders	Focus groups; observations of doctor-patient encounters; and National Questionnaire Survey (high)	Medication	24 GPs (15 females + 9 males)	• The ability to present relevant patient information and medical knowledge was appreciated.
Dikomitis et al [61]	United Kingdom	To obtain views from GPs who piloted the electronic risk assessment tools	Telephone interviews (high)	Diagnosis	23 GPs (13 males + 10 females)	• Key issues over the integration of CRs into existing digital platforms.
Ford et al [59]	United Kingdom	To understand the features of individual clinical decision support systems that were barriers and facilitators to their use	Semistructured interview (high)	Medication	11 GPs (7 males + 4 females); age group 30-39 years, n=8; age group 40-49 years, n=2; and age group 50+ years, n=1	• Issues emerged relating to the accuracy of CRs and their usability.
Jeffries et al [58]	United Kingdom	To understand the factors that influenced clinical decision support system implementation	Semistructured interviews (high)	Medication	14 GPs across 4 regions in the United Kingdom	• There was a shared recognition of the need to use CRs and their potential to support patient care but felt CRs needed to be more relevant.
Heselmans et al [64]	Belgium	To assess users' perceptions toward the EBMeDS system (a computer decision support system provided by EBPNet, a national computerized point-of-care information service in Belgium)	Survey (medium)	Management, medication, and diagnosis	Survey issued to 334 (Dutch-speaking) GPs	• Reminders considered too general and inflexible, with questions over their reliability.
Holt et al [60]	United Kingdom	To investigate the implementation of the CRs in UK general practice	Semistructured interview (high)	Diagnosis	7 GPs (no characteristics described from the sample)	• The advantages of CRs were recognized but with caveats over their specificity.

XSL•FO
RenderX

Reference	Country of study	Study outcomes	Study design (quality of study)	Purpose of CR[a,b]	Participants/setting	Key findings
Slight et al [62]	United Kingdom	To examine the causes of prescribing and monitoring errors in general practice	Semistructured interviews and focus groups (high)	Medication	33 GPs participated in semistructured interviews and 46 contributed in focus groups	• The need for prior training and improved information technology infrastructure and hardware.

[a]CR: clinical reminder.

Table 3. Summary of findings by NASSS[a] domain.

NASSS domain and emergent constructs		Definition	Summary of findings (and review papers)
Condition			
	Medication	• To support safe prescribing and medication adherence.	• Issues accommodated by CRs[b] included drug-drug interactions, drug allergies, and dose-related recommendations [58,59,62-64,66].
	Diagnosis	• To support prompt and accurate diagnosis of a range of chronic and acute conditions.	• Diagnostic use included both acute [60,61] and chronic conditions [64,65].
	Ongoing management	• Providing reminders and alerts for the safe and successful long-term management of (chronically ill) patients.	• CRs included references to reviews of patient medication, symptoms, and testing regimes [64].
Technology			
	Frequency and content of CRs	• The number of CRs and the relevance and accuracy of their content.	• The overabundance of CRs was described [59,61,63,64]. • GPs[c] described a preference for accompanying information that aided comprehension [59].
	Design and integration of CRs	• The presentation and readability of CRs and their integration with existing clinical dashboards.	• GPs described how CRs requiring a response disrupted their workflow [59,63]. • A preference was expressed for CRs with clear color-coded designations of risk or otherwise readily understandable formatting [59]. Dropdown boxes were seen as overly complicated [62].
	Digital infrastructure	• The capacity, capability, and compatibility of hardware and software systems and the interoperability of data.	• The quality of connectivity and the capacity of practice software systems impacted the timely appearance of alerts, frustrating clinicians and increasing the risk of errors [59,60,62,66].
Value proposition			
	Overall quality and safety	• CRs capable of presenting timely prompts with the necessary actions.	• CRs were valued for their ability to provoke a decision [58,61,63], particularly in busy environments [59,60]. Their ability to act as educational tools was mooted [58]. • The constant interruption of tasks by CRs was considered a risk to patient safety [59].
	Self-efficacy	• CRs can provide reassurance for clinicians that they have not missed anything significant.	• The increasing complexity of primary care meant that clinicians welcomed the additional support [59,61,63].
Adopter			

XSL•FO
RenderX

NASSS domain and emergent constructs		Definition	Summary of findings (and review papers)
	Engagement, and compliance in CRs	• The degree to which clinicians follow the recommendations of CRs and the factors that influence this decision.	• There were concerns over the accuracy and relevance of CRs, with a need for more transparent evidence of their efficacy, as well as self-doubt if the CR was ignored [59,63].
	Digital literacy and acceptability	• Ability to understand, use, and incorporate digital technologies in health care.	• Recent cohorts of GPs were more familiar and trusting of digitalization [59]. • There were concerns that training, experience, and context would be subjugated to computer-generated recommendations [59,61].
	Patient-clinician relationship	• The impact on patient interactions, communication, and consultation behaviors.	• CRs could disrupt consultations and inhibit patient communication [61,63].
Organization			
	Training in the purpose and use of CRs	• Importance of providing adequate training and ensuring clinicians understand the purpose of CRs.	• The importance of training was recognized when introducing CRs [58-61,63].
	Practice capacity and workflow	• The capacity, workflow, and protocols of practice organizations.	• Shortening consultation times precluded GPs from interacting with many of the CRs generated [58,60].
Wider system adapting and embedding over time			
	Adaptation over time	• The ability of CRs to incorporate technological advances and reflect the evolving needs and preferences of patients and clinicians.	• The need for greater and earlier engagement of software developers with GPs was described [58,63,65]. • A number of suggestions for future CR design were shared across studies including better integration with existing software systems, patient-specific content, clear graphical formats, and the ability to customize frequency and content [59-61,63,67].
	Systemwide collaboration	• Unified approaches to the long-term introduction of technology including procurement, infrastructure, and shared learning.	• There was a recognized need for improved interoperability and shared data between settings and organizations [63,66] and for continued learning from peer experience was voiced [59].

[a]NASSS: Non-adoption, Abandonment, Scale-up, Spread, and Sustainability.

[b]CR: clinical reminder.

[c]GP: general practitioner.

Condition

The studies identified described how CRs were used to optimize care and manage patient safety in 3 key areas: medication [58,59,62-64,66]; diagnosis, both broadly [64,65] and for specific conditions, namely, atrial fibrillation and stroke [60], and cancer [61]. CRs were also used in the ongoing management of chronically ill patients, providing reminders of reviews or tests [64].

Technology

Challenges in Technological Aspects of CRs: Alerts, Design, and Infrastructure

Seven studies described issues relating to various technological aspects of CRs, specifically the frequency and content of alerts, their design and integration with existing interfaces, and the broader digital infrastructure and capability including the interoperability of data.

Frequency and Content of CRs

Four studies described how the inability to process a large number of alerts was a concern among GPs [59,61,63,64]. As one GP described:

XSL•FO
RenderX

> *There are so many things (...) so many things popping up, so many things prompting you. You don't probably respond to all the prompts, because there's a box here, a box there, a box everywhere, and you don't see everything (...) It's such a busy screen you don't respond to everything...* [61]

The value of presenting accompanying patient-centered information alongside the clinical data of the CR was described in one study. As a GP elaborated:

> *It [the CR] actually comes up with a nice diagram that it can use with your patients, that's got smiley faces of different colours to illustrate risk (...) it's just a different way to help augment that communication with them. For things like that it's quite helpful because patients are wary of tablets, quite rightly.* [59]

Design and Integration of CRs

Three studies described how pop-up CRs that required the checking of drop-down lists or otherwise had to be actioned before any next step were overly disruptive and actually inhibited their engagement with the CRs content [59,62,63]:

> *[when they appear]...you can't go looking in the notes, you can't input anything else, this is now taking priority, so you either suspend it and then re-open it and suspend it and re-open it.* [59]

Digital Infrastructure

The capacity of practice information technology (IT) systems and hardware was also a consideration, for example, some CRs slowed the operating speed of practice computers [59,60,62,66].

> *Our problem here is our computers are rubbish. They work really, really slowly (...) it takes a long time to come through so we scroll down an option, a pick list - it can pick the wrong thing! Which is very frustrating...* [62]

Value Proposition

GPs' Perspectives on CR Quality, Safety, and Educational Impact

GPs described their perspectives on the quality and safety of CRs, their potential to support continuing education and training, and their impact on self-efficacy.

Overall Safety and Quality

In 5 studies GPs reported that CRs were capable of improving patient safety by promoting reflection on their decision [58-61,63]:

> *...even if you immediately dismiss it, at least that millisecond you've thought about it, and I think that is going to be useful at some point, but for how many people I don't know* [61]

GPs also appreciated that CRs could improve the quality of care by providing useful reminders of tasks or actions [59,60]:

> *...in a patient with diabetes where there are 17 things to do and I've just missed out two or three of them (...) it's really nice to have "somebody" say "Oh, don't forget, there's the urine test, and you haven't yet sent the patient for the eye test that you thought somebody else was doing, and it looks like nobody's done after all so maybe get that done?"* [59]

GPs in one study reported how CRs could improve how they practice in the long term by their ability to promote and reinforce appropriate prescribing behaviors.

> *...and it's actually educational, because a lot of them you know the warning before it comes up because you've seen it so many times so you're already aware of it. So I mean some of the things I know now are because of it, so there is an educational element to it [...]* [58]

Self-Efficacy

There were conflicting accounts regarding the extent to which CRs enhance GPs' confidence in practicing safely. In one study, GPs described how the presence of CRs was a source of reassurance, supporting their ability to provide safe care in the increasingly complex environment of modern primary care [61,63].

> *...work in general practice is getting bigger and bigger, and more work's going to come to general practice. So, although it [the CR] can cause irritation, the flip side of that is you can relax a little bit more and that you don't have to remember absolutely everything (...)* [63]

In another study, a GP reflected upon how having to choose a predetermined response outside of their original decision led them to question their ability [59]:

> *...in order to dismiss it you have to select what action you've taken such as, well have you called an ambulance, have you sent them into hospital...you're then panicking thinking gosh I don't want, I don't want to lie, no I haven't sent them into hospital but is that a judgement, is that them saying because I haven't done that I'm a rubbish doctor?* [59]

Adopter

Factors Influencing GPs' Engagement With CRs: Digital Literacy and Consultation Impact

From the perspective of those adopting CRs, GPs described the factors affecting their engagement with CRs, the influence of digital literacy, and the impact of CRs on their consultation.

Engagement and Compliance in CRs

In one study, GPs expressed hesitation in relying on a computer-generated algorithm [59]. Concerns surfaced in 3 studies over the accuracy and relevance of the recommendations associated with CRs, with examples including unrecognized contraindications [58,63,65]:

> *[drug-drug interactions] were mentioned in printed textbooks but were not picked up by the interaction checking facility of their prescribing software* [63]

XSL•FO
RenderX

One study described a preference for greater transparency between the clinical evidence and the presentation of the CR. As one GP described:

> *[We're] inherently distrustful of anything that hasn't got somebody saying "Oh! I've done this trial, and this trial, and we've used it!" and I think that's what we've been taught at medical school - to be sceptical, until we've got the evidence.* [59]

Digital Literacy and Acceptability

The belief emerged that the new generation of GPs more familiar with digital technology in everyday life would be more accepting of computer-generated reminders [59].

> *I think to a certain extent there is a bit of a cultural change in the sense that the newer generation of doctors coming through are much more used to computers telling them things in their own lives and so they're much more accepting of the idea that the computer might give them helpful information.* [59]

GPs in 3 studies described how the reliance on CRs risked undermining the accrual of contextual knowledge of a particular patient [59,61,67].

> *A lot of the patients who I kind of see regularly with chronic problems, I kind of know if they're well or not because I know the patient and I just can tell if they're themselves or if they're not because you have a constant, you know, you lose that with a computer.* [59]

Related to this was the feeling that CRs were overly prescriptive and one GP felt that the value of their input was diminished relative to the diktats of the CR:

> *I think it feels frustrating...when the system is so process-driven that there's no sort of autonomy of the GP to, you know, change it or, kind of, put in what's relevant.* [59]

Patient-Clinician Relationship

Two studies reported that GPs understood the importance of focusing on patients during consultations, acknowledging that referral to, and interaction with, CRs can be an impediment to patient-centered interaction [61,63]:

> *I don't use any separate clinical decision support tool in the consultation because of time problems, losing eye contact with patients* [63]

Organization

Organizational Influences on CR Adoption: Training and System Capacity

In considering organizational influences, evidence emerged of the importance of training and the impact of existing practice capacity and systems.

Training and Purpose

GPs in 5 studies reflected on the importance of training not only to understand the purpose of CRs but also their functionality [58-61,63]. One GP bemoaned the typical lack of training before the introduction of digital tools:

> *...so, yeah things just happen [. . .] They often will appear before you have any training or knowledge of it whatsoever. Then if you're lucky maybe there's a launch event six months after you've already started using it.* [58]

Practice Capacity and Workflow

GPs noted how the pressure on their time restricted their ability to interact with CRs that take time to resolve [58,60]. As one GP explained:

> *We might have six or seven of them [reminders], and once you've got (...) worked through about three or four, and then there's this anticoagulation...you think, well that's another 5 or 10 minutes of consultation (...) so you leave it.* [60]

In another example, one GP likened the appearance of a CR to a colleague bursting through the door during a consultation:

> *It really is like an interruption, you know, no GP wants somebody to just burst in with the door opening or the phone ringing. In the same vein no GP really wants a big thing to just pop up on the screen that they didn't call up.* [59]

Wider System and Embedding Over Time

Enhancing CR Implementation: Systemwide Collaboration and Adaptation Strategies

The potential impact of improved systemwide collaboration was described, and a number of suggestions were made as to how CRs may be adapted to ensure more sustained implementation.

Systemwide Collaboration

It was suggested in 2 studies that more closely integrated data sets across settings would support the quality of the CRs [63,66].

> *I want a dynamic electronic health communication with the possibility of a written dialog and forwarding missing information.* [66]

The importance of sharing best practices and recommendations for certain CR systems between peers was also described:

> *I think there is a degree of sharing these kind of protocols and algorithms amongst GP practises and we certainly, you know, GPs talk to each other and say "oh yeah we've got this thing that alerts for that particular problem", "oh, have you? Right great can we, can we bring it in?"* [59]

Adaptation Over Time

Three studies described how GPs would have liked greater engagement with the software developers in the design of the CRs [58,63,65]. Suggestions for ways in which CRs might be improved included the acquisition of patient-specific alerts, better integration into practice workflows, and customizability informed by GP feedback [59-61,63]. In terms of their design and content, there were also suggestions for the inclusion of

XSL•FO
RenderX

additional details on dosage or color-grading CRs according to severity [63].

Discussion

General Findings

A total of 9 studies published since 2003 were identified, reporting research conducted in Europe, predominantly the United Kingdom, and Australia, 7 of which were judged to be of high quality. The findings from these studies were effectively categorized within the domains of the NASSS framework. Regarding Condition and Value Proposition, the use of CRs in diagnosis, prescribing, and the ongoing management of chronic conditions was seen as an effective means of maintaining or improving safe and high-quality care, albeit with contrasting effects on clinician self-efficacy. In terms of Technology attributes, the efficacy of CRs was found to be directly linked to their frequency, the presentation and accuracy of their content, and the speed and reliability of IT infrastructure and hardware. With respect to Adopter attitudes, GPs raised concerns about the accuracy of CRs and the potential loss of benefits derived from their clinical experience and consideration of individual patient contexts, in favor of algorithm-based decisions. From an Organization perspective, the importance of training and the ability of CRs to integrate seamlessly with existing workflows were emphasized. Finally, in the context of the Wider System, several suggestions were made to improve the usability of CRs, including the sharing of best practices and involving GPs earlier in the design process to ensure successful embedding over time.

Specific Findings and Comparison With Existing Literature

Condition/Value Proposition

Managing the medications of a growing number of patients with multiple long-term conditions is a major contributor to GP workload in the United Kingdom and other countries [68,69]. The studies we identified suggest that CRs can play a positive role in supporting this management [58,59,62-64,66], and it is widely recognized that CRs present a valuable opportunity to reduce adverse drug reactions [70].

The potential of CRs to support diagnosis was highlighted in 4 of the identified studies [60,61,64,65]. This ability has been previously acknowledged as a significant advantage in primary care, where diagnostic errors are a critical concern, particularly for diseases with low incidence but high health risk [71-73].

Primary care is expected to take on an increasing role in managing chronic conditions across various countries and health systems, including the United Kingdom [74,75]. However, this capacity is often hindered by limited consultation times, high patient volumes, and inadequate communication with specialists [75,76]. In such contexts, CRs that draw on patient-specific data to remind GPs to test, review, or conduct periodic interventions appear highly valuable, though only 1 study explicitly examined this functionality [64].

The ability of CRs to prompt reflection on clinical decision-making was viewed positively in 5 of the studies [58-61,63]. The benefits of reflective practice on clinical decisions are well established, particularly when the feedback on decisions, as with CRs, is immediate [77].

Technology

The studies we identified confirmed that GPs felt overwhelmed by the number, complexity, and often poor functionality of CRs [59,61,63,64]. This cognitive overload caused by multiple appearances of CRs reflects previous research suggesting it can hinder clinician interaction with clinical decision support systems [18-20,78]. The cognitive burden associated with CRs also stems from the complexity of their content [59,62,63]. Therefore, CRs should be designed to accurately convey risk and relevant information in a clear, easily interpretable format that adheres to best practices in digital interface design [79-82]. Additionally, they should be better integrated into existing software and workflows [83,84].

Artificial intelligence has begun to be utilized in clinical decision support systems for individual conditions, and it is reasonable to assume it will play a role in refining the specificity of CRs in primary care [85]. However, efforts to minimize the negative impact of CRs, such as improving specificity [18] or allowing clinicians the autonomy to disable certain CRs [83], must remain mindful of patient safety implications [86].

The ability of GPs to respond promptly to CRs was also influenced by the speed and reliability of practice IT infrastructure and hardware [59,60,62,66]. Ensuring that existing IT systems can handle the growing prevalence and complexity of digital health care is widely acknowledged as a critical need in both high- and low- and middle-income countries. However, this challenge has yet to be universally addressed [87,88].

Adopter

GP concerns about CRs that enforce process-driven decisions at the expense of context and experience were described in 4 of the studies we identified [58,59,63,65]. Notably, lasting cynicism expressed by GPs who had experienced prior failures with CRs (described in 2 of the identified studies [59,63]) has been previously recognized in primary care, where digital interventions have failed to meet expectations [89].

A framework for technology developers has emerged that aims to enhance clinician confidence in clinical decision support systems by adhering to a predetermined set of criteria, focusing on understanding and sustaining trust among end users [90,91]. Evidence from one study we identified suggested that resistance to digital interventions may be lower among the generation of clinicians who grew up alongside the proliferation of digital technologies [59]. It is hoped that trust in CRs can be fostered through greater and earlier engagement with clinician end users by software developers and senior decision makers [92-94]. This aligns with long-standing recommendations for increased user involvement in the development of digital health tools [67,89].

The negative disruption of patient consultations by CRs was also highlighted [61,63]. It is already known that technology can interrupt the flow of conversation, reduce nonverbal communication cues, and compromise the overall quality of patient interactions [95,96]. Concerns expressed by GP

XSL•FO
RenderX

participants in the identified studies reflect existing evidence that clinicians highly value uninterrupted in-person consultations, as they build patient trust and foster a constructive provider-patient relationship [97,98].

Organization

The lack of training emerged as a barrier to engagement and compliance with CRs in the studies we identified [58-61,63] and has previously been highlighted as central to their effective use, including sharing with GPs the processes behind their generation [99,100]. However, targeted training to enhance engagement with CRs has yet to be systematically implemented in the high-income countries where they are most prevalent [101].

The pressure on GPs to address increasingly complex care needs and rising patient expectations within shortening consultation times is widely acknowledged [102]. GPs in the identified studies reported that managing multiple CRs was unfeasible within the constraints of limited consultation times [58,60]. Some studies suggest that specific CRs, such as those supporting preventive care, could be delivered to patients before the consultation to alleviate the time pressure on GPs [103].

Wider System and Embedding Over Time

The need for systemwide coordination and collaboration in introducing CRs into primary care, as described in the review's findings [59,63,66], has also been recognized in other health care settings [104-106]. Similarly, the calls for earlier clinician engagement in the design and development of CRs identified in this review [58,63,65] have been previously acknowledged [107-109], alongside the input of clinical informaticists [110]. While there are recognized challenges in engaging time-pressured GPs during the early stages of software development, sustainable adoption of health technology requires understanding its social and organizational contexts. This can only be achieved by involving end users throughout its design and development [111,112].

Strengths and Limitations

The recognized systematic review methodology was applied to identify relevant papers [27,113], including the dual-review process [114]. The comprehensive NASSS framework successfully accommodated all of the data identified [26] and its use demonstrated both the transparency and rigor of our approach but also allowed us to structure and contextualize our data with existing research to avoid distorting our conclusions [28]. We acknowledge that there were a number of potential limitations. First, all the studies identified originated in high-income countries and were presented in English; however, we would suggest that the lessons learned have the potential for broader applicability for digital interventions in health systems of low- and middle-income countries that in reality share many of the same, if accentuated, barriers to technology-enabled care [111,112]. Second, it is possible that the use of an a priori framework might limit the analysis, with some data unable to be allocated within its confines; however, taking the unconstrained matrix approach suggested by Elo and Kyngäs [56] allowed the development and inclusion of emergent themes within the established framework. This meant we could maintain alignment with our established objectives and provide a systematic description of novel findings.

Conclusions

If utilized correctly CRs can enhance patient safety, workflow management, preventative care, and reduce cognitive overload. Based on the findings of the review several recommendations can be made for the future design and implementation of CRs (see Table 4). These include improved graphical designs better suited to the purpose of the CR, more nuanced and patient-specific content, greater clinician autonomy regards if and when CRs are seen, and earlier and more consistent engagement with the workforce in their design and development.

Table 4. Recommendations for future CR[a] design and implementation.

Domain	Recommendation
Technology	• Visual-driven user interface to present information more effectively and reduce information overload. • More directly applicable data (eg, dosage or risk). • The capacity of the infrastructure.
Adopter	• GP[b]-endorsed or GP-recommended CRs would promote and increase their uptake. • Ensuring that CRs transparently reflect the latest clinical evidence.
Organization	• Greater engagement with the workforce in the introduction of CRs. • Additional training would help the uptake of CRs and using them effectively, accommodating the age and experience of the clinician. • Enable organizations to better incorporate CRs in existing/novel workflows.
Wider systems	• GP-stakeholders collaboration would enable feedback and co-design of alert utilization.
Adaptation	• Alert customization would allow GPs to deactivate unnecessary options to change output and will provide flexibility.

Abstract

Background: Obesity and mental health issues present interconnected public health challenges that impair physical, social, and mental well-being. Digital technologies offer potential for enhancing health care communication between health professionals (HPs) and individuals living with obesity and mental health issues, but their effectiveness is not fully understood.

Objective: This scoping review aims to identify and understand the different types of technologies used by HPs in supporting obesity and mental health communication.

Methods: A comprehensive scoping review, which followed a validated methodology, analyzed studies published between 2013 and 2023 across 8 databases. The data extraction focused on HPs' use of communication technologies, intervention types, biopsychosocial considerations, and perceptions of technology use. The review was guided by the following research question: "What are the uses, benefits, and limitations of digital technologies in supporting communication between HPs and persons living with obesity and mental health issues?"

Results: In total, 8 studies—featuring web-based platforms, social media, synchronous video calls, telephone calls, automated SMS text messaging, and email—met the inclusion criteria. Technologies such as virtual learning collaborative dashboards and videoconferencing, supported by automated SMS text messaging and social media (Facebook and WhatsApp groups), were commonly used. Psychologists, dietitians, social workers, and health coaches used digital tools to facilitate virtual appointments, diet and mental health monitoring, and motivational and educational support through group therapy, 1-on-1 sessions, and hybrid models. Benefits included enhanced access to care and engagement, personalized digital cognitive behavioral therapy, perceived stigma reduction, privacy, and improved physical health outcomes in weight reduction. However, improvements in mental health outcomes were not statistically significant in studies reporting *P* values ($P \geq .05$). The limitations included engagement difficulties due to conflicting personal family and work commitments; variable communication mode preferences, with some preferring in-person sessions; and misinterpretations of SMS text messaging prompts. Conflicts arose from cultural and individual differences, weight stigma, and confusion over HP roles in obesity and mental health care.

Conclusions: Digital technologies have diversified the approaches HPs can take in delivering education, counseling, and motivation to individuals with obesity and mental health issues, facilitating private, stigma-reduced environments for personalized care. While the interventions were effective in obesity management, the review revealed a shortfall in addressing mental health needs. This highlights an urgent need for digital tools to serve as media for a deeper engagement with individuals' complex biopsychosocial needs. The integration of data science and technological advancements offers promising avenues for tailored digital solutions. The findings advocate the importance of continued innovation and adaptation in digital health care communication strategies, with clearer HP roles and an interdisciplinary, empathetic approach focused on individual needs.

Introduction

Background

Obesity and mental health issues, two of the greatest global public health challenges [1], are intricately linked in a bidirectional and complex relationship that impacts both physical and mental well-being [2]. People experiencing depression are found to have a 58% increased risk of becoming obese [3]. Conversely, obesity is associated not only with physiological challenges but also social and mental health burdens [4], with persons who are obese facing an increased risk of developing depression over time. This relationship is particularly pronounced among people with serious mental illnesses (SMIs) such as schizophrenia or bipolar disorders, where obesity prevalence ranges between 45% and 55% [5]. Mental disorders account for the leading cause of global disability and determine how individuals make healthy choices [6], impacting personal well-being and quality of life [7]. The intertwined nature of obesity and mental health problems has a substantial impact on socioeconomic and health care systems [7]. The increasing prevalence of these conditions in society [8] calls for an urgent need to address this dual challenge to improve global health outcomes.

Health professionals (HPs) play an integral role in communicating mental health and obesity risks to the public [9]. Effective communication has been shown to positively impact the relationship between the HP and service users, engagement, and patient outcomes [10]. Communication regarding weight and mental health is especially challenging because communication training for HPs focuses on the medical aspects rather than the complexities of the conditions [11]. HPs require appropriate guidelines to identify users at risk of mental health issues [12]. Technology advances have the potential to transform health care, as evidenced by their critical role in communicating health messages during the COVID-19 pandemic [13]. According to Thomas [14], health communication is defined as "the systematic study and practical application of communication strategies in health, to inform and influence the attitudes, knowledge, and practices of individuals and communities." Within this domain, the co-occurrence of obesity and mental health issues presents a challenge. While there is an increasing acknowledgment of the importance of these interrelated health issues, a distinct gap exists in the literature. Currently, there is no review that addresses the intersection of mental health issues and obesity.

The rates of coexisting obesity and mental health issues are rising [15,16] owing to a multitude of physical, psychological, and environmental factors, such as medications, unhealthy diet, alcohol misuse, sedentary lifestyles, and low mood affecting adherence to weight management (WM) interventions [3,17-19]. Despite this growing concern, research studies often overlook the interplay between obesity and mental health issues, particularly in how these conditions are addressed and communicated by HPs. Current multidisciplinary guidelines for HPs dealing with obesity and mental illness recommend that they monitor and address patients' lifestyles; yet, research has found that most HPs have limited lifestyle-related knowledge and skills and that lifestyle treatment protocols are lacking [16]. There is a lack of understanding among HPs of how to integrate digital health solutions into everyday practices and procedures [20]. Existing research shows a need for obesity and mental health communication support for HPs. Obesity and mental health issues are acknowledged as a global health priority, but medical and sociocultural characteristics of the population are not taken into consideration [21]. Thus, research is required to explore the use of digital communication aids among HPs and the growing challenges presented by aging populations with multimorbidities.

Objectives

This scoping review aims to identify and understand the different types of technologies that are used by HPs in supporting obesity and mental health communication. This scoping review was guided by the following broad central research question: "What are the uses, benefits, and limitations of digital technologies in supporting communication between HPs and persons living with obesity and mental health issues?"

Methods

Scoping Review Framework

A scoping review applying a systematic approach was conducted as per the guidance of Munn et al [22] on choosing between different approaches when conducting evidence synthesis. This novel method was selected to address the broad research question guiding this review: to scope the literature for knowledge gaps [23] and gain conceptual clarity on the adoption of digital technologies in health care communication by thematically analyzing the available literature [24]. The framework developed by Arksey and O'Malley [25] guided this review, as recommended by Levac et al [23] and Daudt et al [26]. A scoping review applying a systematic approach was conducted, as per the guidance of Munn et al [22] on choosing between different approaches when conducting evidence synthesis, and the Cochrane Handbook for Systematic Reviews of Interventions [27] for systematic review methodology. This involved the following steps: (1) identifying the research question, (2) identifying relevant studies, (3) study selection, (4) charting the data, and (5) summarizing and reporting the results [25]. The review process applied the rigorous standards of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist [28] (Multimedia Appendix 1) as the latest and most advanced approach for transparent and comprehensive reporting of scoping reviews.

XSL•FO
RenderX

Research Question

The purpose of this scoping review is to present the results of existing literature addressing the role of digital technologies used by HPs in facilitating communication with individuals living with obesity and mental health issues. The guiding research question was as follows: "What are the uses, benefits, and limitations of digital technologies in supporting communication between HPs and persons living with obesity and mental health issues?"

Search Strategy

The inclusion criteria followed the JBI scoping review guide [29], using *population*, *concept*, and *context*. The review included studies of all designs to identify the best evidence available to address the research objective. To support a thorough search, no time frame limit was applied, and all languages were included if translation was possible using Google Translate [30].

Eight electronic databases—Ovid MEDLINE, CINAHL, Scopus, ScienceDirect, PsycINFO, IEEE Xplore, ACM Digital Library, and ClinicalTrials.gov—were systematically searched in April 2023. These databases were chosen to capture articles in health care, psychology, and computer science fields. In addition, manual citation searching was performed to identify any relevant sources that might have been overlooked by the database searches.

Due to the novelty of the topic concerned, a broad search strategy was developed with high sensitivity to the following key terms: (1) "health professional," (2) "digital technology," (3) "obesity," and (4) "mental health." On the basis of the literature, benchmark definitions for these concepts were developed. A total of 144 synonyms were formulated for the search strings (Multimedia Appendix 2) with the guidance of a trained librarian. From the database searches and manual citation searching, 1656 hits were identified (Multimedia Appendix 3).

Study Selection

Following the framework outlined by Arksey and O'Malley [25] and aligning with the exploratory nature of scoping reviews, this study included primary research articles on digital technology interventions supporting HP communication with individuals facing obesity and mental health challenges. Exclusions were made for sources not directly related to HP communication support, such as those focused on technology use during HP training, which were deemed to be outside the scope of this review. In addition, conference papers, design protocols, and abstracts without full studies were excluded. The full eligibility criteria are presented in Textbox 1.

Textbox 1. Eligibility criteria for the scoping review.

Inclusion criteria

- Population: health professionals (HPs) and clients living with obesity and mental health issues
- Concept: studies that implement digital technology interventions aimed at enhancing communication processes
- Context: comorbidities of obesity and mental health issues
- Study characteristics: primary research studies; no time limits applied; all languages included if translation possible using Google Translate

Exclusion criteria

- Population: intervention without a focus on HP communication support
- Concept: digital technology intervention for clients with obesity and mental health issues, with no clear supporting role of HPs
- Context: broad or general comorbidities, not including obesity and mental health issues specifically
- Study characteristics: conference papers and design protocols

Articles identified from the systematic search were managed using the Covidence software platform (Veritas Health Innovation Ltd) [31]. Titles and abstracts were screened by 2 reviewers (AK and AM) independently (n=1078). The full text of relevant articles identified during the title and abstract screening was examined for eligibility against the inclusion and exclusion criteria by 2 independent reviewers (AK and AM). Ultimately, of the 1078 articles screened, 8 (0.74%) studies exemplifying the use of technology in HP communication for obesity and mental health issues were selected for analysis.

Charting and Extracting Data

Adhering to the JBI guidelines, a tailored data extraction template focused on study details, participant characteristics, interventions, and outcomes. The Covidence template was checked for suitability by 2 reviewers (AM and MM) before data extraction commenced. One author (AK) extracted data, which were verified by a second author (AM); disagreements were resolved by discussion. A thematic analysis identified key concepts related to HP communication technologies, including types of technology use, HP roles, biopsychosocial considerations, and perceptions regarding benefits and limitations in obesity and mental health contexts.

Summarizing and Reporting Results

The data charting process identified key themes, which were mapped around the biopsychosocial theoretical model developed by Engel [32] to facilitate an understanding of the results. Data synthesis involved comparing methodologies and results across the 8 studies to identify trends and gaps.

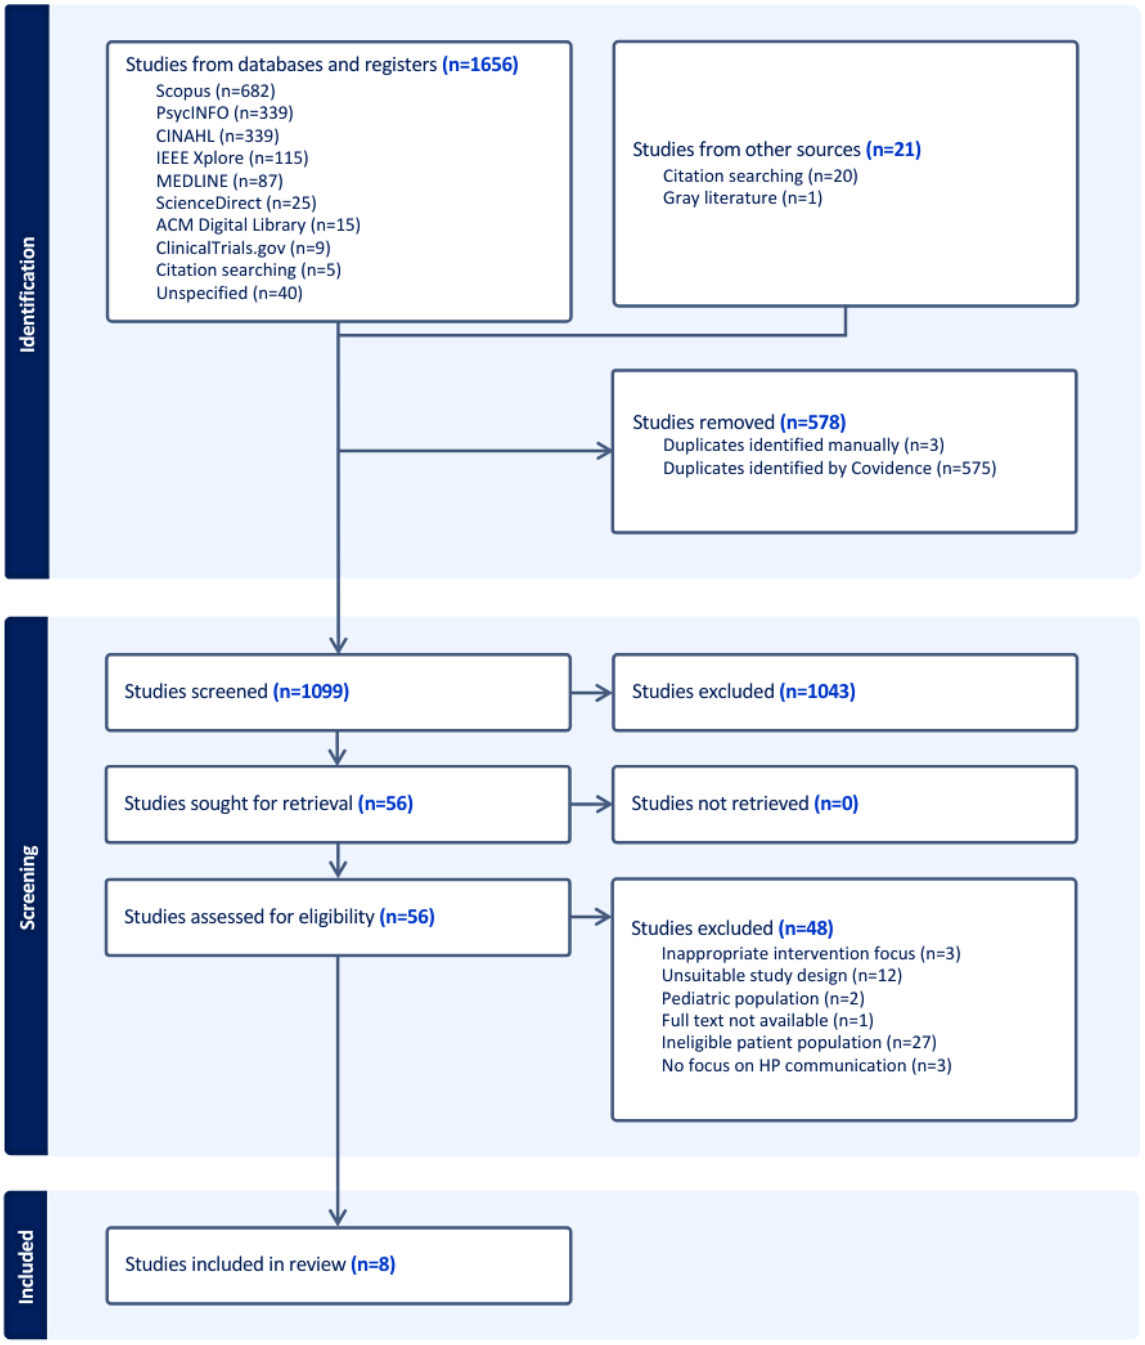
XSL•FO
RenderX

Quality Appraisal

The primary aim of the scoping review was to map out the diversity of technology use in HP communication; however, to enhance the reliability of the findings on technology use in HP communication for obesity and mental health issues, a detailed quality appraisal of the included studies was conducted. This involved using the revised Cochrane risk-of-bias tool for randomized trials (RoB 2) for randomized controlled trials (RCTs) [33] and the Risk of Bias in Nonrandomized Studies of Interventions (The Cochrane Collaboration) tool for nonrandomized studies [34]. This dual approach helped critically evaluate the evidence base, identifying studies with lower risks of bias that could provide more dependable insights into the effectiveness of digital technology interventions for managing obesity and mental health issues.

Eight original research studies integrating technology for HP communication support were critiqued for study design, implementation, and reporting [35-42]. The studies were rigorously assessed by 2 independent reviewers (AK and AM), using a grading key for risk of bias (ROB): (1) low ROB, (2) some concerns, and (3) high ROB.

Results



Selected Studies

This scoping review included 8 studies: 4 (50%) RCTs, 1 (12%) pilot RCT, and 3 (38%) qualitative feasibility studies. They were conducted in the United States (5/8, 62%), the United Kingdom (1/8, 12%), South Korea (1/8, 12%), and Iran (1/8, 12%; the percentages do not add up to 100% due to rounding). The study selection process is detailed in the PRISMA-ScR flow diagram (Figure 1), outlining the inclusion and exclusion steps taken during the literature review.

Key data from each study, including publication year, country, design, sample size, aim, context, demographic details, key findings, and limitations, were systematically charted (Table 1).

XSL•FO
RenderX

Table 1. Data extraction charting for the included scoping review studies (n=8)[a].

Study; year; country; study design	Aim	Participants, n; context; sex: %; age (y)	Key findings and conclusions	Comments
Lee et al [35]; 2023; United Kingdom; qualitative feasibility	Enhance web-based WM[b] program uptake for SMI[c] using VLC[d]	17; web-based, participants with SMI; female: 76; ≥18 (mean 48, SD not reported; range 29-70)	Promising engagement through digitally enhanced augmented WM program, complemented by brief, targeted education and low-intensity check-ins	Small size; potential bias
Bartels et al [38]; 2022; United States; hybrid RCT[e]	Compare web-based VLC vs TA[f] in the InSHAPE health promotion program for individuals with SMI	HPs[g]: 55; CMHC[h], with patients with SMI: 1219; female: % not reported; ≥18 (mean and SD not reported)	VLC as effective as TA in SMI obesity management	Sample representativeness; no cost data
Aschbrenner et al [36]; 2022; United States; 2-arm RCT	Evaluate PeerFIT mHealth[i] online Facebook group vs 1-on-1 mHealth (BEAT[j]) coaching for young adults with SMI who were overweight or obese	150; CMHC, young adults with SMI; female: 55; 18-35 (mean 28.46, SD 4.5)	PeerFIT and mHealth coaching equally effective, indicating that low-intensity mHealth coaching is a scalable, beneficial intervention option	Blinding issues; COVID-19 impact on retention; low engagement; lack of text or activity tracker data access; unexplored intervention format preferences
Nicol et al [41]; 2022; United States; qualitative feasibility	Test web-based iOTA[k] method (SMS text messaging and in-person coaching) for adults with SMI undergoing obesity treatment	26; CMHC, adults with SMI; female: 60; 16-75 (mean 48.5, SD 15.67)	iOTA method feasible; engagement varied; outcomes influenced by symptom severity, indicating a need for tailored adaptations	Small heterogeneous sample; implementation challenges; more comprehensive symptom assessments needed
Haddad et al [39]; 2022; United States; qualitative feasibility	Adapt mHealth obesity treatment for adults with SMI using web-based SMS text messaging I-Corps[l] methods	29; CMHC, various stakeholders, participants with SMI unspecified; sex not reported; age not reported	Feasibility of adapted mHealth obesity treatment; stakeholder insights: need for microadjustments in clinical settings and clarity in health coaching responsibilities	Limited consumer input; reporting bias; no specific differentiation in SMI diagnosis
Abedishargh et al [37]; 2021; Iran; 3-arm RCT	Assess ICBT[m] on WhatsApp for mental health issues of women with overweight	90; online support group, participants with depression or anxiety; female: 100; 18-50, 38.2% 18-30 (mean and SD not reported)	ICBT reduced BMI but not mental health issues	No follow-up; pandemic influence on short duration of therapy; online implementation challenges; sample selection process not detailed
Yu et al [42]; 2021; United States; pilot RCT	Evaluate videoconferencing-based treatment for BED[n]	18; web-based, participants with obesity with BED; female: 100; 20-73 (mean 32, SD 15.27)	Videoconferencing-based treatment improved shape concern but not weight	Small size; high dropout rate; technical issues; potential self-reported bias
Kim et al [40]; 2020; South Korea; 2-arm RCT	Test digital CBT[o] for WM in adults with depression or anxiety using intensive, multifactorial, daily psychologist coaching	70; online, participants with depression or anxiety; female: 100; 18-39 (mean 21.8, SD 3.3)	Effective CBT integration in digital WM combined with multidisciplinary human support	Generalizability; self-report inaccuracies; feasibility: intensive and costly, requiring daily intervention by trained therapists

[a]Summary: study design: 4 randomized controlled trials (RCTs), 1 pilot RCT, and 3 qualitative feasibility studies; conducted in the United States (5/8, 62%); aim: assessed digital interventions including web-based virtual learning collaborative dashboards, SMS text messaging, and online support groups for improving engagement and effectiveness in serious mental illness and obesity; participants: n=17–150; contexts included community mental health centers (50%) and online communities (50%); primarily female, 16–75 years (mean 35.8, SD 9.68; % female unknown in some studies); key findings: interventions improved engagement and effectiveness but faced limitations like small samples, biases, and generalizability issues; comments: limitations included small sample sizes, biases, and feasibility concerns.

[b]WM: weight management.

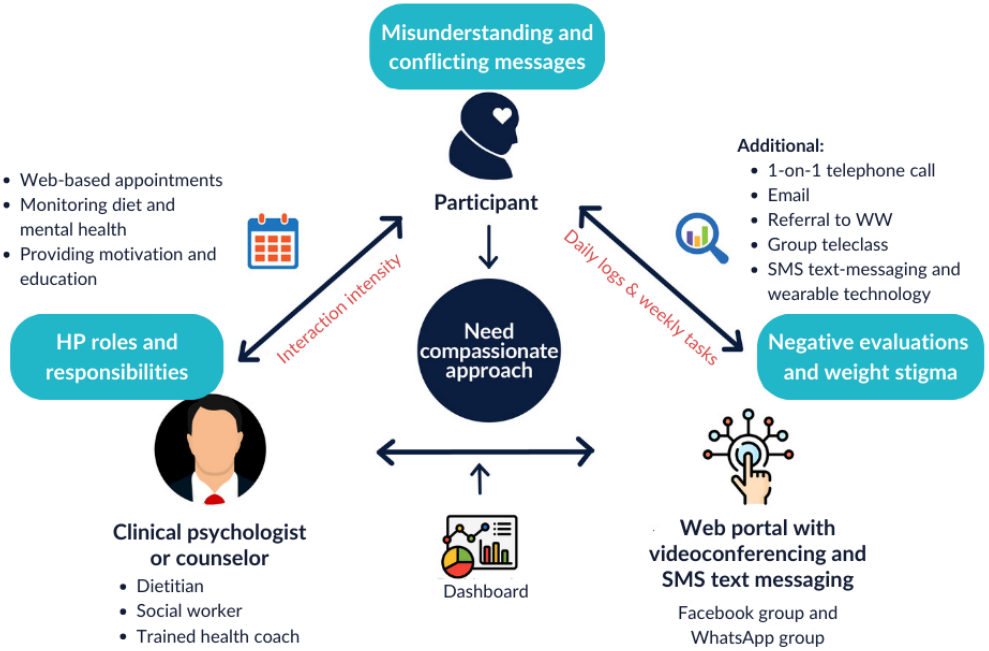
Participant Characteristics

The participant pool varied, ranging from 17 to 150 participants per study. Half of the studies (4/8, 50%) were conducted at community mental health centers [36,38,39,41], and the other half (4/8, 50%) involved web-based recruitment of the general population [35,37,40,42]. Most participants were female, with sex data reported in 75% (6/8) of studies (range 55%-100%). Recruitment ages ranged from 16 to 75 years, with a mean age of 35.8 years. Among the 4 studies that reported SDs (50%), the average SD was 9.68 years (Table 1). The studies used various tools to assess mental health conditions such as SMI, depression, anxiety, and binge eating disorder, providing a diverse insight into mental health evaluations in the context of digital technology use in health care (Table 2).

Table 2. Participant mental health (MH) characteristics and assessment tools in the included studies (n=8).

Participant criteria for MH issues	Studies, n (%)	Specific MH assessment tools	Tools used (n=14), n (%)
SMI[a] (as defined by, eg, schizophrenia, schizophreniform disorder, schizoaffective disorder, bipolar disorder, or depression with psychosis) [41]	1 (12)	• Clinical Global Impression severity score of >5	1 (7)
Depression, anxiety (with stress or self-esteem issues) [37,40]	2 (25)	• Situational Motivation Scale • Korean version of the Beck Depression Inventory-II • Taylor Anxiety Inventory • Rosenberg Self-Esteem Scale • Automatic Thoughts Questionnaire-30 • Depression Anxiety Stress Scales	6 (43)
BED[b] [42]	1 (12)	• Eating Disorder Examination Questionnaire 6.0 • Eating Attitudes Test-26 • Three-Factor Eating Questionnaire–Revised 18 • Yale Food Addiction Scale • Symptom Checklist-90–Revised • Beck Depression Inventory-II • Impact of Weight on Quality of Life–Lite	7 (50)
SMI but no specified assessment tools, that is, no specificity of MH issues [35,39] or measured fidelity and cardiovascular risk reduction only [36,38]	4 (50)	• None	0 (0)

[a]SMI: serious mental illness.



[b]BED: binge eating disorder.

Uses of Digital Technologies in Obesity and Mental Health Communication

The investigation into the use of digital technologies across the 8 included studies highlights their role in addressing obesity and mental health issues. These technologies facilitated virtual appointments, diet and mental health monitoring, and the provision of motivational and educational content. In terms of professional use, psychologists or counselors were consistent users across all studies [35-42], with additional involvement from dietitians [38,42], social workers [36,39], and trained health coaches [35,38] (Figure 2 [35-42]).

XSL•FO
RenderX

Figure 2. Mapping of the uses of digital technologies and key themes from the 8 included studies [35-42] regarding the role of digital technologies in supporting communication between health professionals (HPs) and participants with obesity and mental health issues. WW: WeightWatchers.

The primary digital interventions varied. They included web-based platforms with synchronous video calls (4/8, 50%), automated SMS text messaging (2/8, 25%), and social media (Facebook and WhatsApp groups; 2/8, 25%). Various supplementary support methods were used, including 1-on-1 telephone calls (3/8, 38%), email (3/8, 38%), group teleclasses (2/8, 25%) [37,42], referrals to WeightWatchers (2/8, 25%), and the integration of SMS text messaging with wearable technology (1/8, 12%). The most frequently reported tool was the virtual learning collaborative (VLC) dashboard with its videoconferencing feature [35,38,40,42]. The most common supplementary support methods used were 1-on-1 telephone calls [35,38,40] and email [35,38,42].

The 8 studies illustrated diversity in their approach to digital interventions, with 4 (50%) focusing on group therapy, 2 (25%) on 1-on-1 interventions, and 2 (25%) using a hybrid model that combined both methods. HP interaction frequencies varied, with the most common being daily interactions (3/8, 38%). Typical session durations were either 1 hour (2/8, 25%) or 1.5 hours (2/8, 25%), and the interventions spanned an average duration of 3 months (3/8, 38%, SD 1.63 months), with the total number of sessions ranging from 4 to 52 sessions with an HP (Table 3).

XSL•FO
RenderX

Table 3. Data extraction results for the included studies on digital interventions and health professional (HP) communication (n=8)[a].

Study; year	Intervention name	Secondary support	HPs involved	Contact time	Interaction	Duration (mo)	Sessions, n	Adherence	Theory
Main digital intervention: web portal VLC[b] dashboard with videoconferencing									
Lee et al [35]; 2023	WHEEL[c]; Meet Your Mentor (single 1.5-h, web-based, 1-on-1 consultation)	Telephone call or email mentor check-ins plus referral to WW[d] group	Psychologist	90-min plus 15-min interim booster support	Weekly (fixed day and time) for 12 wk	3	12	Good	PBA[e] (based on the MRC[f] model)
Bartels et al [38]; 2022	InSHAPE VLC	Telephone call or email mentor check-ins plus referral to WW group	Trained fitness instructor receives instruction from health psychologist, dietitian, and senior-level InSHAPE program manager and trainer	4-d InSHAPE training plus 90-min follow-up sessions	Monthly	12-18	50	Good	VLC
Yu et al [42]; 2021	Fruit Street videoconferencing program	Group teleclass and email	Psychologist and dietitian	1 h	Weekly	3	12	Good	CBT[g]
Kim et al [40]; 2020	Noom coach and InBody	1-on-1 telephone calls	Psychologist	Weekly group call plus 15-min interim booster support	Daily	2	8	Good	CBT+MI[h]
Main digital intervention: SMS text messaging									
Haddad et al [39]; 2022	Innovation Corps iOTA[i]	—[j]	Psychologist, prescribing physician, nurse, and social worker	—	—	—	—	Not reported	VLC
Nicol et al [41]; 2022	Working for You iOTA	—	Trained health coach at mental health clubhouse; no specific roles	—	Monthly	3	4	Adequate	Chronic care model
Main digital intervention: Facebook or WhatsApp groups									
Aschbrenner et al [36]; 2022	PeerFIT	SMS text messaging and wearable technology	Psychologist, counselor, social worker, or fitness professionals	1 h	Daily	12	52	Poor	SCT[k]+DPP[l]
Abedishargh et al [37]; 2021	Weight loss	Group teleclass	Psychologist plus peer-led interventions	2 h	Daily	1.5	42	Good	CBT

[a]Table 3 summarizes various digital interventions (web portals, virtual learning collaborative [VLC], SMS text messaging, and social media), with mixed delivery methods (1-on-1 telephone calls, mentor check-ins, and group classes) and diverse health professionals' involvement (psychologists, dietitians, social workers, and fitness instructors). Contact time ranged from 15-minute booster sessions to 90-minute consultations, with interaction frequencies varying from daily to monthly. Intervention durations ranged from 1.5 to 18 months, with 4 to 52 sessions. Adherence varied, and theories included cognitive behavioral therapy, VLC, motivational interviewing, social cognitive theory, Diabetes Prevention Program, and person-based approach.

[b]VLC: virtual learning collaborative.

[c]WHEEL: Weight Change for People With Serious Mental Illness.

[d]WW: WeightWatchers.

XSL•FO
RenderX

[e]PBA: person-based approach.

[f]MRC: Medical Research Council.

[g]CBT: cognitive behavioral therapy.

[h]MI: motivational interviewing.

[i]iOTA: interactive obesity treatment approach.

[j]Not applicable.

[k]SCT: social cognitive theory.

[l]DPP: Diabetes Prevention Program.

Content-wise, the digital interventions drew upon a range of theoretical frameworks and strategies, including cognitive behavioral therapy (CBT; 2/8, 25%), CBT plus motivational interviewing (1/8, 12%), VLC (2/8, 25%), the person-based approach following the Medical Research Council model (1/8, 12%), the chronic care model (1/8, 12%), and the social cognitive theory supplemented with Diabetes Prevention Program content (1/8, 12%; Table 3).

Quality Appraisal

The studies varied in quality. Of the 5 RCT studies, 2 (40%) were rated as high quality with low ROB [38,40], and 3 (60%) were deemed to have an acceptable ROB [36,37,42] based on the ROB 2 (Table 4), while the qualitative feasibility studies were consistently rated as high quality and low ROB [35,39,41] based on the Risk of Bias in Nonrandomized Studies of Interventions tool (Table 5).

Table 4. Quality assessment of 5 included randomized controlled trial studies using the Cochrane risk-of-bias tool for randomized trials (ROB 2)[a].

Study; year	Risk of bias: methods			Risk of bias: results		Overall risk of bias
	Study design	Participants	Assessments and data collection	Reporting quality	Clinical efficacy	
Bartels et al [38]; 2022	++[b]	++	++	++	++	++
Aschbrenner et al [36]; 2022	++	+[c]	+	+	+	+
Abedishargh et al [37]; 2021	++	++	+	+	+	+
Yu et al [42]; 2021	++	+	+	+	+	+
Kim et al [40]; 2020	++	++	++	++	++	++

[a]The studies demonstrated a low risk of bias in methods and results overall, though some concerns were noted in assessments, reporting quality, and clinical efficacy. Variability in risk levels was observed across study design and participant selection

[b]++: high quality and low risk of bias.

[c]+: acceptable risk of bias.

Table 5. Quality assessment of 3 included qualitative feasibility studies using the Risk of Bias in Nonrandomized Studies of Interventions (ROBINS-I) tool[a].

Study; year	Risk of bias						
	Confounding	Participant selection	Intervention classification	Deviations from intended interventions	Missing data	Measurement of outcomes	Selection of reported result
Lee et al [35]; 2023	Low	Low	Low	Low	Low	Moderate	Low
Nicol et al [41]; 2022	Moderate	Low	Low	Moderate	Low	Moderate	Low
Haddad et al [39]; 2022	Moderate	Low	Low	Moderate	Low	Low	Low

[a]Across the studies, deviations from intended interventions were assessed as moderate risk of bias, while low risk of bias was consistently noted for participant selection, intervention classification, missing data, and selection of reported results. Risk of bias for outcome measurement was moderate in 67% (2/3) of studies.

Benefits of Digital Technologies in Obesity and Mental Health Communication

The digital interventions provide benefits such as improved access to personalized care via digital CBT, tailored feedback, and enhanced physical health outcomes, including weight loss and BMI improvement. The study by Haddad et al [39] unveiled that some service users had previous negative in-person interactions with HPs, perceiving limited benefit relative to the "additional burden of time and mental energy" invested, and some participants preferred online intervention delivery because it helped reduce stigma (Multimedia Appendix 4 [35-42]). The digital format offered a supportive and private environment conducive to client adherence, motivation, engagement, and

XSL•FO
RenderX

comfort, thereby reducing the stigma associated with seeking help [36,37]. Participants with mood disorders reported experiences of shame and negative self-evaluation [33], showing the importance of addressing self-esteem issues within digital health platforms. Personalization and engagement emerged as key factors in the success of digital interventions [39]. Programs with digital CBT, adapted to individual characteristics and supported by intensive daily monitoring, were shown to improve participant engagement and adherence with minimal dropout rates: as noted by Bartels et al [38], "only one drop out for personal reasons, and 80% remained active until the end of the treatment session. Authors owe this to motivation construct."

Efforts to enhance the implementation and effectiveness of digital interventions include comprehensive training for health mentors, involving psychologists, dietitians, and program managers [37]. This indicates the significance of a multidisciplinary approach and the need for sustainable funding and training solutions: and training solutions. For instance, Abedishargh et al [37] highlighted the challenge of "finding a funding source to pay for a dietitian," while Bartels et al [38] emphasized the importance of "training changes and sustainability of a wellness program." The collaboration within VLC programs, intensive skill-building training, and the involvement of mentors and leadership emphasize the value of mentorship and a compassionate approach in program delivery [36]. Significant improvements in WM were observed in 7 (88%) of the 8 studies [35-41], showing the efficacy of digital interventions in supporting better physical health outcomes.

The fact that there was no significant improvement in mental health outcomes suggests a potential inadequacy in the ability of the digital interventions to simultaneously address mental health needs and obesity. Yu et al [42] observed no significant changes in weight and binge eating episodes among participants. Conversely, Nicol et al [41] demonstrated that individuals with less severe symptoms and higher engagement achieved statistically significant weight loss (P<.001) compared to those with more severe symptoms. Nonetheless, clarity regarding the inclusion criteria for individuals with SMI was lacking in the studies, and there was inconsistency in the measurement of outcomes related to mental health status (Table 2). These findings indicate a need for further research that adopts a comprehensive and multidisciplinary approach to digital health interventions.

Limitations of Digital Technologies in Obesity and Mental Health Communication

Challenges in implementing digital technologies include misinterpretations of SMS text messaging prompts [41], variability in user engagement, and adherence [35,36,38,42]. These challenges highlight the importance of flexible and adaptable interventions, personalized to individual lifestyles and preferences, and a clear understanding of HP roles in digital interventions. The recurrent call for dietetic expertise [38-40,42] identifies a gap in incorporating comprehensive nutritional guidance within these interventions, advocating for a multidisciplinary strategy that includes dietitians to offer balanced and scientifically sound dietary advice tailored to the needs of individuals managing obesity and mental health issues (Table 6).

Table 6. Key further research questions identified from the scoping review.

Research question	Relevance	Directions for future research
How can digital interventions be tailored to better address the mental health needs of individuals with comorbid obesity and mental health issues?	Psychosocial	Investigate adaptive features and content within digital interventions to provide comprehensive mental health support alongside obesity management.
How can personalized care be enhanced in digital interventions for obesity and mental health care?	Psychosocial	Examine methods for deep personalization in digital interventions, considering the complexity of comorbid conditions and individual user needs, focusing on unique needs, engagement, and outcomes.
What are the optimal strategies for enhancing user engagement and adherence to digital interventions?	Psychosocial	Develop and test engagement strategies that account for individual preferences for, and barriers to, sustained use of digital health tools, while incorporating robust adherence measures.
How can digital interventions be designed to support a more compassionate and empathetic approach to obesity and mental health care?	Psychosocial	Explore the integration of features that enhance empathy, compassion, and effective communication between clients and HPs[a] in digital health platforms, promoting patient satisfaction, trust, and improved outcomes.
What are the optimal roles and responsibilities of HPs in digital interventions to ensure high fidelity and participant retention?	Social	Determine the best practices for multidisciplinary collaboration in digital health interventions, optimizing HP roles, involvement, and training needs.

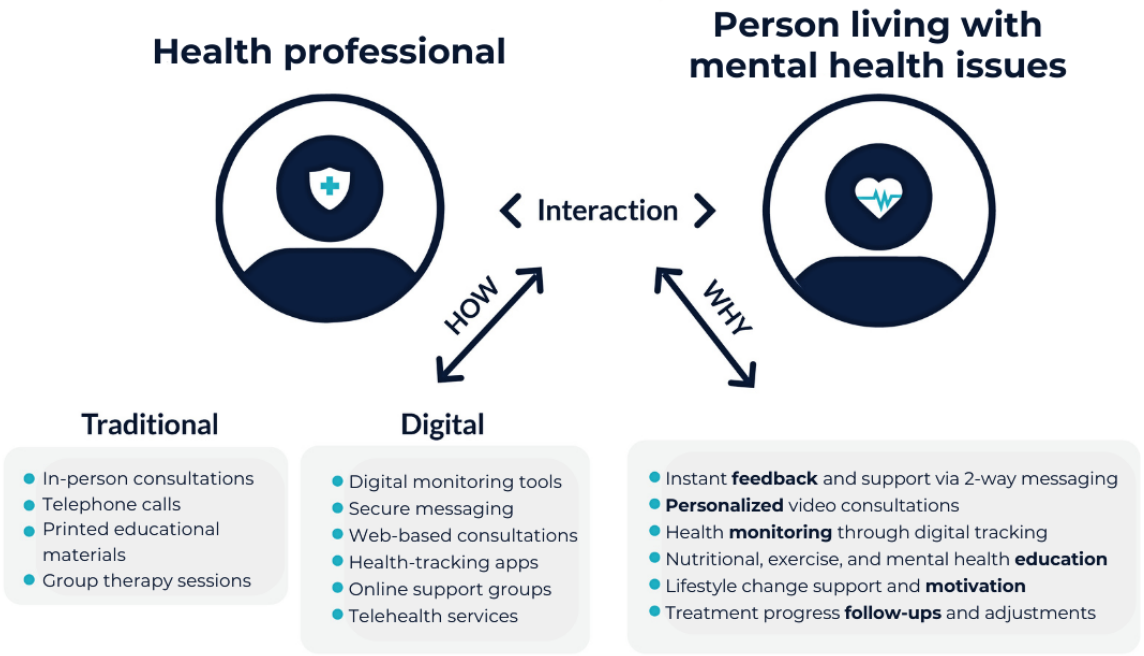
[a]HP: health professional.

Variability in intervention intensity and the roles of HPs present challenges in achieving effective program outcomes. The comparison between a nutritionist-led "treatment as usual" group and a psychologist-led internet-based CBT intervention highlights this issue [37]. The daily delivery of internet-based CBT demonstrated a more substantial reduction in BMI compared to the weekly sessions conducted by nutritionists, suggesting that the interaction frequency rather than the professional role might influence outcomes. Nonetheless, neither approach significantly impacted participants' stress, anxiety, or depression levels [35]. Furthermore, low adherence to tools such as food diaries, perceived as the "least helpful component"

XSL•FO
RenderX

[42], indicates that such tools may trigger feelings of shame or self-criticism among users. Future research should explore the integration of 1-on-1 technical assistance and peer-group problem-solving to address these challenges [38], emphasizing the need for personalization, improved communication, empathetic care, and the integration of multidisciplinary care teams to address both physical and mental health issues in digital health care settings.

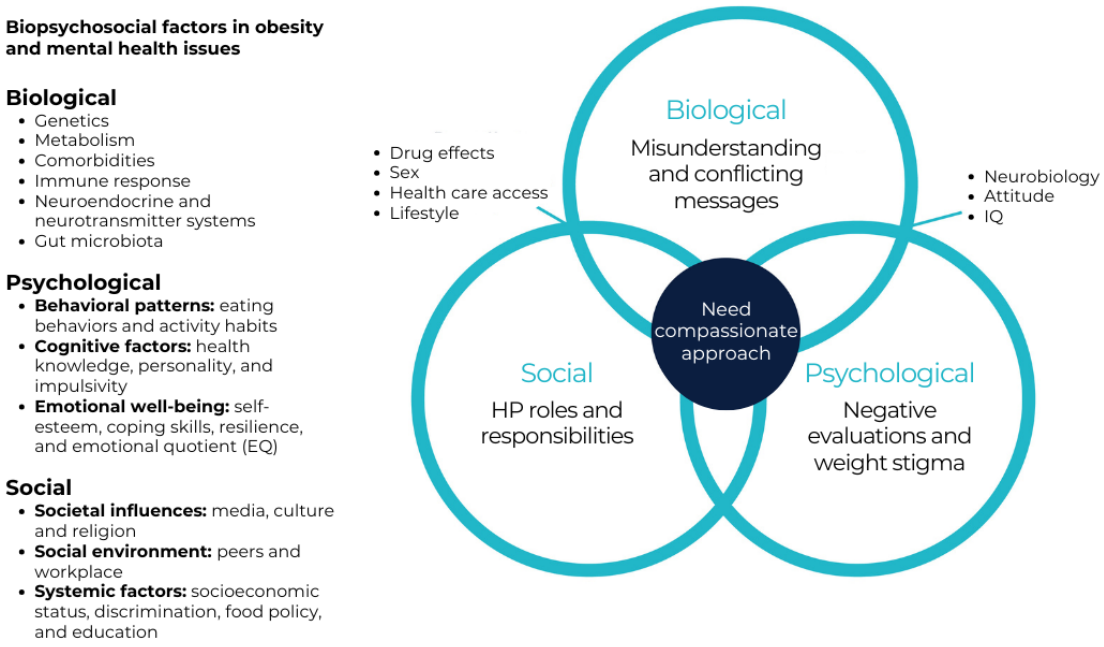
The studies collectively revealed certain key themes: misunderstanding and conflicting messages, negative evaluations and weight stigma, the need for a compassionate and empathetic approach, and confusion about HP roles and responsibilities in the context of obesity and mental health care (Table 3). These themes, along with detailed narratives, benefits, and limitations associated with obesity and mental health communication derived from the 8 included studies, are documented in Multimedia Appendix 4. This compilation aligns with the biopsychosocial theoretical model developed by Engel [32], illustrating the integrated approach needed to address these issues effectively.



Discussion

Overview

This scoping review reveals a significant research gap in the application of digital technologies for health care communication between HPs and individuals with comorbid obesity and mental health issues [43] (Figure 3). Despite the extensive search strategy, only 8 studies were retrieved for this scoping review, showing the scarcity of published research. Significantly, these papers were published after 2020, highlighting the novelty of the interdisciplinary research focus and emerging interest after the COVID-19 pandemic, which has accelerated the integration of digital technologies into health care settings. This trend is observable across various countries, emphasizing the universal shift toward digital modalities in addressing complex health care needs associated with obesity and mental health, particularly in the postpandemic era.



Although prior studies have explored the use of technology in the realms of obesity [17,44,45], no research has yet investigated its role in managing comorbid obesity and mental health communication. This review suggests the necessity for more primary research to evaluate whether digital technologies can enhance health communication practices, improve care, and engage users; however, it also highlights a lack of existing studies addressing the combined challenges of obesity and mental health issues. Further research should aim to understand how technological advances can support communication between HPs and individuals living with obesity and mental health issues to deliver person-centered care that meets the biopsychosocial needs of this population [20]. Figure 4 [35-42] portrays the complexities of these biopsychosocial factors and the mapping of the key research themes from the 8 included studies to the biopsychosocial theoretical model.

Figure 3. The role of digital technologies in supporting bidirectional communication between health professionals and persons living with obesity and mental health issues.

Figure 4. Mapping of the key themes related to obesity and mental health complexities from the 8 included studies [35-42] to the biopsychosocial theoretical model. EQ: emotional quotient; HP: health professional.

Uses of Digital Technologies in Health Care Communication Among Those With Obesity and Mental Health Issues

Although research in this area remains limited, the available evidence suggests that digital platforms have a growing role in bridging the communication gap between HPs and clients, especially in a post–COVID-19 era marked by disruptions in physical access to HPs [46]. Digital platforms, including those providing web-based interfaces, social media networks, and synchronous video call features (Figure 3), facilitate services such as virtual appointments and health monitoring across different professional domains. The findings complement the World Health Organization report [47], highlighting that tele–mental health has emerged as an effective medium for delivering education and psychological treatments, offering an alternative or supplementary approach to traditional therapies [46].

However, this review reveals variability in participant preferences for intervention delivery, highlighting the potential benefits of combining regular HP visits with extended mobile health coaching [35,40,41]. In terms of the frequency and scheduling of HP sessions, some participants found that weekly scheduled telephone check-ins were helpful [35,42], whereas others wanted more flexibility around the competing demands of family or work commitments [35,36,42]. Such clarity is vital for ensuring a comprehensive and unified approach to treating obesity and mental health issues, supporting a more cohesive and integrated care experience for participants.

Benefits of Digital Technologies in Obesity and Mental Health Communication

Digital technologies enhance obesity and mental health care by offering web-based counseling, personalized care, and tailored interventions [35,41], facilitating a more effective response to individual needs. This personalized approach is significant in ensuring that each individual's unique health journey is adequately considered and managed (Multimedia Appendix 4). A key element in the success of digital health care interventions is the formation of a therapeutic alliance within web-based settings. The "Meet Your Mentor" program exemplifies the advantages of digital health care, providing a platform for clients to share their stories in a private, in-depth, initial, 1-on-1, 1.5-hour consultation [35]. This indicates the value of individualized attention in digital interventions to facilitate a deeper connection and understanding between the client and the provider.

The shift toward digital health care platforms has significantly reduced the necessity for in-person interactions, mitigating the stigma and negative perceptions often linked to certain health conditions [48]. This change has enhanced client engagement by alleviating the discomfort of activities such as physical weigh-ins, which are more daunting in a group setting [35]. Digital modalities provide anonymity, supporting an environment that encourages open and honest communication, essential for overcoming the challenges of the stigma prevalent in traditional settings [48]. Prior studies support the effectiveness of digital health care in promoting better client-provider interactions through the privacy and detachment it offers compared to face-to-face consultations [35,49].

Furthermore, digital platforms support social learning and compassionate care through peer-to-peer interactions [36,37],

XSL•FO
RenderX

promoting mutual support and understanding among participants [50]. Digital technologies have been effectively used to maintain connectivity and engagement between participants, with higher adherence observed in interventions that were tailored to unique individual needs [35,40]. A recent scoping review identified the need to explore effective communication techniques that could be adopted to maintain interpersonal client-provider connections in digitally enabled health care environments [49]; however, the evidence is still unclear, and no studies focus on populations with obesity and mental health issues. This review also identifies a need for more comprehensive interventions to simultaneously address the complex challenges posed by comorbid mental health issues and obesity.

Limitations of Digital Technologies in Obesity and Mental Health Communication

Despite the potential of digital technology use for health care communication in the context of obesity and mental health issues, there are certain limitations, as this review reveals. Variability in adherence to digital interventions suggests that not all components are equally effective across different settings. The COVID-19 pandemic restrictions further highlighted engagement and retention issues [36,37], showing the need for adaptable research designs to accommodate unpredictable circumstances [36,41]. Issues such as the inconsistent use of self-reported food diaries [40,42] point to the need for interventions that consider individual preferences and behaviors (Table 6). Nicol et al [41] reported the need for more comprehensive symptom assessments, while Aschbrenner et al [36] noted poor adherence, suggesting that young adults prefer individually tailored mobile health coaching over group-based sessions. The variability in engagement and adherence, especially in group-delivered sessions, points to a need for more customized approaches that consider individual preferences and lifestyles.

The current body of evidence identifies a gap in addressing the social complexities associated with comorbid obesity and mental health issues. The studies included in this review lack sufficient detail on communication preferences within interventions [38], highlighting the need for research into effective, compassionate communication strategies to achieve person-centered care [49]. The complexity of various HP roles involved in implementing digital technologies, compounded by conflicting messages and weight stigma [44,51,52], highlights the necessity for empathy and an understanding of the unique challenges faced by individuals with comorbid conditions. Recent research has explored compassionate digital health care [49] but not specifically in the context of obesity and mental health issues.

Future research should focus on tailoring digital interventions to meet the mental health needs of those with comorbid conditions, enhancing personalization, developing engagement strategies, incorporating compassionate care approaches, and defining optimal roles for HPs in digital settings (Table 6). These areas represent critical steps toward improving the effectiveness of digital health care interventions for individuals facing the dual challenges of obesity and mental health issues.

Interdisciplinary and Person-Centered Care

The integration of HP disciplines and the use of diverse digital technologies in interventions (Table 3) align with the biopsychosocial model of health [32], offering holistic care for those with comorbid obesity and mental health issues. Government initiatives, such as the UK Department of Health's Mental Health Strategy 2021-2031, support digital, multidisciplinary, person-centered care [53-55]; yet, organizational barriers often prevent effective care delivery [39]. This review identified a potential disconnect between policy recommendations and their practical implementation in health care settings [39], while the recollection of weight stigma experiences, known to harm mental and physical health, underscores the need for action at the policy level [51].

This review points to a lack of technology acceptance theoretical models in current research [4], suggesting a need for frameworks, such as the Unified Theory of Acceptance and Use of Technology 2 formulated by Venkatesh et al [56], to understand the adoption of digital technology in obesity and mental health care. The studies included in this review did not use advanced technologies such as artificial intelligence and virtual reality (VR) [53,57,58], which could offer personalized immersive interventions and create new avenues for engagement. Innovative treatment modalities such as exposure therapy in VR [59] and detailed behavioral data collection through digital phenotyping [57] could help better understand and treat mental health conditions. This disparity suggests a gap in using emerging technologies to enhance the quality and reach of digitally supported health care services [53].

The interdisciplinary nature of interventions aimed at improving physical and mental health among individuals with SMI is evident in the collaborative efforts across various disciplines, including mental health services, fitness professionals, and digital technology experts [35,36,38-40]. Programs such as InSHAPE and PeerFIT demonstrate the benefits of community-based partnerships and professional diversity [36,38] by providing health-mentoring sessions at local community fitness facilities. Integrating individuals with SMI into the broader community promotes social inclusion and reduces stigma. However, this review also points to a deficiency in compassionate communication through digital health care, emphasizing the necessity for strategies that support empathy and understanding in treating obesity and mental health issues.

The PeerFIT and Weight Change for People With Serious Mental Illness interventions illustrate the value of interdisciplinary collaboration, engaging professionals from various backgrounds, such as mental health, fitness, psychology, and social work, trained in health coaching [35,36]. These initiatives, alongside the stakeholder engagement strategy proposed by Haddad et al [39] show the effectiveness of integrating diverse expertise and community involvement in health interventions. Such approaches ensure that the interventions are responsive to the real-world needs of individuals with SMI, leveraging digital technology for more accessible, inclusive health care solutions. This emphasizes the need for interdisciplinary and person-centered principles in developing next-generation communication tools, aiming to

XSL•FO
RenderX

comprehensively address the multifaceted needs of those with comorbid conditions (Table 7).

Recent research has acknowledged that technology use influences how HPs perform their work and interact with clients [49]; however, little is known about how compassion is conveyed through digital health care modalities, especially in the context of obesity and mental health care. Despite the widespread adoption of digital health technologies and their potential to impact client outcomes positively [49,55,57,60], strategies for compassionate digital communication for complex health issues are underexplored, signaling a need for research on compassionate, digital approaches for obesity and mental health support (Table 7).

This review emphasizes the need for sociocultural sensitivity in tailoring messages and goals in digital interventions. While most of the included studies reported improvements in physical health outcomes such as weight and BMI, the lack of significant progress in mental health outcomes was a significant finding. This discrepancy raises questions about the comprehensiveness of these interventions in addressing the dual challenges of obesity and mental health issues [42]. Individuals with mental health issues may have trouble engaging with routine WM interventions, and bespoke options are rarely offered in routine practice [35].

Table 7. Proposed requirements for next-generation communication tools based on the findings from the reviewed studies (n=8).

Requirement	Description	Justification
Comprehensive care	• Content addressing both physical and mental health needs, including modules for digital CBT[a], stress management, dietary tracking, and physical activity monitoring with real-time feedback and support	• Ensures holistic care by addressing the intertwined nature of physical and mental health, improving overall well-being
Personalization and tailoring	• Customized content and dynamic intervention adjustments using AI[b] and machine learning based on user data (eg, behavior, cognition, and emotion)	• Personalization and feedback based on individual user data (eg, behavior, cognition, and emotion) have been shown to improve engagement and adherence [39,40]
Enhanced engagement and adherence	• Engaging interfaces, gamification, reminders, incentives, and progress-tracking features	• Increases user motivation and sustained tool use, crucial for long-term health management
Compassionate design	• Features promoting empathy, including personalized messaging, web-based support groups, videoconferencing, secure messaging, and forums for peer support • Training for HPs[c] on compassionate care delivery	• A compassionate approach addresses psychological and social needs in health care, supporting a sense of community and belonging [35,36,38,42]
Multidisciplinary support	• Tools for HPs to monitor progress, provide feedback, and collaborate across disciplines	• Enhances care fidelity and patient retention through comprehensive, coordinated care approaches [38,39,42]
Stigma reduction	• Anonymous participation options and educational content to counteract stereotypes and misinformation	• Reduces barriers to seeking help by mitigating stigma and promoting a more inclusive care environment
Anonymity and privacy	• Ensuring user anonymity and privacy to reduce fears of judgment and stigma	• Encourages wider participation by providing a secure and confidential user experience. Anonymity encourages participation by mitigating concerns about judgment [35,37]
Integration with existing health care systems	• Compatibility with health care platforms for streamlined care coordination. Adaptability across health care settings and comprehensive training for users and providers	• Seamless integration with health care systems can enhance the efficacy and sustainability of digital interventions [37,38] • Compliance with health care regulations and data protection standards
Technical assistance	• Continuous support and education for users and providers to maximize digital tool benefits and adapt to updates	• Ensures that users and providers can effectively use the full range of tool capabilities, enhancing overall intervention success

[a]CBT: cognitive behavioral therapy.

[b]AI: artificial intelligence.

[c]HP: health professional.

Digital technologies play a vital role in extending health care reach, especially to communities considered marginalized, by providing anonymous, unbiased access to services, thus reducing pressure on health care systems [60]. They serve as an accessible

XSL•FO
RenderX

bridge for support while individuals await further assistance [57,60]. However, achieving their full potential requires ongoing innovation, tailored designs, and an inclusive and interdisciplinary strategy that equally addresses physical and mental health [12,18,58,61].

To address these gaps, future research should explore more extensive interventions with larger participant groups and extended follow-up assessments to gauge the sustained impacts of digital interventions. Customizing digital tools to fit individual needs, aligned with policy support, is essential [47,54]. These tools should facilitate deeper engagement with the complex needs of those facing both obesity and mental health challenges, moving beyond mere information dissemination. High-quality data use could improve direct client interactions [57], although the included studies lack detailed insights into the specific characteristics and preferences of this demographic, highlighting a gap in effective digital communication strategies for HPs catering to individuals with comorbid obesity and mental health issues.

Limitations

Study limitations included the small sample of 8 selected studies, with limited sample sizes (ranging from 17 to 150 participants), which may limit the generalizability of the findings. A common reliance on self-reported data, such as food diaries, introduces susceptibility to inaccuracies and social desirability bias. Of the 8 included studies, 7 reported intervention durations. Most (6/7, 86%) were of short duration (≤12 weeks) and lacked long-term follow-ups, limiting insights into the sustainability of outcomes. One study did not specify its duration, highlighting the need for standardized reporting. The interventions noted feasibility challenges related to the labor intensity required from HPs and implementation costs [38]. The predominance of female participants and varied study designs, including RCTs and feasibility studies, offer varied perspectives but also raise questions about the broader applicability of the results.

Digital interventions, while beneficial, risk exacerbating social isolation or excluding certain populations due to reduced physical contact and digital accessibility issues, such as a lack of digital skills, limited resources, or unwillingness to engage with digital platforms. There was a lack of exploration of participant preferences for intervention format, which is crucial for tailoring interventions to individual needs and enhancing engagement and effectiveness. This highlights a need to consider digital inclusion in future digital health initiatives.

Methodologically, inconsistencies in the inclusion criteria for SMI and the measurement of mental health outcomes were noted (Table 2). This ambiguity hinders the ability to definitively assess the impact of digital interventions on mental health issues, pointing to the need for more standardized criteria in future research. In addition, the focus on diagnostic criteria may limit the understanding of underlying processes common across weight and mental disorders, suggesting a shift toward a more process-oriented approach in future studies [19].

Conclusions

This scoping review sheds light on the evolving role of digital technologies in health care communication for individuals living with obesity and mental health issues. It reveals the use of diverse modalities to bridge communication gaps; deliver education, motivation, and counseling; and enhance care accessibility and multidisciplinary support. However, it also highlights limitations related to inconsistent adherence, challenges in implementation, and the absence of technology acceptance theoretical models in current research. A key finding is the tangible improvement in physical health outcomes in obesity management through digital means. However, the effectiveness of these technologies in concurrently addressing mental health issues is less conclusive, marking a critical area for further investigation. The limited but insightful studies show the interdisciplinary and evolving nature of this field, accelerated by recent advancements in digital health care delivery.

The findings advocate for future research to be more extensive and inclusive, with an emphasis on the long-term impacts of digital interventions. This includes conducting follow-up assessments to understand the sustained effects and integrating innovative technologies such as artificial intelligence, VR, and machine learning to enrich mental health interventions [53,59]. The application of frameworks such as the Unified Theory of Acceptance and Use of Technology 2 model [56] could provide valuable insights into the adoption and use of digital technology by HPs in addressing complex health issues. While digital tools offer promise for enhancing health care communication in obesity management, their full potential in addressing concurrent mental health issues is yet to be realized. The review calls for custom digital solutions that address the biopsychosocial needs of those facing both obesity and mental health challenges, advocating for an interdisciplinary approach that encompasses various HP roles and comprehensive nutrition support [40]. This research is pivotal for advancing clinical practices and informing health policy, emphasizing the ongoing need for innovation and adaptation in digital health care communication strategies.

In conclusion, the journey toward using the full potential of digital technologies in health care communication is ongoing, with enhanced accessibility, reduced stigma, and personalized care as key benefits. Nevertheless, there remains a need to develop more comprehensive and integrated digital solutions to effectively tackle the complex interplay of obesity and mental health issues [36]. The vital steps for moving forward include addressing participant preferences; encouraging collaborative design [57]; and ensuring that interventions provide consistency, cohesion, and choice for participants [54].

Data Availability

All data generated or analyzed during this study are included in this published paper (and its supplementary information files).

Authors' Contributions

AK led the systematic search and study selection, adhering to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, and was responsible for data extraction and result synthesis, formal analysis, and manuscript writing. AM assisted in designing the study and the methodology, guided the thematic analysis, oversaw the quality appraisal of the included studies, assessed the risk of bias, and contributed to manuscript review and editing. AM, MM, and RB supervised the research process. All authors engaged in discussions to synthesize the results and to draw meaningful conclusions. Each author reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Although catheter ablation (CA) is currently the most effective clinical treatment for atrial fibrillation, its variable therapeutic effects among different patients present numerous problems. Machine learning (ML) shows promising potential in optimizing the management and clinical outcomes of patients undergoing atrial fibrillation CA (AFCA).

Objective: This scoping review aimed to evaluate the current scientific evidence on the application of ML for managing patients undergoing AFCA, compare the performance of various models across specific clinical tasks within AFCA, and summarize the strengths and limitations of ML in this field.

Methods: Adhering to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, relevant studies published up to October 7, 2023, were searched from PubMed, Web of Science, Embase, the Cochrane Library, and ScienceDirect. The final included studies were confirmed based on inclusion and exclusion criteria and manual review. The PROBAST (Prediction model Risk Of Bias Assessment Tool) and QUADAS-2 (Quality Assessment of Diagnostic Accuracy Studies-2) methodological quality assessment tools were used to review the included studies, and narrative data synthesis was performed on the modeled results provided by these studies.

Results: The analysis of 23 included studies showcased the contributions of ML in identifying potential ablation targets, improving ablation strategies, and predicting patient prognosis. The patient data used in these studies comprised demographics, clinical characteristics, various types of imaging (9/23, 39%), and electrophysiological signals (7/23, 30%). In terms of model type, deep learning, represented by convolutional neural networks, was most frequently applied (14/23, 61%). Compared with traditional clinical scoring models or human clinicians, the model performance reported in the included studies was generally satisfactory, but most models (14/23, 61%) showed a high risk of bias due to lack of external validation.

Conclusions: Our evidence-based findings suggest that ML is a promising tool for improving the effectiveness and efficiency of managing patients undergoing AFCA. While guiding data preparation and model selection for future studies, this review highlights the need to address prevalent limitations, including lack of external validation, and to further explore model generalization and interpretability.

Introduction

Background

Atrial fibrillation (AF) is the most common type of cardiac arrhythmia [1], and its incidence has risen steadily over the past 3 decades, making it an urgent public health problem worldwide [2,3]. While AF substantially impacts patients' quality of life, it also increases the risk of serious medical conditions [4-7], such as stroke and thromboembolism. This contributes to long-term rises in both morbidity and mortality rates [8] as well as a growing strain on health care costs [9].

Catheter ablation (CA) represents the most effective clinical intervention currently available for AF [10]. When patients receive their first CA treatment, the effectiveness rate can reach 60%-80% within 1 year [11,12]. However, the long-term efficacy is not optimal , and the success rate decreases to 50%-60% at 3 to 5 years [13-15]. The type and degree of AF, cardiac stroma, obesity, alcohol consumption, and obstructive sleep apnea syndrome are all known to be potential contributors to high rates of recurrence in the long term [16,17]. In addition, the surgical modality and ablation strategy used in treatment have an impact, particularly for those patients who require additional non–pulmonary vein (PV) ablations [18]. Consequently, developing tailored management strategies that consider different patient conditions, optimizing the surgical approach and enhancing its long-term efficacy, is a challenge that needs to be resolved in this field.

In clinical practice, to better manage patients, clinical risk scores (such as APPLE [19]) specifically for predicting postoperative recurrence of AF CA (AFCA) have emerged in the past decade, or attempts have been made to use other scores (such as $CHADS_2$ [20] and CHA_2DS_2-VASc [21]) to evaluate patients' postoperative rhythm outcomes after AFCA [22]. These risk scores typically use a limited number of risk factors as predictors. Although this simplicity facilitates their adoption and use in clinical settings, it concurrently caps their predictive effectiveness. In addition, these scoring models predominantly rely on the evaluation of specific biomarkers in previous literature when selecting predictors. This approach may easily lead to the neglect of some potential predictors [23], thus failing to truly capture the complexity of the AFCA recurrence mechanism and making it difficult to truly meet the pursuit of efficient and personalized patient management.

Rapidly developing machine learning (ML) techniques hold significant promise as a formidable support in grappling with the complexities of this challenge. In recent years, the ability of ML to analyze large biomedical datasets, such as electronic health records (EHRs), medical imaging, and multiomics data, has made it increasingly popular in medical research [24,25]. ML models have become promising tools for enhancing the precision and efficiency of AF diagnosis and treatment. By analyzing complex, multidimensional datasets, they help identify individuals at high risk for AF, uncover risk factors and biomarkers associated with the disease's progression, and guide personalized interventions for prognosis. One branch of ML, deep learning (DL), stands out due to its powerful capabilities in automatic feature recognition and prediction. In processing complex data types such as images and electrophysiological signals, DL has demonstrated performance comparable to that of human experts [26,27]. Several studies have attempted to apply ML technology to the management of patients undergoing AFCA. As the application prospects of ML technology in this field become increasingly clear, a comprehensive overview and evaluation of the existing relevant literature is needed.

Objectives

The purpose of this scoping review is to systematically review the current progress in using ML technology in the management of patients undergoing AFCA. Specifically, the studies discussed in this review explore a wide range of ML models and multiple data modalities, including EHR, imaging omics, and cardiac electrophysiological signals. We will summarize how these studies prepare data, select models, and evaluate results across different clinical tasks. In addition, we will emphasize the advantages and limitations of ML technology in this field based on the integration and comparison of these study findings.

Methods

This scoping review was conducted following the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) guidelines [28].

Information Sources and Search Strategies

A comprehensive search was conducted to identify relevant studies across 5 databases as of October 7, 2023: PubMed, Web of Science, Embase, the Cochrane Library, and ScienceDirect. The specific search strategies used for each database are detailed in Table S1 in Multimedia Appendix 1. In addition to obtaining literature through search formula, additional relevant articles (3/246, 1.2%) were manually identified by using a forward-backward snowballing approach.

Study Inclusion and Exclusion Criteria

In line with the thematic focus and objectives of our review, the studies included in this scoping review were required to meet the eligibility criteria outlined in Textbox 1. Studies were excluded from this scoping review if they met any of the exclusion criteria.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for published studies applying machine learning (ML) technology for the management of patients undergoing catheter ablation for atrial fibrillation.

Inclusion criteria

- Article type: articles (peer reviewed and formally published)
- Study topic: specializes in the management of patients undergoing catheter ablation for atrial fibrillation
- Study participants: real patients with atrial fibrillation
- Study design: ML techniques were clearly applied and described; results of the study and the ML model performance outcome metrics were explicitly presented
- Language of publication: English

Exclusion criteria

- Article type: reviews; meta-analyses; editorials; case reports; editorial materials; other types of publications
- Study topic: atrial fibrillation disease detection; risk prediction of new onset of atrial fibrillation
- Study participants: only used fictional patient data
- Study design: did not apply ML techniques; did not explicitly report on the model outcome metrics
- Language of publication: non-English

Study Selection

After removing duplicates, all retrieved studies were manually screened by title and abstract to exclude those clearly not aligned with the objectives of this review. Studies that passed this initial screening were then downloaded in full and assessed based on the inclusion and exclusion criteria during a full-text review. This process was independently conducted by 2 reviewers, with any disagreements resolved through consultation with a third reviewer to reach a consensus.

Data Extraction

Two reviewers independently extracted data from the selected studies, and a third reviewer was responsible for assessing and addressing any discrepancies and biases in data extraction. The following data items were extracted: author names and publication years, data sources, dataset sizes, ML models, model variables, model tasks (such as prediction or detection), and model results. If multiple ML models were used in a study, we will report only the one with the best performance.

Quality Assessment

We selected the widely recognized Quality Assessment of Diagnostic Accuracy Studies-2 (QUADAS-2) [29] and Prediction model Risk Of Bias Assessment Tool (PROBAST) [30] as methodological quality assessment tools. We divided the included studies into 2 subgroups for independent evaluation based on different research objectives, namely, subgroup A: studies that aim at image classification or segmentation, assessed using an adapted version of QUADAS-2; and subgroup B: with the goal of predicting patient prognosis, assessed using PROBAST. This assessment was independently conducted by 2 reviewers, and any disagreements or discrepancies that arise during the assessment process were resolved with the involvement of a third reviewer.

During our review, we adjusted some signal questions in QUADAS-2 as needed. Tables S2 and S3 in Multimedia Appendix 1 report the specific signal questions and assessment instructions for the tools used in the quality assessment process for this review.

Results

Study Selection and Study Characterization

A total of 246 studies were identified from different databases using the method described in the Information Sources and Search Strategies section (Figure 1). After excluding duplicate publications (65/246, 26.4%), nonarticle publications (32/246, 13%), and studies that did not match the research objectives of this scoping review (115/246, 46.7%), 34 (13.8%) studies remained for full-text assessment. Ultimately, 23 studies were deemed eligible and were included for data extraction and synthesis. Table S4 in Multimedia Appendix 1 provides a detailed list of the studies excluded after full-text assessment, along with the reasons for their exclusion.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of study selection.

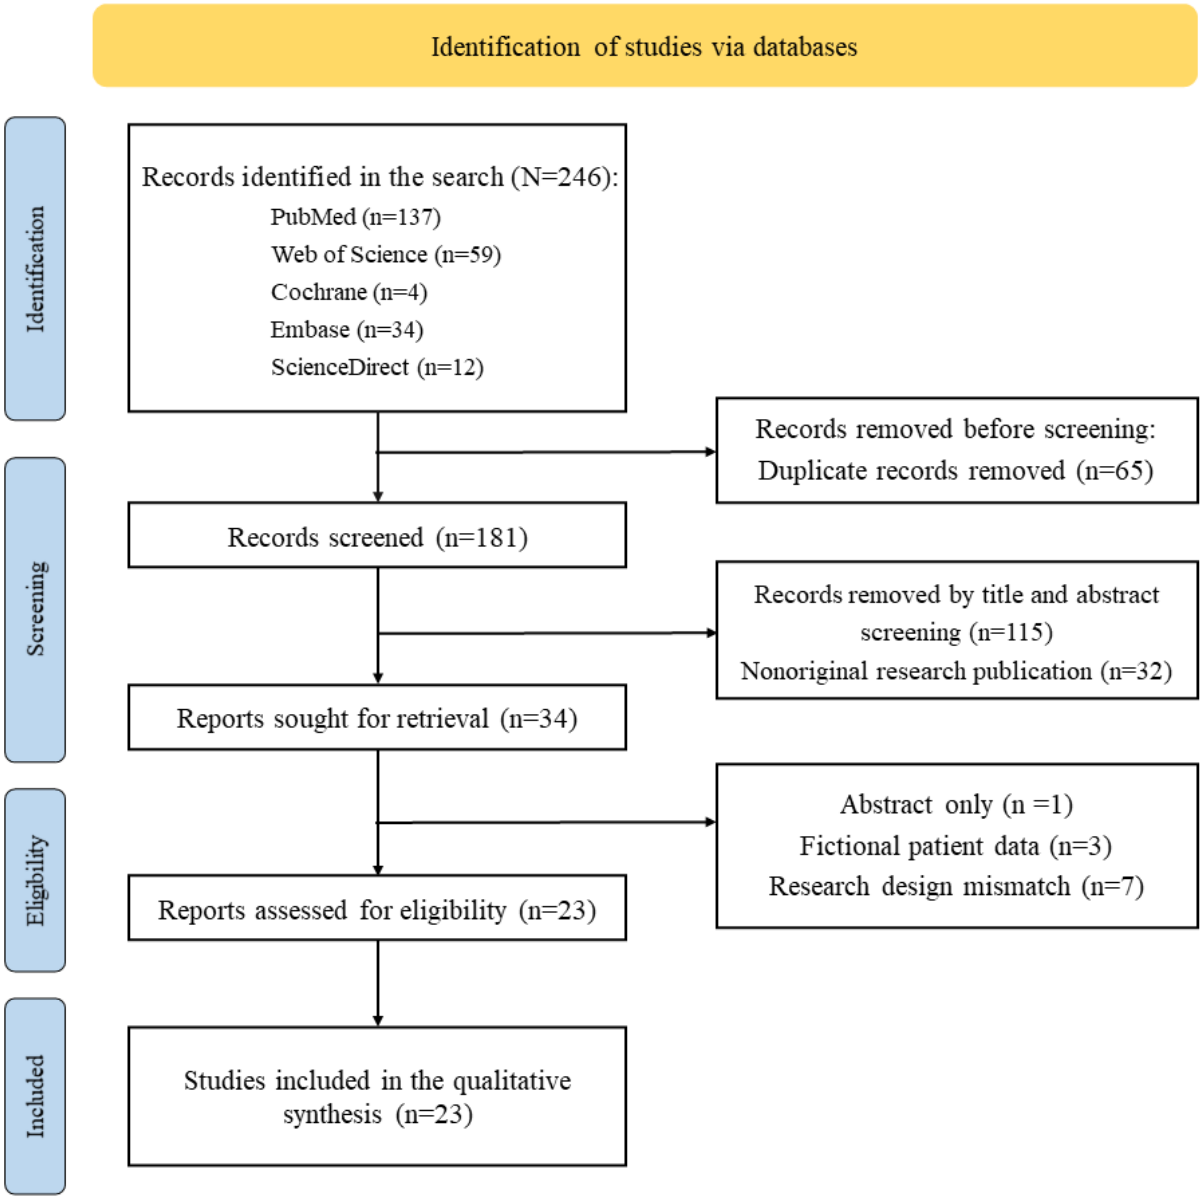

Table 1 provides the basic characteristics of the studies included in this review. The publication of these studies was concentrated within the past 5 years, which can be attributed to the maturation of ML technologies and the growing interest in precision medicine among researchers in the field of AF. The included studies were conducted in 9 different countries, with the United States (7/23, 30%) having the largest number of studies, followed by China (5/23, 22%) and the United Kingdom (4/23, 17%). This diversity in publication countries reflects the global interest in using ML models for the management of patients undergoing AFCA. Regarding the types of models used, most of the included studies (14/23, 61%) used DL techniques.

Table 1. Basic characteristics of the included studies (N=23).

Characteristic	Studies, n (%)
Country of study	
United States	7 (30)
China	5 (22)
United Kingdom	4 (17)
Korea	2 (9)
Spain	1 (4)
The Netherlands	1 (4)
Canada	1 (4)
Italy	1 (4)
Japan	1 (4)
Year of publication	
2023	3 (13)
2022	7 (30)
2021	6 (26)
2020	6 (26)
2019	1 (4)
Type of models	
Machine learning	23 (100)
Deep learning	14 (61)
Key medical tasks	
Patient prognosis prediction	16 (70)
Ablation targets identification	3 (13)
Ablation strategy improvement	4 (17)

Regarding the application direction of ML in AFCA patient management, this review divides the included studies into 3 subgroups corresponding to 3 key medical tasks based on the purpose of the model. The first and most common focus is the development of prognostic models for patients undergoing AFCA (16/23, 70%). These studies aim to provide accurate, timely, and personalized postoperative risk predictions for patients undergoing AFCA [31-46]. Although these studies share similar objectives, they use diverse types of data, with EHRs being the primary data source. The second key task focuses on the identification of ablation targets (3/23, 13%), aiming to use the feature extraction capabilities of DL models to identify potential ablation targets, such as rotors [47,48] and focal sources [49], from electrophysiological and medical imaging data. Third, some studies focus on using preoperative imaging data of patients to improve ablation strategies (4/23,17%), assisting physicians in recognizing interpatient differences to guide ablation treatments [50-53].

Characteristics of the Data in the Included Studies

When developing ML models for patient management, key factors to consider include dataset size, data modality, and resource availability. Table 2 outlines the wide range of data modalities covered in this review, and we note that there is a wide variation in the choice of variables and the number of features across studies, which highlights the diversity and complexity of factors associated with influencing patient management in AFCA.

[ae]LAAV: left atrial appendage volume.

The characteristics of the data used in the included studies are provided in Table 3, which summarizes dataset size, data modality, data source, and whether the data were multicenter. There was substantial variation among the included studies in the size of the dataset used to develop the ML model, with patient numbers ranging from 8 to 5872, but few studies adequately described their methodology or reasons for determining the sample size, in contrast to studies of randomized controlled trials based on statistical methods. In terms of data resource availability, only 17% (4/23) of the studies used publicly available datasets of patients with AF (2013 Nationwide Readmissions Database [43], 2018 Atria Segmentation Data [51,52], and European Society of Cardiology-European Heart Rhythm Association Long-Term Registry for AF Ablation [44]) for model development or validation, while most of the remaining studies (19/23, 83%) used private single-center retrospective datasets. In addition, 17% (4/23) of the studies used multicenter datasets in model development or external datasets for validation after model development [39,44,51,52].

To provide a more intuitive integration and comparison of the data modalities of the included studies, an evidence heat map was used to visualize the results (Figure 2), which highlights and reveals the medical imaging data and electrophysiological signal data involved in the included studies. In studies aimed at predicting patient prognosis, the most commonly used data type was the EHR (10/16, 63%), and it is worth noting that a small number of studies (4/16, 25%) in this segment also used multimodal data, combining either imaging data or electrocardiographic signals (or both) with clinical features to build model, and reported superior model performance relative to their constructed unimodal models. Intracardiac electrograms (EGMs) are a key data modality in studies focused on identifying ablation targets, whereas imaging data are commonly used in studies aimed at improving ablation strategies.

Modeling Approaches and Performance

Distinct medical tasks and research objectives necessitate the application of various ML techniques. Table 4 provides the ML models constructed in each study and the specific values of their performance indicators. It should be noted that if >1 ML model was constructed in 1 study at the same time, only the optimal model performance among them will be reported in this review, and the complete information of the ML models is provided in Table S2 in Multimedia Appendix 1. In this review, if a study reports multiple ML models simultaneously, we will report only the optimal model performance among them. Table 4 provides details on the used ML techniques, medical tasks, and model performances in the included studies.

The classical ML models covered in this review are diverse, with random forest (6/23, 26%) and support vector machines (6/23, 26%) appearing most frequently, and in some studies, although they are not the best-performing models, they have been applied for feature selection or as comparative models. Of the 23 studies, 5 (22%) used the k-nearest neighbors algorithm, 3 (13%) used logistic regression, and 2 (9%) used the decision tree. In addition, 17% (4/23) of the studies used integrated learning models such as XGBoost and AdaBoost. It is important to note that DL models represented by convolutional neural network (CNN) and RestNet were the most frequently used as performance-optimized models in all the included studies, particularly in those studies that used image data and electrical signal data as model inputs, and 61% (14/23) of the studies reported performance-optimized models belonging to the DL type. Specifically, CNN and its variants were applied in 30% (7/23) of the studies, and ResNet was applied in 9% (2/23) of the studies.

In terms of model performance evaluation indicators, the main ones used were area under the receiver operating characteristic curve (AUC; 17/23, 74%), sensitivity and specificity (11/23, 48%), and accuracy (11/23, 48%), while some studies chose to assess the model performance with metrics such as F_1-score. From the information in Tables 4 and 5, it can be seen that the performance of ML models in the included studies was good overall. Among them, 74% (17/23) of the studies reported the AUC values of the ML models, and the values of this performance indicator ranged from 0.5 to 0.98. The average AUC for ML models predicting patient prognosis was 0.8 (SD=0.11), with a median of 0.83 (IQR 0.74-0.86), and 13% (3/23) of the studies had a model AUC >0.90. Furthermore, 48% (11/23) of the studies reported model sensitivity and specificity, with sensitivity ranging between 0.71 and 0.97 and specificity ranging from 0.79 to 0.99. In terms of accuracy, 48% (11/23) of the studies reported this statistic, with values ranging from 0.72 to 0.99. All models aimed at improving ablation strategies reported accuracy, with an average of 0.87.

Findings of the Included Studies

Identifying AFCA Targets

Three studies discussed the application of ML techniques in identifying potential targets for CA in AF [47-49]. Clinically, electrophysiologists must resort to time-consuming and complex invasive cardiac electrophysiological examinations to confirm ablation targets; deep neural networks can help improve this process. Liao et al [49] applied ResNet to classify raw intracardiac EGMs during AF, accurately identifying patients' putative focal source target site with performance approximating that of human experts, obtaining an AUC of 0.98. Two other studies [47,48] applied CNN to detecting rotors in the intracardiac EGMs, with one of the them taking into account the interpretability of DL model and using gradient-weighted class-activation mapping (Grad-CAM) to explore how the model classifies AF electrical patterns [48], and the other designed the convolutional recurrent neural network from the perspective of improving model, while experimenting with multiple types of input signals, resulting in improved classification performance of the model.

Improving CA Strategies for AF

Due to varying degrees of individualization among patients, the development of a rational and effective strategy for AFCA relies on the judgment and surgical experience of the physician [16]. Notably, 17% (4/23) of the studies demonstrated the potential of DL to improve this process [50-53]. A common factor among these studies is that they were all based on imaging data. Liu et al [50] used the patient's preablation PV computed tomography (CT) images to construct a ResNet-based prediction model, which identified potential non-PV triggering factors before ablation treatment with an AUC of 0.88, thereby prompting physicians to perform necessary additional ablation on the basis of PV isolation. In 3 other studies, cardiac late gadolinium-enhanced cardiac magnetic resonance (LGE-MRI) was used [51-53]. Muffoletto et al [52] and Muizniece et al [51] used CNN and reinforcement learning (Q-Learning) algorithms, respectively, to directly engage in the process of formulating personalized ablation strategies for patients with AF and achieved success rates of 79% and 72%, respectively, in their respective test sets. Yang et al [53] proposed a joint segmentation method based on the multiview two-task recursive attention model to provide clinicians with segmented left ventricular (LV) anatomical structures and LV scars directly and simultaneously from LGE-MRI, which can be used to provide valuable guidance for ablation treatment.

Prognosis for Patients With AFCA

The high long-term recurrence rate of CA has been troubling patients and clinicians. Of the 23 included studies, 16 (70%) focused on the prognosis of patients after AFCA. Furthermore, 35% (8/23) of the studies [38,40-46] attempted to predict the risk of postprocedural recurrence of AF using easily accessible preprocedural patient clinical characteristics, with commonly used variables including age, gender, BMI, comorbidities, and electrocardiogram (ECG), but their modeling performance varied widely, with reported AUC ranging from 0.667 to 0.965. Four studies [31,32,34,37] chose to fuse features from multiple modalities as the input of ML model for recurrence prediction of AF. For example, Tang et al [37] proposed a CNN-based multimodal fusion framework to predict AF recurrence 1 year after CA using patients' clinical features, EGMs, ECG, and their combinations. The comparison of multiple experimental results showed that the recurrence prediction AUC of the multimodal feature fusion model was improved by 13.2% (0.86 vs 0.76) compared with the single-modality model. Independent prediction of AF recurrence using various types of examination images is also a feasible approach, but the relative performance is not particularly impressive. In contrast, several other studies have shown that models combining radiomics data with common clinical features exhibit predictive performance with better results [31,32,34].

Quality Assessment

The risk of bias and applicability of the included studies in subgroup A (5/23, 22%; targeting patients classification and image segmentation) were confirmed by using the adapted QUADAS-2 tool. The results presented in Figure 3 indicate that the "index test" domain is the most susceptible to bias. All studies exhibit a high risk of bias in this domain because they rely solely on single-center data for model development and lack external validation, which is essential to fully assess the model's generalizability. The applicability of 60% (3/5) of the studies showed unclear or high risk of bias in different fields.

For subgroup B (16/23, 70%; targeting patient prognosis prediction), the result indicated that the overall risk of bias and applicability was determined to be low in 25% (4/16) of the studies and high in 69% (11/16) of the studies, and the latter was also due to insufficient consideration of model generalization issues in the assessment of the "analysis" domain, resulting in a high risk of bias. Furthermore, 12% (2/16) of the studies were rated as uncertain risk in terms of applicability due to unclear inclusion criteria for the study participants. The results are shown in Figure 4.

The detailed risk of bias and applicability assessment results for both subgroups are shown in Figure S1 and Table S5 in Multimedia Appendix 1.

Discussion

Principal Findings

ML has shown great advantages in processing and analyzing medical data and has been increasingly applied to solve various medical problems [24], including those in the field of AF. Compared with several existing ML-related reviews in this field [55-57], we focus more on the research of applying ML in the management of patients undergoing AFCA. We systematically evaluated the 23 highly relevant studies and found that ML performed well overall in AFCA patient management. Models constructed in several studies performed as well as human clinicians in identifying potential ablation targets (rotors and focal sources) and assisting in improving ablation strategies (left atrium scar segmentation) [48,49,53]. It should be noted that comparisons between all included studies are hampered to some extent by the heterogeneity of ML results, and some findings may require discussion at a smaller granularity.

General Overview of the Studies

The results of our review suggest that the application of ML techniques to the prognosis of patients undergoing AFCA seems promising and has received the most attention from researchers within the scope of this review (16/23, 70%). Compared with traditional prediction models, ML models have a better prediction effect on the long-term recurrence of AF after CA. In the past decade, the construction of AF recurrence prediction models was mainly based on 2 methods; the first is to directly use clinical risk scores, such as APPLE [19], CAAP-AF [58], and MB-LATER [59]. The second is to use some specific biomarkers of patients with AF (such as LA volume [60] and LA sphericity index [61]) or to combine the scoring system with clinical variables and biomarkers for statistical inference. Several different evaluation studies have shown that the AUC range for the prediction of AF recurrence of the models constructed using the abovementioned methods is 0.55 to 0.67 [19,20,22], which is lower than the results of ML models reported in most of the included studies. Most of these ML models achieved performance values >0.8 in terms of AUC, accuracy, and F_1-score indicators. The reason for the poor predictive performance of the traditional methods may lie in the limitations of the predictor dimensions, as scoring and statistical models usually rely on previous literature to select a limited number of clinical variables and specific markers due to the need to fully consider clinical ease of use and interpretability, which also leads to some extent to the neglect of the interactions between variables.

XSL•FO
RenderX

In contrast, ML models are capable of handling much larger and diverse datasets, particularly including imaging and electrophysiologic signal data that were not directly amenable to statistical analysis in the past. Through comprehensive learning of complex data patterns and nonlinear relationships, ML models can achieve more accurate predictive results, which will have many positive impacts for effective intervention in the long-term health of patients undergoing AFCA. On the one hand, the predictive results provided by ML models will guide postprocedure medical management and expectations [37] and help clinicians to take interventions in advance, including medication, lifestyle modifications, or regular follow-ups; on the other hand, the application of ML models can also improve patient engagement in health management and treatment adherence, as in the case of the web calculator developed by Saglietto et al [44], which allows the free personalized prediction of the probability of recurrence after 1 year of AFCA treatment, serving as a decision-support tool that facilitates patient-centered care and joint decision-making between physicians and patients.

Similarly, optimizing CA strategies and identifying potential ablation targets could also benefit from the integration of ML. Because of the different mechanisms of AF triggering and maintenance among patients and the difficulty of identifying patients with one or more of several different mechanisms [16], physicians need to develop ablation strategies and identify ablation targets with the help of different means, such as imaging (including MRI and CT) or invasive electrophysiologic examinations. When dealing with some specific patient groups, such as patients with non–PV-triggered AF, this process not only tests the physician's clinical experience but also raises the patient's exposure time to radiation [62]. Several studies in this review demonstrated that the DL models can identify potential ablation targets based on the patient's EGM data, with 82.5% and 80.4% accuracy[47,49], or guide CA according to personalized appropriate strategies based on LGE-MRI images [51,52], which is conducive to guiding clinicians to implement targeted treatment and shorten the duration of radiation exposure. In addition, using ML technology and patient preoperative data to determine whether additional ablation is needed on the basis of PV isolation is also meaningful for improving patient selection and reducing the risk of postoperative recurrence in patients [31,50]. With the help of ML technology, physicians were given the opportunity to intuitively gain insights from these data into the mechanisms that initiate or maintain arrhythmias in patients, thereby efficiently locating ablation targets, reducing uncertainty in CA treatment and late recurrence, optimizing the allocation of medical resources, and ultimately improving patients' clinical outcomes.

In terms of model training, using multimodal data from patients with AF to develop ML models might be a promising approach to improve model performance. Models benefit from multimodal data that more fully reflect the demographic characteristics, clinical features, and actual cardiac condition with electrophysiological characteristics of patients with AF, as reported in some previous studies [31,32,34,37]. In traditional prognostic studies involving patients who have undergone ablation, factors such as AF type, ejection fraction values, LA volume [63], and obstructive sleep apnea [10] have been acknowledged as potential predictors that may be independently or jointly associated with recurrence. However, after comprehensively analyzing the cardiac morphological structure, electrophysiological structure, and clinical characteristics with the help of ML, factors that have been ignored, such as fractal characteristics [31,32], have attracted attention. This suggests that ML will reveal previously unknown associations and patterns that will drive new insights and innovations in the management of patients undergoing CA for AF. It is worth noting that the use of ML techniques to process multimodal data is common across the medical field (eg, oncology [64] and lymphocytosis [65]), but it needs to be further popularized in the field of AF, particularly for the management of patients undergoing AFCA.

In addition, compared with classical ML methods, DL seems to have more obvious advantages in the field of AFCA patient management. As shown in Tables 1 and 4, >60% (14/23, 61%) of the studies included in this scoping review used DL technology, and a notable characteristic of this subset of studies is that many involved data modalities beyond general clinical features, encompassing imaging data (CT, echocardiography, etc) or electrophysiological signal (ECG, EGM, etc). This is attributed to DL's demonstrated prowess in complex feature learning, time series processing, and other aspects, contributing to its gradual emergence as a mainstream technology in the field of computer-aided detection and diagnosis [66]. In a blinded, randomized controlled trial designed by He et al [67] for DL algorithm, the initial assessment of LV ejection fraction by DL was even superior to that of sonographers. Therefore, we believe that in the future, there will be more data-driven instances of applying DL to AFCA patient management to promote substantive progress in this field, such as optimizing treatment strategies, reducing the risk of complications, and conducting early intervention in patient populations prone to recurrence.

Existing Limitations of the ML Models

We also noted some general limitations to the current use of ML techniques in AFCA patient management, which have hindered its more comprehensive implementation. In using the adapted QUADAS-2 and PROBAST to assess the risk of bias for all included studies, we found that most of the studies (19/23, 83%) were conducted based on single-center, retrospective data and lacked external validation, which raises concerns as to whether ML models can be generalized to a high level. Limited by data availability, some ML models with excellent results will not be perfectly reproduced on other datasets. In addition, the absence of an external validation set may result in overestimating the model's performance, preventing an accurate assessment of the ML model's true capability [68]. Therefore, how to break through the limitations of single-center studies is an issue that has to be considered when further promoting the in-depth use of ML.

In addition, there remain some difficulties in effectively comparing and evaluating the results of ML models applied to the management of patients undergoing AFCA. We found that even for the similar medical task (eg, patient prognosis prediction or ablation strategy improvement), existing studies

XSL•FO
RenderX

still showed significant heterogeneity in the reporting and analysis of results [36,46], which hinders objective comparisons between the results of different ML models.

It is also worth noting that when considering the use and introduction of ML techniques from a practical perspective, we should correctly recognize that there are differences in the level of trust and acceptance of ML among different individuals (both physicians and patients). This phenomenon is partly caused by the "black box" problem of some DL models [69], which was rarely discussed in the studies included in this scoping review. Without the ability to understand how models make decisions, physicians will be more likely to trust their own clinical experience and medical knowledge to confirm treatment decisions based on interviews, symptom judgments, and clinical examinations, as they may not be willing to take responsibility for suboptimal results of ML models [70]. More critically, the "black box" prevents clinicians and researchers from fully understanding or explaining the principles behind model decisions [55], which is a limitation that cannot be ignored for research with the original intention of explaining medical problems.

Future Research

In future studies, the composition of the patient cohort and the construction of the dataset are primary issues that need to be considered. The challenges of conducting multicenter studies primarily stem from the legal, ethical, and privacy constraints associated with sharing raw AFCA patient data [71]. Distributed learning, represented by paradigms such as integrated learning and federated learning, would be a strategy for future studies to realize effective collaboration among multicenters [72]. In a network of distributed learning nodes, individual institutions do not need to share patient data externally. Instead, they contribute to constructing the final model across multiple centers by updating the model (eg, adjusting the weighting parameters) [73].

In addition, efforts should be accelerated to develop standardized protocols and consensus guidelines for the evaluation of ML models, thus helping clinicians in selecting more appropriate ML techniques to address specific clinical tasks in the management of patients undergoing AFCA [74,75].

To address the issue of limited clinical interpretability of ML models, commonly used techniques in medical research, such as Shapley Additive Explanation and attention mechanisms [45,76-78], can generate input importance maps to highlight the features that contribute most to model detection. We believe that more research will be devoted to opening this "black box" in the future [79]. Whether it is physicians, patients, or researchers, the real hope is that ML will be able to prompt as much human-understandable auxiliary information as possible to prove its usefulness as an additional decision point in the complex, changing, practice-based patient management environment of AFCA.

Strengths and Limitations

To the best of the authors' knowledge, this is the first scoping review of studies applying ML techniques to the management of patients undergoing AFCA. We summarized the various ML methods, variables, model results, and clinical application scenarios that have emerged; emphasized the huge potential for further in-depth application of ML and the limitations that need to be overcome; and provided guidance for future research in terms of data preparation and model selection. Moreover, some sources of evidence were critically evaluated using modified QUADAS-2 and PROBAST to make the conclusions of the review more reliable and convincing. This study has several limitations. First, the results of the included studies could not be synthesized into quantitative analysis. Although all studies reported model performance, different indicators were not directly comparable. Second, this review only focused on studies published in English and did not cover other languages and gray literature, which may have led to the omission of some important findings in this field.

Conclusions

The rapid development of ML has injected vitality into the transformation of AFCA patient management to become more precise and reliable. It could improve the identification of ablation targets, ablation strategies, and prediction of patient prognosis, which will effectively improve treatment effectiveness and patient management efficiency. Despite its broad prospects, the widespread and in-depth application of ML technology in AFCA patient management still requires consideration of issues from data and the model itself, such as data quality, model generalization, and model interpretability.

Abstract

Background: Hypertension (HTN) is the leading cause of cardiovascular disease morbidity and mortality worldwide. Despite effective treatments, most people with HTN do not have their blood pressure under control. Precision health strategies emphasizing predictive, preventive, and personalized care through digital tools offer notable opportunities to optimize the management of HTN.

Objective: This scoping review aimed to fill a research gap in understanding the current state of precision health research using digital tools for the management of HTN in adults.

Methods: This study used a scoping review framework to systematically search for articles in 5 databases published between 2013 and 2023. The included articles were thematically analyzed based on their precision health focus: personalized interventions, prediction models, and phenotyping. Data were extracted and summarized for study and sample characteristics, precision health focus, digital health technology, disciplines involved, and characteristics of personalized interventions.

Results: After screening 883 articles, 46 were included; most studies had a precision health focus on personalized digital interventions (34/46, 74%), followed by prediction models (8/46, 17%) and phenotyping (4/46, 9%). Most studies (38/46, 82%) were conducted in or used data from North America or Europe, and 63% (29/46) of the studies came exclusively from the medical and health sciences, with 33% (15/46) of studies involving 2 or more disciplines. The most commonly used digital technologies were mobile phones (33/46, 72%), blood pressure monitors (18/46, 39%), and machine learning algorithms (11/46, 24%). In total, 45% (21/46) of the studies either did not report race or ethnicity data (14/46, 30%) or partially reported this information (7/46, 15%). For personalized intervention studies, nearly half (14/30, 47%) used 2 or less types of data for personalization, with only 7% (2/30) of the studies using social determinants of health data and no studies using physical environment or digital literacy data. Personalization characteristics of studies varied, with 43% (13/30) of studies using fully automated personalization approaches, 33% (10/30) using human-driven personalization, and 23% (7/30) using a hybrid approach.

Conclusions: This scoping review provides a comprehensive mapping of the literature on the current trends and gaps in digital precision health research for the management of HTN in adults. Personalized digital interventions were the primary focus of most studies; however, the review highlighted the need for more precise definitions of *personalization* and the integration of more diverse data sources to improve the tailoring of interventions and promotion of health equity. In addition, there were significant gaps in the reporting of race and ethnicity data of participants, underuse of wearable devices for passive data collection, and the need for greater interdisciplinary collaboration to advance precision health research in digital HTN management.

precision health; hypertension; digital health; prediction models; personalization; phenotyping; machine learning; algorithms; mobile apps; mobile health

Introduction

Background

Hypertension (HTN) is the leading preventable cause of cardiovascular disease and premature mortality worldwide, affecting an estimated 1.28 billion adults [1]. It surpasses smoking, diabetes, and obesity as the most significant modifiable risk factor, contributing to 54% of stroke and 47% of ischemic heart disease cases [2,3]. Despite mounting evidence that antihypertensive treatment can reduce morbidity and mortality, HTN remains underdiagnosed and undertreated [4,5]. Globally, nearly half of adults with HTN are unaware that they have the condition, and only 21% have their blood pressure (BP) under recommended levels [1]. Significant disparities exist in HTN prevalence and management. While 82% of individuals with HTN live in low- and middle-income countries, only 7.7% achieve BP control, compared to 28.4% in high-income countries [4,6]. These disparities have been linked to various social and environmental determinants that disproportionately affect individuals from racial and ethnic minority groups [7]. Given the considerable global health burden and inequities stemming from suboptimal HTN management, there is an urgent demand for innovative and scalable solutions for effective HTN prevention and control.

Challenges in HTN Management

Despite the availability of effective treatments, only 21% of adults with HTN worldwide have their BP under control [6]. Longitudinal analyses have shown that up to 50% of patients stop taking their prescribed medications within 1 year; this is attributed to factors such as sociodemographics, medication side effects, lack of knowledge, comorbidities, lack of access to care, and patient-clinician relationship [8,9]. Current HTN treatment approaches are based on evidence from randomized controlled trials (RCTs) that reflect the mean results for the average patient [10]. This “one-size-fits-all” approach fails to consider the wide variation in an individual’s genetic, biological, behavioral, sociodemographic, and environmental factors that profoundly influence HTN treatment adherence and outcomes. This lack of personalization contributes to suboptimal treatment adherence and poor overall HTN control [9]. Effective management strategies must incorporate more nuanced approaches that adapt to the unique characteristics and contexts of individuals within diverse populations.

Digital Precision Health for HTN Management

The emergence of precision health as a paradigm to empower individuals, predict and prevent disease before it starts, and personalize care addresses these challenges and presents a promising road map for transforming HTN management [11]. Expanding on precision medicine’s focus on personalized medical care, precision health goes beyond treatment, emphasizing health promotion and disease prevention for a more proactive approach to addressing population health [11-14]. Interventions in precision health are customized to the individual’s unique variations in genetic, biological, behavioral, sociocultural, and environmental determinants to improve health outcomes [14-16]. While personalized care has always been a goal in clinical practice, it is only with recent technological advancements in artificial intelligence, data analytics, and digital tools that the depth of personalization and predictive capabilities in disease risk or treatment response are becoming truly attainable [16]. Digital health technologies, including mobile apps, wearable devices, and remote monitoring, enable the harnessing of data to tailor interventions, predict disease risk, and engage patients more effectively in their care [11]. These tools present an opportunity to overcome traditional care barriers, facilitating more accessible, accurate, timely, and personalized HTN prevention and management strategies.

Objectives

Although existing research has examined the effectiveness of digital interventions in improving health outcomes for HTN, there is a notable lack of prior reviews that integrate these findings in the context of precision health [12-15]. The primary objective of this scoping review is to synthesize the existing studies pertaining to precision health using various digital health technologies for the management of HTN in adults. Specifically, we aimed to address the following questions:

1. Which aspects of precision health are addressed (ie, prediction models, personalization, and phenotyping), and what are the characteristics of these studies?
2. Which digital health tools are being used in precision HTN management?
3. What are the characteristics of participants in precision health studies for HTN management?
4. For personalized interventions, what types of data are used for personalization, and what are the characteristics of personalization?

By mapping out the current state of digital precision health for HTN management, we seek to provide a foundation for future research, policy, and the development of effective and equitable interventions to improve the prevention, diagnosis, and management of HTN on a global scale.

Methods

Design

This scoping literature review was conducted following the framework for scoping reviews developed by Arksey and O’Malley [17]. This framework consists of five stages: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing, and reporting the results. Thematic analysis of findings were conducted based on the 3 categories of studies included in the review: personalized interventions, phenotyping, and prediction models. The review used the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews)

XSL•FO
RenderX

reporting guidelines to increase methodological transparency (Multimedia Appendix 1) [17]. The review protocol was registered with the OSF Registries (osf.io/yuzf8).

Search Methods

In July 2023, assisted by a research librarian, we conducted comprehensive searches across 5 databases: PubMed, CINAHL, Web of Science, Embase, and Inspec. We filtered the search for peer-reviewed articles published between 2013 and 2023 in the English language. This 10-year time frame was chosen to capture the most recent and relevant advancements in digital health technologies and their application in HTN management. Search terms included "precision health" (eg, *precision medicine* OR *personalized* OR *tailored* OR *individualized*) AND "digital health" (*telemedicine* OR *telehealth* OR *mobile apps* OR *wearable electronic devices* OR *electronic health*) AND "hypertension" (*high blood pressure* OR *elevated blood pressure*). Medical subject headings terms were adapted across databases. The full search strategy is provided in Multimedia Appendix 2.

Final search results were transferred to an EndNote (version 20) database, and duplicates were removed. The remaining articles were imported into Covidence, a web-based software platform designed for conducting literature reviews. Blinded screening of title, abstract, and full texts was conducted by 3 authors (NC, RT, and AA), with each study independently reviewed by 2 of these authors. Any conflicts in opinion were reconciled through discussion or, if needed, by involving a third reviewer (HR).

Eligibility Criteria

This scoping review sought to comprehensively map key concepts within the identified research area by including all types of research designs of original, peer-reviewed research papers. In addition, studies were included if they (1) sampled adults aged ≥18 years, (2) contained a diagnosis of HTN, (3) had a precision health focus, and (4) used a digital health technology. If studies included participants with >1 diagnosis (ie, HTN and diabetes mellitus), and HTN management was a primary focus of the intervention, they were included. To identify studies with a focus on precision health, if the term precision health or its synonyms (ie, personalized, tailored, individualized, predictive, and phenotype) were in the title, abstract, or main text, they were included. For the detailed eligibility criteria, refer to Textbox 1.

Textbox 1. Eligibility criteria for scoping review.

Inclusion criteria

- Study type: original peer-reviewed research paper
- Period: studies published between January 1, 2013, and July 20, 2023
- Language: English
- Population: adults aged ≥18 years with a diagnosis of hypertension
- Had a precision health focus (ie, predictive, personalized, or phenotyping)
- Used a digital health technology (eg, mobile phones, telemedicine, wearable devices, or electronic health records)

Exclusion criteria

- Study types: case studies, editorials, opinion pieces, gray literature, dissertations, literature reviews, and trial protocols
- Period: studies published before January 1, 2013, or after July 20, 2023
- Language: any language other than English
- Population: pediatric or pregnant patients
- Pulmonary artery hypertension diagnosis
- Interventions targeting health care providers

Studies were excluded if they involved pediatric or pregnant participants, had a diagnosis of pulmonary artery HTN, or reported interventions targeting health care providers. Pregnant individuals were excluded due to the unique physiological and treatment differences in managing HTN during pregnancy, such as gestational HTN or preeclampsia, which is considerably outside the scope of this review. Furthermore, we excluded case studies, editorials, opinion pieces, gray literature, dissertations, literature reviews, and trial protocols, as these are secondary or nonempirical sources lacking original research data essential for our analysis.

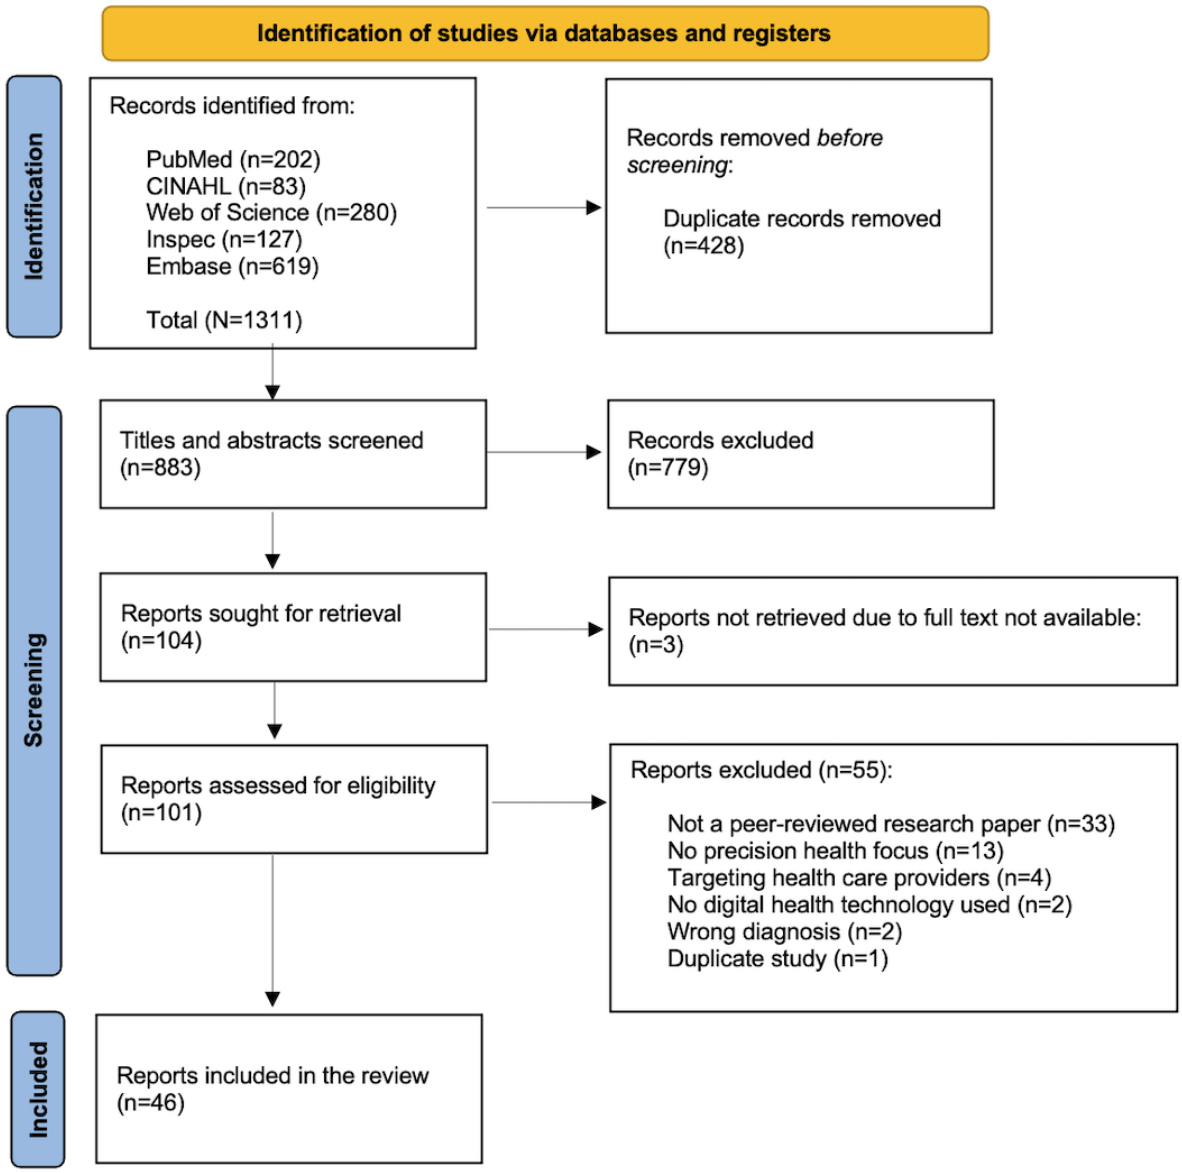
Data Extraction

We developed 3 separate data extraction templates, each containing fields for all identified key data elements. The first template was used to extract data on study characteristics, including study location, design, sample characteristics, precision health focus, digital health technology used, and disciplines involved. The other templates were used to extract data on personalization characteristics and types of data used for personalization of tailored intervention studies. For each included study, the first author (NC) and 1 of the 3 coauthors (RT, AA, and HY) independently extracted data using the standardized templates. This dual-reviewer approach was used to minimize errors and biases in the data extraction process.

XSL•FO
RenderX

Any discrepancies between reviewers in the data extraction were resolved through discussion, with a third author available for consultation if consensus could not be reached.

Data Synthesis



Included studies were categorized based on their precision health focus: personalization, phenotyping, and prediction models. We conducted thematic analysis to identify recurring themes and patterns across the studies, with themes derived both deductively from the research objectives and inductively from the study findings [18]. Studies were cross-compared to highlight differences and similarities in methodologies, designs, and outcomes. Synthesizing the extracted data allowed us to identify gaps in the current research landscape, generating recommendations for future research directions which we discuss in this study.

Results

Search Results

The search yielded 883 studies after the removal of duplicates; after title and abstract screening, we identified 104 (12%) studies for full-text review. Of the 104 studies, a final sample of 46 (44%) studies met the inclusion criteria for this review (Figure 1). In alignment with the scoping review methodology, we did not conduct a quality appraisal of the included studies, as our goal was to rapidly identify and synthesize the existing evidence of digital precision health research for HTN management [16].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of study selection.

Summary of the Included Studies

Table 1 provides an overview of the included studies. Most studies were conducted in or used data from North America, predominantly from the United States (30/46, 65%), with 1 (2%) study conducted in Canada. Of the 46 studies, 7 (15%) were conducted in or used data from Europe, followed by 6 (13%) from Asia and 1 (2%) from Brazil in South America. Of the 46 studies, 1 (2%) study on genome sequencing used data from both the United States and the United Kingdom [19]. Nearly half of the studies (21/46, 46%) were RCTs, of which 8 (17%) were pilot or feasibility RCTs. There was a diverse

XSL•FO
RenderX

mix of studies comprising qualitative, mixed methods, and analytical observational (eg, cohort and cross-sectional) designs in addition to the RCTs.

In terms of precision health focus, most studies (34/46, 74%) focused on personalization, 8 (17%) focused on prediction models, and 4 (9%) focused on phenotyping (Figure 2). Disciplines involved were predominantly within the health sciences (29/46, 63%), with over a third of studies (15/46, 33%) featuring interdisciplinary teams comprising ≥2 disciplines (eg, medical and health sciences, informatics, and computer and electrical engineering). All included studies (46/46, 100%) sampled populations with HTN, with additional diagnoses of diabetes mellitus (16/46, 35%), hyperlipidemia (7/46, 15%), and classifications of overweight or obesity (3/46, 7%).

Study Characteristics

Study characteristics are presented in Multimedia Appendix 3, and a summary of the sample characteristics is presented in Table 2. Sample sizes in the studies ranged from 7 to 764,135. Nearly half (21/46, 46%) of the studies had a sample size <100, followed by 11 (24%) studies with a sample size between 100 and 499 and 6 (13%) with a sample size >10,000. Most studies (33/46, 72%) included participants with a mean age between 50 and 69 years. The range of female participants across all studies was 1.4% to 100%, with a median of 51% (IQR 40-62). Of the 46 studies, 14 (30%) did not report the race or ethnicity of participants.

Digital Personalization for HTN Management

Overview

Of the 46 studies, 34 (74%) had a precision health focus of personalization in HTN management (Table 3). These studies tested or assessed digital interventions that were tailored to the individual or group characteristics of its users. Most studies (30/34, 88%) tested a personalized digital intervention and were primarily quantitative in design (eg, cohort, RCTs and mixed methods). Of the 34 personalization studies, 4 (13%) were qualitative and described participants' views on technology-based interventions. Sample sizes ranged from 11 to 10,803, and the most commonly reported primary outcomes included BP (21/34, 62%), medication adherence (4/34, 12%), participants' views or feedback (4/34, 12%), and feasibility and satisfaction of the intervention (3/34, 9%). Digital technologies used most often in these studies included mobile phones (30/34, 88%), followed by BP monitors (17/34, 50%), wearable devices (4/34, 12%), electronic medication trays or pillboxes (3/34, 9%), web platforms (2/34, 6%), and tablets (2/34, 6%).

Of the 34 studies, 4 (12%) qualitative studies highlighted participants' perceived importance of personalization in digital interventions. Participants emphasized the need for digital interventions to be customizable, allowing for tailoring based on their preferences, such as personalizing functions for SMS text messages, the inclusion of all medications in the app, and the ability to adjust reminder settings [28,50]. A study on the design of a mobile app intervention found distinct differences in preferences between participants from a federally qualified health center and a university cardiovascular clinic; the former group placed greater value on social support themes and addressing health-related social needs [30]. McBride et al [38] found that participants using a mobile app for home BP monitoring felt the app's visual feedback and medication reminders improved their understanding of their condition as well as their sense of control and responsibility, resulting in improved self-management practices.

Personalization Characteristics of the Digital Interventions

Modalities and Approaches

For the 30 studies that tested a personalized digital intervention (Table 4), the modality of intervention delivery occurred exclusively through mobile apps for half of the studies (n=16, 53%), phone calls only (n=5, 17%), SMS text messages only (n=2, 7%), and web- or tablet-based only (n=2, 7%). Of the 30 studies, 6 (20%) used ≥2 modalities (ie, phone calls, texts, emails, and mobile apps) for intervention delivery. Of the 30 studies, 19 (63%) used personnel (eg, case managers, patient navigators, and clinicians) for some aspect of the intervention design and delivery, while 11 (37%) studies relied solely on digital technology for intervention delivery.

Shea et al [47]	—	Automated	• Tailored educational texts based on participants' priority topics and most recent BP reading	CS
Steinberg et al [48]	—	Automated	• Tailored messages based on adherence to the DASH diet • Content was tailored for women and provided behavioral tips to reinforce dietary change and provide social support	NS
Thiboutot et al [49]	—	Automated	• Customized feedback and recommendations on questions to discuss with their health care providers	NS
Wang et al [51]	—	Automated	• Individual monitoring of treatment response and tailored recommendations for follow-up based on BP levels	CS
Willis et al [52]	MDs	Human	• Individualized remote treatment based on BP levels	SS
Zhang et al [53]	Health facilitators	Human	• Tailored feedback on self-management behaviors	CS

[a]CS: clinically significant but not statistically significant.
[b]NP: nurse practitioner.
[c]MD: medical doctor.
[d]SS: statistically significant.
[e]NS: no statistical or clinical significance.
[f]BP: blood pressure.
[g]SDoH: social determinants of health.
[h]Not applicable.
[i]AI: artificial intelligence.
[j]DASH: dietary approaches to stop hypertension.

Personalization strategies varied, with 13 (43%) of the 30 studies using a fully automated personalization approach without the need for human involvement. For example, interventions used automated SMS text messages to improve treatment adherence and provide feedback to participants [24,26,34] or used an artificial intelligence–driven system to generate weekly tailored lifestyle recommendations [35]. Of the 30 studies, 10 (33%) used human-driven personalization, in which study personnel

XSL•FO
RenderX

were the primary avenues for personalization of the intervention. For example, nurses and case managers offered patients personalized education on self-management behaviors and treatment adherence [31,36], and pharmacists and physicians provided individualized medication adjustments based on treatment response [22,52]. Of the 30 studies, 7 (23%) used a hybrid approach (ie, both the technology and human study personnel contributed to the personalization of the intervention).

Most personalized intervention studies (25/30, 83%) had either statistically significant positive outcomes (16/30, 53%) or improved or clinically meaningful outcomes, although not statistically significant (9/30, 30%). The studies with nonsignificant, yet positive findings tended to be pilot studies or had small sample sizes (ie, <40 participants). Among the 25 studies with significant positive outcomes, 16 (64%) involved personnel in intervention delivery, with involvement levels varying from comprehensive multidisciplinary teams (pharmacists, nurse practitioners, physicians, and patient navigators) offering patient education, medication management, and monitoring [21], to minimal, such as research assistants giving participants tablet use instructions [46]. In addition, 48% (12/25) of these studies used an automated tailoring approach, followed by 28% (7/25) of the studies using human-led tailoring and 24% (6/25) using a combination of both human-led and automated tailoring.

Personalized Elements of the Interventions

Personalized interventions included tailored education on self-management (ie, medication adherence, diet, and exercise), along with motivational messages and feedback aligned with each participant's adherence, values, beliefs, and goals. For instance, a culturally adapted mobile health intervention sent the following message to a Hispanic man hoping to find a wife and start a family: "Get back on track taking your meds for building that stronger, healthier body for when you meet that special woman" [24]. Studies also provided personalized reminders for medications, appointments, laboratory tests, and individualized medication management based on treatment adherence and BP levels. Of the 30 studies, only 2 (7%) provided assessment and referrals for social determinants of health needs (ie, housing, utilities, and affordable prescription options) [23,25].

Data Used for Personalization

Tailored intervention studies used a range of data types for personalization of the intervention (Table 5). From 8 categories of data available for personalization (eg, demographic, clinical, and behavioral), just over half the studies (16/30, 53%) used ≥3 types of data, with 14 (47%) studies using ≤2 data types. Of the 30 studies, 6 (20%) used 5 categories of data for personalization, with no studies using >5 data types. The 3 most common types of data used for personalization were behavioral (28/30, 93%), clinical (24/30, 80%), and psychological (17/30, 57%). Behavioral data were typically used to monitor patients' adherence to key behaviors relevant to HTN management, such as taking medication, physical activity, and diet. Collecting real-time information on participants' health behaviors allowed for individualized feedback in many studies. For example, in the study by Steinberg et al [48], participants reported their food intake and could receive texts with feedback and guidance, such as "You did best with reducing saturated fat and boosting your fiber intake and seemed to struggle with getting enough potassium and magnesium...to get more magnesium, try dried fruit as a snack!" Similarly, clinical data such as BP or medication-related information were used to offer feedback tailored to participant's clinical metrics. For instance, Wang et al [51] developed a telehealth system that used decision rules to adjust care based on BP levels; if BP was optimal and participants were adherent to medications without side effects, follow-up appointments could be deferred and medication refills could be automatically prescribed. Psychological data included information on participants' attitudes, beliefs, values, and goals. For example, a few studies assessed participants' "stage of change" [43,44] and readiness to modify behaviors [25], while others took into account their values, attitudes, and beliefs [24,27,34] or their perceived barriers to self-management [25,36,43,46].

The other types of data used for personalization were all used by less than one-third of the studies: health literacy (6/30, 20%), social and economic (6/30, 20%), demographics (4/30, 13%), and cultural (4/30, 13%). No studies obtained physical environment data for personalization of the intervention. For health literacy, the prevailing strategy involved designing interventions for a low-literacy population as a whole, rather than tailoring it at the individual participant level, and none of the studies tailored interventions to the level of digital literacy [36,45,54]. Similarly, studies implementing cultural tailoring primarily focused on specific populations as opposed to tailoring at the individual level. For example, Brewer et al [23] and Schoenthaler et al [46] both conducted studies with only Black participants and offered culturally tailored content geared for this population, such as education on the impact of racism and discrimination on BP. However, not all studies applied cultural tailoring broadly. Davidson et al [27] assessed cultural values and beliefs at an individual level, sending customized SMS text messages based on these insights.

Digital Phenotyping

There were 4 studies with a precision health focus on phenotyping [19,55-57] using a range of demographic, behavioral, clinical, and genetic data to apply phenotyping in diverse ways to enhance understanding and management of HTN (Table 6). Sample sizes ranged from 13 for a qualitative study [57] to 764,135 in a whole-genome sequencing analysis [19]. Digital tools used included mobile phones (2/4, 50%), web

XSL•FO
RenderX

platform (1/4, 25%), electronic health record (EHR; 1/4, 25%), machine learning (ML) algorithms (1/4, 25%), BP monitor (1/4, 25%), and genomic databases (1/4, 25%).

Table 6. Summary of the studies on digital phenotyping for HTN[a].

First author	Study design	Sample size	Digital technology	Description of the study
Bakre et al [55]	Secondary data analysis	11,934	Mobile phone and web platform	The study analyzed demographic, dietary, and clinical data of participants with stage 2 HTN who used a digital nutrition platform to identify characteristics associated with greater reductions in BP[b].
Chen et al [56]	Secondary data analysis	2521	EHR[c] and ML[d] algorithm	The study developed an ML framework to identify predictive features and cluster patients with HTN into 4 clinically meaningful groups of disease severity.
Hellem et al [57]	Qualitative	13	Mobile phone and BP monitor	The study examined participants' determinants of engagement from a digital intervention through interviews, phenotyping participants into high engagers, low engagers, and early enders.
Kelly et al [19]	Genome sequencing	764,135	Genomic databases	This is the first study to identify a promising but unconfirmed intergenic rare variant associated with BP. This variant lowered SBP[e] by an average of 33 mm Hg in carriers compared with noncarriers, and all participants were of Asian ancestry.

[a]HTN: hypertension.

[b]BP: blood pressure.

[c]EHR: electronic health record.

[d]ML: machine learning.

[e]SBP: systolic blood pressure.

Of the 4 studies, 2 (50%) used secondary data analysis to apply phenotyping. Bakre et al [55] applied phenotyping by analyzing demographic, dietary, and clinical data of participants with stage 2 HTN who used a digital nutrition platform, identifying characteristics associated with a decrease in BP. They found that participants who achieved greater BP reductions had higher reductions in weight and dietary improvements, suggesting the effectiveness of digital nutrition guidance on management of HTN [55]. Chen et al [56] used EHR data to develop an ML framework to phenotype patients with HTN into 4 clinically meaningful groups, aiming to improve personalization of care and resource allocation. They used demographic and clinical data for cluster analysis, identifying 2 groups with mild disease and 2 with more severe disease profiles.

The qualitative study by Hellem et al [57] explored participants' determinants of engagement from a SMS text messaging intervention to reduce BP among patients with HTN. Through interviews with participants purposely sampled from 3 engagement categories—high engagers, low engagers, and early enders—this study phenotyped individuals based on a mix of social, psychological, and environmental factors, including digital literacy and access. They found that high engagers had a better understanding of the intervention, the least number of social needs, and the greatest social support. In contrast, early enders and low engagers expressed greater amounts of social needs and less social support [57]. Finally, the study by Kelly et al [19] phenotyped participants at a genetic level, offering a direct link between genotype and phenotypic expression of BP, presenting a road map for targeted genetic interventions for personalized management of HTN.

Digital Prediction Tools

There were 8 studies with a precision health focus on prediction models (Table 7). These studies collectively explored advanced ML techniques for personalized risk prediction for HTN management. Study designs were primarily ML model development (7/8, 88%), with 1 (13%) proof-of-concept study [58] and 1 (13%) hybrid design comprising both ML model development and RCT [59]. Sample sizes varied from 7 for the proof-of-concept study [58] to 245,499 for the study using EHR data [60]. Digital technologies used for these studies included the following: ML algorithms (8/8, 100%), EHR (5/8, 63%), wearable devices (4/8, 50%), mobile phone and web platform (1/8, 13%), and BP monitor (1/8, 13%). Various ML models were used for each of these studies, with half of the studies using random forest models (4/8, 50%), with others including online recurrent extreme learning machine and long short-term memory.

XSL•FO
RenderX

Table 7. Summary of the studies on prediction models for HTN[a] (n=8).

First author	Study design	Sample size	Digital technology	Study description	ML[b] models
Abrar et al [61]	ML model development	35	ML algorithms	Development of a personalized BP[c] prediction model tailored to individual physiology and lifestyle factors	OR-ELM[d]
Bernal et al [58]	Proof of concept	7	ML algorithms, wearable device, mobile phone, and web platform	Development of an intelligent web-based ecosystem that integrates clinical, behavioral, and environmental data to predict adverse high BP events	Bayesian ridge, support vector regression, and random forest
Bertsimas et al [62]	ML model development	19,926	ML algorithms and EHR[e]	Development of ensemble ML models for personalized predictions and treatment recommendations, with significant improvements in HTN through optimal treatment prescriptions based on individual patient data	Classification models (eg, multivariate logistic regression and random forests) and regression models (eg, support vector regression and optimal regression trees)
Cano et al [63]	ML model development	86	ML algorithms, wearable device, and EHR	Development of a system for improved discrimination between healthy individuals, individuals with prehypertension, and individuals with HTN using PPG[f] and ECG[g] signals, focusing on improving the accuracy of HTN detection	A total of 37 different classification models were used: logistic regression, support vector machines, and nearest neighbors, with the Coarse Tree model achieving the highest discrimination
Chiang et al [59]	RCT[h] and ML model development	25	ML algorithms, wearable device, and BP monitor	Development of a personalized BP model for each individual using clinical and behavioral data, identifying the most important lifestyle factors impacting BP trend, and providing precise recommendations for HTN management	Random forest with Shapley value–based feature selection model outperformed other models in prediction accuracy
Hu et al [64]	ML model development	42,792	ML algorithms, wearable device, and EHR	Development of an ML model for personalized antihypertensive medication classes for patients with HTN using a robust algorithm that accommodates outliers in EHR data	The distributionally linear regression–informed k-nearest neighbors model resulted in a 14.22 mm Hg reduction in SBP[i] on average
Jimeng et al [65]	ML model development	1294	ML algorithms and EHR	Development of ML model to predict transition points in HTN control status, aiming to inform personalized management strategies	Logistic regression, naïve Bayes, and random forests
Ye et al [60]	ML model development	245,499	ML algorithms and EHR	Development of deep learning models to predict individualized HTN treatment pathways based on EHR data	LSTM[j] and bidirectional LSTM

[a]HTN: hypertension.

[b]ML: machine learning.

[c]BP: blood pressure.

[d]OR-ELM: online recurrent extreme learning machine.

[e]EHR: electronic health record.

[f]PPG: photoplethysmography.

[g]ECG: electrocardiogram.

[h]RCT: randomized controlled trial.

[i]SBP: systolic blood pressure.

[j]LTSM: long short-term memory.

Emphasizing personalized health care, these studies demonstrate improved accuracy in HTN control by tailoring recommendations to individual patient profiles, challenging traditional one-size-fits-all approaches. One key difference lies in the scale and nature of the datasets used, with some researchers analyzing extensive patient data over extended periods [62], whereas others focus on smaller, more controlled patient groups [59]. In addition, the scope of each study varies; some studies aim to improve BP prediction accuracy, while others focus on optimizing treatment pathways [64], integrating lifestyle data [59], or providing real-time [58] and personalized health care recommendations [59].

Discussion

Principal Findings

This scoping review provided a comprehensive mapping of the literature on the trends and gaps in digital precision health research for the management of HTN in adults. Analysis of 46 studies identified 3 main categories of precision health focus:

XSL•FO
RenderX

personalization, phenotyping, and prediction. The predominance of personalization (34/46, 74% of studies), compared to prediction (8/46, 17%) and phenotyping (4/46, 9%), highlights a strong emphasis on tailored interventions but reveals limited attention to predictive modeling and comprehensive phenotyping, which are essential for predicting HTN outcomes and identifying and categorizing patient subgroups.

Gaps in Digital Precision Health Research

The review revealed geographic, disciplinary, and demographic gaps in digital precision health research for HTN. Most studies (30/46, 65%) reviewed were conducted in the United States, followed by Europe (7/46, 15%), Asia (6/46, 13%), and South America (1/46, 2%), with no studies from Africa or Oceania. This contrasts with high HTN prevalence rates in Africa and Oceania, underscoring the need for more region-specific research to better understand local challenges and develop culturally sensitive and effective strategies for HTN prevention and management [5].

Disciplinary gaps were evident, with >60% (29/46) of the studies originating solely from the medical and health sciences. Less than a third of the studies (15/46) involved interdisciplinary teams, highlighting the need for collaborative efforts across disciplines such as engineering, informatics, and social sciences. Transdisciplinary research, in which team members from diverse fields develop unified conceptual frameworks that transcend their respective disciplinary views, is essential for advancing precision health research in HTN [66].

Demographic reporting was inconsistent and insufficient across studies. While 96% (44/46) of the studies reported participants' gender and age, 45% (21/46) did not report race and ethnicity, or only did so partially. Of those that reported race and ethnicity, the median percentages of participant representation were skewed heavily toward non-Hispanic White (51%), followed by African American (40%), with underrepresentation of Hispanic or Latinx (5%) and Asian (1%) groups. This lack of diversity raises concerns about generalizability of findings, concern for bias, and underscores the need to for transparency in reporting demographic data, which is especially salient in the context of precision health [67].

Personalized Digital Interventions: Tools, Modalities, and Data Types

Mobile phones were the predominant tools for digital HTN interventions (30/34, 88%), while only 50% (17/34) incorporated home BP monitors and 12% (4/34) used wearable devices. This highlights an opportunity to integrate wearable sensor devices for richer data collection (eg, sleep, heart rate, and physical activity), fostering a more holistic understanding of HTN and its management. Wearable BP monitoring devices is a growing area of research and offers noninvasive, continuous BP monitoring through methods such as photoplethysmography [68]. These devices offer a more comprehensive view of cardiovascular health over time, enabling continuous monitoring, personalized treatment plans, and enhanced predictive capabilities for early intervention. However, further research is needed to enhance their accuracy, calibration, and validation for clinical use [68].

Traditional communication methods such as phone calls and texting were still used (5/30, 17% and 2/30, 7% of studies, respectively), demonstrating their relevance especially for reaching underserved populations with limited digital literacy or access to advanced technology. However, only 20% (6/30) of the studies used multiple intervention delivery modalities (ie, phone calls, texting, and apps), suggesting the need for more integrative approaches to improve access, engagement, and efficacy of digital interventions by catering to different user preferences and needs.

Most studies used behavioral (28/30, 93%), clinical (24/30, 80%), and psychological (17/30, 57%) data for personalization, but only 7% (2/30) of the studies incorporated social determinants such as housing needs or prescription affordability [23,25]. No studies included physical environment or digital literacy data, highlighting key gaps in personalized digital interventions for HTN. Prior studies have documented poor digital literacy and lack of support and training as significant barriers to the use of digital health tools by populations considered disadvantaged [69]. This underscores the need to incorporate diverse sources of data to provide the additional context that can help address disparities in digital intervention engagement and efficacy. Health equity–focused frameworks, such as the Digital Health Equity framework [70], can be used to guide the development and implementation of digital interventions to ensure holistic data collection and personalization, mitigate intervention-generated inequalities, and better address existing health disparities in HTN.

Defining Personalization Strategies

This review identified a critical need for greater clarity and specificity in the use of terminology such as "personalization" or "tailoring" to improve the understanding and application of tailored interventions. As personalization is so broadly defined, it remains challenging to assess the most effective characteristics of personalization for digital interventions. For example, Steinberg et al [48] wrote that "only 28% of participants said they felt the texts were personalized, despite the use of an algorithm designed to personalize messages about intake of specific DASH nutrients." Such findings indicate the importance of research that specifically delineates which strategies and approaches to personalization are most impactful for users; specifically, there is a need for tools to characterize these approaches to personalization. Fan and Poole [71] provide a useful classification scheme for how personalization can be implemented. Two of the dimensions they describe, in particular, are highly relevant to our corpus: the target of the intervention (either individual or categorical) and the automation approach (either explicit or configured by the user or implicit or automated by the system).

Studies in this review used both individual and categorical targets. For instance, in the study by Kario et al [32], personalization was implemented broadly to group characteristics through tailored BP infographics developed for the target population. This is in contrast to personalization at the individual level, such as in the study by Brewer et al [23], in which participants were assessed for individual social needs and referred for needed services (ie, housing and utilities). While

XSL•FO
RenderX

categorical-level personalization strategies can be effective and impactful, we caution against their widespread use in personalization discussions, as precision health primarily focuses on individual-level differences within a patient population. Further research is needed to better understand the characteristics and levels of personalization that are most effective for diverse populations.

In addition, the distinction of whether personalization is automated or human driven is an important lens in understanding an intervention and its effects, and studies in this review leveraged both these approaches as well as hybrid versions of them. While automated models can streamline interventions, they may lack the adaptability of human-led approaches.

Hybrid methods, combining automated and human input, could address the limitations of each approach alone. For example, Schoenthaler et al [46] mentioned the following in their paper: "despite high acceptability, one-third of intervention participants recommended including a health educator as an adjunct to the mHealth intervention, suggesting that some in-person contact is important and could not be replaced by the design of this intervention." Several papers in our review demonstrate hybrid approaches to personalization, which could guide future research. For example, the intervention developed by Choudhry et al [25] involved a pharmacist-led, semistructured consultation with specific guidelines for mapping barriers to adherence and developing corresponding response strategies. This human-driven, semistructured consultation is paired with automated, system-driven intervention elements, such as SMS text messages. Such hybrid approaches to the design of digital health interventions present a promising avenue for future research.

Digital Phenotyping

The 4 studies focusing on phenotyping within digital precision HTN management illuminate the potential for leveraging a wide spectrum of data—demographic, clinical, behavioral, and genetic—to identify unique phenotypes of participants with HTN to tailor treatment strategies. Multiple study designs, including qualitative interviews and whole-genome analysis, have been used to enhance understanding of HTN. Leveraging secondary data from EHRs and past RCTs for analysis using ML algorithms can help cluster phenotypes of patients with HTN and explain variations in treatment response [72]. Classifying individuals into meaningful groups based on HTN phenotypes is a crucial step toward personalized care and advancing precision health.

By contrast, qualitative approaches, despite having smaller sample sizes, have the ability to provide a more contextual, holistic, and nuanced understanding of the social and psychological determinants of HTN treatment adherence and outcomes from digital interventions, which is crucial for understanding disparities. Future areas of research should integrate the use of multiple sources of data, such as surveys, wearable devices, remote BP monitoring, and ecological momentary assessments, to derive digital phenotypes of participants' self-management behaviors and provide more effective interventions [73].

Prediction Models

The 8 studies with a precision health focus on prediction models for digital HTN management highlight significant advancements and challenges in the field. These studies collectively demonstrate the innovative use of advanced ML techniques for personalized risk prediction and intervention strategies. Using a wide array of digital tools, including EHR data, wearable devices, mobile platforms, and remote monitoring, these studies are shifting the paradigm beyond one-size-fits-all approaches to care to offer more personalized and preventive care. ML models can help identify factors to predict individuals' risk of HTN, potentially preventing the development of high BP through early intervention. There are a growing number of studies using diverse ML methods (eg, support vector machine, deep learning, and XGBoost) and data types (eg, genetic, behavioral, and sociodemographic) to accurately predict the development of HTN [74-76].

Despite the potential of prediction models to transform HTN care, these studies also illuminate the hurdles that must be overcome to realize this potential fully. For instance, the generalizability of findings is a significant concern, with varying sample sizes and potential biases from using specific datasets that may not be representative of the population at large. A recent analysis of 63 HTN research studies using ML methods found that only 46% of studies described the participant demographics, and none of the studies provided a rigorous assessment of algorithmic bias, with only 6 studies acknowledging a risk of bias [77]. Algorithmic bias occurs when the diversity of the input dataset used for model development does not match that of the target population, resulting in inaccurate predictions for underrepresented groups and disparities in outcomes [77]. The effectiveness of ML models to accurately predict risk and personalize care relies heavily on the quality of data on which they are trained. The lack of representativeness of participants in training data for these models poses significant concerns regarding their generalizability and potential for bias [67]. To address these limitations, reporting guidelines such as CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) or TRIPOD-AI (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis–Artificial Intelligence) should be used when reporting ML prediction models for HTN; these guidelines provide specific criteria for authors to follow, ensuring transparency, completeness, and standardization in study reporting [78,79]. These guidelines emphasize detailed reporting of model development, training, validation, performance metrics, data sources, and patient characteristics which enable comparisons across studies. Furthermore, the prediction models reviewed focused primarily on development, underscoring a key research gap in model deployment and real-world implementation. Advancing precision health in HTN management requires research on best practices for deploying, evaluating, and monitoring models in clinical care.

Strengths and Limitations

This scoping review on digital precision HTN management followed a systematic approach based on the framework

XSL•FO
RenderX

developed by Arksey and O'Malley [17], ensuring a rigorous and comprehensive exploration of the field. By adopting a precision health lens, the review covers a broad spectrum of studies, including personalized interventions, prediction models, and phenotyping, offering valuable insights into these areas. The detailed analysis of personalized intervention studies, particularly regarding the characteristics of personalization and data used for personalization, adds depth to the understanding of how digital tools can optimize HTN care. In addition, the interdisciplinary composition of the review team, drawing expertise from nursing, informatics, and computer science, further strengthens this review by incorporating diverse perspectives.

However, the broad scope of this review and the heterogeneity of included studies introduce certain limitations. For example, a detailed examination of intervention effectiveness and statistical significance was limited due to diverse study designs, such as underpowered pilot studies or qualitative designs. The absence of a quality assessment for the included studies may also compromise the validity of the conclusions drawn, as it overlooks methodological rigor and potential biases within studies. Finally, our search terms included "precision health" and only the "personalization" derivatives (eg, *precision medicine* OR *personalized* OR *tailored* OR *individualized*), which could have limited the number of studies on prediction models or phenotyping. However, the review team chose to include the studies on prediction models and phenotyping as these were considered to be important aspects of precision health research. Future reviews could emphasize a more comprehensive search of these specific aspects of precision health research for digital HTN management.

Conclusions

This scoping review of 46 studies synthesized the current state of precision health research encompassing personalization, phenotyping, and prediction using digital health tools for the management of HTN in adults. The findings from our review demonstrate that the majority (34/46, 74%) of the included studies had a precision health focus of personalization in digital HTN management, followed by prediction models and phenotyping. Our analysis highlighted significant gaps in reporting of participant race and ethnicity data, geographic distribution of research in digital HTN management, and use of wearable devices for capturing passive data. Furthermore, the analysis of personalization characteristics in interventions underscores the need for the integration of multiple sources of data for personalization, such as social determinants of health, physical environment, and digital literacy, to promote health equity. There is a need for more precision in the use of the term "personalization" as well as further research that explores the impact of specific types of personalization on health outcomes. Finally, greater interdisciplinary collaboration and ultimately a transdisciplinary approach are needed to meaningfully advance the field of precision health for HTN risk prediction, prevention, and management.

Acknowledgments

The authors extend their sincere gratitude to Imelda Vetter, health sciences librarian, for her expert guidance in systematic database searches to identify eligible studies for this scoping review. Research reported in this publication was completed with support from the National Institute of Nursing Research of the National Institutes of Health (Award Number T32NR019035, Precision Health Intervention Methodology Training in Self-Management of Multiple Chronic Conditions). The funding agency played no role in the design, data collection, analysis, or writing of the manuscript.

Abstract

Background: Numerous studies have explored interventions to reduce digital addiction outcomes, but inconclusive evidence makes it difficult for decision-makers, managers, and clinicians to become familiar with all available literature and find appropriate interventions.

Objective: This study aims to summarize and assess the certainty of evidence of interventions proposed to decrease digital addiction from published meta-analyses.

Methods: An umbrella review of published meta-analyses was performed. We searched PubMed, Cochrane Library, Web of Science, and Embase for meta-analyses published up to February 2024. Eligible studies evaluated interventions using randomized controlled trials, nonrandomized controlled trials, or quasi-experimental studies and were assessed for methodological quality using Assessment of Multiple Systematic Reviews version 2. A random effects model was used to analyze data, considering heterogeneity and publication bias. Grading of Recommendations, Assessment, Development, and Evaluations was applied to assess evidence with certainty.

Results: A total of 5 studies assessing 21 associations were included in the umbrella review, of which 4 (80%) were high-quality meta-analyses. Weak evidence was observed in 19 associations, whereas null associations appeared in the remaining 2 associations. These associations pertained to 8 interventions (group counseling, integrated internet addiction [IA] prevention programs, psychosocial interventions, reality therapy, self-control training programs, cognitive behavioral therapy, interventions to reduce screen time in children, and exercise) and 9 outcomes (self-control, self-esteem, internet gaming disorder symptoms, time spent gaming, IA scores, screen use time, interpersonal sensitivity longlines, anxiety, and depression). Cognitive behavioral therapy reduces anxiety (standardized mean difference [SMD] 0.939, 95% CI 0.311 to 1.586), internet gaming disorder symptoms (SMD 1.394, 95% CI 0.664 to 2.214), time spent gaming (SMD 1.259, 95% CI, 0.311 to 2.206), and IA scores (SMD –2.097, 95% CI –2.814 to –1.381). Group counseling had a large effect on improving self-control (SMD 1.296, 95% CI 0.269 to 2.322) and reducing IA levels (SMD –1.417, 95% CI –1.836 to –0.997). Exercise intervention reduced IA scores (SMD –2.322, 95% CI –3.212 to –1.431), depression scores (SMD –1.421, 95% CI –2.046 to –797), and interpersonal sensitivity scores (SMD –1.433, 95% CI –2.239 to –0.627).

Conclusions: The evidence indicates that current interventions to reduce digital addiction are weak. Data from more and better-designed studies with larger sample sizes are needed to establish robust evidence.

KEYWORDS

digital addiction; interventions; umbrella reviews; systematic review; internet addiction; loneliness; quality of life; well-being; internet; psychological; pharmacological treatment; cognitive behavioral therapy

Introduction

The World Health Organization has officially recognized digital addiction as a global problem in which excessive digital activities and internet use lead to the inability to manage time, decreased energy and concentration during the day, and procrastination of bedtime and shortened total sleep time due to disrupted sleep patterns at night, thereby reducing an individual's subjective happiness [1,2]. A survey in 31 countries revealed that 6% of internet users aged 12-41 years had symptoms of digital addiction [3]. The prevalence of digital addiction varies globally, with an average of 4.6% in Western countries and 8.9% in other countries [4]. Digital addiction has negative effects on personal work and life; damages personal physical and mental health; causes physical health problems such as fatigue and a lack of sleep; causes negative emotions such as anxiety, depression, and anger; reduces work concentration and work efficiency; damages social relationships; leads to loneliness; reduces life satisfaction; and affects the growth of adolescents [5-8].

Many studies in the fields of psychology and medicine have focused on the harms of digital addiction and potential intervention strategies. Moreover, numerous studies have pointed to personal traits and emotional self-regulatory mechanisms (eg, self-esteem and self-control) as key factors associated with the propensity to become digitally addicted [9-11]. In addition, elevated "fear of missing out" awareness compels individuals to consistently use digital networks to maintain social connections, which may lead to inappropriate use of digital media and the emergence of anxiety symptoms that exacerbate digital addiction [12,13]. Resilience is an expression of positive adaptation in the face of great adversity, which can neutralize the harmful effects of stress and thus reduce the tendency to become addicted to the internet; however, when faced with stress that exceeds their resilience, individuals may be inclined to overuse the internet as a coping strategy to alleviate stress [14,15]. Owing to the magnitude of the impact of psychological disorders on digital addiction, for individuals, the prevention and treatment of digital addiction are mainly psychological and pharmacological [1]. Beute et al [16] report that cognitive behavioral therapy (CBT) can play a role in treating adolescent internet addiction (IA)**.** CBT and CBT-based psychotherapies are the psychotherapy most commonly used for digital addiction [17]. Similarly, psychosocial intervention, a unique type of psychotherapy, is believed to alleviate digital addiction by enhancing an individual's self-esteem and self-regulation [18]. In addition, adjuvant therapies such as sports interventions can be effective in preventing and treating IA [19]. Alternative therapy uses alternative methods such as reading to reduce dependence on the internet, thereby achieving the purpose of relieving emotions. Many researchers have also tried to combine two or more interventions to achieve better therapeutic effects.

Currently, there are several meta-analyses on the prevention and intervention of digital addiction [20-22]. Liu et al [20] combine 58 randomized controlled trials (RCTs) and report that group counseling programs, CBT, and sports interventions reduce IA symptoms. Matthew et al [22] report that CBT was a short-term intervention for reducing internet gaming disorder (IGD) and depression symptoms, but its role in reducing actual time spent gaming was unknown. A study by Zhang et al [21] indicates that exercise can effectively reduce the symptoms of anxiety, depression, and loneliness among internet-addicted students and is beneficial to mental health. However, the heterogeneity of most meta-analyses on the treatment and prevention of digital addiction, due to reasons such as lack of a consistent definition, different outcome measurements, and wide variation in study design, limit the clinical impact of such results. Therefore, it is necessary to summarize the current evidence related to digital addiction intervention methods and conduct an overall assessment of their quality based on comprehensive evidence grading standards by using umbrella reviews which could consolidate the highest quality level of evidence by merging and assessing the meta-analyses [23,24].

Accordingly, this study conducted an umbrella analytic review of relevant meta-analyses with the purpose of evaluating the effects of various intervention modalities for digital addiction; systematically examined, organized, and assessed the strength of evidence and potential degree of bias from multiple reviews and meta-analyses; and conducted a literature review of interventions for digital addiction to identify the most effective interventions and provide recommendations to guide future health-related research and develop effective therapeutic interventions.

Methods

Study Design

This umbrella review was conducted in accordance with the registered protocol (Open Science Framework Registry) and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 statement [25]. Our study protocol has been registered with PROSPERO.

Search Strategy and Selection Criteria

We searched the following databases for English language studies published up to February 2024: PubMed, the Cochrane Library, Web of Science, and Embase. We used key terms related to digital addiction and interventions. The following search strategy was used: ("Internet" OR "digital" OR "screen" OR "net" OR "online" OR "media" OR "electronic device" OR "electronic gadgets" OR "computer" OR "mobile" OR "phone" OR "smartphone" OR "television" OR "TV" OR "video" OR

XSL•FO
RenderX

"Facebook" OR "game" OR "gaming") AND ("addict" OR "use" OR "dependent" OR "overuse" OR "abuse" OR "disorder" OR "excessive" OR "effects" OR "habits" OR "intervene" OR "treatment" OR "therapy" OR "compulsive" OR "heavy") AND ("meta-analy" OR "meta-analytic" OR "metaanaly" OR "meta-regression" OR "meta synthesis" OR "meta-analysis" OR "meta-analysis") AND ("intervention" OR "interfere" OR "intervene" OR "treatment" OR "therapy" OR "cure" OR "therapeutic" OR "exercise therapy" OR "counseling"). Studies were published in full peer-reviewed literature without language or date restrictions.

The studies included in the meta-analysis had to meet the following inclusion criteria: (1) research topics related to digital addiction intervention; (2) participants diagnosed with digital addiction; (3) a study design limited to RCTs, nonrandomized controlled trials, and quasi-experimental studies; and (4) different forms of digital addiction with similar effects.

The exclusion criteria were as follows: (1) duplicate publications; (2) full-text documents could not be obtained, and other experimental-related basic research was performed; and (3) meta-analysis without any effect size. When 2 or more meta-analyses were performed for the same association, only the most recent systematic review with the largest number of individual studies was included to avoid duplication of samples (Multimedia Appendix 1 [18,20,21,26-39]).

Study Selection

Documentation records were extracted and imported into Covidence (Veritas Health Innovation). After excluding duplicates, titles and abstracts were assessed independently by 2 researchers. The full texts of the relevant studies were independently reviewed by 2 researchers to ensure that the inclusion and exclusion criteria were met. In the event of discrepancies, a final assessment was made by a third independent researcher.

Data Extraction and Methodological Quality Assessment

Data extraction was independently completed by 2 researchers. The information extracted from each meta-analysis was as follows: first author; publication year; design and number of included studies; statistical estimates of the meta-analysis; number of original studies; sample size and region; intervention; comparison; any relevant subgroup analyses; and intervention-related outcome indicators. Any disputes during data entry were resolved through discussion with a third researcher. When a meta-analysis contained multiple intervention outcome indicators, each indicator was extracted and analyzed separately.

Two reviewers independently assessed the methodological quality of each systematic review via the Assessment of Multiple Systematic Reviews version 2 (AMSTAR 2) rating scale [40]. AMSTAR 2 consists of 16 items and is a measurement tool used to evaluate meta-analyses. The scale has good consistency, reliability, construct validity, and feasibility. It covers key questions of the included studies, proposals, literature searches, literature screening, data extraction, basic characteristics of the included original studies, data analysis, and conflicts of interest. The overall quality of a systematic review is informed by assessing how well the study meets each of the criteria. Overall quality is classified as "high," "medium," "low," or "very low" [40].

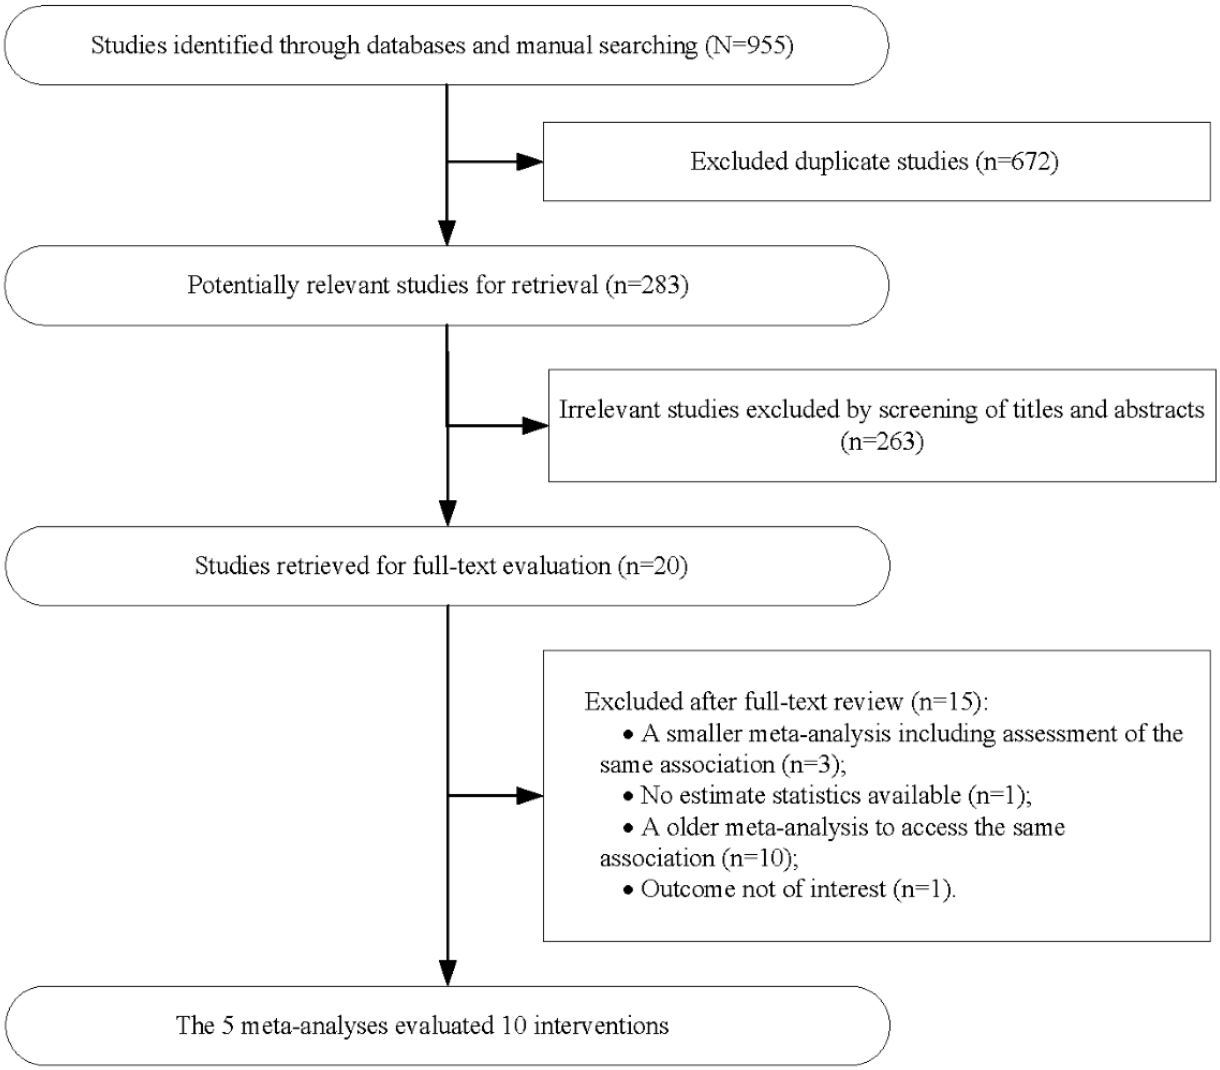
Data Analysis

The umbrella review compiles the evidence of multiple clinical-related issues in the system reviews and meta-analyses and then comprehensively evaluates the strength of the meta-analyses related to specific issues. First, the combined effect values and their 95% CIs associated with digital addiction interventions in each meta-analysis and their 95% CIs were extracted, and the combined effect sizes, 95% CIs, and *P* values were reestimated after the normalization of the mean difference (MD) and Hedges *g* to the standardized mean difference (SMD) via a random effects model (DerSimonian and Laird) by referring to the analyses of the previous omnibus review. I^2 and Cochran *Q* were used to evaluate the heterogeneity of the evidence in the literature, with $I^2 \geq 50\%$ or Cochran *Q* test *P* value of less than .10 indicating significant heterogeneity in the evidence. The estimated values of the publication bias of various studies through Egger inspection and evaluation, *P* value of less than .10, indicate that there is a significant publication bias. When the results indicate that there is a significant bias, if the total estimated effect value of the meta-analysis is greater than the effect value of the original research with the largest proportion of its effect, it indicates that the meta-analysis has a small-scale research effect. By determining whether the number of statistical results (*P* value of less than .05) in each meta-analysis (*P* value of less than .05) is greater than its expected quantity (E), the meta-analysis is excessive E, and *P* value of less than .10 indicates excessive significance. The rest of the analyses used a difference of *P* value of less than .05 to determine whether the difference was statistically significant.

The results are presented in forest plots and tables, and all analyses and mapping were performed via Stata (version 17.7, StataCorp) and R (version 4.2.1; R Foundation for Statistical Computing).

Determining the Credibility of Evidence

The Grading of Recommendations, Assessments, Development, and Evaluations (GRADE) approach was used to evaluate the strength of the evidence in each included study. According to the statistical analysis results, the credibility of each piece of evidence is further divided into 5 levels: I, II, III, IV, and NS, which represent "convincing evidence," "highly suggestive evidence," "suggestive evidence," "weak evidence," and "insignificant evidence," respectively [41].



Results

Study Characteristics

We retrieved 284 meta-analyses from PubMed, 277 from Embase, 319 from Web of Science, and 75 from Cochrane. Two investigators independently screened the studies, and 5 meta-analyses were ultimately included in this umbrella review through 2 rounds of literature screening (Figure 1).

XSL•FO
RenderX

Figure 1. Flowchart of the study selection process.

The number of studies included in the 5 meta-analyses ranged from 11 to 59, with a median of 7 (IQR 6-11). The sample size ranged from 580 to 4656, with a median of 407 (IQR 107-1490). The original research covered multiple regions, including Asia, Europe, Oceania, and the Americas. AMSTAR 2 conducted a methodological quality assessment of the 5 meta-analyses included in this umbrella review. Among them, 4 studies were rated as “high,” and 1 study was rated as “low” (Table 1).

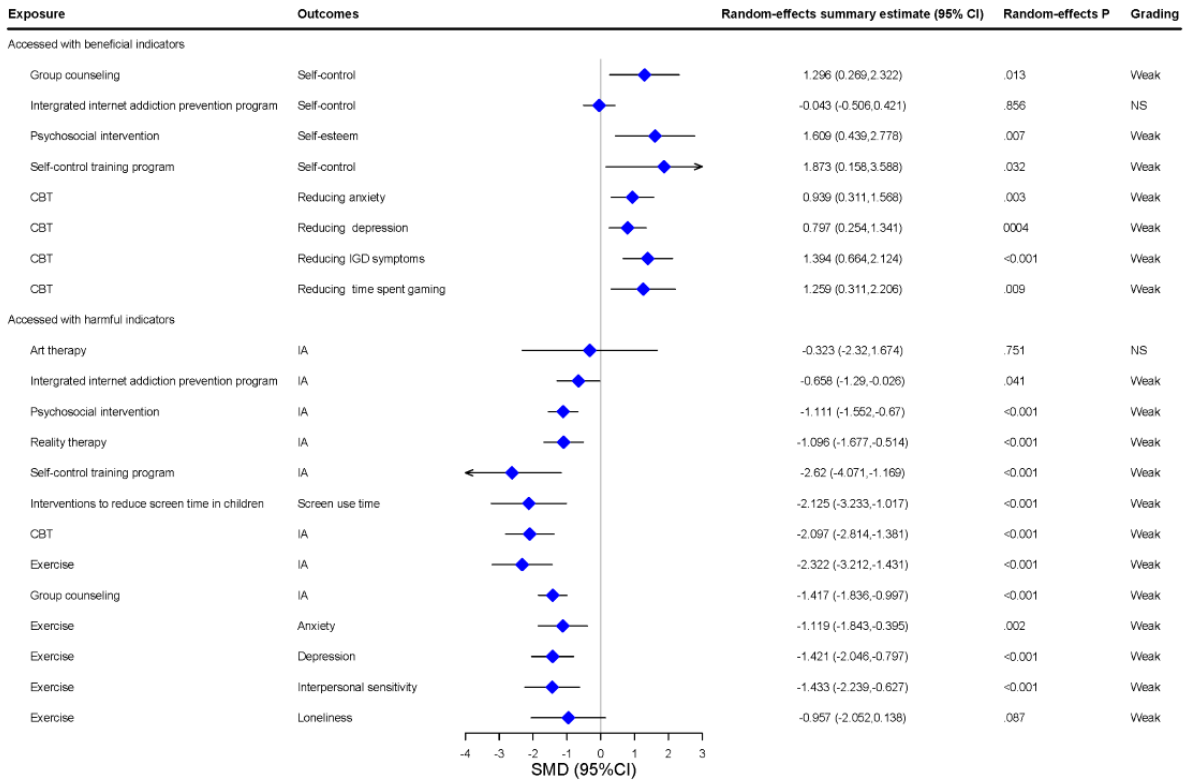
Quantitative Synthesis and Evidence Grading of the Meta-Analysis

Five meta-analyses evaluated 9 interventions: CBT, group counseling, exercise, integrated IA prevention programs, psychosocial interventions, reality therapy, self-control training programs, and interventions to reduce screen time in child and art therapy. The general characteristics of the studies included in the meta-analysis are presented in Table 1. Four of the selected meta-analyses were graded as “high quality” on the



XSL•FO
RenderX

basis of the AMSTAR 2 score, and only 1 review was graded as "low quality." However, the evidence class of most meta-analyses included evidence rated as "weak evidence" (19/21, 90%) and "not significant" (2/21, 10%). A summary of the quality appraisals of the meta-analyses and the AMSTAR 2 scores are presented in Table 1 and Multimedia Appendix 2 [18,21,22,26,42].

Cognitive Behavioral Therapy

CBT is effective in treating substance abuse, gambling, and affective and eating disorders. CBTs are based on the cognitive behavioral model, which holds that thoughts determine feelings; thus, changing one's thoughts can help with behavioral change [43]. CBT can reduce anxiety, depression, IGD symptoms, time spent gaming, and IA scores, as shown in this review. Two meta-analyses previously examined the effectiveness of CBT for patients with digital addiction [22,44]. For example, Stevens et al [22] report that CBT demonstrated high efficacy in reducing IGD symptoms (SMD 1.394, 95% CI 0.664-2.214) and depression (SMD 0.797, 95% CI 0.254-1.341) and moderate efficacy in reducing anxiety (SMD 0.939, 95% CI 0.311-1.586) and time spent on gaming (SMD 1.259, 95% CI 0.311-2.206). However, owing to the evidence base, there is a need for more rigorous studies to determine the potential long-term benefits of CBT for IGD [22]. The heterogeneity in the effects of CBT on reducing anxiety (I^2=92.5), depression (I^2=87.1), IGD symptoms (I^2=96.6), and time spent gaming (I^2=95.9) was high, although the effects of CBT on depression exhibited publication bias, albeit the evidence was weak. Another review explored the impact of CBT on IA levels [44] and found CBT to be significantly superior to routine intervention and paroxetine combined with buspirone drug therapy (*P* value of less than .05) on the IA test scale and also superior to routine intervention and no intervention (*P* value of less than .05) on the basis of the Revised Chen Internet Addiction scale and Young Diagnostic Questionnaire scale (*P* value of less than .05) [40]. Finally, the heterogeneity for the effects of CBT on reducing IA scores was high (I^2=92.5; Figure 2 and Table 2).

Group Counseling

The main components of group counseling include identifying previous solutions and acknowledging problems while also realizing that exceptions to the problem are key to the solution, with a focus on the present and future [45]. Two meta-analyses previously explored the effectiveness of group counseling on digital addiction. Yeun et al [18] reported that group counseling

XSL•FO
RenderX

had a large effect on improving self-control among school-aged children with IA (SMD 1.296, 95% CI 0.269-2.322). The heterogeneity for the effects of group counseling on improving self-control was high (I^2=66.9), but the evidence was weak. Another review reported that group counseling reduced IA levels (SMD –1.417, 95% CI –1.836 to –0.997) [44]. The heterogeneity for the effects of group counseling on reducing IA scores was high (I^2=95.9; Figure 2 and Table 2).

Exercises

Exercise is an important intervention method that positively impacts individual cognition, emotion, and physical fitness [5]. Two meta-analyses examined this intervention's effectiveness in reducing digital addiction outcomes. One review reported that sports interventions reduced IA scores (SMD –2.322, 95% CI –3.212 to –1.431) [44]. The heterogeneity for the effects of exercise on reducing IA scores was high (I^2=88.1), although the evidence was weak. Another review conducted by Zhang et al [21] included a total of 2408 students from 39 RCTs. Six exercise types (team sport, double sport, single sport, team + double sport, team + single sport, and team + double + single sport) were compared on the basis of their effectiveness in reducing IA and maintaining mental health. The meta-analysis results revealed that, compared with the control group, exercising significantly improved loneliness, anxiety, depression, and interpersonal sensitivity (*P* value of less than .05) [21]. The heterogeneity in the effects of exercise on improving loneliness (I^2=93.1), anxiety (I^2=87), depression (I^2=70.7), and interpersonal sensitivity (I^2=79.9) was high (I^2=95.9; Figure 2 and Table 2).

Psychosocial Interventions

Psychosocial interventions capitalize on psychological or social actions to produce changes in psychological, social, biological, and functional outcomes [46]. One review examined the efficacy of psychosocial interventions on school-aged children's IA, self-control, and self-esteem and revealed that psychosocial interventions had a strong effect on reducing IA (SMD –1.111, 95% CI –1.552 to –0.67) and improving self-esteem (SMD 1.609, 95% CI 0.439-2.778) [18]. The effect on IA had high heterogeneity (I^2=82.5) and published bias (*P*=.004), and the heterogeneity of self-esteem was high (I^2=87.7; Figure 2 and Table 2).

Integrated IA Prevention Program

The integrated IA prevention (IIAP) program combines 2 or more interventions, including CBT, play, art therapy, conflict, stress management, and CBT. [18] A meta-analysis of data on the efficacy of IIAP for self-control and IA revealed that IIAP had no effect on self-control (SMD –0.043, 95% CI –0.506 to 0.421), although the evidence was insignificant [18]. IIAP was found to reduce the IA, and while the evidence was weak, the effect showed high heterogeneity (I^2=88.1), publication bias (*P*=.027), and excessive significance (observed number of studies with positive findings=3; expected number of studies with positive findings=0.23; *P* value of less than .01; Figure 2 and Table 2).

Self-Control Training Program

A meta-analysis of data on the efficacy of self-control training programs for self-control and IA reported in 5 studies revealed that self-control training programs improved self-control (SMD 1.873, 95% CI 0.158 to 3.588) and reduced IA (SMD –2.62, 95% CI –4.071 to –1.169) [18], but the evidence was weak. In addition, the effects were highly heterogeneous and highly significant (*P* value of less than .1). There was a publication bias in terms of the effect on IA (*P*=.02; Figure 2 and Table 2).

Reality Therapy

Weak evidence has indicated that in a review of the effect of reality therapy on IA based on two trials, reality therapy reduced IA (SMD –1.096, 95% CI –1.677 to 0.514) [18] without heterogeneity between the 2 trials (Figure 2 and Table 2).

Interventions to Reduce Screen Time in Children

A meta-analysis suggested that interventions for screen use and sleep can achieve a small reduction in screen time (SMD –2.125, 95% CI –3.233 to –1.017) [47]. Heterogeneity was high (I^2=98.7), and the evidence was weak (Figure 2 and Table 2).

Discussion

Principal Findings

This umbrella review provides an overview of the relationships between digital addiction intervention-related outcome indicators and intervention methods derived from 5 meta-analyses. Four of the selected meta-analyses were of "high" quality. We found that most interventions (eg, CBT and exercise) can improve related outcomes, such as lifestyle, emotional health, mental health, and social relationships, among people with digital addiction. However, this conclusion was derived from weak evidence and has significant heterogeneity and excessive significance. The evidence in this review was rated as "weak evidence" (19/21, 90%) or "not significant" (2/21, 10%). The evidence was downgraded to "weak" considering that most of the included studies were RCTs, which generally involved a limited number of participants, that is, fewer than 1000 in total after pooled analyses, easily causing the small sample sizes limitation, and second, the articles were considered to have exhibited heterogeneity as well as publication bias, suggesting that more high-quality, credible research is needed to further clarify the associations between intervention methods and digital addiction outcomes.

Comparison With Prior Work

On the basis of the results of this umbrella review, CBT not only reduces IA scores but also reduces IGD symptoms, depression, and anxiety. CBT, the psychotherapy most commonly used for digital addiction, can improve symptoms of depression and anxiety by reshaping negative thoughts to help patients understand routine and problematic behaviors and motivate the creation of more adaptive, goal-oriented routines [48]. Compared with other interventions (such as drug replacement therapy), CBT has the advantage of being less invasive and effective in the short term. Furthermore, CBT is the most effective intervention for reducing internet use and improving self-perception [49]. CBT emphasizes the connection

XSL•FO
RenderX

among behaviors, thoughts, and emotions, prompting patients to pay attention to these behaviors [20]. A previous meta-analysis revealed that CBT was associated with positive changes in depression, anxiety, and psychoticism in patients with IA [20]. Ding KY et al [48] also reported that most interventions for digital addiction in children and adolescents were CBT- or CBT-based interventions, which can improve anxiety, depression, and digital addiction-related symptoms. However, another meta-analysis did not conclude that the CBT intervention had a significant effect on the severity of IA [50]. Our analysis of the effect of CBT on digital addiction suggested that genuine heterogeneity likely exists. The high heterogeneity might be related not only to the potential bias in the original studies but also to the differences across the studies included in this meta-analysis. These associations are both supported by a weak level of evidence; thus, more studies are needed to further document the effect of CBT on patients with digital addiction.

There is evidence that group counseling is one of the main treatments for addiction. One of the advantages of group programs is their economic value since they target many students simultaneously [51]. A previous study reported that groups of fewer than 14 people presented effect sizes exceeding 90% [52]. Group counseling programs enable group members to understand and help each other, increase social participation and interpersonal interactions among patients, improve adaptability, develop personalities, and eliminate the symptoms of digital addiction [53]. Group counseling programs can gain patient support and insight through experiencing similar cognitions and emotions, providing a major modality in the treatment of digital addiction [54]. In this review, we conclude that group counseling improved self-control and reduced IA scores among patients with digital addiction. A meta-analysis suggested that group counseling programs improve relationships, health problems, time management, tolerance, and compulsive internet use [20]. A previous meta-analysis by Park et al [55] identified the beneficial effects of group counseling programs for adolescents with IA. However, group counseling may not be truly beneficial until the barriers related to social anxiety, social isolation, and a lack of social skills are overcome. Therefore, developing a protocol for appropriate methods on the basis of the characteristics of the participants is necessary.

Exercise, including running, badminton, basketball, table tennis, and other outdoor sports games, was found to be helpful in reducing IA scores and improving loneliness, anxiety, depression, and interpersonal sensitivity in patients with digital addiction. Exercise is an important intervention method that positively impacts individual cognition, emotion, and physical fitness, in addition to psychological interventions. Digital addiction alters the neural structure, reduces the activity of the dopaminergic system, and limits neurocognitive functions [56]. However, exercise-based interventions can effectively improve the autonomic nervous system in patients with IA and normalize, to a certain extent, the structure of specific parts of the central nervous system [57]. Moreover, it can increase plasma glial cell-derived neurotrophic factor and glucocorticoid levels [58], neurotransmitter release [57], and telomere protection [59]. Exercise-based interventions have been shown to reduce the prevalence and symptoms of IA, and participation in physical activity may prevent IA. Exercise has replaced most internet experiences and improved an individual's physical and mental health [19]. Long-term physical exercise has been found to significantly reduce the degree of IA and depression and improve sleep quality among college students with IA [44]. The meta-analysis included in this review of exercise interventions included only exercise type classification, that is, it did not compare exercise intensity or exercise strength. Thus, more studies on exercise interventions are needed to demonstrate their effects on digital addiction.

Digital addiction may constitute impulsive behavior, although the consequences are negative impacts and involve continuous participation [60]. The impulse theory suggests that the behavior of addiction is the result of the generally excessive active brain reward system. Individuals with excessively active brain reward systems may show strong reactions to the prompts of predicting potential rewards, thereby explaining the pursuit of novelty, impulses, and powerful motivation to obtain internet or other addictive stimuli [61]. Therefore, impulses have been proposed as potential marks and treatment targets of digital addiction [62]. Reality therapy helps individuals control their behavior and consider other options related to internet use [63]. As reality therapy is based on the theory of selecting, the theory holds that people are responsible for their own lives, their feelings, their actions, and their behaviors [64]. In a sense, reality therapy helps individuals reflect on their behavior, evaluate their choices, choose more effective choices, and directly target the choice and self-control of target guidance [64]. In this method, the participants are required to determine the goals of their behavior and realize what they are actually doing. They were then guided to determine whether their behavior promoted or hindered their ability to achieve their original goals. Finally, they are encouraged to seek more appropriate and healthier alternatives to replace their current behavior, achieve their goals, and formulate plans to change negative behaviors [63]. Real-world therapy has been widely used to treat addictive diseases, including diseases involving drugs, sex, and food [63]. For people with addiction and impulses, reality therapy can help them improve their self-control and thereby reduce their problems. Research has shown that reality therapy can increase self-esteem and decrease IA [64]. Similar impacts have also been proven in the study of material addiction in real-world therapy [65]. In this review, we found that real-world therapy reduces IA scores. Despite the study being graded as having high methodological quality, the level of research evidence was weak due to the small number of participants included in the study.

IIAPs are characterized by the simultaneous or sequential delivery of several different types of interventions, including pharmacology, psychotherapy, and group counseling. A composite approach may help solve complex problems, whereas combinations of different therapies with different therapeutic targets and mechanisms may produce synergistic effects. The effects of CBT in combination with other psychosocial or pharmacological therapies for IA have been studied and determined that the combination of CBT with other therapies affects IA severity, somatization, paranoid ideation, psychosis,

XSL•FO
RenderX

obsessive-compulsive traits, interpersonal sensitivity, depression, and anxiety [66]. In this umbrella review, the assessments of IIAPs had high between-study heterogeneity, with public bias and excessive salience, and the evidence of the effect on IA scores was weak. The IIAP showed a null evidence class of effects on self-control, suggesting that there is no clear scientific evidence to support the link between IIAP and self-control in patients with digital addiction.

The evidence reviewed here suggests that CBT, group counseling, exercise, IIAP programs, psychosocial interventions, reality therapy, self-control training programs, and interventions to reduce screen time may be beneficial to patients with digital addiction. Nonetheless, more robust population-based studies are essential to substantiate these potential benefits, as the current evidence is largely inconclusive or weak. It is imperative to conduct further research to evaluate the long-term efficacy and cost-effectiveness of these interventions, as well as to investigate their suitability and generalizability across diverse cultural and socioeconomic settings.

Limitations

This umbrella review has certain limitations. First, this review was based on the results of published and available meta-analyses and meta-analyses, so other results that have not been evaluated by meta-analysis and missing data in the original literature could not be considered. However, our results were not significantly affected because repeated meta-analytic evaluations yielded similar results. Second, throughout the study, original studies covering multiple regions were included in this analysis, and although we were not able to describe subgroups of regions based on the meta-analysis that was conducted, a cross-cultural analysis of multiple geographic sources provides a better description of the effects of various interventions on digital addiction. Third, studies suggest that gender plays a role in digital addiction, as evidenced by the greater susceptibility of males, but the meta-analysis included did not stratify gender to examine the differences in the efficacy of interventions for digital addiction and therefore cannot be discussed further in this study [67]. Fourth, the statistical methods we used to test for the presence of bias indicate only its existence, not its exact source. Finally, the methodological quality of the meta-analyses included in this umbrella review and the quality of evidence for most prognosis-related outcome indicators were not sufficient. Therefore, more high-quality studies are needed in the future to further verify the results of this study.

Abstract

Background: The COVID-19 pandemic catalyzed an uptake in virtual care. However, the rapid shift left unanswered questions about the impact of virtual care on the quality of primary care and its appropriateness and effectiveness. Moving forward, health care providers require guidance on how best to use virtual care to support high-quality primary care.

Objective: This study aims to identify and summarize clinical studies and systematic reviews comparing virtual care and in-person care in primary care, with a focus on how virtual care can support key clinical functions such as triage, medical assessment and treatment, counseling, and rehabilitation in addition to the management of particular conditions.

Methods: We conducted a scoping review following an established framework. Comprehensive searches were performed across the following databases: Embase, MEDLINE, PsycInfo, Emcare, and Cochrane Database of Systematic Reviews. Other well-known websites were also searched. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines were followed. Articles were selected by considering article type, language, care provided, intervention, mode of care delivery, and sample size.

Results: A total of 13,667 articles were screened, and 219 (1.6%) articles representing 170 studies were included in the review. Of the 170 studies included, 142 (83.5%) were primary studies, and 28 (16.5%) were systematic reviews. The studies were grouped by functions of primary care, including triage (16/170, 9.4%), medical assessment and treatment of particular conditions (63/170, 37.1%), rehabilitation (17/170, 10%), and counseling (74/170, 43.5%). The studies suggested that many primary care functions could appropriately be conducted virtually. Virtual rehabilitation was comparable to in-person care and virtual counseling was found to be equally effective as in-person counseling in several contexts. Some of the studies indicated that many general primary care issues could be resolved virtually without the need for any additional follow-up, but data on diagnostic accuracy were limited. Virtual triage is clinically appropriate and led to fewer in-person visits, but overall impact on efficiency was unclear. Many studies found that virtual care was more convenient for many patients and provided care equivalent to in-person care for a range of conditions. Studies comparing appropriate antibiotic prescription between virtual and in-person care found variable impact by clinical condition. Studies on virtual chronic disease management observed variability in impact on overall disease control and clinical outcomes.

Conclusions: Virtual care can be safe and appropriate for triage and seems equivalent to in-person care for counseling and some rehabilitation services; however, further studies are needed to determine specific contexts or medical conditions where virtual care is appropriate for diagnosis, management outcomes, and other functions of primary care. Virtual care needs to be adapted to fit a new set of patient and provider workflows to demonstrate positive impacts on experience, outcomes, and costs of care.

Introduction

Background

The COVID-19 pandemic led to a significant uptake of virtual care use, with increasing recognition that virtual care will continue to play a key role in Canada's health care system [1]. Before the onset of the pandemic, 1.2% of all primary care visits in Canada occurred virtually [2]. By contrast, between January 2021 and March 2022, there was a significant uptake of virtual care use in primary care, with 38% of all family physician appointments in Canada being conducted virtually [3]. Similar trends are also observed globally. In the United States, the proportion of primary care physicians using virtual care increased from 5% before the pandemic to 46% during the pandemic [4,5]. In addition, economic evaluations of virtual care suggest that virtual care may be more cost-effective in some circumstances, reducing the cost per episode of care and the cost to attend the appointment (eg, travel and parking costs) compared to in-person care [6]. These cost savings and conveniences for patients contribute to their positive perceptions about using virtual care. By contrast, some studies have found that neither patients nor providers perceive the quality of virtual visits to be better than that of in-person visits [7-10]. In particular, the rapid shift in care delivery without care redesign has raised concerns about appropriateness, effectiveness, and equity [3]. Furthermore, as health systems return to prepandemic visit volumes, there are concerns that these new care modalities could increase workload, leading to increased burnout and eventually reduced staff resource capacity [11].

A broad range of stakeholders have suggested that patients should be the focal point of decision-making and that virtual care should be built into streamlined workflows that cover all aspects of primary care, with meaningful incentives to drive system impact [12]. However, there is little empirical evidence to support putting these principles into practice. Reviews to date looking at outcomes related to virtual primary care have shown mixed or uncertain outcomes, with minimal guidance to drive care decisions [13]. Nevertheless, strong continued interest from patients suggests that virtual care can provide benefits in supporting quality primary care [13]. Studies have suggested that high-quality, sustainable models for primary virtual care require mechanisms to support triage and shared decision-making on the use of different modalities in clinical practice [12,14]. Consensus guidelines have also suggested that the use of virtual care in primary care should be based on multiple factors, including clinical appropriateness, patient preferences, and equity [15,16]. Primary care involves many functions, such as triaging incoming requests, diagnosing acute conditions, managing chronic conditions, providing counseling, and supporting rehabilitation (among others). Despite the ongoing use of virtual care by many providers, questions remain about which primary care functions are best suited to this mode of care.

This paper is based on an evidence summary developed by the Program in Evidence-Based Care (PEBC) at McMaster University at the request of the Population Health and Value-Based Health Systems portfolio of Ontario Health (a government agency in Canada) as one of the inputs into a guidance document, "Clinically Appropriate Use of Virtual Care in Primary Care" [16]. This paper focuses on a subset of the results of this broader review to explore various primary care use cases for virtual care.

Objectives

The main objective of this review was to identify and summarize clinical studies of virtual care use in primary care. Of particular interest were studies indicating the circumstances when synchronous virtual care (primarily videoconference or telephone interactions) was likely to be equivalent, superior, or inferior to in-person care to inform decisions about appropriate modes of interaction with patients. Rather than make definitive statements on the benefits or harms of virtual care or the value of virtual-only primary care, we have organized the findings in ways that highlight potential benefits across a range of primary care functions to indicate which functions of primary care may be most suitable for virtual care. We have also suggested ways of conducting and reviewing future studies.

Methods

Literature Search and Screening

The literature search strategy and screening were performed according to systematic review methodology. The review protocol was developed by the coauthors and approved at the PEBC and by the sponsor (Population Health and Value-Based Health Systems, Ontario Health) before the commencement of the review; a post hoc decision was made to analyze and present the results as a scoping review rather than as a systematic review. A scoping review includes a predefined protocol and systematic approach to literature searches, but instead of focusing on the rigor of included studies, it reviews the literature to identify or map the state of knowledge and gaps and the research conducted, as well as identify further research needs [17-19]. This scoping review follows the guidelines formulated by Arksey and O'Malley [17] and aligns with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) statement [20]. The PRISMA checklist was also used to support reporting (refer to Multimedia Appendix 1) Research team members, using an inductive process, grouped the results into different categories, representing distinct use cases in primary care. While a formal assessment of the strength or quality of evidence was not conducted for each study—an aspect that differentiates a scoping review from a systematic review—characteristics such as study design (eg, randomized controlled trial [RCT] and prospective or retrospective comparative study), sample size, and type of comparison were extracted. In interpreting and discussing the

results, we considered factors such as study size, trial design, consistency of results, and whether the studies addressed very narrow, specific issues or broader topics.

Definitions

The following subsections provide definitions and explanations of the key terms used throughout this paper.

Virtual Care

The term *virtual care* was defined as synchronous remote interaction between patients and clinicians to replace all or a portion of face-to-face (in-person) interactions. Care is considered synchronous when the patient and clinician are both present at the same time, and there is 2-way communication without delays in response (ie, in real time). It can include both video and telephone interactions. By contrast, asynchronous communication does not take place in real time. Asynchronous communication was included only if it was used as part of synchronous communication.

Primary Care

Primary care was defined as "the first point of contact between a patient and the health care system and includes illness prevention, health promotion, diagnosis, treatment, and rehabilitation and counseling" [21]. It included care by family or general practice physicians and nurse practitioners, general practice pediatricians and geriatricians, midwives, psychologists, psychotherapists, social workers, pharmacists, and physiotherapists. Care provided by dentists, psychiatrists, or medical specialists normally seen only by referral or in a hospital setting was excluded. The definition encompassed a variety of health care providers to reflect the broadest range of staff typically found in a multidisciplinary primary care team.

Triage

Triage refers to the initial decision process within primary care practice upon first patient contact, resulting in the allocation of patients to either in-person or virtual family practice appointments or, in some cases, to administrative assistance or other types of care. Articles categorized under triage included those that discuss signposting—a strategy designed to direct patients to the right provider at the right time and the right place at the first point of contact with primary care [22]. As the first point of contact for many patients, triage is often considered a core function of primary care.

Research Question

To explore the effectiveness of virtual care in primary care settings, this study addresses the following research question:

When using virtual modalities to seek or deliver primary care, are there differences in the outcomes of interest (either in general or for specific medical conditions or purposes of appointments) between

- synchronous virtual care by telephone or video compared to exclusive in-person care;
- synchronous virtual care by telephone or video plus asynchronous care (SMS text or secure messaging and email) compared to exclusive in-person care?

Outcomes of Interest

Outcomes of interest from a patient perspective included equity and accessibility (race, ethnicity, socioeconomic status, urban or rural or remote residence, age, gender, computer literacy, and mobility), availability of appointments (time, location, and wait time to get an appointment), and on-time appointments. Outcomes relevant to multiple stakeholders—patients, care providers, and health systems—included disease stability, improvement or deterioration, complications, or death; satisfactory resolution of the reason for visit; subsequent in-person visit to primary care practitioner because virtual care was not appropriate for assessment or treatment; referral to specialists, emergency department use, or hospital admissions; rates of blood tests, clinical laboratory tests, and diagnostic imaging; prescription of antibiotics or other medications; overall health of patients of primary practice team; and continuity of care.

Search Strategy

Embase, MEDLINE, PsycInfo, Emcare, and Cochrane Database of Systematic Reviews databases using the Ovid platform were searched from 2014 to November 24, 2021, using terms related to the concepts of *virtual care* and *primary care* (refer to Multimedia Appendix 2 [6,23-240] for the full search strategy). Due to time constraints for the project, a pragmatic decision was made to begin the database search in 2014. Therefore, publications before 2014 were not screened and only included in the literature review if cited elsewhere. Websites that the PEBC routinely consults to identify guidelines and reviews were also searched from 2015 to March 2022 (Multimedia Appendix 2); we did not search the websites of health care organizations devoted to primary care or specific diseases. Articles cited in other publications were included, regardless of publication year, if they met the other inclusion criteria.

Inclusion and Exclusion Criteria and Screening of Primary Studies

The inclusion and exclusion criteria are outlined in Textbox 1. Articles were screened based on these criteria, which included categories such as article type, language, care provided, intervention, mode of delivery, and sample size.

A post hoc decision was made to include noncomparative studies that did not initially meet the inclusion criteria, but only if they were categorized as relating to triage. This adjustment was made because triage is a core component of first-contact care provided by primary care practitioners.

A review of the titles and abstracts of the primary literature, followed by data extraction for studies meeting the specified criteria, was conducted by GGF, a professional health research methodologist at the PEBC at McMaster University. The coauthors were consulted in cases of uncertainty. An independent audit of the extracted data was conducted by Jilian Sing (refer to the Acknowledgments section). Discrepancies were noted and addressed.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Study type: randomized controlled trial; other comparative studies (virtual vs in-person care)
- Language: abstract or full text in English
- Care provided: primary care study (refer to the definition of *primary care* in the Definitions subsection); care provided in a continuous primary care practice or a clinic that offered both walk-in and virtual care
- Intervention: virtual care provided by the same clinician or primary care team responsible for in-person care
- Mode of care delivery: synchronous virtual care (telephone or video), which replaced in-person care, including replacing of a subset of in-person appointments
- Sample size: sample size ≥30 (this is often considered sufficient for the central limit theorem to hold true, enabling the detection of differences between 2 study groups) [241]

Exclusion criteria

- Article type: trial registries or other study or review protocols without published results; editorials or commentaries; noncomparative surveys or questionnaires about patient or clinician experience; case studies; case series without a comparison group; conference abstracts
- Language: not English
- Care provided: study investigated the role of education, materials, lifestyle adaptation, exercise, diet, and so on, and the main study comparison was not virtual versus in-person delivery of these interventions; replacement of in-person care provided by 1 professional or treatment team or unit with virtual or in-person care provided by a different professional or team
- Intervention: study related to virtual-only practices (eg, “walk-in” telephone clinics or hotlines); app or remote patient monitoring;
- Mode of care delivery: SMS Text, email, or other asynchronous interventions, unless as a supplement to synchronous virtual care components
- Sample size: sample size <30

Systematic Reviews

Publications described as being systematic reviews or meta-analyses by their authors (primarily in the title or abstract) were included if they reported on primary studies meeting the inclusion criteria (Textbox 1). Reviews were also considered to be systematic reviews if the authors reported the databases searched, search strategy, and inclusion and exclusion criteria; the results section included a list of the reviewed studies along with extracted data; and the review was not otherwise classified by the authors. Systematic reviews on virtual care that passed initial screening but predominantly included studies not meeting the inclusion criteria were excluded; these reviews were used only to identify additional primary studies not found in the database search. Only reviews published in English were considered, with no restrictions placed on the publication date of individual studies.

Results

Overview

The database search identified 14,916 citations. In addition, 26 studies were identified through website searches, and 69 studies were found from the reference lists of other publications (Figure 1). The included studies were categorized into primary care functions, including triaging of incoming requests, diagnosis of a range of conditions through general primary care, rehabilitation, and counseling. A breakdown of the 170 included studies is presented in Table 1. Data for each study have been extracted and are reported in the tables in Multimedia Appendix 2. Primary studies on triage (24 publications representing 14 studies) are summarized in Table S1 in Multimedia Appendix 2 [23-46], and systematic reviews on triage are summarized in Table S2 in Multimedia Appendix 2 [47,48]. As the number of studies addressing specific types of virtual care was very limited, we decided not to subdivide results further by this category.

For studies on virtual care other than counseling, there were 64 publications representing 62 primary studies and 19 publications representing 18 systematic reviews (Tables S3-S13 in Multimedia Appendix 2 [6,49-130]). These have been subdivided by the categories listed in Table 1 and consisted of 11 RCTs and 18 possibly prospective nonrandomized trials; the rest were retrospective studies that generally used chart review or registry data. Only a few of the studies used multivariate analysis to control for possibly confounding factors. Table S3 [49-68] and Table S4 [6,69-73] in Multimedia Appendix 2 summarize studies and systematic reviews, respectively, in general primary care. Table S5 in Multimedia Appendix 2 [74-82] summarizes studies conducted during COVID-19–related restrictions; Table S6 in Multimedia Appendix 2 [83-90] and Table S7 in Multimedia Appendix 2 [91,92] summarize studies and systematic reviews of minor infections, respectively; and Table S8 in Multimedia Appendix 2 [93-96] summarizes studies of COVID-19 diagnosis and management. Table S9 in Multimedia Appendix 2 [97-106] and Table S10 in Multimedia Appendix 2 [107,108] summarize studies and reviews of virtual care in chronic disease management, respectively, while Table S11 in Multimedia Appendix 2 [109-113] reports on the use of virtual care in medical abortion. Clinical studies and systematic reviews in rehabilitation are covered in Table S12 in Multimedia Appendix 1 [114-121] and Table S13 in Multimedia Appendix 2 [107,122-130], respectively.

XSL•FO
RenderX

Primary counseling studies (102 publications representing 66 studies) are summarized in Table S14 in Multimedia Appendix 2 [131-232], while systematic reviews on counseling (n=8) are reported in Table S15 in Multimedia Appendix 2 [233-240]. The number of studies on counseling was slightly more than the number of other studies combined. Most of the counseling studies (50/65, 77%) were RCTs, providing stronger and higher-quality evidence on this topic.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram showing the number of studies identified, screened, assessed for eligibility, and included in the final analysis. *Studies were excluded for the following reasons: did not meet our definition of primary care or virtual care (3134/11,026, 28.42%); an additional intervention was being studied (2076/11,026, 18.83%); not full publications of completed studies (protocols, trial registrations, or conference abstracts; 2060/11,026, 18.68%); no comparison group for the outcomes of interest (1318/11,026, 11.95%); focused on the education of clinicians or interprofessional consultation (864/11,026, 7.84%); asynchronous interventions or not involving patient-clinician contact (821/11,026, 7.44%); case studies or <30 patients per group (362/11,026, 3.28%); letters, editorials, or commentary (195/11,026, 1.77%); virtual reality (142/11,026, 1.29%); and other (54/11,026, 0.49%).

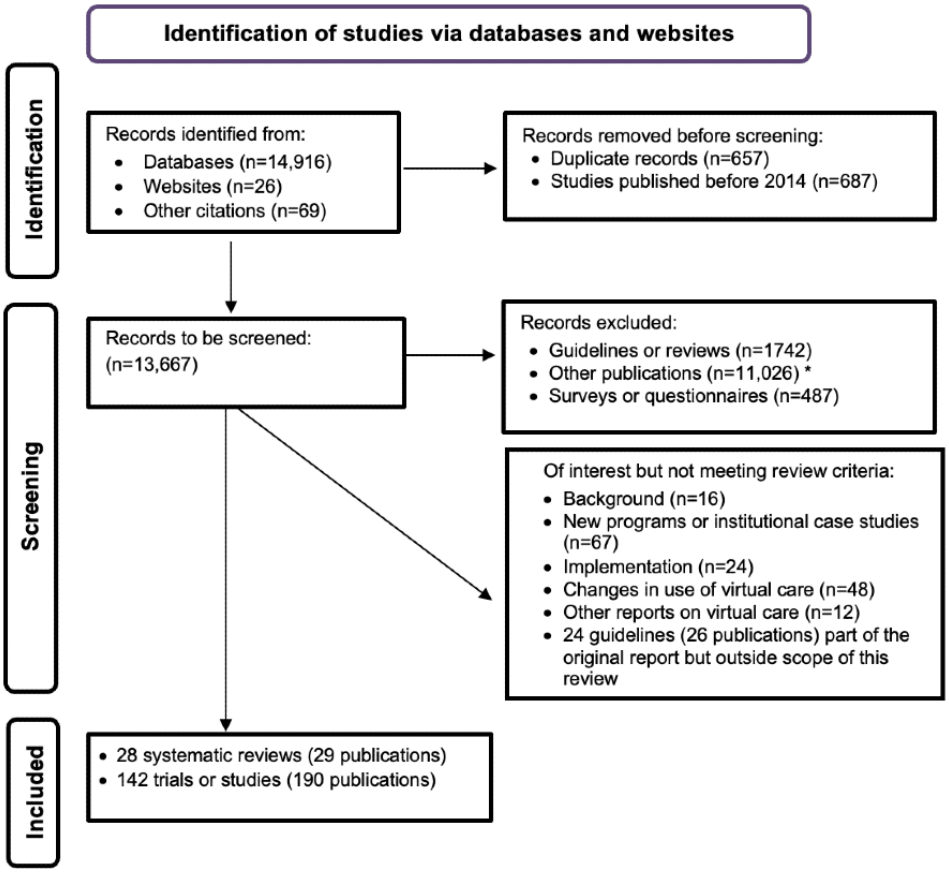

Table 1. Breakdown of included studies by primary care function.

Reason for consultation	Studies, n (%)		
	Primary studies (n=142)	Systematic reviews (n=28)	Total (n=170)
Triage	14 (9.9)	2 (7.1)	16 (9.4)
Medical assessment and treatment	54 (38)	9 (32.1)	63 (37.1)
General primary care	19 (35.2)	5 (55.6)	24 (38.1)
Primary care during COVID-19–related restrictions	9 (16.7)	0 (0)	9 (14.3)
Minor infections	8 (14.8)	2 (22.2)	10 (15.9)
COVID-19 management	4 (7.4)	0 (0)	4 (6.3)
Chronic disease management	9 (16.7)	2 (22.2)	11 (17.5)
Medical abortion	5 (3.2)	0 (0)	5 (7.9)
Rehabilitation	8 (5.6)	9 (32.1)	17 (10)
Counseling	66 (46.5)	8 (28.6)	74 (43.5)

Triage

Overview

The 14 primary studies involving triage (Table S1 in Multimedia Appendix 2 [23-46]) used various designs and often did not allow a direct comparison of virtual versus in-person care. Of these 14 studies, 10 (71%) were conducted in the United Kingdom, while 1 (7%) study each was conducted in Canada, Israel, and the Netherlands, 2 studies were conducted in Denmark. The 2 systematic reviews—1 (50%) on telephone triage [47] and 1 (50%) on remote triage [48]—are summarized in Table S2 in Multimedia Appendix 1.

Telephone Triage

The most common practice involved telephone triage by a nurse or other office staff and the assignment of patients to telephone consultation if appropriate and if the patient did not object. Both patient and disease characteristics determined the modality of care. Of the 16 studies on triage, only 2 (13%) were of this design [42,44]; most reports of this type were excluded because there was generally no comparison group. A variation used by 3 (19%) of the 16 studies was a telephone-first approach, where a general practitioner (GP) spoke by telephone with all patients (except those with administrative queries) and either addressed the issue during the call or scheduled an in-person visit [24-29,39]. Of the 16 studies, 2 (13%) involved triage by GPs in Denmark [43,46]. Of these 2 studies, 1 (50%) found that approximately 40% of the calls resulted in face-to-face consultation [43], while 1 (50%) reported medication prescription rates [46]. In 2 (13%) of the 16 studies, patients accessed the medical office using a web-based form, and patients with nonadministrative concerns were allocated to a GP who decided on the mode of contact [30,31,45].

The only RCT was the ESTEEM trial, and 7 (44%) of the 16 publications on triage covered various aspects of this trial [32-38]. Conducted in England, this trial, which used a combination of the aforementioned approaches, may serve as the most significant source of insights into triage. Patients (n=15,394) requesting same-day appointments were randomized to triage by a nurse, triage by a GP, or usual care. Estimated overall contact durations (triage+subsequent contacts on the same day) were 10.3 minutes for GP triage, 14.8 minutes for nurse triage, and 9.6 minutes for usual care. The number of deaths, emergency hospital admissions, and accident and emergency department attendances were not different [36]. Triage by a nurse practitioner resulted in fewer in-person visits than triage by practice nurses (odds ratio 0.19, 95% CI 0.07-0.49); nurse practitioners were more likely to definitively manage patients within the triage consultation [33].

Signposting

Another study from the United Kingdom [41] used signposting in 2 practices to reduce GP telephone workload; only patients for whom a physician visit was judged essential were given a telephone appointment. The remaining callers were referred to allied health professionals, alternative services, nonmedical staff, or self-help [41]. Approximately 40% to 60% of telephone appointments were eliminated. The proportion of essential consultations taking place at the 2 practices increased from 28.6% and 27.3% at baseline to 82.6% and 71.4%, respectively.

Emergency Assessment

A total of 4 (25%) out of 16 studies on triaging explored the use of virtual care to assist in triaging and managing emergency calls within health systems. Of the 16 studies on triaging, 1 (6%) looked at adding GP support to emergency calls, either in person or by telephone [40]. The study found that 8.1% of all calls to emergency services could be triaged to ambulance personnel plus GP support. Of these patients, 78% were not transported to hospital, although a transfer was more often avoided if the patient was assessed in person by the GP. The remaining study, which was conducted in British Columbia reported experience using HealthLink BC Emergency iDoctor-in-assistance [23]. It looked at patients who called an 811 nurse care navigation service. Callers who were triaged to seek care within 24 hours were referred to a physician by videoconferencing. Of the callers directed to videoconferencing with HealthLink BC Emergency iDoctor-in-assistance physicians, 33.8% were advised to attempt home treatment, 38.3% to contact a primary care physician within 1 week, 15% to attend an emergency department immediately, and 7.1% to contact their primary health care provider right away.

Medical Assessment and Treatment

General Primary Care

A total of 24 (38%) of the 63 studies on medical assessment and treatment were on general primary care. These studies in general primary care are summarized in Table S3 in Multimedia Appendix 2 [49-68] and systematic reviews in Table S4 in Multimedia Appendix 2 [6,69-73]. Of the 19 primary studies classified as general primary care, 15 (79%) involved general practice contacts for all or several reasons [49-58,60-65], while 1 (5%) reviewed those with acute deterioration within 3 days of a primary care visit [59] and found a slightly higher rate of self-referral to emergency services after telephone consultations compared to in-person visits.

Of the 15 studies involving general practice contacts for all or several reasons, 1 (7%) focused on the 11 most common illnesses managed via telehealth: sinusitis, upper respiratory infection, urinary tract infection, conjunctivitis, bronchitis, pharyngitis, influenza, cough, dermatitis, digestive symptoms (nausea, vomiting, or diarrhea), and ear pain [65]. This large retrospective study used insurance company claims and focused on the treatment of acute non-urgent conditions. It found that follow-up rates for both virtual and in-person care were similar, suggesting comparable clinical resolution of these issues through virtual modalities, although antibiotic use was higher and laboratory testing lower for the virtual care group [65].

Of the 2 RCTs that looked at a broad range of virtual primary care issues, 1 (50%) crossover study involved evaluations of patients by 2 physicians [49,50]: patients were randomized to either 1 virtual and 1 in-person assessment the same day or 2 in-person assessments. Follow-up for chronic diseases such as hypertension, elevated cholesterol level, and diabetes and consultations for acute diseases such as upper respiratory illness or sinusitis and musculoskeletal complaints were the most

XSL•FO
RenderX

common. The diagnostic agreements between the physicians were 84% between face-to-face and virtual visits and 80% between the 2 face-to-face visits. This study was among the few that directly compared the reliability of diagnosis for common conditions via in-person or virtual care.

The other RCT randomized patients to either a face-to-face appointment on that day or a callback that morning by a physician who either offered advice or arranged an in-person visit [51]. Telephone consultations were shorter (6.7 vs 8.2 min; *P*=.002) but resulted in slightly more follow-up consultations within 2 weeks (0.6 vs 0.4 consultations; *P*=.01), thus offsetting the time savings. Blood pressure was more frequently measured in person (13.3% vs 6.6%), but there were no significant differences in patient perceptions or other secondary outcomes.

Of the 24 studies on general primary care, 1 (4%) [67] compared video to telephone communication in emergency paramedicine response and found that video enhanced clinical evaluation 85% of the time; the odds ratio for emergency transport was 0.80 (95% CI 0.62-1.03).

Of the 9 systematic reviews on medical assessment and treatment, 5 (56%) were on virtual care in general without specifying any diseases or conditions [6,69-73]. The reviews by Totten et al [71-73] for the US Agency for Healthcare Research and Quality [71-73] concluded that telehealth consultations are effective in providing services or improving outcomes, although evidence is stronger for some applications. The reviews found evidence of effectiveness for counseling and the management of chronic conditions. However, overall impact, including cost-effectiveness, varied significantly based on how virtual care was integrated into the larger health service delivery ecosystem.

Primary Care During COVID-19–Related Restrictions

Of the 63 studies on medical assessment and treatment, 9 (14%) reported the use of virtual care due to COVID-19–related restrictions and are summarized in Table S5 in Multimedia Appendix 1 [74-82]. Of these 9 studies, 1 (11%) found that there was a rapid increase in the use of virtual care—from 31% in April 2019 to 90% in April 2020. Of the visits conducted virtually, 89% were by telephone and 1% by video [80]. Another study found that 71% of the video visits included visual observation–dependent findings that could not be assessed using a telephone; however, common barriers to using video visits were the lack of appropriate equipment and patient preferences [74]. Among the studies looking at primary care during the COVID-19 pandemic, there were variable results on the impact of age on the use of video visits: the study by Eberly et al [75] found that older individuals were less likely to use video visits, whereas Schenker et al [76] found that age was a significant positive predictor of having video visits.

Minor Infections

Of the 63 studies on medical assessment and treatment, 10 (16%) discussed antibiotic prescription (primary studies: n=8, 80%; Table S6 in Multimedia Appendix 1 [83-90]; systematic reviews: n=2, 20%; Table S7 in Multimedia Appendix 1 [91,92]). The 2 reviews did not have sufficient evidence to draw strong conclusions about the impact of virtual care on antibiotic prescribing but noted variable effects by condition, with higher rates for some conditions and lower rates for others. Of the 8 primary studies, 5 (62%) retrospective studies evaluated antibiotic prescribing for acute respiratory infections [83,85-88], while 1 (12%) evaluated antibiotic prescribing for urinary symptoms or infections [84]; in addition, 4 (50%) studies found similar or lower antibiotic prescribing rates with virtual compared to in-person care, while 1 (12%) reported higher antibiotic prescribing rates for telemedicine than in-person visits. This varied by condition within the same health care organization, with a chart review finding lower rates of antibiotic prescribing for sinusitis by SMS text and telephone than face-to-face visits and similar rates for urinary tract infections across all 3 modes [83,84]. By contrast, a review of claims data with matched populations showed higher rates of prescribing for acute respiratory infections for direct-to-consumer telemedicine versus urgent care or care provided by the patient's usual primary care provider [86]. A similar pattern was found in a study comparing retail health clinics with urgent care and primary care providers [65].

Some of the other general studies [55,63,65] also noted antibiotic prescribing as one of the outcomes. 1 of the 10 studies on minor infections (10%) compared the outcomes of patient-selected modality with the same provider, finding higher rates of antibiotic prescribing for in-person visits (10.6% for video vs 9.7% for telephone vs 13.5% for in-person visits) [55]. Of the 10 studies, 2 (20%) evaluated and found higher antibiotic prescribing rates with telephone consultations for patients with conjunctivitis, a condition that usually requires visual assessment [89,90].

COVID-19 Management

Of the 4 studies that reported on the assessment of patients with symptoms consistent with COVID-19 infection (Table S8 in Multimedia Appendix 2 [93-96]), 3 (75%) compared remote assessment (by telephone, video, or unspecified) with in-person care. Some studies conducted during the COVID-19 pandemic used antibiotic prescribing as one of the outcomes. Of these 4 studies, 1 (25%) [94] found that in-person visits involved more testing for influenza and higher antibiotic prescribing rates.

Chronic Disease Management

Of the 63 studies focused on medical assessment and treatment, 11 (18%) focused on chronic disease management (primary studies: n=9, 82%; Table S9 in Multimedia Appendix 1 [97-106]; systematic reviews: n=2, 18%; Table S10 in Multimedia Appendix 1 [107,108]). Of the 9 primary studies, 3 (33%) RCTs were conducted in patients with asthma [97-99], and all found higher rates of follow-up appointments in the telephone groups; 2 (22%) retrospective studies found similar diabetes control using either telephone [100] or videoconferencing [101] compared to face-to-face or usual care; and, by contrast, 1 (11%) retrospective study examining the use of telehealth by community health care workers to support Hispanic patients with low-income status with uncontrolled diabetes (defined by glycated hemoglobin level ≥9%) reported that patients were much less likely to achieve glycemic control with telephone visits alone compared to either exclusively in-person visits or a mix of in-person and virtual visits [102].

XSL•FO
RenderX

However, 1 in-person visit plus ≥1 telephone visit was worse (longer time to diabetes control) than 1 in-person visit alone [102], suggesting that adjustment for the confounders was not adequate.

Medical Abortion

Of the 63 studies on medical assessment and treatment, 5 (8%) explored the use of virtual care in medical abortion assessment or follow-up (Table S11 in Multimedia Appendix 1 [109-113]). These studies found no difference in successful abortion rates or adverse events, reported similar satisfaction, and suggested that providing care by telephone improved access compared to in-person care.

Rehabilitation

Rehabilitation studies (17/63, 27%) included those focusing on physiotherapy and cardiac rehabilitation. Of the 17 studies, 8 (47%) were primary studies (Table S12 in Multimedia Appendix 2 [114-121]), and 9 (53%) were systematic reviews (Table S13 in Multimedia Appendix 2 [107,122-130]). Specifically, of the 8 primary studies, 2 (25%) involved cardiac rehabilitation. The noninferiority RCT compared remotely monitored telerehabilitation to center-based programs and found similar benefits remote noninferior in terms of improvement in maximal oxygen consumption and health state [114]. The quasi-experimental study compared home-based videoconference rehabilitation to in-hospital rehabilitation; there was similar improvement in the 6-minute walk test, and the authors concluded that video rehabilitation was feasible [115].

Of the 8 primary studies, 2 RCTs (25%) [116,117] and 1 (12%) retrospective study [118] found that telerehabilitation after total knee or total hip and knee arthroplasty was noninferior or comparable to traditional therapy. Studies on movement assessment in children [119] and physiotherapy assessment [121] found 92% and 83% agreement between video and in-person assessment, respectively; it is unclear whether this is sufficient. A study on physical activity coaching [120] found no significant differences between control (no intervention), in-person, and telephone intervention.

Counseling Studies

Of the 8 systematic reviews on counseling (Table S15 in Multimedia Appendix 2 [233-240]), 3 (37%) focused on psychotherapy [233,234,236]; 1 (12%) explored interventions targeting smoking, nutrition, alcohol consumption, physical activity, and obesity [235]; 1 (12%) each focused on depression [237], posttraumatic stress disorder [238], and suicide [239]; and 1 (12%) investigated traumatic stress during a pandemic [240]. Overall, these reviews concluded that virtual care is an established medium for delivering counseling, with evidence suggesting equivalence to in-person care in many areas of counseling.

Most of the counseling studies (50/74, 68%; Table S14 in Multimedia Appendix 2 [131-232]) were RCTs. Of the 50 RCTs, 19 (38%) were designed as noninferiority studies. Many studies compared counseling by either telephone or videoconferencing to the same counseling provided in person (face-to-face). Of the 74 counseling studies, 3 (4%) [177,191-193] used real-time SMS text or chat conversations (all other studies involving SMS text-based communication were asynchronous and had been excluded). Cognitive behavioral therapy (CBT) was used in 18 (24%) of the 74 studies for treating depression, anxiety, pain, insomnia, eating disorders such as bulimia nervosa, and obsessive-compulsive disorder. Components of CBT may be present in some other studies that were described as behavioral studies, although they were not explicitly labeled as CBT. The overall evidence indicates that outcomes for telephone and video CBT are similar or noninferior to those for face-to-face CBT, although some differences for specific populations were noted. Other commonly used counseling types were problem-solving therapy, behavioral activation therapy, behavioral treatment interventions, prolonged exposure therapy, and cognitive processing therapy, with the latter 2 names used especially for posttraumatic stress disorder. For lifestyle-type interventions for weight loss, smoking cessation, and alcohol use, the type of counseling was less likely to fit within the traditional psychotherapy categories. While evidence for CBT is the greatest, the overall evidence suggests a role for telephone or video counseling in many other areas.

Discussion

Principal Findings

This scoping review synthesized studies that compared in-person and virtual care in primary care, with a mix of studies conducted before and during the COVID-19 pandemic. The studies were categorized into primary care functions, including triaging of incoming patient requests, medical assessment and treatment (including general primary care, minor infections, COVID-19 management, chronic disease management, and medical abortion), rehabilitation, and counseling. The review showed strong evidence that virtual care is equivalent to in-person care for counseling and comparable for some types of rehabilitation. The results suggest that virtual triaging is clinically appropriate and may lead to fewer in-person visits, especially when conducted by a physician or a nurse practitioner. However, for other primary care functions, outcomes from the included studies varied. Several studies demonstrated that many general primary care issues could be resolved virtually without the need for in-person follow-up, but only a few looked at diagnostic accuracy. A study that focused on diagnostic agreement between modalities for common primary care conditions found strong alignment [49,50]. Studies on chronic disease management observed variability in their benefit in using virtual care. Studies comparing appropriate antibiotic prescription between virtual and in-person care found variable impact depending on the clinical condition, whether patients chose a modality or were randomized to one, and the clinical context. A few of the studies measured the impact on emergency department visits or hospitalizations and found no difference, but they did not adjust for the type or severity of the illness [53,55]. Overall, the variation in impact may be a result of the relative effectiveness of the modality for a given condition or use case, but in some of the studies the differences may be driven by how the modality is selected, the practice context, and health care provider incentives within a health care organization.

XSL•FO
RenderX

The evidence for the overall experience and value of virtual care is evolving, but our review suggests some advantages for patients and unclear impacts on provider workload and system costs. This aligns with previous reviews that have found uncertain outcomes for virtual primary care as a whole [6,13]. In our review, most patients reported a similar overall experience between virtual and in-person interactions; however, certain benefits of virtual care were noted, including in terms of cost, travel time, convenience, waiting time, and access to more specialized care [39,42,69,70]. Therapeutic alliance was similar between in-person and virtual counseling in the studies reviewed. This contrasts with an earlier systematic review of virtual care in cancer, where some clinicians reported that they found it more difficult to comfort patients during vulnerable times, found virtual care more stressful, and had concerns about therapeutic alliance [242].

The included studies did not assess the impact on continuity of care or health equity, both of which are key components of primary care and patient experience. Other studies that aim to explore continuity of care after a primary care visit only do so by examining primary care as a whole; for example, the study by Reed et al [243] found a slightly higher percentage of in-person return visits and emergency department visits after video or telephone visits compared to in-person primary care visits, but the authors did not examine the differences based on the type of primary care function. Given that continuity of care is a defining characteristic of primary care and has been shown to be instrumental in driving primary care's positive impact on equity and quality of care, future studies should explore the impact of virtual care use on different primary care functions in the context of its impact on continuity of care [244,245]. In addition, the impact of virtual care on provider workload and system costs was less clear in our review. Telephone visits tended to be shorter than in-person interactions, but it was unclear how the addition of virtual care affected overall workloads. An initial telephone-based clinical triage by nonphysicians resulted in a higher proportion of visits being deemed essential by primary care physicians, suggesting that triage reduced low-value appointments with a physician [48]. Having said that, although the overall workload was not addressed, other studies in the literature highlight the value of virtual triage to physicians, notably that it can improve a clinician's experience by streamlining patient-clinician communication and could help clinicians better manage their time by reducing their administrative workload [246].

To our knowledge, this is one of the first comprehensive reviews to examine the appropriateness of virtual care in terms of key functions of primary care. Studies examining virtual care use in primary care tend to examine primary care as a whole; for example, the study by Reed et al [243] found that 50% of primary care visits used telemedicine (19% by video and 31% by telephone); however, the impact on these numbers based on primary care function was not studied. Similarly, previous reviews have also focused on examining virtual care use more broadly through categories such as cost and health care use. However, given the shift in practice since the COVID-19 pandemic, it is now more important to understand how and when in the clinical process virtual care should be used [6,13]. In addition, these reviews only included publications from 2020 onward and did not include RCTs, which are a focus of our review. Our review shows that there is significant variability in evidence across different clinical use cases in primary care, making it difficult to provide broad conclusions about the appropriateness of virtual primary care for specific conditions. Instead, our work provides evidence that the impact and outcomes of virtual modalities in primary care should be examined according to the various interaction points along a patient's journey; for example, there is strong evidence for equivalence between in-person and virtual care for counseling, and thus counseling could be more readily integrated into sustainable, high-quality primary care workflows. By contrast, the use of virtual care for situations that are likely to result in antibiotic prescribing requires further study to understand whether it is indeed equivalent to in-person care. Our review suggests that virtual triage can play a role in supporting primary care workflows, but more research is required to determine the best implementation model. A rapid review by Barnabe et al [247] highlighted some implications for health care organizations to consider before implementing virtual triage. These include ensuring that the platforms are locally based; that they are flexible, responsive, and tailored to regional circumstances; and that implementation is carried out, keeping partnerships and collaborations in mind [247]. These results contrast with those of other reviews on the use of virtual modalities in primary care, which analyzed clinical appropriateness and outcomes across all use cases and were generally unable to make strong recommendations to guide clinical care [15]. Several authors have suggested that a more nuanced approach, one that looks at different uses of primary care, might ultimately provide more insight into driving decisions around patient care and system planning [6,248,249].

Virtual care during the COVID-19 pandemic has expanded to cover a wide range of conditions, and our review suggests that there is still limited evidence to broadly define the optimal mode of interaction (in-person, video, telephone, or asynchronous contact); however, the evidence does provide some guidance. Our review suggests that virtual care is likely at least as good as in-person care for a wide range of primary care issues and should be offered as part of routine practice. Overall, for any given visit, the choice of modality remains a question of clinical judgment and shared decision-making between a patient and their care team. Patient factors, including access to technology, comfort with virtual visits, and maintaining a strong therapeutic relationship, must be considered when deciding the best modality for a given interaction [250]. Virtual care should be embedded in larger service models that allow for easy escalation to in-person follow-up when required. Enabling virtual triage can provide clinics with certain advantages, including improving overall access, better prioritization for the most appropriate modality, and determining whether any information should be provided in advance of the visit. Furthermore, providing counseling, self-management support, education, and ongoing monitoring virtually also offers advantages over regular in-person appointments, including improved convenience and similar outcomes for many patient populations. Virtual care could also be offered to support chronic disease management but may not work well for all patients. Options such as providing

XSL•FO
RenderX

smartphones, tablet devices, or computers and limited telephone or internet service were used in some of the studies for individuals with limited technology accessibility [139,152-154,167,195]. However, health organizations and systems would benefit from continued investment in understanding how to better integrate and optimize virtual care to achieve the quintuple aim of improving patient experience, improving population health, improving clinician well-being, reducing health care costs, and advancing health equity [251], using human-centered methods such as co-design, service design, and participatory research or other frameworks [252]. Now that the practice of virtual care is so widespread, ongoing research can help in understanding how it can be leveraged to improve access and quality of care [248].

Limitations

This review has several limitations. First, it was restricted to studies comparing virtual care to in-person care instead of care (regardless of delivery method) to an objective standard. Therefore, it is applicable only to clinical areas in which there is established in-person care for evaluation and treatment. While many of the included studies were designed to measure the noninferiority of virtual care to in-person care, in-person treatment should not necessarily be the gold standard, especially for counseling studies where effectiveness is often based on a validated tool to measure disease, symptom intensity, or patient-reported outcomes. Second, this is a scoping review rather than a systematic review; therefore, we did not evaluate the methodological quality of the studies or determine which studies might provide more reliable results. In addition, we did not include gray literature in our search to ensure the reliability of the evidence underpinning the recommendations provided in the paper. Having said that, although we supplemented our search using trusted websites, it is possible that the exclusion of gray literature resulted in underrepresented perspectives from policy makers and community organizations that are not captured in academic publications. This could mean that insights from the practical applications of real-world data could have been missed. Furthermore, articles were only screened by a single reviewer, which could have introduced bias in the results if personal biases impacted the interpretation of the literature. Although these limitations were mitigated through an audit conducted by another member of the team, the likelihood of errors is increased when only 1 reviewer is involved. Third, the study contexts varied substantially. Most were cross-sectional studies focused on the initial consultation or ongoing chronic disease management and did not assess the impact on continuity of care, a key component of primary care. Finally, given the time frame for the database search, it is possible that new literature has become available that contributes additional evidence to this topic. Nonetheless, the study demonstrates a novel approach to organizing the literature on virtual care, moving from the question of whether virtual care is as effective as in-person care for a given health problem to thinking about how virtual care supports the core functions of primary care. It argues for a different way of conducting studies in the future and provides a framework for organizing this research. Much of the included literature covers the period during the COVID-19 pandemic, when most ambulatory care was virtual in many jurisdictions. This context is not as broadly applicable to the current state of care. However, we believe that our findings still provide valuable insights into how virtual care can be leveraged in primary care and can suggest appropriate ways of structuring future studies to better understand when and how voice, video, and SMS text-based interactions are best used in clinical care.

Conclusions

This scoping review found no consistent differences in the appropriateness of care or patient outcomes between virtual and in-person care across the included studies. Virtual care is perceived as equivalent to in-person care for many common uses, despite some variation by condition. The overall impact of virtual care will likely depend on whether it is used for triage, diagnosis, treatment, or counseling and whether patients or providers determine the choice of modality. Moreover, we found that the overall value of virtual care for the health system, including potential cost savings, remains unclear. Our findings highlight that although the rates of virtual care use may decrease as concerns about COVID-19 infection lessen, for functions such as triage, counseling, and rehabilitation, virtual care may remain the norm. Further studies, incorporating options for patient and provider choice, are needed to determine the optimal use of virtual care from a resource and outcome perspective. This comprehensive review is one of the first that aims to understand how virtual care can be leveraged in the various components of routine primary care functions. Given the recent changes in practice, this evidence base will continue to grow, and timely reviews will be needed to keep up with the literature. These modalities are no longer just a temporary measure to get through the pandemic and now need to be adapted to fit a new set of patient and provider workflows to demonstrate positive impacts on experience, outcomes, and costs of care. Future reviews should focus on when to use virtual modes of communication in a patient's primary care journey.

Acknowledgments

The authors would like to thank Population Health and Value-Based Health Systems, Ontario Health, for funding this study. The funder played no part in the collection, analysis, or interpretation of the data; the writing of the report; or the decision to submit the paper for publication. The authors also thank Jilian Sing for screening and summarizing reviews and for supporting the data audit.

Data Availability

Data sharing is not applicable to this paper as no datasets were generated or analyzed during this study.

Abstract

Background: Various mobile technologies and digital health interventions (DHIs) have been developed for type 2 diabetes mellitus (T2DM) management. Strategies are crucial for ensuring the effectiveness of DHIs. However, there is currently a lack of categorization and summarization of the strategies used in DHIs for T2DM.

Objective: This study aims to (1) identify and categorize the strategies used in DHIs for T2DM management; (2) assess the effectiveness of these DHI strategies; and (3) compare and rank the efficacy of different strategy combinations on glycated hemoglobin A_{1c} (HbA_{1c}) levels, fasting blood glucose (FBG) levels, BMI, and weight loss.

Methods: Relevant randomized controlled trials (RCTs) were extracted from PubMed, Web of Science, and Scopus databases. Three rounds of screening and selection were conducted. The strategies were identified and categorized based on the principles of behavior change techniques and behavior strategies. The synthesis framework for the assessment of health IT was used to structure the evaluation of the DHI strategies qualitatively. A network meta-analysis was performed to compare the efficacy of different strategy combinations. The data quality was assessed using the Cochrane Risk of Bias tool.

Results: A total of 52 RCTs were included, identifying 63 strategies categorized into 19 strategy themes. The most commonly used strategies were *guide*, *monitor*, *management*, and *engagement*. Most studies reported positive or mixed outcomes for most indicators based on the synthesis framework for the assessment of health IT. Research involving a medium or high number of strategies was found to be more effective than research involving a low number of strategies. Of 52 RCTs, 27 (52%) were included in the network meta-analysis. The strategy combination of *communication*, *engagement*, *guide*, and *management* was most effective in reducing HbA_{1c} levels (mean difference [MD] –1.04, 95% CI –1.55 to –0.54), while the strategy combination of *guide*, *management*, and *monitor* was effective in reducing FBG levels (MD –0.96, 95% CI –1.86 to –0.06). The strategy combination of *communication*, *engagement*, *goal setting*, *management*, and *support* was most effective for BMI (MD –2.30, 95% CI –3.16 to –1.44) and weight management (MD –6.50, 95% CI –8.82 to –4.18).

Conclusions: Several DHI strategy combinations were effective in reducing HbA_{1c} levels, FBG levels, BMI, and weight in T2DM management. Health care professionals should be encouraged to apply these promising strategy combinations in DHIs during clinical care. Future research should further explore and optimize the design and implementation of strategies.

Introduction

The Severity of Type 2 Diabetes

Type 2 diabetes mellitus (T2DM) has become a serious public health problem worldwide. It is a progressive disease that can impair health-related quality of life [1,2] while also imposing substantial economic burdens on individuals, health systems, and society [3]. By 2040, there will be 642 million patients with diabetes worldwide, with the incidence of T2DM on the rise across all regions [4]. T2DM accounts for >90% of the diagnosis in all types of diabetes, and it can cause various complications [5]. The goal of diabetes treatment is to prevent or delay complications and optimize quality of life [6]. Poor glucose control is associated with the occurrence of complications [7]. Glycated hemoglobin A_{1c} (HbA_{1c}) can be used to determine glucose control levels [8]. Continuous monitoring of fasting blood glucose (FBG) can provide an intuitive reflection of changes in the patient's glucose levels. Obesity is closely related to T2DM, and weight gain is an independent risk factor for T2DM [9]. Controlling glucose levels and body weight within the normal range can effectively reduce the complications of patients with diabetes [10]. Many studies have shown that T2DM can be slowed down, stopped, or even reversed by changing lifestyle (eg, low-calorie diet and increasing physical activity) [11,12]. This can reduce long-term complications and may extend life expectancy [13].

The Effect of Digital Health Interventions

Maintaining glycemic control is a challenge for both patients and health care providers, making it difficult to encourage or motivate patients to make long-term lifestyle changes, explain their self-monitoring of blood glucose data, provide immediate feedback, and understand their lifestyle [14]. Recognizing that patients require more self-management support, various mobile technologies (ie, mobile health care) and digital health interventions (DHIs) have been developed [15-18], including mobile apps, SMS, wearable and ambient sensors, and social media. These technologies can provide early support for the improvement of health behaviors in patients with diabetes, encouraging patients with T2DM to eat healthily, engage in physical exercise, and collect and analyze personal data to assess clinical conditions. The data reported by patients can be used to customize personalized feedback information, including health promotion, motivation, encouragement, reminders, and emotional support information [19,20]. Relevant systematic reviews and meta-analyses have confirmed the effectiveness of DHIs on behavior change, blood glucose control, and weight loss in patients with diabetes [21-24].

The Critical Role of Strategies in DHIs for T2DM Management

Strategies play a pivotal role in enhancing the efficacy of DHIs for patients with T2DM, with the careful selection and implementation of appropriate strategies being crucial to DHI success [25]. Within the realm of digital interventions, using suitable strategies, such as user-centered participatory design, can heighten user engagement, thereby rendering intervention measures more appealing and efficacious [26]. Furthermore, mobile technology interventions informed by strategies, such as health behavior theory, hold the potential for more comprehensive mechanisms of behavior change, fostering a health care approach that is both impactful and sustainable [27]. Through the identification and categorization of diverse strategies, researchers and practitioners can gain deeper insights into the effective methodologies and techniques used in DHIs. This involves assessing the strengths and limitations of various strategies and their applicability to specific health domains or populations [28].

Current Findings on DHI Strategies for T2DM Management

There have been studies that systematically summarize the strategies used in DHIs currently. For example, various engagement strategies have been reported in DHIs for mental health promotion, including personalization, human and social support, gamification, personalized feedback, and reminders, which work best to promote engagement [29]. A study indicated that the effectiveness of internet-based interventions correlates with the extensive use of theory, particularly the theory of planned behavior; the incorporation of a greater number of behavior change techniques; and the integration of additional methods for interacting with participants [25]. A systematic review and meta-analysis of lifestyle interventions in postpartum women found that the provision of certain strategies including problem-solving, goal setting of the outcome, reviewing the outcome goal, providing feedback, and self-monitoring of behavior was associated with greater decreases in energy intake [30]. In addition, the review analyzed loneliness reduction strategies including improving social skills, enhancing social support, increasing opportunities for social interaction, and addressing deficits in social cognition [31]. It was suggested in a narrative umbrella review that credible sources, social support, prompts and cues, graded tasks, goals and planning, feedback and monitoring, and human coaching and personalization components increased the effectiveness of DHIs targeting the prevention and management of noncommunicable diseases [32]. Moreover, substantial strategies have been found to be effective in improving recruitment, reducing loss to follow-up, and enhancing retention during intervention in some trials [33-36]. However, there is a lack of categorization and summarization of the strategies used in DHIs of T2DM at present. Although previous research has compared the effectiveness of 5 strategies for T2DM management, it has primarily focused on telemedicine within DHIs and compared several independent strategies, without providing a systematic summary of the strategies used in DHIs [37]." Meanwhile, most interventional studies incorporate different numbers and combinations of strategies rather than focusing on individual strategies, and it is not yet known which strategy combination has the best effect.

XSL•FO
RenderX

Therefore, it is essential to summarize and compare strategies and strategy combinations, identify the content of these strategies, and further determine the optimal number and form of strategy combinations to provide more practical guidance for precise and personalized digital health management of T2DM.

Study Objectives

This study aims to (1) identify and categorize the strategies used in DHIs on T2DM management; (2) assess the effectiveness of these DHI strategies; and (3) compare and rank the efficacy of different strategy combinations on HbA_{1c} levels, FBG levels, BMI, and weight loss.

Methods

Protocol and Registration

This systematic review followed the PRISMA-NMA (Preferred Reporting Items for Systematic Review and Meta-Analyses extension for Network Meta-Analysis) 2020 statement for designing and reporting [38]. The PRISMA checklist for this study can be found in Multimedia Appendix 1. The protocol for this study has been registered with PROSPERO (CRD42024544629).

Data Sources

We conducted a comprehensive search for papers published in English from PubMed, Web of Science, and Scopus databases. This search used a combination of DHI-related terms, along with database-specific subject headings and filters, to ensure thoroughness and focus. The detailed search strategy is provided in Multimedia Appendix 2. The time span was from January 1, 1999, to March 10, 2024.

Data Selection and Extraction

All the searched records were imported into EndNote X9 (Clarivate) to eliminate duplicate studies. The first round of screening and selection focused on identifying DHIs. Our criteria were as follows:

1. The means of intervention should be digital, primarily including wearable devices, telemedicine, electronic health records, electronic medical records, mobile phone apps, web pages, blogs, emails, SMS text messages, social media, and similar technologies.
2. The intervention must be health related, encompassing areas such as health behavior improvement, disease treatment, and health education.
3. We selected studies that used randomized controlled trials (RCTs) as the intervention as eligible, including both individual and cluster RCTs, as they provide the highest level of evidence for evaluating interventions.

The second round of screening and selection concentrated on identifying specific strategies within the selected DHIs. A strategy is defined as a specific approach or technique used within the intervention to promote health behavior change or improve health outcomes. We used the framework of potential strategies (Multimedia Appendix 3) based on behavior change techniques [39] and behavior strategies [30].

The third round of screening and selection focused on identifying the population with T2DM based on the second round of work. A data extraction form was developed to facilitate electronic comparison of entries. The extracted data include the author, year of publication, study setting (ie, country), characteristics of the participants, details of the interventions, strategies, and outcomes. The inclusion criteria were as follows:

1. Population—patients diagnosed with T2DM and aged ≥18 years
2. Comparisons—the effectiveness of DHIs was compared to no intervention
3. Outcomes—the outcomes for the overview of the effectiveness of DHI strategies included, but were not limited to, acceptability, usability, satisfaction, appropriateness, and efficiency. The outcome of the meta-analysis included the changes in HbA_{1c} (%) level, FBG (mmol/L) level, BMI (kg/m^2), and weight loss (kg).
4. Study design—we only included RCTs.

During the second and third screening, full manuscripts of the studies identified as potentially relevant were obtained and assessed by 6 independent reviewers according to the inclusion criteria. Any discrepancies were resolved by discussion or through adjudication by a senior researcher.

Quality Appraisal

Two independent reviewers assessed the individual quality of the final selected studies using the Cochrane Collaboration Risk of Bias tool [40], with any discrepancies being resolved by consensus. The quality evaluation items of each trial included selection bias (random sequence generation and allocation concealment), performance bias (blinding of participants and personnel), detection bias (blinding of outcome assessment), attrition bias (incomplete outcome data), reporting bias (selective reporting), and other bias. Each item was scored as low, high, or unclear risk of bias.

Data Analysis and Synthesis

Methods of Analysis

The variability in some outcomes, such as changes in physical activity, diabetes self-efficacy, medication adherence, quality of life, acceptability, and satisfaction, precluded the possibility of conducting a meta-analysis for these specific measures. Therefore, we reported a structured analysis of the findings to draw conclusions about the effectiveness of different DHI strategies on T2DM management. If a certain outcome measure had a statistically significant ($P<.05$) improvement compared to the control group or over time, it was considered effective. If the outcome measures did not show significant changes over time or there was no statistically significant difference from the control group, it was considered that there was not enough evidence to prove their effectiveness. The synthesis framework for the assessment of health IT (SF/HIT) was used to structure the evaluation of the studies because it included a whole system set of outcome variables [41]. These comprised variables such as adherence or attendance, acceptability, effectiveness, satisfaction, and perceived ease of use or usefulness. Following

XSL•FO
RenderX

the framework, evidence for each of the outcome variables was coded as *positive or mixed* or *neutral or negative.* If the study did not address the outcome in question, it was coded as neutral or negative.

For the meta-analysis, the outcome included HbA_{1c} levels, FBG levels, BMI, and weight loss. These were continuous variables, and thus, network estimates were presented as mean differences (MDs) with 95% CIs. We assumed that a P value<.05 indicated statistical significance. We measured the level of heterogeneity with the I^2 statistics; an I^2<50% was considered to have no significant heterogeneity, in which case we would use a fixed-effects model to calculate the pooled effect sizes. Otherwise, a random-effects model would be used. Stata software (version 15.1, *network package* and *network graphs package*; StataCorp) was used to conduct network meta-analysis [42,43]. The *network package* performed the network meta-analysis based on the frequentist framework using random-effects models. The approach was to test the research hypothesis, as this was simpler than the problem of establishing prior probability [44]. This approach is not complex and has few limitations for ordinary researchers using network meta-analysis [45]. A network diagram with nodes and lines was constructed to represent different interventions, where the size of nodes represents the number of populations, and the thickness of lines between nodes represents the number of studies. The results of the network meta-analysis were summarized based on all possible pairwise comparisons, including mixed comparisons (ie, the combined effect of direct and indirect comparisons) and indirect comparisons. The effect of different interventions was estimated based on the surface under the cumulative ranking curve (SUCRA). The SUCRA value ranges from 0% to 100%, where a SUCRA value of 100% indicates that the treatment was the most effective, and the smaller the value, the poorer the treatment effect.

Assessment of Inconsistency

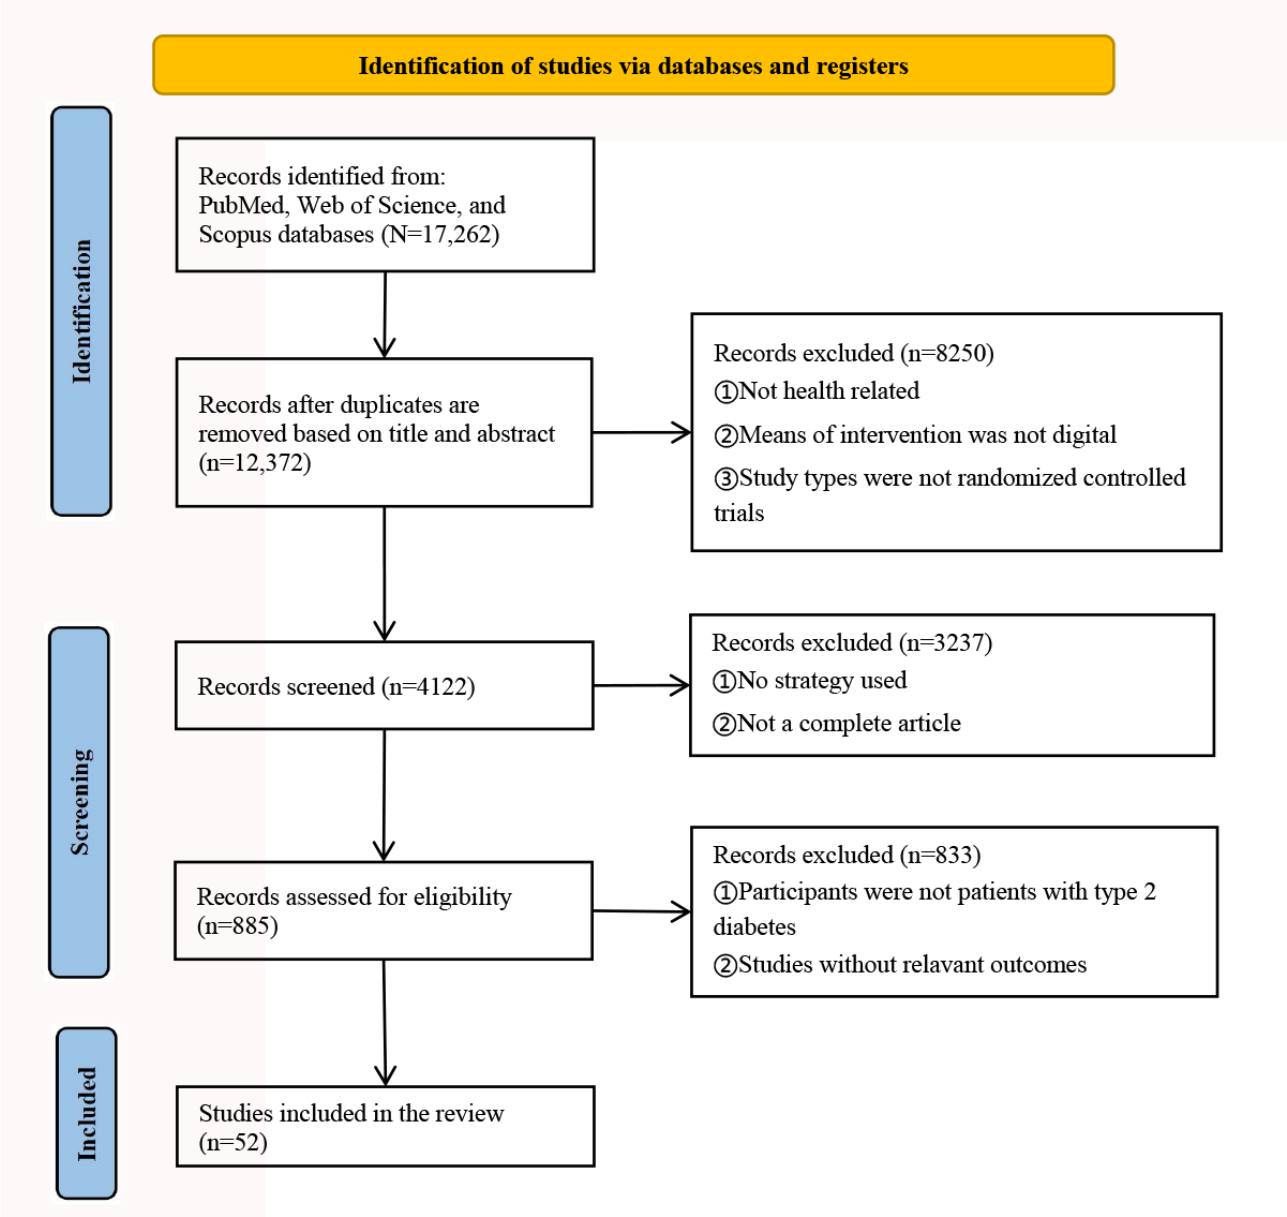
The node-splitting test was used to assess the local inconsistency between direct and indirect comparisons. Differences between direct and indirect coefficients (assessed via the P value) were used to estimate inconsistency: if P<.05, local inconsistency was considered to exist [46]. If inconsistency was observed, nontransitivity was also suspected to exist, and potential modifiers influencing treatment effects were examined.

Risk of Bias Across Studies

The risk of publication bias in network meta-analysis was analyzed using the Egger test [47]. The symmetry of the generated funnel plots was assessed visually using the Egger test, together with adjusted rank correlation and regression asymmetry tests [48,49].

Sensitivity Analyses

We used the method of removing individual studies separately.



Results

Characteristics of Included Studies

The schematic flow for the selection of the included studies is presented in Figure 1. A total of 12,372 studies were identified, of which only 52 (0.42%) trials [14,50-100] met the eligibility criteria and were included. The characteristics of the included studies are provided in Multimedia Appendix 4 [14,50-100]. Among the 52 included studies from the literature, the publication year was between 2000 and 2023. The number of publications has also increased over the years, with the highest publication volume in 2022 and 2023. Most research was conducted in the United States (20/52, 38%), followed by China (5/52, 10%). The minimum sample size was 30, and the maximum was 1926. The duration of intervention ranged from 3 to 24 months, with most studies lasting 12 months (15/52, 29%). The outcome indicators in intervention mainly included HbA_{1c} levels, FBG levels, BMI, blood pressure, weight loss, waist circumference, low-density lipoprotein cholesterol levels, high-density lipoprotein cholesterol levels, total cholesterol levels, diabetes self-efficiency, diabetes medication adherence, quality of life, self-management, depression, diabetes distress, and other outcomes.

XSL•FO
RenderX

Figure 1. Flow diagram for the search and selection of the included studies.

Synthesis of Different DHI Strategies

Among the 52 studies included, we identified 63 different strategies, and they were categorized into 19 themes. Among the identified strategies, *monitor* and *guide* were the most frequently used, appearing in 77% (40/52) and 67% (35/52) of the total papers, respectively. Following closely was *management* (32/52, 61%) and *engagement* (28/52, 54%). More than 40% of the studies used *stimulate*,*communication*, and *goal setting*. In addition, more than one-fifth of the research used *support*,*shape*, *feedback*, *prompt*, *action*, and *tailor*. The usage frequencies were notably lower for cues, *identity*, *reward*, *model or demonstrate*, and *restructure*. The studies ranged from using a minimum of 1 to a maximum of 32 strategies. We categorized studies into 3 groups based on the number of strategies used: low (1 to 3 strategies), medium (4 to 6 strategies), and high (≥7 strategies). Among the 52 studies, 18 (35%) were categorized as high-strategy study, 23 (44%) as medium-strategy study, and 11 (21%) as low-strategy study. In these 52 studies, 37 different combinations of strategies were identified based on the thematic strategies used in each study. Detailed information about these strategies and strategy combinations is provided in Multimedia Appendix 5. The strategy themes and the number of identified studies are listed in Table 1.

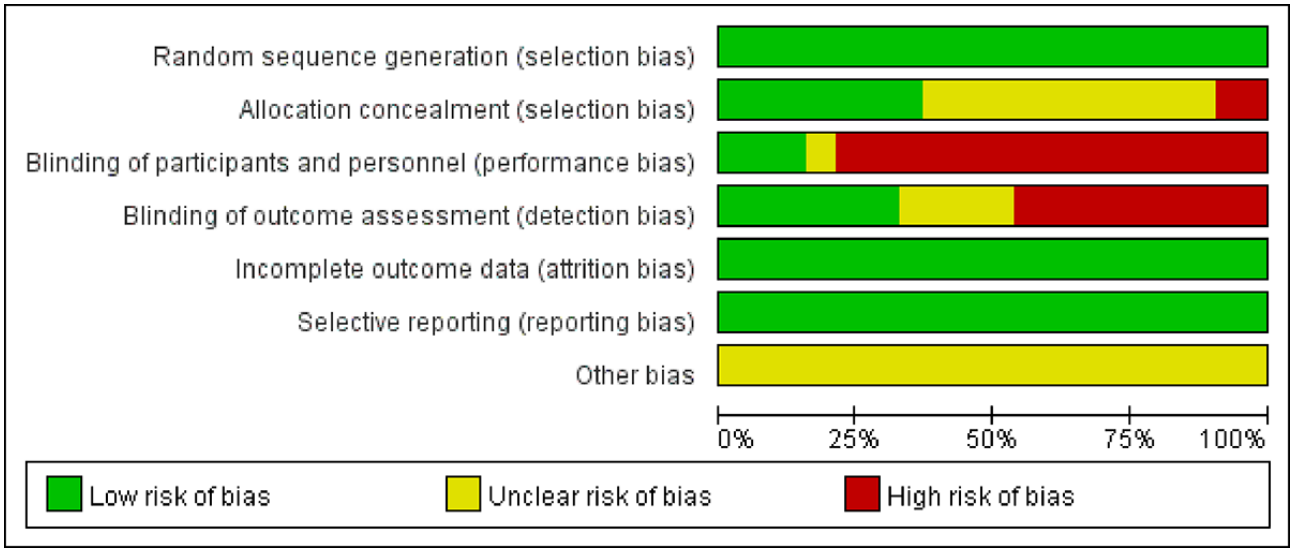
Evaluation of the Effectiveness of Different DHI Strategies



In this assessment, we encoded positive or mixed as 1 and neutral or negative as 0. Overall, most studies have reported positive or mixed outcomes for most outcome indicators. The number of positive or mixed results that studies achieved ranged from 6 to 11. In total, 41 (79%) of the 52 studies have reported having ≥10 positive or mixed results as stipulated in the SF/HIT. For the preventive care; efficiency; perceived ease of use or usefulness; safety, privacy, or security; acceptability; appropriateness; and satisfaction domains nearly all studies (>50) have reported positive or mixed results. Following closely were the process of service delivery or performance, effectiveness, and adherence or attendance domains, with 49 (94%), 47 (90%), and 45 (86%) of the 52 studies reporting positive or mixed results. However, in terms of cost-effectiveness, most studies (35/52, 67%) either did not report relevant results or reported neutral or negative findings. Out of 18 high-strategy studies, 16 (89%) reported ≥10 positive or mixed results. Out of 23 medium-strategy studies, 20 (87%) reported ≥10 positive or mixed results. However, 7 (64%) out of the 11 low-strategy studies reported having ≥10 positive or mixed results. Meanwhile, it is noteworthy that the 2 studies with the fewest positive or mixed results were both high-strategy studies. The evaluation summary of SF/HIT results is presented in Multimedia Appendix 6.

Risk of Bias and Quality Assessments of Included Studies

We conducted a synthesis of bias risk assessment results using RevMan software (version 5.4; Cochrane), as shown in Figure 2. Overall, all included RCTs exhibited a relatively low risk of bias. All studies reported the generation of random sequences and described specific randomization methods assessed as low risk. There were no incomplete outcome data across all studies assessed as low risk. Selective reporting was not observed in any of the studies assessed as low risk. Regarding allocation concealment, 36% (19/52) of the studies reported using this method, assessed as low risk; 54% (28/52) did not provide such reporting, assessed as unclear risk; and 10% (5/52) explicitly stated not using allocation concealment, assessed as high risk. For blinding of participants and personnel, most studies (41/52, 79%) did not use blinding, assessed as high risk, often due to the nature of the intervention precluding blinding; 15% (8/52) of the studies implemented blinding for participants, assessed as low risk, while 6% (3/52) did not report blinding status, assessed as unclear risk. For the blinding of outcome assessment, 46% (24/52) of the studies did not use blinding, resulting in high risk, whereas 33% (17/52) reported using blinding for outcome assessment, assessed as low risk, with the remainder (11/52, 21%) assessed as unclear risk. The risk of bias in each study is presented in Multimedia Appendix 7.

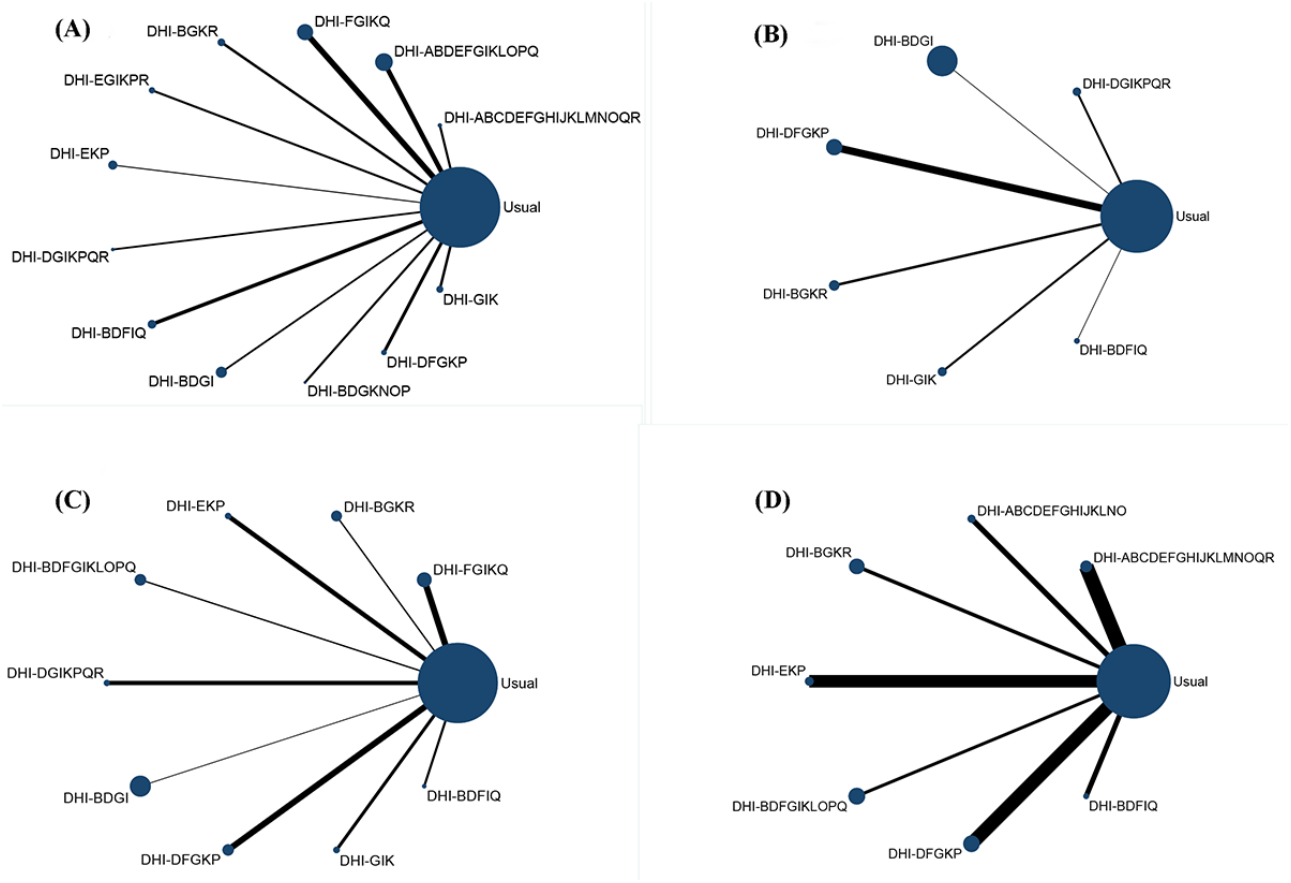
Meta-Analysis



Effects of Strategy Combinations in Reducing HbA1c Levels

Of 52 included RCTs, 27 (52%) RCTs [14,50,53-55,57,59,60,66,68,70,72,74,77,78,80,82,84,85,87,88,93,94,96-98,100] assessed the effects of 12 different DHI strategy combinations on HbA_{1c} levels in patients with T2DM. These 12 strategy combinations encompassed (1) ABCDEFGHIJKLMNOQR (action planning, communication, cues, engagement, feedback, goal setting, guide, identity, management, model or demonstrate, monitor, prompt, restructure, reward, shape, support, and tailor); (2) ABDEFGIKLOPQ (action planning, communication, engagement, feedback, goal setting, guide, management, monitor, prompt, shape, stimulate, and support); (3) FGIKQ (goal setting, guide, management, monitor, and support); (4) BGKR (communication, guide, monitor, and tailor); (5) EGIKPR (feedback, guide, management, monitor, stimulate, and tailor); (6) EKP (feedback, monitor, and stimulate); (7) DGIKPQR (engagement, guide, management, monitor, stimulate, support, and tailor); (8) BDFIQ (communication, engagement, goal setting, management, and support); (9) BDGI (communication, engagement, guide, and management); (10) BDGKNOP (communication, engagement, guide, monitor, reward, shape, and stimulate); (11) DFGKP (engagement, goal setting, guide, monitor, and stimulate); and (12) GIK (guide, management, and monitor). The specific strategy represented by the letters in each strategy combination is provided in Table 1.

The network evidence plot for HbA_{1c} levels is shown in Figure 3A. The SUCRA probability ranking for the reducing effect of HbA_{1c} levels in different DHI strategy combinations is shown in Figure 4A. Of the 12 DHI strategy combinations, the possibility of DHI-BDGI (communication, engagement, guide, and management) being the best strategy combination was the highest. The SUCRA value predicted the possibility of different strategy combinations as the best way, and the effects were ranked as follows: DHI-BDGI (91.8%)>DHI-DFGKP (76%)>DHI-DGIKPQR (73.2%)>DHI-FGIKQ (67.4%)>DHI-ABDEFGIKLOPQ (62.1%) > DHI-EGIKPR (52.8%)>DHI-GIK (52.1%)>DHI-EKP (40.5%) > DHI-BDGKNOP (39.4%) > DHI-ABCDEFGHIJKLMNOQR (30.1%)>DHI-BDFIQ (27.7%)>DHI-BGKR (24.1%)>usual (12.8%). Compared with the usual care groups, DHI-BDGI (MD –1.04, 95% CI –1.55 to –0.54), DHI-DFGKP (MD –0.76, 95% CI –1.36 to –0.16), DHI-FGIKQ (MD –0.61, 95% CI –1.01 to –0.22), DHI-ABDEFGIKLOPQ (MD –0.55, 95% CI –0.92 to –0.18), and DHI-GIK (MD –0.44, 95% CI –0.85 to –0.03) strategy combinations were statistically significantly effective in reducing HbA_{1c} levels (Figure 5A). On the basis of the interval estimation of direct and indirect comparison (Table 2), DHI-BDGI was more effective than the DHI-EKP, DHI-BDFIQ, and DHI-BGKR strategy combinations.

Effects of Strategy Combinations on FBG Levels

Of 52 included RCTs, 7 (13%) RCTs [74,78,84,85,87,97,98] assessed the effects of 6 different DHI strategy combinations on FBG levels in patients with T2DM. These 6 strategy combinations encompassed (1) DGIKPQR (engagement, guide, management, monitor, stimulate, support, and tailor); (2) BDGI (communication, engagement, guide, and management); (3) DFGKP (engagement, goal setting, guide, monitor, and stimulate); (4) BGKR (communication, guide, monitor, and tailor); (5) GIK (guide, management, and monitor); and (6) BDFIQ (communication, engagement, goal setting, management, and support).

The network evidence plot for FBG levels is shown in Figure 3B. The SUCRA probability ranking for the reducing effect of FBG levels of different DHI strategy combinations is shown in Figure 4B. Of the 6 strategy combinations, the possibility of DHI-GIK (guide, management, and monitor) being the best strategy combination was the highest. The SUCRA value predicted the possibility of different strategy combinations as the best way, and the effects were ranked as follows: DHI-GIK (86.7%)>DHI-DGIKPQR (62.8%)>DHI-DFGKP (61.6%)>DHI-BGKR (53.6%)>DHI-BDGI (42.7%)>DHI-BDFIQ (24.4%)>usual (18.2%). Compared with the usual care groups, only the DHI-GIK strategy combination (MD –0.96, 95% CI –1.86 to –0.06) was statistically significantly effective in reducing FBG levels (Figure 5B). On the basis of the interval estimation of direct and indirect comparison (Table 3), no strategy combination was superior to the others.

Effects of Strategy Combinations on BMI

Of 52 included RCTs, 11 (21%) RCTs [60,66,70,72-74,78,84,85,97,98] assessed the effects of 9 different DHI strategy combinations on BMI levels in patients with T2DM. These 9 strategy combinations encompassed (1) FGIKQ (goal setting, guide, management, monitor, and support); (2) BGKR (communication, guide, monitor, and tailor); (3) EKP (feedback, monitor, and stimulate); (4) BDFGIKLOPQ (communication, engagement, goal setting, guide, management, monitor, prompt, shape, stimulate, and support); (5) DGIKPQR (engagement, guide, management, monitor, stimulate, support, and tailor); (6) BDGI (communication, engagement, guide, and management); (7) DFGKP (engagement, goal setting, guide, monitor, and stimulate); (8) GIK (guide, management, and monitor); and (9) BDFIQ (communication, engagement, goal setting, management, and support).

The network evidence plot for BMI is shown in Figure 3C. The SUCRA probability ranking for the reducing effect of BMI of different DHI strategy combinations is shown in Figure 4C. Of the 9 strategy combinations, DHI-BDFIQ (communication, engagement, goal setting, management, and support) was most likely to be the optimal strategy combination. On the basis of the SUCRA values, the effects were ranked as follows: DHI-BDFIQ (92.6%)>DHI-BDGI (90.9%)>DHI-DGIKPQR (75.2%)>DHI-BGKR (65.1%)>DHI-BDFGIKLOPQ (41.4%)>DHI-FGIKQ (40.9%)>DHI-EKP (32%)>DHI-GIK (26.8%)>DHI-DFGKP (24.3%)>Usual (10.8%). Compared with the usual care groups, DHI-BDFIQ (MD –2.30, 95% CI –3.16 to –1.44), DHI-BDGI (MD –2.20, 95% CI –2.50 to –1.90) and DHI-BGKR (MD –1.00, 95% CI –1.53 to –−0.47) strategy combinations were statistically significantly effective in reducing BMI (Figure 5C). On the basis of the interval estimation of direct and indirect comparison (Table 4), DHI-BDFIQ was superior to all other strategy combinations except for DHI-BDGI and DHI-DGIKPQR. In addition, except for DHI-BDFIQ and DHI-DGIKPQR, DHI-BDGI was superior to the rest of strategy combinations. DHI-BGKR was also superior to the DHI-DFGKP strategy combination.

Effects of Strategy Combinations on Weight Loss

Of 52 included RCTs, 8 (15%) RCTs [50,52,70,72,73,84,85,98] assessed the effects of 7 different DHI strategy combinations on weight loss in patients with T2DM. These 7 strategy combinations encompassed (1) ABCDEFGHIJKLMNOQR (action planning, communication, cues, engagement, feedback, goal setting, guide, identity, management, model or demonstrate, monitor, prompt, restructure, reward, shape, support, and tailor); (2) ABCDEFGHIJKLNO (action planning, communication, cues, engagement, feedback, goal setting, guide, identity, management, model or demonstrate, monitor, prompt, reward, and shape); (3) BGKR (communication, guide, monitor, and tailor); (4) EKP (feedback, monitor, and stimulate); (5) BDFGIKLOPQ (communication, engagement, goal setting, guide, management, monitor, prompt, shape, stimulate, and support); (6) DFGKP (engagement, goal setting, guide, monitor, and stimulate); (7) BDFIQ (communication, engagement, goal setting, management, and support).

XSL•FO
RenderX

The network evidence plot for weight loss is shown in Figure 3D. The SUCRA probability ranking for the effect of weight loss of different DHI strategy combinations is shown in Figure 4D. Of the 7 strategy combinations, DHI-BDFIQ (communication, engagement, goal setting, management, support) was most likely to be the optimal strategy combination. On the basis of the SUCRA values, the effects were ranked as follows: DHI-BDFIQ (98.5%)>DHI-BGKR (72.9%)>DHI-ABCDEFGHIJKLNO (63%)>DHI-BDFGIKLOPQ (49.8%)>DHI-ABCDEFGHIJKLMNOQR (39.2%)>DHI-EKP (36.2%)>DHI-DFGKP (27.5%)>Usual (12.9%). Compared with the usual care groups, DHI-BDFIQ (MD –6.50, 95% CI –8.82 to –4.18), DHI-BGKR (MD –3.00, 95% CI –4.66 to –1.34) and DHI-BDFGIKLOPQ (MD –1.50, 95% CI –2.92 to –0.08) strategy combinations were statistically significantly effective in weight loss (Figure 5D). On the basis of the interval estimation of direct and indirect comparison (Table 5), DHI-BDFIQ was superior to DHI-BGKR, DHI-ABCDEFGHIJKLNO, DHI-BDFGIKLOPQ, and DHI-DFGKP strategy combinations. In addition, DHI-BGKR was also superior to the DHI-DFGKP strategy combination.

Heterogeneity and Consistency Analysis

The global inconsistency and local inconsistency were assessed using the node-splitting test for inconsistency analysis. The results showed no statistical inconsistency in each outcome comparison (P>.05). High heterogeneity between studies was only observed in BMI and weight loss outcomes. However, we did not find significant publication bias for these 2 outcomes through Egger test (P=.29 for BMI and P=.11 for weight loss). The net split function analyses found no statistically significant inconsistencies when assessing differences between direct and indirect effects. More details are provided in Table 6.

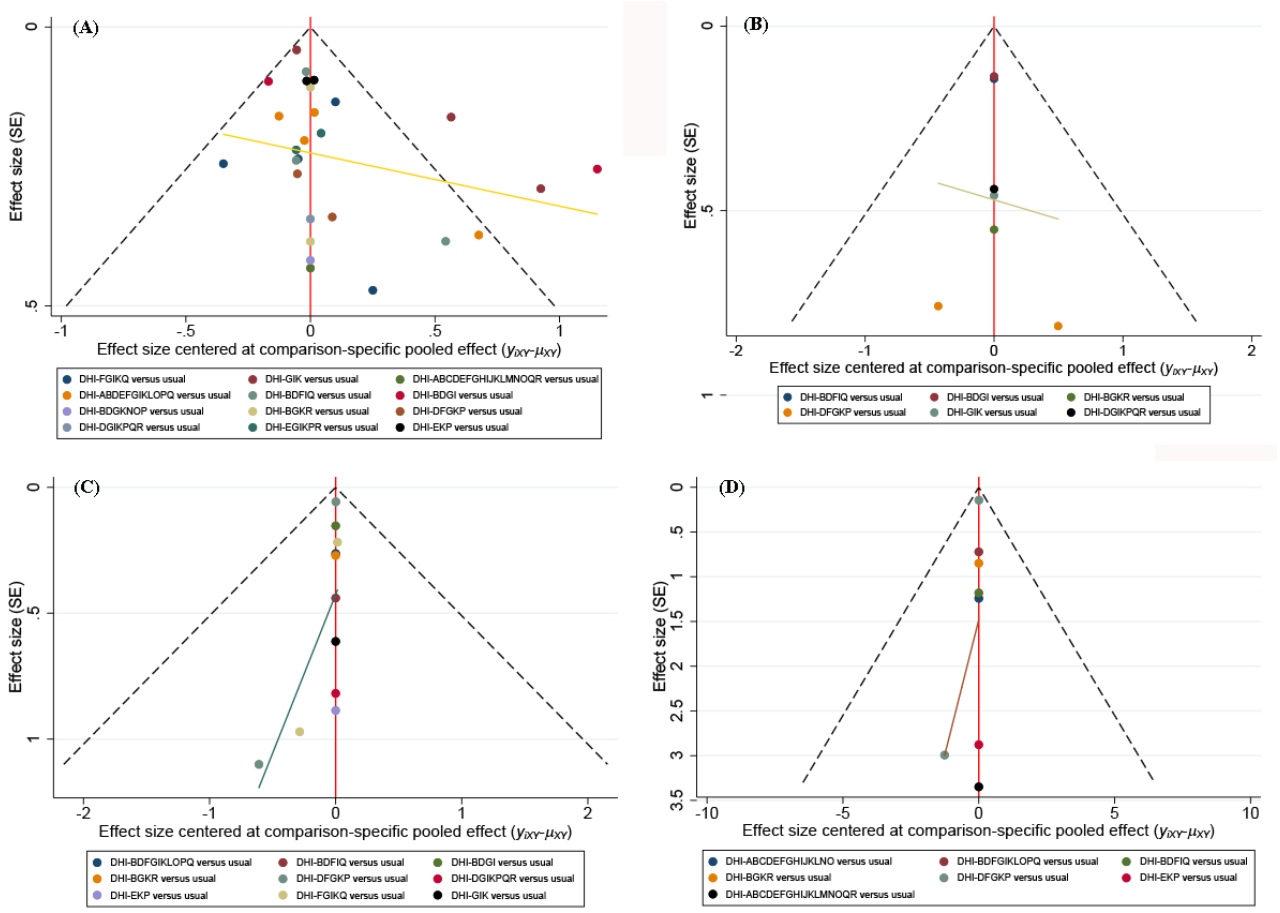
XSL•FO
RenderX

Table 6. The results of heterogeneity and inconsistency.

Outcome	Heterogeneity		Inconsistency (*P* value)
	I^2 (%)	*P* value	
HbA_{1c}[a]	7.3	.37	—[b]
FBG[c]	0.0	.42	—
BMI	95.8	<.001	—
Weight loss	85.6	<.001	—

[a]HbA_{1c}: glycated hemoglobin A_{1c}.

[b]Data not available.



[c]FBG: fasting blood glucose.

Assessment of Publication Bias

We conducted a comparison-adjusted funnel plot of trials included in the network meta-analysis for each result (Figure 6): (A) HbA_{1c}, (B) FBG, (C) BMI, and (D) weight loss. The included studies were generally symmetrically distributed in the upper and middle parts of the funnel and around the left and right sides of the midline, indicating a low possibility of publication bias. Individual studies were distributed at the bottom, which may be related to the small sample size.

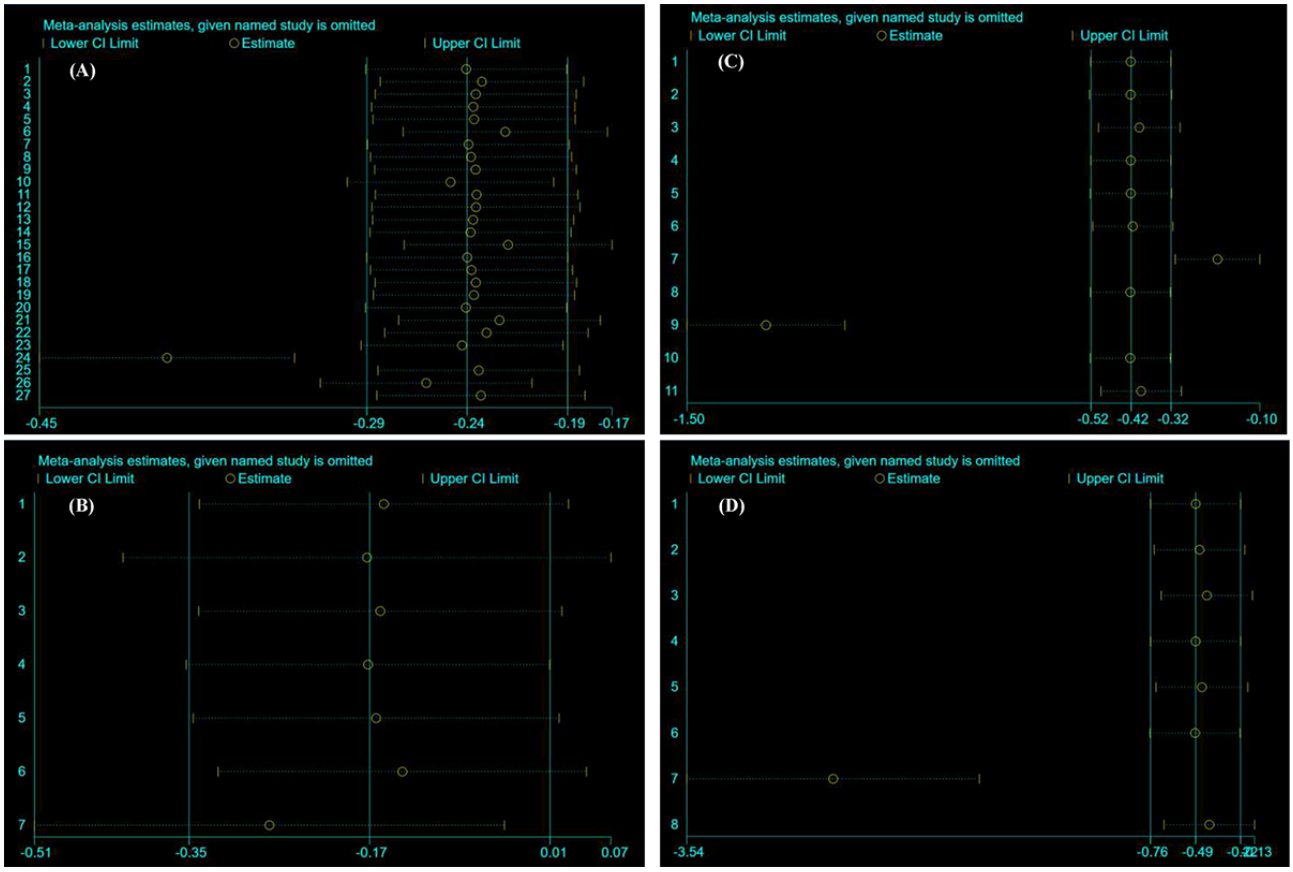
RenderX

Figure 6. Comparison-adjusted funnel plots of trials included in the network meta-analysis: (A) comparison-adjusted funnel plots for glycated hemoglobin A1c, (B) comparison-adjusted funnel plots for fasting blood glucose, (C) comparison-adjusted funnel plots for BMI, and (D) comparison-adjusted funnel plots for weight loss. ABDEFGIKLOPQ: action planning, communication, engagement, feedback, goal setting, guide, management, monitor, prompt, shape, stimulate, and support; ABCDEFGHIJKLNO: action planning, communication, cues, engagement, feedback, goal setting, guide, identity, management, model or demonstrate, monitor, prompt, reward, and shape; ABCDEFGHIJKLMNOQR: action planning, communication, cues, engagement, feedback, goal setting, guide, identity, management, model or demonstrate, monitor, prompt, restructure, reward, shape, support, and tailor; BDFGIKLOPQ: communication, engagement, goal setting, guide, management, monitor, prompt, shape, stimulate, and support; BDFIQ: communication, engagement, goal setting, management, and support; BDGI: communication, engagement, guide, and management; BDGKNOP: communication, engagement, guide, monitor, reward, shape, and stimulate; BGKR: communication, guide, monitor, and tailor; DFGKP: engagement, goal setting, guide, monitor, and stimulate; DGIKPQR: engagement, guide, management, monitor, stimulate, support, and tailor; DHI: digital health intervention; EGIKPR: feedback, guide, management, monitor, stimulate, and tailor; EKP: feedback, monitor, and stimulate; FGIKQ: goal setting, guide, management, monitor, and support; GIK: guide, management, and monitor.



Sensitivity Analysis

We used the method of removing individual studies separately. Our results were generally stable and credible. As shown in Figure 7, the 2 vertical bright lines, except for the vertical axis, represent the CI of the merged population. Each study corresponds to 2 yellow short lines and a yellow circle, representing the CI of the remaining studies combined after excluding this study. If all yellow circles are within the range of 2 vertical bright lines, it indicates that this set of data is stable. Although the results showed that the combined effect value of HbA_{1c} levels, BMI, and weight loss appeared outside the CI of the original combined effect value, all CIs did not include 0; they were significant in treatment effects. The details are shown in Figure 7.

Discussion

Principal Findings

Our study offered a comprehensive insight into the strategies used in DHIs for T2DM management. A total of 52 RCTs were included, identifying 63 strategies categorized into 19 strategy themes. The most commonly used strategies were *guide*, *monitor*, *management*, and *engagement*. Most studies reported positive or mixed outcomes for most indicators based on the SF/HIT. Research involving a medium or high number of strategies was found to be more effective than research involving a low number of strategies. A total of 27 RCTs were included in the network meta-analysis. The strategy combination composed of *communication*, *engagement*, *guide*, and *management* was most effective in reducing HbA_{1c} levels, while the strategy combination that included *guide*, *management*, and *monitor* was effective in reducing FBG levels. A strategy combination composed of *communication*, *engagement*, *goal setting*, *management*, and *support* was most effective for BMI and weight management.

In the identified strategies, *monitor* and *guide* were the most frequently used ones, accounting for 77% (40/52) and 67% (35/52) of the total papers, respectively. Following closely were *management* (32/52, 61%) and *engagement* (28/52, 54%) strategies. The frequency of the use of these strategies indicates the trend and focus in this field. First, the *monitor* strategy reflects the role of digital tools in monitoring patients' physiological indicators and behavior habits in diabetes management. It allows health care professionals and patients to track key parameters such as blood glucose level, weight, and exercise volume in real time, which helps to adjust the treatment plan in time and reduce the risk of complications [101]. Second, the use of a *guide* strategy reflects the value of digital health management in providing personalized and real-time advice and guidance to patients. Through intelligent algorithms and personalized settings, digital platforms can provide patients with accurate nutritional advice, exercise plans, and medication guidance based on their individual characteristics and historical data, helping them better manage their diseases and improve treatment outcomes [102]. These results are consistent with previous research that highlights the crucial role of *monitor* and *guide* strategies in DHIs [103,104]. On this basis, the *management* strategy emphasizes the important role of digital platforms in assisting health care professionals in disease management and treatment decision-making. Through data analysis and predictive models, digital platforms can provide health care professionals with more comprehensive and timely patient information, help them develop more effective treatment plans, and improve the accuracy and efficiency of clinical decision-making [105]. Furthermore, the *engagement* strategy emphasizes the promoting role of digital health management in patient participation and self-management. By providing personalized educational content, social support, and behavioral motivation, digital platforms can stimulate patients' treatment motivation and enhance their awareness and self-management abilities toward the disease, thereby improving treatment compliance and long-term efficacy [106].

XSL•FO
RenderX

The number of strategies used in each study varies greatly, ranging from 1 to 32. Among 52 studies, 18 (35%) were categorized as high-strategy study, 23 (44%) as medium-strategy study, and 11 (21%) as low-strategy study. In digital health management, the use of a different number of strategies in research may reflect the diversity of research design, objectives, and methods. Many studies have chosen a medium number of strategies to comprehensively consider multiple aspects and evaluate the effectiveness of disease management. Research using a low number of strategies may focus more on the intervention effects in specific aspects to further explore the mechanisms of action of specific strategies. On the contrary, studies using a high number of strategies may aim to explore the combined effects of multiple intervention methods to achieve more comprehensive disease management. However, the results of the studies we included did not indicate that more strategies have more effective effects. Therefore, we further evaluated the impact of different numbers of strategies and compared the effect of different strategy combinations to provide more practical guidance for accurate and personalized digital health management.

We assessed the effectiveness of DHI strategies qualitatively based on the SF/HIT. Overall, most (≥50/52, ≥96%) studies have reported positive or mixed outcomes for most outcome indicators, such as preventive care; efficiency; perceived ease of use or usefulness; safety, privacy or security; acceptability; appropriateness; satisfaction process of service delivery or performance; effectiveness; and adherence or attendance. However, in terms of cost-effectiveness, most (50/52, 96%) studies have not reported positive results. This may be due to the introduction and development of digital health management tools, which provide more convenient, safe, and efficient management methods for patients with diabetes [60]. These tools include remote monitoring devices, mobile apps, and web-based platforms that can help patients better monitor blood glucose levels, manage diet, and engage in exercise, thereby improving the effectiveness of preventive care and service delivery processes and enhancing patient acceptance and satisfaction with treatment plans [105]. However, the negative results in terms of cost-effectiveness may be due to the significant investment required for the implementation and operation of digital health management tools, and the long-term cost-effectiveness has not been fully demonstrated [59,62,73]. In high-strategy and medium-strategy studies, most (36/41, 88%) studies reported positive outcomes, while low-strategy (7/11, 64%) studies reported fewer positive outcomes. This reflects the investment of more resources and technology, which can more comprehensively meet the needs of patients and improve treatment effectiveness. In contrast, low-strategy research may not have achieved the same effect due to resource constraints or insufficient technology. This was consistent with research by Brueton et al [35], which indicates that using a combination of strategies rather than a single approach can be more effective in enhancing participant retention. Future research should focus on cost-effectiveness analysis, explore the long-term economic benefits of digital health management tools, and propose more effective low-cost strategies to promote the sustainable development of diabetes management strategies.

In the meta-analysis, we included 27 studies evaluating the efficacy of 12 different DHI strategy combinations on HbA_{1c} levels. We found several high-quality combinations that can significantly reduce the HbA_{1c} levels, which reflects that, in diabetes management, using a specific strategy combination may have more advantages than using a single strategy. Among numerous strategy combinations, the SUCRA probability ranking suggested that DHI-BDGI (communication, engagement, guide, and management) might be the most effective strategy combination, followed by DHI-DFGKP (engagement, goal setting, guide, monitor, and stimulate); DHI-FGIKQ (goal setting, guide, management, monitor, and support); and DHI-ABDEFGIKLOPQ (action planning, communication, engagement, feedback, goal setting, guide, management, monitor, prompt, shape, stimulate, and support). The effect of only using the combination of DHI-GIK (guide, management, and monitor) was relatively weak. First, in the current medical practice, the treatment of diabetes is no longer a simple drug treatment but a comprehensive management, including lifestyle intervention, psychological support, drug treatment, and other comprehensive interventions [5]. Among these, communication and patient engagement are considered crucial factors that can enhance patients' understanding and compliance with treatment and improve treatment effectiveness [106]. Meanwhile, guidance and management provide specific action guidelines and treatment plans to help patients better control their blood glucose levels [102,105]. The combination of these strategies complements each other and can comprehensively cover all aspects of the treatment process, maximizing the therapeutic effect. Second, these 2 combinations of DHI-DFGKP (engagement, goal setting, guide, monitor, and stimulate) and DHI-FGIKQ (goal setting, guide, management, monitor, and support) also showed good results. They emphasize aspects such as patient engagement, goal setting, guidance, monitoring, and support. The combination of these strategies makes the treatment process more systematic and orderly, helping patients better understand and execute treatment plans and improving the success rate of treatment [59]. However, the combination of DHI-ABDEFGIKLOPQ (action planning, communication, engagement, feedback, goal setting, guide, management, monitor, prompt, shape, stimulate, and support) encompasses more strategies and may seem more comprehensive, but there may be some challenges in practical applications. This complex combination may require more resources and time to implement while also increasing the cognitive burden on patients, which may affect treatment compliance. Finally, the combination of DHI-GIK (guide, management, and monitor), which only includes a few strategies, was relatively weak. This may be due to a lack of communication and patient engagement, reflecting insufficient communication between health care professionals and patients in real clinical practice and a lack of enthusiasm and participation from patients during treatment [78,106]. In addition, relying solely on guidance and management while ignoring the psychological and lifestyle factors of patients can easily lead to poor treatment outcomes.

At the same time, we included 7 studies evaluating the efficacy of 6 different DHI strategy combinations on FBG levels. Only

XSL•FO
RenderX

DHI-GIK (guide, management, and monitor) was shown to have an effect. The advantage of this effective strategy combination is that it integrates 3 key elements: guidance, management, and monitoring. These strategies can provide systematic treatment support, help patients develop and execute effective treatment plans, and monitor treatment outcomes in a timely manner, thereby better controlling FBG levels [97]. Our result was consistent with research that has shown that multidimensional interventions, including guidance, management, and monitoring, are critical to the success of diabetes management [5]. However, other strategy combinations may lack sustained guidance and monitoring or may not fully motivate patients to actively participate in treatment, resulting in poor effect compared with DHI-GIK (guide, management, and monitor). Meanwhile, this result may also be influenced by the bias caused by the insufficient amount of original studies on FBG levels in our meta-analysis. Therefore, there is a certain difference in the results between studies evaluating FBG and HbA_{1c} levels.

In general, our research results highlight the importance of comprehensive strategy combination in blood glucose management of T2DM. Future research can further explore other combinations of strategies to find more effective management models for diabetes. There is a need to strengthen communication and interaction between health care professionals and patients, as well as to improve patient participation and compliance. Furthermore, it is essential to strengthen the long-term tracking and evaluation of diabetes management strategies.

This review showed that DHI-BDFIQ (communication, engagement, goal setting, management, and support) and DHI-BGKR (communication, guide, monitor, and tailor) combination strategies were significantly effective for both BMI and weight loss. Among these, DHI-BDFIQ (communication, engagement, goal setting, management, and support) was considered the optimal combination. First, it covers the following key aspects: effective communication promotes cooperation and understanding between patients and medical teams; active engagement enhances the patient's participation and execution of treatment, such as physical activity and dietary intake control; clear goal setting helps guide the direction and progress of treatment [98]; effective management can provide systematic treatment plans and continuous management support; and continuous support can help patients overcome difficulties and maintain a positive attitude during the treatment process [59], to help patients better manage their weight. On the other hand, DHI-BGKR (communication, guide, monitor, and tailor) emphasizes personalized guidance and monitoring, which is more targeted, allowing patients to adjust their weight management plan according to their own situation [56,64,70], thereby reducing weight and BMI. In addition, the combination strategy of DHI-BDGI (communication, engagement, guide, and management) was found to be effective for BMI, and DHI-BDFGIKLOPQ (communication, engagement, goal setting, guide, management, monitor, prompt, shape, stimulate, and support) was effective for weight loss. Our research results have indicated that DHI-BDGI (communication, engagement, guide, and management) was the most effective combination strategy in reducing the HbA_{1c} levels, and therefore, it has a good effect on controlling BMI. Studies have shown that comprehensive treatment plans, including communication, engagement, guidance, and management, can effectively improve blood glucose control and weight management in patients with T2DM [107,108]. The effectiveness of these strategies may stem from their ability to comprehensively influence the patient's lifestyle and behavioral habits, thereby promoting the achievement of treatment goals [73,79,94]. The combination of DHI-BDFGIKLOPQ (communication, engagement, goal setting, guide, management, monitor, prompt, shape, stimulate, and support) includes multiple strategies, from goal setting to behavior shaping and support. While it has a positive effect on weight loss, it may encounter some challenges in practical applications, leading to a relatively weak overall effect. Therefore, the effect was relatively weak.

Our research emphasizes the advantages of the combination of communication, patient engagement, goal setting, personalized management, external support, and continuous monitoring strategies in the DHIs of BMI and weight management of patients with T2DM. Future research can further explore the applicability of these strategy combinations in different outcomes, such as quality of life, complication rate, and other indicators. In addition, precise personalized intervention based on artificial intelligence and big data analysis is necessary. At the same time, more interactive and personalized digital health platforms can be developed to improve patient engagement and treatment compliance.

Limitations

This study has several limitations. First, despite conducting a comprehensive search, it is possible that some relevant papers published in non-English languages or from nonindexed sources might have been overlooked. Second, we conducted 3 rounds of data screening and extraction, which could have introduced inconsistencies in certain cases. In addition, in our quantitative analysis, we only performed meta-analyses on specific outcome measures, thereby limiting the generalizability of our conclusions. Regarding BMI and weight loss outcomes, there was substantial heterogeneity among studies, which we addressed through sensitivity analyses and publication bias assessments. Furthermore, the number of original studies included in the meta-analyses was relatively small, potentially leading to some degree of bias in the conclusions. Finally, due to the nature of the interventions, blinding was not feasible in most studies. This might have exaggerated the estimated intervention effects in the network meta-analysis and contributed to the low to moderate quality of the evidence and the low methodology quality of included studies.

Conclusions

Our research provided a comprehensive analysis and summary of the strategies used in DHIs for T2DM. We identified 63 strategies and categorized them into 19 strategy themes. *Guide*, *monitor*, *management*, and *engagement* were the most commonly used strategies. Most studies reported positive or mixed outcomes for most outcome indicators based on the SF/HIT. Research involving a medium or high number of strategies was found to be more effective than research involving a low number of strategies. The strategy combination composed

XSL•FO
RenderX

of *communication*, *engagement*, *guide*, and *management* was most effective in reducing HbA_{1c} levels, while the strategy combination that included *guide*, *management*, and *monitor* was effective in reducing FBG levels. The strategy combination composed of *communication*, *engagement*, *goal setting*, *management*, and *support* was most effective in BMI and weight management. Future research should further confirm the effectiveness of these strategies in other indicators and populations, explore more strategy combinations, and optimize the design and implementation of strategies for patients with diabetes. Furthermore, it is necessary to develop more interactive and personalized digital health platforms. Finally, the cost-effectiveness analysis of strategy use should be strengthened to provide more effective guidance for disease management and clinical practice of T2DM.

Acknowledgments

This study was supported by the Key Research and Development Plan of Shaanxi Province, China, (2021SF-144) and National Higher Medical Education Association, Nursing Education Branch, Education Science Fund Project (GJHL160008). The authors would like to sincerely appreciate all the authors who participated in this systematic review and meta-analysis.

Abstract

Background: Critical thinking is a crucial skill in the nursing profession and must be fostered through nursing education. Simulation-based learning (SBL) with technological modalities is a pedagogical approach to enhance critical thinking skills for nursing students. The use of technology in SBL to achieve critical thinking skills is diverse. No previous scoping review has systematically mapped studies on SBL supported by technology to enhance critical thinking in nursing students.

Objective: This scoping review aimed to systematically map research on the use of SBL supported by technology to enhance critical thinking in nursing students.

Methods: This scoping review was conducted according to the framework by Arksey and O'Malley and was reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. A systematic, comprehensive literature search was performed in the LILACS, ERIC, MEDLINE, Embase, PsycINFO, and Web of Science databases in 2021 and repeated in 2023 and 2024. Pairs of authors independently assessed titles, abstracts, and full-text papers and extracted data from the included studies. The data underwent summative and thematic analysis and were categorized according to the findings.

Results: In total, 4 main categories of technology applied in SBL were identified: computer-based simulations, human-patient simulators, virtual reality or immersive virtual reality, and others. The findings revealed a shift across time in the technology used for SBL to enhance critical thinking, from human patient simulators to computer-based simulations. A dominant part of the included studies published after 2018 (21/44, 48%) incorporated a combination of asynchronous and synchronous learning activities. The theoretical foundation of the studies revealed a range of scientific theories and conceptual frameworks and models. Enablers of or barriers to the enhancement of critical thinking skills in nursing students were identified within the following themes: affinity for and availability of technology, realism, accessibility, engagement and motivation, validation, return on investment, and enhanced critical thinking through SBL using technology.

XSL•FO
RenderX

Conclusions: There has been a noticeable shift in the technology and use of technology in SBL. Descriptions of the applied technology and pedagogical considerations are pivotal for comparing or synthesizing research results. There has been a trend toward a blended educational approach combining synchronous and asynchronous learning activities. User technological proficiency and the perceived quality of the technology are imperative in the development of critical thinking. Realism, engagement, and motivation play pivotal roles in the enhancement of critical thinking in technologically supported SBL. The establishment of robust theoretical foundations of research and standardized research practices will strengthen the evidence obtained from the research conducted.

critical thinking; simulation-based learning; technologically supported simulation-based learning; nursing education; nursing students; review

Introduction

Background

Critical thinking skills are vital for professional nurses to perform nursing care in a safe, evidence-based manner. Nurses need to be able to analyze, summarize, and evaluate information and initiate appropriate actions. Critical thinking skills empower nurses to manage the uncertainties inherent in nursing practice, thus contributing to safe, effective care across diverse clinical settings [1-4]. Critical thinking includes purposeful and self-regulatory judgment in a process of interpretation, analysis, evaluation, and inference [5]. Critical thinking also includes evidential, conceptual, methodological, criteriological, or contextual considerations based on the relevant judgment [5]. Critical thinking is driven by internal motivation and characterized by reflection, self-monitoring, and self-correction. This process cultivates a reflective judgment on what to do, believe, or make sense of in any given context [6]. However, critical thinking is a concept that has no established or agreed upon definition [7]. As Cassum et al [8] have pointed out, individuals may often define critical thinking based on their own understanding and choose to emphasize certain aspects of critical thinking. Several studies have pointed out that critical thinking is used synonymously with other concepts, such as clinical decision-making, analytical thinking, clinical judgment, critical judgment, creative thinking, problem-solving, reflective thinking, and diagnostic reasoning or higher-order thinking [9,10]. This is mirrored in a study by Geng [11], who identified 64 definitions of critical thinking. The common characteristics of critical thinking in these definitions were judgment, argument, questioning, information processing, problem-solving, and meta-cognition. These characteristics can be found both in definitions of critical thinking, for example, in the definition by Facione [5], and in definitions of other concepts, such as clinical reasoning, decision-making, or clinical judgment [12,13]. Although achieving consensus on the definition of critical thinking poses challenges for identifying studies related to this concept, there is no doubt about its vital importance in the field of nursing.

To facilitate the development of critical thinking skills in nursing students, educators could encourage active student participation in the learning process. Simulation-based learning (SBL) is one pedagogical approach based on principles of active learning [1-3]. Bland et al [14] have conceptualized and defined SBL in nursing education as “a dynamic process involving the creation of a hypothetical opportunity that incorporates an authentic representation of reality, facilitates active student engagement and integrates the complexities of practical and theoretical learning with opportunity for repetition, feedback, evaluation and reflection.” SBL offers possibilities for experiential learning and deliberate practice through the integration of theoretical and practical knowledge, application of skills, and development of the ability to reflect and give and receive feedback [15]. Furthermore, SBL aims to replicate features of clinical practice that require learners to use critical thinking and clinical reasoning, involving cognitive, psychomotor, and affective skills [16,17].

Technological solutions for SBL in nursing education are rapidly evolving, and different simulation modalities are applied according to pedagogical and practical considerations [15,18]. SBL in nursing education can be divided into 2 main categories: SBL in the physical learning environment and SBL in the virtual learning environment. The physical learning environment is typically represented by simulation laboratories within universities but can include SBL in the clinical environment and context as well. The virtual learning environment refers to a digital or computerized environment that provides opportunities for independence in learning and diverse approaches to interacting with technology and others within the virtual world [19]. The types of simulation technology or equipment used as part of the simulation activity are often referred to using the term *simulation modality* [20]. The modality is the platform and resources used to support the simulated experience and may incorporate a variety of technologies [21,22]. One common modality for SBL is human-patient simulators (HPSs), which are advanced physical simulators with humanlike features and responses driven by computers [22]. Other modalities often applied in virtual learning environments can be categorized as technology-enhanced simulation (TES). TES is a blanket term for SBL with direct or assisted interaction with an electronic medium presented through computers or other technology that provides learners with a virtual environment in which they complete certain tasks, use information, assess, make clinical decisions, and observe results [20]. TES modalities include computer-assisted simulation, serious games, and computer simulation games, collectively referred to as computer-based simulation (CBS). CBSs are interactive simulation games in which learners are assigned roles, typically as the nurse, and

XSL•FO
RenderX

nursing students are involved in a scenario targeted to interpreting information and problem-solving [23]. Virtual reality (VR) and immersive VR (IVR) are the most recently introduced TES modalities, with different levels of immersion. These modalities seek to replicate specific clinical settings in a virtual environment. IVR distinguishes itself from other VR technologies by using special headsets that immerse the participants in a virtual world [24-26]. IVR experiences are often designed to promote specific learning outcomes in scenarios with patient-nurse interactions in a suitable clinical environment [27].

Several previous reviews have examined the prevalence and effectiveness of SBL to enhance critical thinking in nursing education [16,18,28-30]. SBL is the predominant learning activity that uses digital tools in nursing education [18]. A scoping review on teaching strategies for the development of clinical reasoning in advanced nursing clinical practice reported that SBL is the most frequently encountered teaching strategy [28]. Systematic reviews have examined the effectiveness of SBL on clinical reasoning and critical thinking skills in nursing education [16,29,30]. These reviews have determined that there is insufficient evidence to form definitive conclusions on the effect of SBL on clinical reasoning and critical thinking. However, the use of technology to enhance critical thinking in SBL has not been thoroughly addressed in these reviews.

Reviews have also examined the prevalence of SBL supported by technology and compared SBL that uses different technologies or SBL that uses technology versus traditional teaching methods [15,26,31,32]. A systematic review and meta-analysis of 12 randomized controlled trials concluded that VR offers higher potential than conventional teaching methods in nursing education for advancing outcomes of overall satisfaction, theoretical knowledge, and practice proficiencies without providing an advantage in enhancing critical thinking skills [31]. This review limited the examination to randomized controlled trials, excluding studies with other research designs [31]. Another systematic review examined game-based learning in undergraduate nursing education and found serious games to be the most used game type. Game-based learning was effective in achieving learning outcomes, particularly in the cognitive domain [32]. However, critical thinking was not a specific outcome, and only mixed methods studies were included in the review. In addition, a scoping review explored the use of virtual simulation (VS), an interactive recreation of real-life clinical scenarios using computer technology, to enhance diagnostic reasoning in health care professional education. VS was found to be at least as effective if not superior to traditional SBL, but only 3 of the 12 included studies were related to nursing education [26]. Another literature review also supported the effectiveness of VS in improving skills, learning, and critical thinking in nursing education [15]. However, critical thinking was the least explored outcome, the literature search was limited to 2 databases, and solely English-language papers were included.

Moreover, reviews have investigated the effectiveness of SBL in enhancing critical thinking in nursing education incorporating technology [33,34]. A systematic review and meta-analysis focused on VS as a tool to enhance clinical reasoning in nursing education and found that VS can improve clinical reasoning skills [34].

A systematic review comparing VR to traditional SBL practices concluded that the effectiveness of VR on clinical reasoning educational outcomes was similar or superior to that of traditional methods, although the evidence is limited [33]. A meta-analysis on technology in the SBL learning environment for the development of complex skills such as critical thinking across different educational domains stated that recent technologies can greatly enhance the effect of SBL [4]. A qualitative literature review explored nursing students' experiences with virtual screen-based simulations and found that a comfortable atmosphere; engagement and feedback; and improved skills, including critical thinking and decision-making skills, positively impacted learning in VS. Negative experiences with VS stemmed from the need for more support, poor design, and lack of authenticity [35].

Objectives

In nursing education, SBL supported by technology is increasingly applied as a learning strategy given the collective demand for active and flexible educational approaches and the growing interest and need for technological solutions [36]. Understanding the enablers and barriers associated with these solutions may be of great value for selecting suitable technological modalities for SBL to promote the development of critical thinking. Previous reviews have not comprehensively examined the range and use of technology for supporting SBL in enhancing nursing students' critical thinking skills. Therefore, there is a need for a broad, comprehensive literature review, such as a scoping review, including scientific papers in several languages and that use diverse research methods. Such a review is important to summarize the scope and variety of published peer-reviewed studies in this area while also identifying potential gaps in the existing peer-reviewed studies [37]. To the best of our knowledge, no scoping review has investigated the variety and use of technology in SBL for enhancing nursing students' critical thinking skills. Consequently, this scoping review aimed to systematically map studies on the use of SBL supported by technology to enhance critical thinking in nursing students.

Methods

Overview

This scoping review was conducted according to the methodological framework by Arksey and O'Malley [37], which includes the following steps: (1) identifying the research questions (RQs); (2) identifying relevant studies; (3) selecting studies; (4) charting the data; and (5) collating, summarizing, and reporting the results. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines were followed for the reporting of this review [38,39]. The research protocol was published in *JMIR Research Protocols* [40], and the deviations from the protocol are described in Multimedia Appendix 1.

Identifying the RQs

The following RQs were asked:

XSL•FO
RenderX

1. What variety of technology is used in SBL to enhance critical thinking skills in nursing education? (RQ 1)
2. How is technology used in SBL to enhance critical thinking skills in nursing education? (RQ 2)
3. What barriers and enablers do nursing students report in the use of technology in SBL to enhance critical thinking? (RQ 3)

Identifying Relevant Studies

The Sample, Phenomenon of Interest, Design, Evaluation, and Research Type framework determined the inclusion and exclusion criteria [41] (Textbox 1).

Textbox 1. Eligibility criteria for inclusion of the selected studies.

Inclusion criteria

- Sample: papers focused on undergraduate and postgraduate nursing students
- Phenomenon of interest (the main aim of this scoping review was to systematically map studies on the use of simulation-based learning [SBL] supported by technology to enhance critical thinking in nursing students. As such, it is warranted to use critical thinking as a concept interchangeably with other concepts): SBL supported by technology to stimulate critical thinking, clinical decision-making, analytical thinking, creative thinking, problem-solving, reflective thinking, diagnostic reasoning, clinical reasoning, or clinical judgment in educational or institutional contexts; SBL supported by technology, including human patient simulator–based modalities, virtual reality (VR), immersive VR, virtual simulation, augmented reality, or computer-based simulation
- Design: studies with quantitative, qualitative, or mixed methods designs
- Evaluation: undergraduate and postgraduate nursing students' perspectives and experiences regarding the use of technology in SBL to enhance critical thinking or similar concepts
- Research type: studies of any research type published in Portuguese, Spanish, English, Norwegian, Swedish, or Danish in peer-reviewed journals

Exclusion criteria

- Sample: papers focused health care students other than nursing students
- Phenomenon of interest: SBL that does not use technology; SBL that uses technology but is not related to critical thinking or similar concepts; SBL in clinical practice not related to education
- Evaluation: nurse educators' perspectives and experiences regarding the use of technology in SBL to stimulate critical thinking
- Research type: case studies, case reports, clinical guidelines, all types of reviews, master's and PhD theses, conference proceedings and abstracts, letters, comments, discussions, editorials, and book chapters

Selecting Studies

A systematic search was conducted in CINAHL, ERIC, Embase, LILACS, Ovid MEDLINE, PsycINFO, and Web of Science on June 28, 2021. The database search was updated on March 17, 2023, and November 13, 2024. Each database was searched from its inception.

The search strategy in Ovid MEDLINE, using Medical Subject Headings and text words, was designed by an experienced research librarian (MAØ) in collaboration with the rest of the research team and encompassed 3 elements: SBL, technology, and nursing students and nursing education. A second research librarian (Kari Larsen Mariussen) reviewed the search strategy using the Peer Review of Electronic Search Strategies Checklist [42]. The search strategy in Ovid MEDLINE is outlined in Multimedia Appendix 2. In addition, we manually examined the reference lists of the included papers to determine whether any studies mentioned in those references were relevant to our review. Moreover, we conducted forward citation searching using the Google Scholar platform to identify relevant studies that had cited the included papers.

The identified citations were exported to EndNote (Clarivate Analytics) for removal of duplicates using the method described by Bramer et al [43]. The citations were randomly divided into 8 groups and transferred to the web application Rayyan (Qatar Computing Research Institute) [44] for storage, organization, and blinding of the study selection process. HVS and AAGN screened the titles and abstracts of 10% of the papers to pilot-test the eligibility criteria and deemed that the eligibility criteria did not require modification. In total, 8 pairs of authors and nonauthor contributors (HVS and CFA, SCWL and SAS, MTS and JZ, Andrea Mohallem and Fernando Riegel [nonauthors], PB and JGM, ALS and CS-L, CO and HVS, and IP and AAGN) performed the study selection process. Pairs of authors independently assessed whether titles and abstracts and then full-text articles met the eligibility criteria. When there was any doubt regarding inclusion, a third author (HVS or AAGN) independently assessed the full-text paper, and the decision was based on a negotiated consensus. The second updated search in 2024 was conducted by 2 pairs of authors (HVS and SAS and AAGN and MTS) consistent with the previous procedure for study selection.

Charting the Data

A standardized data collection form was developed in Microsoft Excel for data extraction from the included papers, including the following data: authors, year, and country; aim; sample; design; technology; simulation procedures; scenario design; and results related to the RQs. HVS and AAGN piloted the data collection form on 5 of the included papers, and some small revisions were made. Pairs of authors (Andrea Mohallem and Fernando Riegel, SCWL and SAS, PB and JGM, CO and CFA, IP and AAGN, JZ and MTS, and ALS and CS-L) extracted data

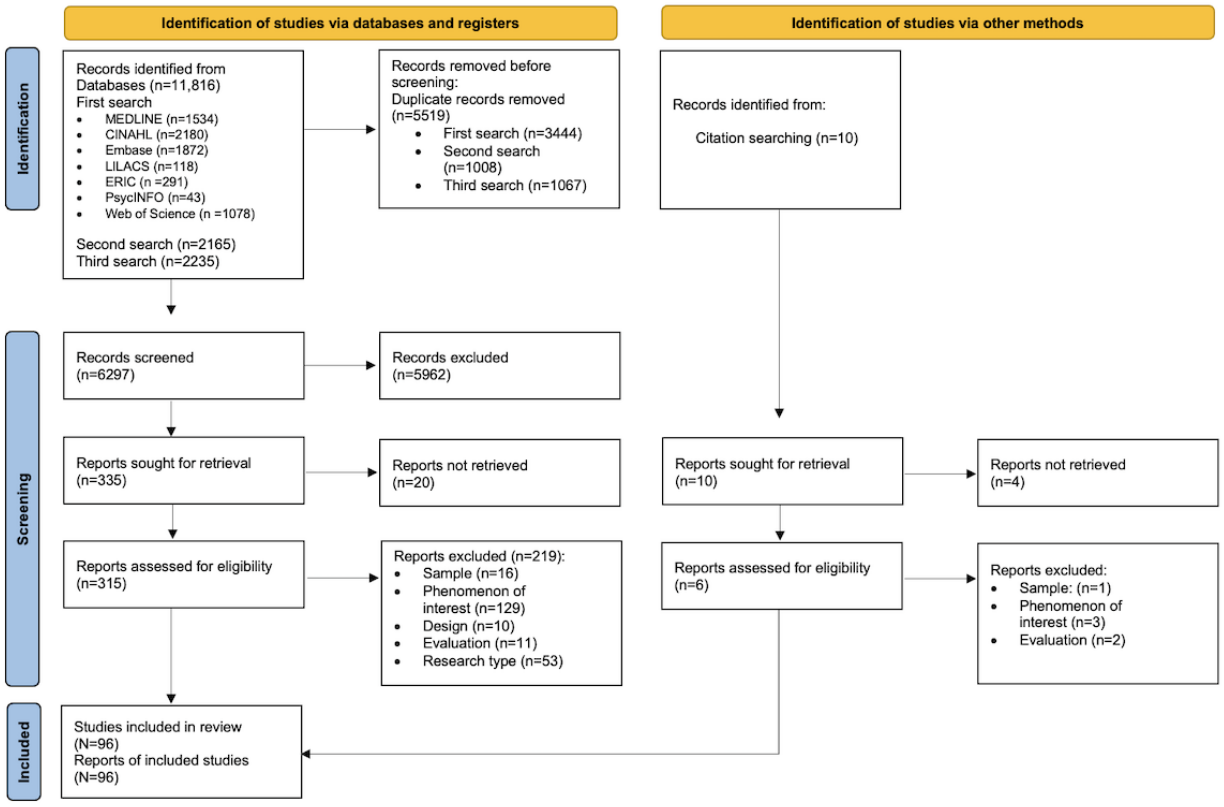
XSL•FO
RenderX

from the full-text papers. One author extracted the data, and the other checked their accuracy against the papers. Disagreement or uncertainties among pairs of authors were resolved through an independent assessment by HVS, and the agreement was based on negotiated consensus. The extracted data were also checked by the first (HVS) and last (AAGN) authors to ensure quality and consistency in data extraction.

Collating, Summarizing, and Reporting the Results

Data from the included papers regarding RQ 1 and RQ 2 were analyzed by HVS and AAGN using summative analysis. Regarding RQ 3, data were analyzed using an inductive approach to organize the results thematically, a method previously used in scoping reviews [45-47]. HVS and AAGN read the extracted data several times to identify patterns of similarities and differences related to the RQ, and the patterns were organized into subthemes and themes using a low level of interpretation and abstraction. An example of inductive thematic analysis for RQ 3 includes participants highlighting the ability to attend the SBL regardless of time and place, which was categorized under subtheme Flexibility and Theme Affinity for technology. Uncertainties of owns performance was categorized under subtheme Need for feedback and theme Validation.

SAS provided feedback on the preliminary thematic groupings. The data were then analyzed deductively from the perspective of the 6 dimensions (system quality, information quality, service quality, use and intention to use, user satisfaction, and net benefits) of the DeLone and McLean (D&M) [48,49] model of information system (IS) success. These themes were sorted accordingly and subsequently positioned within the predetermined categories of the framework of the D&M IS Success Model through deductive analysis. This model aims to evaluate the success of an IS and suggests that its dimensions are interrelated and influence each other [48]. The model has been widely used in research and practice to assess the success of various types of ISs, including enterprise systems, e-commerce platforms, and educational technology [19,49,50]. Studies exploring learners' (nursing students') experiences with technology have provided valuable insights into how technology affects their ability to develop critical thinking skills. User satisfaction, a key indicator of IS success, served as the basis for evaluating the technology's effectiveness [50]. The reported enablers and barriers for critical thinking enhancement through SBL using technology were sorted according to the results of the inductive analysis. The outcomes of all the studies were related to the development of critical thinking among nursing students through learning activities with technologically supported SBL. Therefore, the outcomes would be synonymous with learning and the achievement of learning outcomes.



Results

Overview

After the screening of 6297 records and 315 (5%) full-text papers, a total of 96 (1.52%) studies were included. Citations with additional information are listed in Multimedia Appendix 3 [51-146]. The study selection process and reasons for exclusion of full-text papers are presented in Figure 1 [39].

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram of the study selection process for this scoping review.

Sociodemographic Findings

The studies originated from 20 countries: the United States (42/96, 44%) [51-92], South Korea (12/96, 12%) [93-104], Australia (6/96, 6%) [105-110], China (6/96, 6%) [111-116], Turkey (6/96, 6%) [117-122], Canada (4/96, 4%) [123-126], Finland (3/96, 3%) [127-129], Saudi Arabia (3/96, 3%) [130-132], Taiwan (3/96, 3%) [133-135], France (1/96, 1%) [136], Hong Kong (1/96, 1%) [137], Indonesia (1/96, 1%) [138], Iran (1/96, 1%) [139], Israel (1/96, 1%) [140], Lebanon and Jordan (1/96, 1%) [141], Norway (1/96, 1%) [142], Portugal (1/96, 1%) [143], Sweden (1/96, 1%) [144], Thailand (1/96, 1%) [145], and the United Kingdom (1/96, 1%) [146].

The years of publication ranged from 1986 to 2024. Most studies (66/96, 69%) used a quantitative design [51, 52, 54-69, 71-74, 78, 86, 89-96, 98-104, 111, 114-119, 121, 127-130, 132-137, 139-141, 143-146]. A mixed methods, multimethod, or blended research approach was applied in 20% (19/96) of the studies [53,77,83-85,87,97,106,107,109,110,112,113,122-126,138], and 11% (11/96) of the studies incorporated a qualitative design [58,75,79,81,82,88,105,108,120,131,142].

Most studies (92/96, 96%) included undergraduate nursing students. The studies also included Master of Science nursing students [83]; nurse practitioner master's degree students [86]; postgraduate nurse anesthesia students [82]; and nursing students preparing at the diploma, associate, and baccalaureate levels [54]. The sample sizes ranged from 8 to 675 participants. The reported ages of the participants (73/96, 76% of the studies) ranged from 15 to 56 years. All studies that reported demographic data on gender (67/96, 70%) had a majority of female participants, ranging from 57% to 100% except for one study that reported 52% male participants [131]. A total of 23% (22/96) of the studies did not report demographic data regarding age or gender [59, 63, 66, 67, 73, 78, 80, 82, 83, 85, 88-91, 97, 98, 101, 105-107, 129, 146]. In total, 10% (10/96) of the studies reported age but not gender [76, 96, 102, 103, 109, 126-128, 133, 134], and 4% (4/96) of the studies reported data on gender but not on age [77,112,121,137].

Theoretical Foundations and Measurement of Critical Thinking

More than half (56/96, 58%) of the studies [51-55, 61, 63, 65, 69, 74-77, 80, 81, 83-92, 97, 100, 102-105, 107, 109, 111, 112, 114, 115, 118-126, 128-131, 135-137, 139, 140, 145] presented a theory or conceptual framework as a foundation for the study conducted. Scientific theories such as learning theory (24/96, 25%), nursing theory (7/96, 7%), and philosophical-methodological theory (2/96, 2%) were applied alone or in combination 33 times across the studies. Specific theoretical models or conceptual frameworks were presented as the theoretical foundation alone or in combination 36 times across the studies.

Most studies (54/96, 56%) used one or more validated instruments to evaluate the development of critical thinking skills or equivalent concepts [51, 55-57, 60, 64, 65, 67, 69, 72, 74, 76, 77, 84-87, 91-93, 95-104, 111-119, 121-124, 126, 129, 132-137, 139, 141, 144]. Across these 54 studies, 42 validated

XSL•FO
RenderX

instruments were used to assess outcomes. The California Critical Thinking Disposition Inventory, including its Chinese version, was used in 13% (7/54) of these studies to measure critical thinking. The Lasater Clinical Judgment Rubric was the second most frequently used instrument, applied in 11% (6/54) of the studies. The Critical Thinking Disposition Tool was used in 9% (5/54) of the studies, whereas the Simulation Effectiveness Tool–Modified was used in 7% (4/54) of the studies, including one instance of using the Turkish version. Notably, 29 instruments were used in only one study each. A detailed overview is provided in Multimedia Appendix 3.

Range and Features of the Technology Applied in SBL for Enhancing Nursing Students' Critical Thinking (RQ 1)

The technology in SBL to enhance critical thinking was divided into 4 main categories. The first category of applied technology was CBS (44/96, 46%) [52, 53, 55, 59, 67, 76, 78, 83, 85, 86, 89, 90, 93, 96, 97, 99, 101, 104, 105, 108, 109, 111, 114, 117-125, 127, 128, 130-133, 136-140, 143]. A wide variety of terms was used in the studies, and details are presented in Multimedia Appendix 3. The second category of applied technology was HPSs (26/96, 27%) [51, 57, 60, 62-66, 68-73, 80-82, 84, 87, 91, 94, 100, 107, 141, 145, 146]. The third category of applied technology in SBL was VR or IVR (7/96, 7%) [75,77,95,98,103,110,126].

The fourth category comprised studies (19/96, 20%) that used several or combinations of technologies or technology not consistent with the first 3 categories. In these studies, technology was applied through a combination of CBS, an HPS and case studies [116], a combination of CBS and IVR simulation [115,129], a combination of CBS and simulated electronic health records [61], multimedia technologies combined with an HPS [58], videotaped vignettes combined with an HPS [54], FaceTime technology [79], an interactive videodisc system [134], telehealth simulation and real-time video and audio technology [142], telehealth simulation and an HPS [135], mixed reality [106], a combination of CBS and HPSs [56,102,110,112,113,144], a combination of an HPS and interactive case studies [74], and a VS designed in Microsoft PowerPoint [88]. An overview is provided in Table 1.

The analysis revealed an evolution of the technology used in the included studies across time, from most studies (21/32, 66%) based on HPSs as the modality before 2018 to TESs using CBS as the major modality category in studies after 2018 (Figure 2).

The technology applied was diversely described in the studies. Some studies using HPS technology (25/96, 26%) gave descriptions of features and functions, but these studies generally provided limited description of the HPSs, which were often described only by the HPS's name and producer [51, 62-64, 68-71, 81, 82, 87, 91, 94, 96, 100, 102, 107, 113, 116, 135, 141, 144-146]. For CBS and VR or IVR, there was generally a richer description of the technology used, with descriptions of features that could contribute to enhancing critical thinking in SBL through learning. Several studies (23/96, 24%) used commercially developed technology featuring preprogrammed scenarios with virtual patients and VS [52, 53, 59, 61, 67, 75, 83, 86, 89, 92, 93, 96, 99, 105, 106, 109-117, 121, 122, 125, 126, 131, 133, 143, 144]. Some studies (16/96, 17%) investigated technological solutions or software for CBS, VR, or IVR that was self-developed or developed in a cooperation between expert nursing educators and IT engineers [78, 85, 88, 90, 98, 101-104, 108, 118, 120, 124, 130, 133, 136]. One study combined already developed commercial platforms and developed its own scenarios using various technologies [97].

Table 1. Categories of technology applied in simulation-based learning to enhance critical thinking in the included studies (N=96).

Category of applied technology	Studies, n (%)
CBS[a] [52,53,55,59,67,76,78,83,85,86,89,90,93,96,97,99,101,104,105,108,109,111,114,117-125,127,128,130-133,136-140,143]	44 (46)
HPS[b] [51,57,60,62-66,68-73,80-82,84,87,91,94,100,107,141,145,146]	26 (27)
VR[c] or IVR[d] [75,77,95,98,103,110,126]	7 (7)
Other—combination of technologies, technologies not consistent with the first 3 categories, or unclear description of technology [54,56,58,61,74,79,88,102,106,110,112,113,115,116,129,134,135,142,144]	19 (20)

Use of Technology in SBL Activities to Enhance Critical Thinking (RQ 2)

Technology Integration Into SBL

HPS technology was integrated into SBL mainly by nursing students playing out active roles in real-world clinical scenarios, with HPSs representing patients. SBL was typically described as being built around clinical scenarios, with nursing students as nurses caring for the patient by assessing and taking necessary measures in the scenario [51, 62-64, 68-71, 81, 82, 91, 94, 96, 100, 107, 141, 144, 146]. SBL using telehealth technology in the studies was built around clinical telehealth scenarios [79,135,142]. The digital technology used in TES, CBS, and VR or IVR was usually built around clinical cases and scenarios in which nursing students took on the role of a nurse caring for a patient. Nursing students applied their knowledge and skills to assess, solve problems, and make clinical decisions [53, 59, 67, 78, 83, 85-90, 93, 96, 101-104, 106, 109, 112, 114, 115, 118, 120-122, 124, 125, 128, 130, 131, 133, 134, 136, 140, 143]. Several studies (34/61, 56%) incorporated scenario design and game mechanics aimed at developing clinical reasoning or clinical judgment and critical thinking skills [61, 75, 77, 85-90, 92, 96,97,99, 101-104, 109, 111, 112, 114, 116, 117, 119, 122, 124-126, 130-132, 137, 139, 144]. Some studies (12/61, 20%) stated that they used a narrative approach, constructing patient stories that evolved over time following a cause-and-effect structure to demonstrate the consequences of decisions and actions, thereby contributing to the development of critical thinking [77,85,88-90,105,111,117,122,128,131,143].

Synchronous and Asynchronous Learning Activities

The studies used technology in SBL to promote critical thinking through both synchronous and asynchronous learning activities. The learning activities in SBL that used an HPS were predominantly conducted synchronously, featuring scenarios in real time that aimed to enhance critical thinking and the clinical reasoning process through experiential learning [51, 56, 57, 60, 62-66, 68-73, 81, 82, 84, 87,91, 94, 100, 107, 113, 116, 135, 141, 144, 145]. These learning activities were conducted in groups ranging from pairs to larger numbers of nursing students. Asynchronous learning activities were often designed using TESs in SBL intended for self-directed, individual learning, providing more flexibility and independence for nursing students [52, 53, 55, 59, 61, 67, 78, 83, 85, 88, 92, 99, 104, 108, 113, 114, 116-122, 125, 127-129, 131-134, 140, 144]. This approach also gave nursing students the possibility of repetition and repetitive learning [61,99,109,127,134,144]. A third approach to using technology in SBL was to combine asynchronous and synchronous learning activities. The most common technologies applied for the combined approach were CBS and VR or IVR [77, 86, 90, 93, 96-99, 101-103, 105, 110-112, 115, 124, 126, 130, 136-139, 144], with SBL most commonly conducted as a combination of individual performance in CBS, VR, or IVR followed by group reflections and debriefing facilitated by trained faculty. One study reported conducting all parts of SBL using CBS synchronously on the web via a videoconferencing platform [89].

Other combinations included videotaped vignettes of a scenario combined with individual performance testing [54], an HPS in combination with multimedia in prerecorded simulated assessments, offering eighter synchronous or asynchronous debriefing for online students using a learning management

XSL•FO
RenderX

system [58], and guided workshops of CBS content before asynchronous individual learning [109]. The studies that used a combined approach were predominantly published after 2019 as 50% (8/16) of the included studies in the first updated search (2021-2023) and 46% (13/28) in the second updated search (2023-2024) reported using this approach compared to 6% (5/52) of the studies in the initial search (1986-2021). Of the 96 included studies, 6 (6%) did not give sufficient descriptions of the learning activities [75,76,80,95,123,146].

Feedback for Developing Critical Thinking Skills

The feedback described in studies that used HPS technology in SBL was provided in 2 ways: feedback provided by the HPSs giving human patient responses to actions taken during the scenario, including both physical reactions and verbal interactions, and feedback provided by educators or peers during the debriefing phase of SBL (21/96, 22%) [51,56,57,60,62-66,68-74,81,84,87,91,94,100,107,112,135,141]. In the SBL modality that used FaceTime and audiovisual equipment for telehealth scenarios, feedback was also provided during debriefing by trained facilitators [79,135,142]. A total of 3% (3/96) of the studies reported using video recordings during debriefing to evaluate, reflect, and provide feedback on student performance [62,72,100]. One study reported feedback provided through asynchronous discussion within a learning management system [58]. TESs using CBS and VR or IVR technology provided other and additional feedback models compared to SBL using HPS technology, with both audio and visual automated responses. Some TESs provided feedback in real time as the game unfolded or cumulatively at the end of the scenario or gaming session [59, 88, 89, 96, 109, 110, 112, 114, 115, 121, 122, 125, 127-129, 131]. Feedback in both CBS and VR or IVR was also delivered indirectly through patients' responses to actions and communication with a cause-and-effect approach that demonstrated the consequences of decisions and actions taken [75,103,110,117,129,131,143]. Feedback was given in diverse forms, such as written messages or verbal feedback from a patient, via facilitators or peers during the SBL session [90,115,127-129], quizzes within the CBS [102], and pop-up messages or summaries on execution compared to expected nursing performance at the end of the VR, IVR, or CBS session [52,55,95,102,103,108,109,120,136]. CBSs could provide feedback tailored to debriefing purposes [93,117,143]. In some studies (9/61, 15%), TESs provided students with a performance score, typically in the form of points or a percentage reflecting the accuracy of their actions when the game was completed [53,61,78,86,108,127,128,136]. Several studies (10/61, 16%) using TESs combined feedback from CBSs or IVR with face-to-face synchronous debriefing and group discussions [86,89,90,101-104,110,114,124].

Enablers and Barriers of the Applied Technology in SBL to Enhance Critical Thinking (RQ 3)

Overview

From the inductive data analyses, seven distinct themes emerged: (1) affinity for and availability of technology, (2) realism, (3) accessibility, (4) engagement and motivation, (5) validation, (6) return on investment, and (7) enhanced critical thinking through SBL using technology. The studies explored aspects of developing critical thinking skills through learning in SBL using technological modalities such as HPSs, CBSs, VR or IVR, and others. An overview of the dimensions of the D&M IS Success Model [48], the identified themes, their respective subthemes, and examples of both barriers and enablers is provided in Table 2.

XSL•FO
RenderX

Table 2.

Dimension of the D&M IS Success Model, main theme, and subthemes	Examples of measures for IS success enablers	Examples of measures for IS success barriers
System quality—ease of learning, ease of use (usability), intuitiveness, flexibility, reliability, response times, availability, and desirable characteristics		
Affinity for and availability of technology		
Understanding technology	• Well-structured and logical design [87,90,131].	• Challenges in understanding computer or accessory context [85,108,121] • Outdated software [138]
Understanding game features	• Easy to navigate [131]	• Challenges in navigating the game setting [92,108,123,138]
Flexibility	• Possibility of repetition [58,75,97,103,109,110,112,125] • Native language [120] • Independent of time and space [103,109,121,131]	• Foreign language [124,138]
Information quality—relevance, completeness, accuracy, conciseness, personalization, understandability, currency, timeliness, and security		
Realism		
Real-life scenarios	• Provides all aspects of the patient and context, giving a realistic experience [58, 75, 84, 88, 90, 102, 103, 106, 108, 112, 122, 124-126, 131, 138, 142]	• Low flexibility for changing a situation (compromised reality) [58,81,110] • Situations lacking resemblance to real life [82,113,123]
Physiological realism	• Replication of real human physiological features [75,81,107,131,138]	• Limited human features of the patient presented by technology [81,82,87,107]
Theory-to-practice transition	• Being able to visualize patient status and the effect of measures [75,81,107,108,131]	• Technology with low and intermediate fidelity [81,82] • Context perceived as not relevant [123]
Service quality—the quality of the support that system users receive from the service providers; this could entail IT support as well as other types of user support and empathy from staff		
Accessibility		
Technical accessibility	• Technology functioning as expected [142]	• Technical problems that cause interruptions [92,110,120,124] • Technical issues such as internet access and connection [90,120,138]
Use (behavior) and intention to use (attitude)—amount, frequency, use patterns, appropriateness, and purpose of use; attitude toward using and reusing the system		
Engagement and motivation		
Preferred learning styles	• Visual learning [106-108,120,122,125] • Autonomy in learning [75,77,97,106,130,131,138] • Being challenged [77,81,84,92,107,108,122,126,132,136]	• Perceived as not sufficient for “hands-on” learning [110,120,123] • Limited variability [113,121]
Physiological and psychological experiences	• Safe learning environment [87,88,109,110,112,122,124,126] • Immersion [92,97,103,108,110,112,126] • Sparked curiosity [108,113,126] • Activation of thoughts and feelings [92,108,122,131]	• Negative physiological reactions [89,106,110] • Confusion [82] • Feeling of incompetence and frustration and low sense of mastery and self-efficacy [82,108]
Experienced use	• Time to become familiar with features of the technology [79,142] • Proper training and instructions [79,110,142] • Appropriate taxonomical level [97,107]	• Limited time to become familiar with technology [103,107,138] • Viewing the learning tool negatively [108,123] • Content not adapted to the taxonomical level [89,107,123] • Inappropriate time frame allotted to tasks [123]
Validation		

XSL•FO
RenderX

Dimension of the D&M IS Success Model, main theme, and subthemes	Examples of measures for IS success enablers	Examples of measures for IS success barriers
Need for feedback	• Feedback provided on the actions taken [79,82,97,103,107,109,112,138] • Feedback enables engagement [102,107,109,125,138] • Provision of examples and explanation of how to perform patient care and why [53,79,125,138]	• No feedback offered [58] • Insufficient feedback offered [81,85]
Satisfaction—overall opinions about the system		
Return on investment		
Student investment	• No information available	• No value for money [123]
Net benefits—impacts on individual users, groups, organizations, industries, and nations		
Enhanced critical thinking through SBL [a] using technology		
Meta-cognition	• Reflecting on one's own actions and thinking [58,75,81,83,84,92,97,109,123,124,126] • Self-reflection and self-evaluation [58,75,83,97,126,131]	• Insufficient debriefing provided [107,112]

[a]SBL: simulation-based learning.

System Quality: Affinity and Availability

This theme pertains primarily to TESs, in which students interact with technology such as CBS and VR or IVR in self-directed, individual learning activities. Well-structured and logical technological platforms with easy navigation were reported as perceived enablers for achieving outcomes in SBL [87,90,131]. Challenges in understanding technological and game features [85,108,121], outdated software [138], and challenges navigating the technological platform [92,108,123,138] were reported as barriers because they limited options and influenced the interaction and the flow of the simulation [92,108,138]. Disorientation and difficulties obtaining information were viewed as time-consuming and hindering to nursing students' learning process, which caused frustration and negative experiences [92,108,123,138]. Flexibility encompassed the use of TESs individually and regardless of time and space [109,121,131] and the possibility of repetition [58,75,97,103,109,110,112,125], which was perceived positively in terms of motivation to use the applied technology and improve performance [58,75,97]. Interacting with TESs in the students' native language enhanced the availability of learning situations [120]. Options in a foreign language and lack of multiple language options were reported perceived barriers that made learning less available to nursing students [124,138].

Information Quality: Realism

Technology that provided all aspects of patient context with a realistic experience was reported as likely to enable learning and the development of critical thinking [58, 75, 84, 88, 90, 102, 103, 106, 108, 112, 122, 125, 126, 131, 138, 142]. Realistic replication of the human physiological features of the patient [75,81,107,131,138], realistic changes in patients' conditions, and being able to visually inspect the patient's status and see the effect of measures [75,81,107,108,131] were reported as increasing perceived realism; theory-to-practice transition; and, hence, nursing students' development of critical thinking skills. Low flexibility for changes in the scenario [58,81,110], limited resemblance to real-life situations [82,113,123], and failure to replicate realistic human features of the patient [81,82,87,107] were factors of technology that were reported to compromise realism in SBL [58,81,82,107,110,123] and cause confusion for nursing students.

Service Quality: Accessibility

When technology functions as expected, it may enhance critical thinking by making learning opportunities accessible [142]. Technical problems caused interruptions that interfered with learning and the smooth development of the scenario in SBL and were reported as a barrier to the development of critical thinking skills by negatively influencing the accessibility of the learning opportunity [82,120]. Another barrier reported, especially with TESs conducted individually, was technical issues related to internet access and connection [120,138].

Use and Intention to Use: Engagement, Motivation, and Validation

The preferred learning style may influence nursing students' engagement and motivation for interacting with technology in SBL and achieve critical thinking outcomes. Nursing students reported that the visual elements of the technology enabled the development of critical thinking through increased engagement from visual learners [106-108,120,122,125]. The perceived autonomy of self-directed learning in TESs, with the opportunity to try out behaviors and apply knowledge and skills without being supervised [75,77,97,106,130,131,138], as well as being challenged on skills and knowledge [77, 81, 84, 92, 97, 107, 108, 126, 132, 138], increased nursing students engagement and motivation. Some nursing students perceived that SBL using HPSs, CBSs, or VR or IVR did not constitute hands-on learning and, hence, was not appropriate for gaining enhanced critical thinking skills outside the clinical environment [110,120,123]. Across several studies (13/42, 31%), nursing students reported that TESs provided a safe learning environment

XSL•FO
RenderX

[87,88,109,110,112,122,124,126] where a high level of immersion [92,97,103,108,110,112,126], sparked curiosity [108,113,126], and the activation of thoughts and feelings [92,108,122,131] enabled involvement and engagement and facilitated the development of critical thinking for nursing students. Limited variability and opportunity to explore inhibited motivation for some nursing students [113,121]. Negative physiological reactions from immersive technology, such as dizziness and headaches, influenced nursing students' engagement and motivation [89,106,110]. Emotions such as confusion, frustration, feelings of incompetency, and a low sense of mastery related to technology led to decreased engagement and loss of motivation and, hence, critical thinking development [82,108].

Experienced use of technology in SBL influenced engagement and motivation. Time to become familiar with features of the technology [79,142], proper training [79,110,142], and appropriate taxonomical level [97,107] were factors associated with enhanced motivation to engage in learning reported by nursing students. Failure to become familiar with the technology [103,107,138], content not adapted to the appropriate taxonomical level [89,107,123], and an inappropriate time frame for conducting a task [123] resulted in decreased engagement and motivation for nursing students, leading to a negative perception of the technology [108,123].

Validation and feedback with provision of examples and explanations of patient care [53,79,125,138] and feedback on actions taken [79,82,97,103,107,109,112,138] were perceived as valuable for nursing students in SBL, enabling critical thinking development [79,82,97,105,107,138]. Feedback enabled motivation and engagement [102,107,109,125,138]. Insufficient or absence of feedback led to uncertainties regarding nursing students' own performance and the accuracy of their problem-solving, ultimately influencing the learning experience and development of critical thinking skills [58,81,85].

Satisfaction: Return on Investment

Chircop et al [123] found that nursing students were not satisfied with the CBS program they were required to buy and that several expressed that the CBS was not perceived as providing value for the money spent.

Net Benefits: SBL Using Technology

Nursing students reported that they perceived that SBL using technology can enhance critical thinking development through opportunities for meta-cognition and engagement in reflection [58,75,77,97,123,138]. Nursing students expressed a perceived value of opportunities to think about their own actions and thinking [58,75,81,83,84,92,97,109,123,124,126], engage in self-reflection and self-evaluation, and consider the benefits of receiving and giving feedback in debriefing sessions with peers and faculty [58,75,83,97,126,131]. Insufficient or no debriefing could decrease nursing students' opportunities for meta-cognition and development of critical thinking [107,112]

Discussion

Principal Findings

This scoping review aimed to systematically map studies on the use of SBL supported by technology to enhance critical thinking in nursing students. We identified 4 main categories of applied technology in SBL to enhance critical thinking as well as a shift across time in the use of the technology applied: from HPSs to CBSs. The technology applied in SBL to enhance critical thinking skills was closely connected to pedagogical considerations and educational approaches. This technology was applied in asynchronous and synchronous learning approaches. Learning approaches and use of technology in SBL have developed over time and trend toward a more blended or combined educational approach after 2019. Our main findings on RQ 3 were related to the information quality and use and intention to use dimensions of the D&M IS Success Model, with themes associated with realism as well as engagement and motivation as prominent findings. The included studies were diverse in origin, which indicates that the topic of interest is relevant worldwide. However, 44% (42/96) of the included studies originated in the United States. This poses the question of whether the use of technology in SBL to enhance critical thinking is more emphasized in the United States or whether this is an expression of a geographical bias in conducting research on the topic. Another concern is about the global applicability. Although a significant proportion of the studies in this review (42/96, 44%) were from the United States, it is important to consider whether and how the findings can be transferred to other educational contexts. Educational systems vary significantly worldwide, and factors such as cultural differences, resource availability, and teaching methods can impact the effectiveness of SBL supported by technology. For instance, in countries with limited resources, access to advanced technology may be a challenge. This may affect the implementation and outcomes of SBL. In addition, cultural differences in learning styles and teaching methods may require adaptations to ensure that SBL methods are effective [147]. It is also crucial to consider how different health care systems and nursing education requirements can influence the transferability of the findings. For example, in countries with different nursing education standards, adaptations may be necessary to ensure that SBL is relevant and effective [148].

Range of Technology

The included studies spanned a 38-year time frame, necessitating consideration of the significant technological development during this period. The technologies applied in SBL must be evaluated within the context of the studies' time frames as they might be outdated by present standards. From a historical perspective, the findings showed a shift in the technology applied in SBL to enhance critical thinking from HPS to TES modalities, such as CBS and VR or IVR. From 2018 to 2023, the predominant technology was CBS, with even more studies conducted using VR or IVR technology than HPSs. This showcases the evolving landscape of educational technology for SBL and active learning in nursing education. Although there is an increased use of health care and telehealth technology in SBL for future registered nurses [149], our findings suggest

XSL•FO
RenderX

that there is limited research on the use of telehealth technology, which is in line with the results of a study by Giuffrida et al [28]. The lack of studies on the use of telehealth in SBL to enhance critical thinking is striking considering the global emphasis on technology and technological advancements as well as the impact of the COVID-19 pandemic and its consequences. The limited number of studies regarding telehealth technology in SBL could be due to publication delay [150], and more research could emerge in the near future.

The descriptions of the applied technology varied across the studies. To consider the validity and generalizability or transferability of the findings in relation to technology as well as compare findings across studies, detailed descriptions of the technology are necessary [151,152]. Our review suggests that studies incorporating a digital technology into TESs generally provided a richer description of the technology involved than those that used HPSs. This may be due to the technology being more novel and complex and researchers acknowledging the importance of providing this information.

Use of Technology in SBL Activities to Enhance Critical Thinking

The use of technology in terms of learning design and teaching strategies in SBL to enhance critical thinking varied across the included studies. Synchronous learning was predominant in SBL that used HPSs, featuring real-time scenarios with physical presence. Conversely, digital technology such as TES leaned toward asynchronous activities, fostering self-directed learning with flexibility for learners. Wong et al [153] argue that developing skills to optimize self-directed learning is essential, with senior nursing students potentially being more adapted to mastering this skill compared to their junior counterparts, who may require more support, guidance, and validation. The need for validation, especially in self-directed learning within SBL, indicates the importance of aligning technological tools with educational objectives and providing comprehensive support for nursing students. As highlighted by the International Nursing Association of Clinical Simulation and Learning [154], there is a need to align tools or modalities in SBL with specific learning outcomes in the design phase of SBL. According to Nadelson et al [155], several nursing programs are looking to provide nursing students with more opportunities for online SBL, and the authors indicate that one important pedagogical choice is whether this should be provided as a synchronous or asynchronous learning activity. Research suggests that both formats yield similar outcomes, with TES offering efficiency through standardized content and the possibility of individualized training [156]. The potential for asynchronous, individualized training and multiple iterations as offered by TES could make these modalities resource efficient due to lower staff costs [25,26,157], with time freed for supportive teaching activities [158]. Hence, pedagogical considerations and cost efficiency should be determined before the choice of technological modality.

The evolution of teaching strategies was evident in the included studies published after 2019, with an increased number of studies that reported combining asynchronous and synchronous aspects in learning activities. According to Kalanlar [149], findings across 30 international nursing education programs reveal that 81% transitioned from traditional teaching to online classes during the pandemic, and of these, 61% conducted SBL using TES, 12% conducted SBL using HPSs, and 10% conducted SBL using telehealth. However, nursing students have expressed low satisfaction with excessive asynchronous activities and pointed out quality differences compared to tactile learning, thus highlighting the challenges of online SBL [149,159]. In a national postpandemic survey in the United States, nursing students reported that the virtual environment and online SBL were inadequate to prepare them for clinical reasoning in direct patient care [160]. The shift to online nursing education accelerated by the COVID-19 pandemic posed challenges to both educators and students, and this may have prompted the shift to a more blended teaching approach [161]. This evolution tends toward combined approaches in teaching critical thinking skills using technology in SBL, typically through individual asynchronous scenarios conducted virtually with TESs followed by synchronous debriefing. This may signal a shift toward a more balanced and comprehensive teaching strategy that considers aspects of social constructivism in learning, in which meaningful interactions influence learning positively [162]. The trend of applying a blended learning approach may represent a recognition that technology is not yet capable of replacing an experienced facilitator in guiding proper reflection processes. Debriefing, integral to SBL, facilitates reflection and learning, with feedback playing a crucial role in developing critical thinking skills [163,164]. Our review identified several methods of receiving feedback for the development of critical thinking through SBL using different technological modalities and tools. Consistent with a systematic review of VR in nursing education [15], we found that TESs offered more diverse feedback models and debriefing practices compared with HPSs, such as scoring systems and real-time feedback on actions taken and communication. This prompts exploration of the factors influencing the choice of educational strategies applied in nursing education to achieve the desired outcome and the optimal technology and design for SBL for effective critical thinking development.

Enablers and Barriers of the Applied Technology in SBL to Enhance Critical Thinking

An evident finding is the crucial role of realism, including real-life scenarios and the replication of human features in simulated patients, for nursing students' learning enhancement. Our findings showed that nursing students' perceptions of realistic patients, with both consistent human and physiological features and contexts, enable learning and enhance critical thinking skills. This could link to nursing students' experience of learning opportunities' relevance in SBL, connecting them to real nursing experiences. Nursing students value realistic features in the SBL environment to perform effectively. The term *relational realism* refers to the degree of realism experienced when interacting with HPSs in a simulated clinical setting [165]. Learning activities using an HPS in SBL may fail if there is no perceived relational realism, leading to learners being reluctant to interact and engage. In designing SBL, educators need to consider several aspects of reality, such as physiological, psychological, and conceptual realism, as well

XSL•FO
RenderX

as technological simulation modalities and tools [21]. Furthermore, experiences of immersion were reported by nursing students to enhance realism and, hence, learning and critical thinking skill development through engagement, motivation, and emotional activation. The literature supports that immersion and interactivity are key to virtual technology learning experiences [166]. The effectiveness of VR or IVR technologies relies on the users' sense of presence [167]. Motivation theories highlight the impact of emotions on students' engagement in learning activities, suggesting the importance of realism factors, as noted by Dubovi [168]. These insights emphasize the importance of creating SBL environments that mirror real-life patients and contexts closely for nurturing critical thinking skills in nursing education.

Our findings highlight the pivotal role of engagement, motivation, and personalized learning styles, emphasizing the need for adaptive and learner-centered approaches in designing and implementing technology in SBL through different modalities and tools. A systematic review on the use of VR among nursing students and registered nurses identified 2 disadvantages with the virtual world: a lack of realism and technical issues [169]. Our scoping review suggests that technical issues and problems could compromise realism and be barriers to learning and the development of critical thinking skills as these issues limit the availability of learning opportunities in the learning environment. The absence of realism may diminish immersion, consequently reducing engagement and the achievement of learning outcomes. Our results emphasize the importance of nursing students' technological proficiency in effectively interacting with technology. Harerimana and Mtshali [170] found that students' computer skills influenced their perception of the effectiveness of teaching and learning using technology. Consequently, using teaching and learning strategies to facilitate students' development of computer proficiency and technological literacy may enhance learning using technology in other areas, such as the development of critical thinking skills [46]. A lack of technological proficiency can be a major source of frustration for nursing students, potentially leading to a negative perception of technology [169] and decreasing their motivation and engagement [170]. Studies have identified poorly structured and designed digital learning interventions and technical problems as major causes of negative outcomes when introducing digital learning interventions in higher education [170,171]. They emphasize that technical difficulties diminish the value of the learning experience, decrease motivation, and contribute to feelings of inequality among students. This is particularly crucial in synchronous learning situations, in which interaction is essential [171]. Coupled with providing comprehensive technical support, ensuring technological functionality and quality is crucial for motivating and engaging nursing students in technology-based learning activities to enhance their critical thinking skills.

Theoretical Foundation for Pedagogy and Outcome Evaluation

The variety in theoretical foundations and the diverse outcome measures identified in our review pose a challenge regarding the comparison of research outcomes. More than half (56/96, 58%) of the studies in our scoping review incorporated an underlying theory or conceptual framework to inform their interventions. Establishing a scientific theoretical foundation for future studies may secure more robust research outcomes in the field of SBL with the support of technology to enhance critical thinking. Bauce et al [172] highlight that theory is needed in research to support pedagogy and emphasize that theory has served to underpin pedagogy and provide a foundation for outcome evaluation. The use of scientific theories in SBL research is important in formulating precise RQs, guiding study design and analysis, and contributing to a cumulative research program. It is crucial to differentiate between scientific theories, which are explanatory and descriptive, and a conceptual framework, which represents some aspects of reality [173]. Conceptual frameworks have a different scientific meaning from that of a scientific theory, and thus, the studies conducted based on them are different in nature. Varpio et al [174] underscore the need for a standardized understanding of terms such as *theory*, *theoretical framework*, and *conceptual framework* within health profession education and research. This is essential for enhancing the clarity and rigor of research reporting, subsequently fostering a more robust theoretical foundation for future studies in the field of SBL supported by technology to augment critical thinking skills. Furthermore, there was diversity in the validated instruments and self-developed questionnaires used across the included studies to measure outcomes. Adib-Hajbaghery and Sharifi [29] question the use of general measurement instruments to assess the outcome of critical thinking when evaluating effects in relation to specialized nursing interventions. This underscores the necessity for standardization and consensus on global research practices, facilitating more meaningful cross-study analyses and enabling the development of comprehensive reviews and meta-analyses.

Future Research Directions

The extensive body of research, comprising 96 studies included in this scoping review, highlights the potential for future systematic reviews and meta-analyses of both quantitative and qualitative scientific studies on SBL using technology to enhance critical thinking. This would provide deeper insights into the effectiveness of SBL strategies and identify best practices for integrating technology to foster critical thinking development. Furthermore, there is a need for consistency and standardization in the use of scientific theory to enhance the clarity and rigor of research reporting and establish a robust theoretical foundation for future studies in the field of SBL supported by technology to augment nursing students' critical thinking skills.

Future research should investigate SBL in relation to different learning styles, variations in SBL outcomes among nursing students at different stages of their education, generational differences in technology use, content and design of SBL, and the choice of technology applied to achieve the outcome of enhanced critical thinking. Studies should also explore factors influencing educators' choice of technology and design for SBL in nursing education to achieve outcomes and the enhancement of critical thinking skills in nursing students. Despite the increasing emphasis on health care technology and telehealth,

XSL•FO
RenderX

there is limited research on such technology use in SBL in nursing education to enhance nursing students' critical thinking skills. This calls for further research to inform nursing education on the pedagogical aspects of SBL using health care technology generally and telehealth technology specifically to enhance nursing students' critical thinking skills. Furthermore, studies comparing and evaluating the impact of different technologies on higher-order thinking outcomes may provide valuable insights that could inform nursing education.

Strengths and Limitations

The strengths of this scoping review were that our scoping review protocol was peer reviewed and published, and we used an acknowledged methodological framework and reported the review according to PRISMA-ScR checklist [38,39] to enhance transparency (Multimedia Appendix 4). A comprehensive search strategy was developed in collaboration with an experienced research librarian. The inclusion of various concepts often considered synonymous with critical thinking that share several similar factors was important due to the vague and diverse definitions of critical thinking. However, the fact that the studies may have used these concepts in ways that are not conceptually equivalent must be considered. Our inclusion criteria were limited to specified languages. Consequently, we may have introduced selection bias. Other limitations may be the dominant population of undergraduate students in the included studies, which might limit transferability to other contexts and populations. Furthermore, the dominance of included studies originating in the United States should be considered when interpreting the findings. However, we believe that, by including studies from 20 different countries, this reflects SBL with technology to enhance critical thinking in nursing education as a universal theme and the review exhibits global trends in nursing education and the use of technology in SBL to enhance critical thinking. Therefore, an understanding of each country's educational system is imperative in interpreting the findings. In addition, the variability in theoretical foundations and outcome measures across the studies may have hindered cross-study comparisons in this review. Finally, the findings need to be interpreted with caution due to the diversity in research contexts, technology used, and SBL interventions in the included studies and because the methodological quality of the included studies was not appraised and the data were organized and not synthesized.

Conclusions

This scoping review highlights a global relevance through a range of diverse studies. Over time, there was a noticeable shift from HPSs to TESs such as CBS and VR or IVR, emphasizing the importance of detailed descriptions of the applied technology to ensure validity and comparability across studies. After 2018, a trend toward blended educational approaches combining asynchronous and synchronous learning activities emerged. The feedback provided to nursing students in SBL to enhance critical thinking varied in delivery, with technology-driven feedback tailored to learning objectives playing a pivotal role in enhancing critical thinking. This highlights the need for educators to carefully select and tailor technology-based tools and programs to deliver feedback aligned with learning objectives and outcomes of critical thinking development. The establishment of robust theoretical foundations of research and standardized research practices will strengthen the evidence obtained from the research conducted. Realism, user proficiency, and the perceived quality of the technology significantly influence engagement, motivation, and the development of critical thinking in nursing students. This review provides valuable insights for educators, designers, and technology developers to enhance the effectiveness of technologically supported SBL in nursing education. Our findings can inform evidence-based practices, guide the design of effective educational interventions, and contribute to the ongoing discourse on the integration of technology into SBL in nursing education.

Acknowledgments

The authors acknowledge and extend their gratitude to Kari Larsen Mariussen for peer reviewing the search strategy and conducting the second updated search in 2024. They extend their acknowledgment for the vast amount of input to Andrea Mohallem, who chose not to continue in the process of completing the scoping review, and to Fernando Riegel for a substantial and invaluable contribution to the process until he sadly passed away before completion of this work. The authors extend their deepest gratitude and appreciation for his memory and express their condolences to his family and loved ones. This research was funded by the Educational Research Focusing on Competence Development and Quality in Nursing Education research group at Lovisenberg Diaconal University College, Oslo, Norway. The authors received no grants from any funding agency in the commercial, public, or nonprofit sector.

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files).

Abstract

Background: Recovery of upper limb function after stroke secondary to ischemia or hemorrhage is crucial for patients' independence in daily living and quality of life. Virtual reality (VR) is a promising computer-based technology designed to enhance the effects of rehabilitation; however, the results of VR-based interventions remain equivocal.

Objective: This study aims to review the plausible factors that may have influenced VR's therapeutic effects on improving upper limb function in patients with stroke, with the goal of synthesizing an optimal VR intervention protocol.

Methods: The databases PubMed, EMBASE, Web of Science, and Cochrane Library were queried for English-language papers published from May 2022 onward. Two reviewers independently extracted data from the included papers, and discrepancies in their findings were resolved through consensus during joint meetings. The risk of bias was assessed using the Physiotherapy Evidence Database Scale and the Methodological Index for Non-Randomized Studies. Outcome variables included the Action Research Arm Test, Box-Block Test, Functional Independence Measure, Upper Extremity Fugl-Meyer Assessment, and Wolf Motor Function Test. The plausible factors examined were age, total dosage (hours), trial length (weeks), session duration (hours/session), frequency (sessions/week), and VR content design. The Bonferroni adjustment was applied to *P* values to prevent data from being incorrectly deemed statistically significant.

Results: The final sample included 15 articles with a total of 1243 participants (age range 48.6-75.59 years). Participants in the VR therapy (VRT) group (n=455) demonstrated significantly greater improvements in upper limb function and independence in activities of daily living compared with those in the conventional therapy group (n=301). Significant factors contributing to improved outcomes in upper limb function were younger age (mean difference [MD] 5.34, 95% CI 2.18-8.5, *P*<.001; I2=0%), interventions lasting more than 15 hours (MD 9.67, 95% CI 4.19-15.15, *P*<.001; I2=0%), trial lengths exceeding 4 weeks (MD 4.02, 95% CI 1.39-6.65, *P*=.003; I2=15%), and more than 4 sessions per week (MD 3.48, 95% CI 0.87-6.09, *P*=.009; I2=0%). However, the design of the VR content, including factors such as the number of features (eg, offering exercise and functional tasks; individualized goals; activity quantification; consideration of comorbidities and baseline activity level; addressing patient needs; aligning with patient background such as education level; patient-directed goals and interests; goal setting; progressive difficulty levels; and promoting self-efficacy), did not demonstrate significant effects (MD 3.89, 95% CI –6.40 to 1.09; effect Z=1.36, *P*=.16).

Conclusions: Greater VR effects on improving upper limb function in patients with stroke were associated with higher training doses (exceeding 15 hours) delivered over 4-6 weeks, with shorter sessions (approximately 1 hour) scheduled 4 or more times per week. Additionally, younger patients appeared to benefit more from the VR protocol compared with older patients.

virtual reality; stroke; upper limb function; exercise training; meta-analysis

Introduction

Recovery of upper limb function after stroke is crucial for patients' independent daily living and quality of life [1-3]. Previous studies have demonstrated the positive effects of incorporating neurodevelopmental, proprioceptive neuromuscular, and motor relearning theories in designing interventions to improve patients' upper limb function [4-7]. Advances in technology have enabled virtual reality (VR) to serve as a common medium for delivering interventions aimed at enhancing upper limb function [8]. VR is a promising computer technology that allows users to interact with a simulated multisensory environment [9]. It is designed to enhance the effectiveness of rehabilitation and provide feedback on performance. However, a review of clinical studies examining the use of VR as an intervention for patients with stroke produced inconsistent findings. Compared with usual practice, VR interventions were found to be more effective in improving upper-extremity and hand functions in patients with stroke [10-12]. By contrast, 1 study reported that VR interventions were effective in improving cognitive functions but not motor functions in patients with traumatic brain injury [13], while another study found no significant differences between VR and conventional therapy for patients with stroke [14].

A review of recent studies suggested that the inconsistent results described above may stem from variations in the design, content, duration, and intensity of VR interventions [14], as well as patient-specific characteristics such as independence level and emotional state [12]. For example, VR exercise training was found to be more effective than usual practice for improving upper limb function in patients with stroke only when they participated in a high-dose program (eg, 15 hours or more) [15], whereas this effect was not observed with a low-dose program (eg, 12 hours) [16]. In the high-dose study, the VR exercise training included a variety of limb movements with varying levels of difficulty. Conversely, the low-dose study used a VR protocol consisting of 3 modes of hand and arm movements performed at different speeds. Inconsistent findings are also evident in studies evaluating the effects of VR in patients with Parkinson's disease. For example, a VR game using a 1-group pre- and posttest design demonstrated improvements in hand grip strength, dexterity, and speed among patients with stroke [17]. The VR game comprised 4 activities delivered in sequence: the reach game, the sequence game, the grab game, and the flip game. The intervention involved 30-minute individual sessions conducted 3 times per week over 6 weeks (18 sessions, totaling 9 hours). These results contrast with those of a randomized controlled trial (RCT), which found no significant effects [18]. The RCT protocol involved tracking and touching moving objects displayed on a screen while maintaining a standing balance. The schedule consisted of 40-minute individual sessions, 3 sessions per week over 6 weeks (18 sessions, totaling 12 hours). Many national clinical guidelines for stroke emphasize the importance of applying recovery principles. Beyond dosage (ie, duration per session, frequency, and overall intervention period), the design of VR training content appears to influence treatment outcomes. For instance, the 2023 edition of the National Clinical Guideline for Stroke for the United Kingdom and Ireland [19] recommends therapy for motor recovery and function that incorporates individualized content, a variety of practice modes, intensity, and the practice of functional skills. Additionally, studies have highlighted the critical role of repetitions in reshaping neuronal structures and enhancing motor system function following brain injury [20-22]. Research on nonprimates has shown that performing repeated reaching tasks can induce synaptogenesis and changes in cortical representations [23,24]. In human studies, evidence suggests that functional recovery of the upper limbs, driven by the brain's plasticity, requires at least 300 repetitions per day [25] or 100 active movements or more per treatment session [26].

The inconsistent findings regarding the effects of VR-based interventions motivated us to undertake this meta-analytic study. We aimed to examine 6 plausible factors that might influence the therapeutic effects of VR on improving upper limb function in patients with stroke. These factors included patients' age, dosage (hours), delivery schedule (session duration, frequency, and trial length), total dosage (hours), and content design. We hypothesized that all these factors would significantly impact intervention outcomes. Identifying the factors contributing to variability in intervention outcomes would enhance the content design of VR interventions and provide guidance on setting appropriate dosages and schedules to achieve better treatment results for patients.

Methods

Design

This study followed the scope and methods outlined in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement and its accompanying checklist [27].

Search Strategy

The relevant materials for review and analysis were extracted on May 7, 2022, from PubMed (1966 to present), EMBASE via Ovid (1974 to present), Web of Science (1956 to present), and the Cochrane Library databases (no date restriction). The medical terms and free-text search terms were related to VR, upper limb, and rehabilitation. Detailed search strategies for each database are provided in Multimedia Appendix 1.

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria set for the studies are presented in Textboxes 1 and 2.

XSL•FO
RenderX

Textbox 1. Inclusion criteria.

- Randomized controlled trial and group comparison studies.
- Results published in English in peer-reviewed journals.
- The treatment group used virtual reality–enhanced exercise alone or combined with conventional therapy, while the control group used conventional therapy alone or without treatment.
- Patients showed upper limb functional disabilities with outcome variables including the Action Research Arm Test, Box-Block Test, Functional Independence Measure, Upper Extremity Fugl-Meyer Assessment, and Wolf Motor Function Test.
- Means, SD, and effect sizes were presented; or means, SEs, *t* values, or *P* values were presented; or range or 95% CIs were presented.

Textbox 2. Exclusion criteria.

- Abstracts, case reports, or review studies.
- Non-English or nonbilingual journal articles.
- Research design without group comparison.
- Patients without stroke or measuring lower limb functions of patients with stroke.
- Missing data or additional information (means, SD, and effect sizes) cannot be obtained from the corresponding author within 1 month after initial contact.

Study Selection

All studies were imported into the EndNote referencing software (Thomson Research Soft, version X9), and duplicates were identified and removed. Two reviewers, SX and JW, co-authors of this paper, independently conducted the relevance screening. The screening process began with an evaluation of the title and abstract content of each publication based on the inclusion and exclusion criteria outlined above. Reviewers were instructed to read the full text if the abstract contained ambiguous content. Discrepancies between the 2 reviewers were resolved through consensus during joint meetings.

Data Extraction

Two research team members (SX and YX) independently extracted data from the included papers. For each paper, the researchers identified the trials and specific content, recording them in preformatted tables. The recorded information included trial design and setup, sample sizes of all groups, intervention program details, overall characteristics, and clinical outcome results. Discrepancies between the 2 reviewers were resolved through consensus during joint meetings.

Assessment of Risk of Bias

Two research team members (YX and YQ) independently assessed the risk of bias in the included trials using the Physiotherapy Evidence Database (PEDro) Scale [28] and the Methodological Index for Non-Randomized Studies (MINORS) [29]. The 11-item PEDro Scale evaluates the quality of the trials, with a score of “1” indicating the criterion is met and “0” indicating it is not. PEDro quality grades are categorized as high (6-8: good; 9-10: excellent), fair (4-5: acceptable), and poor (≤4). For nonrandomized trials, the first 8 items of the MINORS were used to assess methodological quality (risk of bias). Each MINORS item is scored as follows: “0” for not reported, “1” for reported but insufficient, and “2” for reported and sufficient. For a single-group trial, the maximum score is 16, while for a 2-group trial, it is 24. A score of 0-9 for a single-group trial indicates poor quality and 10-16 indicates high quality. In this study, the cut-off for inclusion was set at high quality or above: a score of 6 or higher on the PEDro Scale or 10 or higher on the MINORS [30]. Discrepancies in the scores assigned by the 2 reviewers were resolved through consensus during joint meetings.

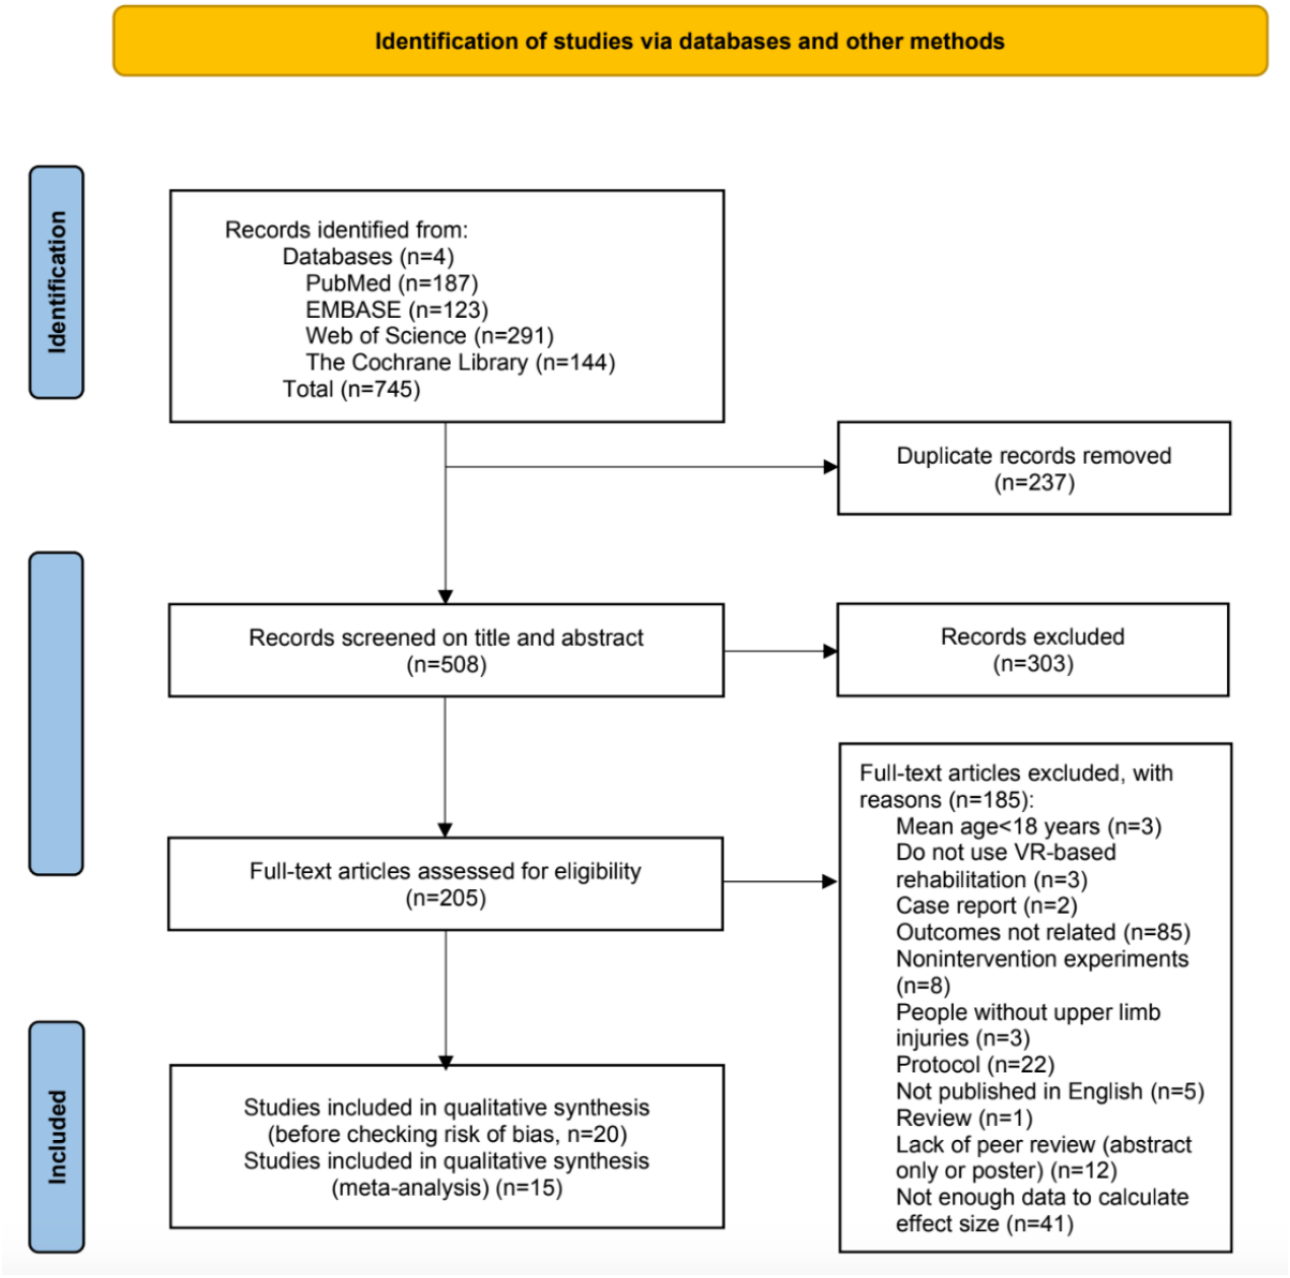
The principles of therapy content (motor recovery and function) outlined in the 2023 edition of the National Clinical Guideline for Stroke for the United Kingdom and Ireland [19] were adopted as feature criteria to guide the analysis of VR content. Ten content features were identified: offering exercise and functional tasks; setting individualized goals; quantifying activity; considering comorbidities and baseline activity levels; incorporating patient needs; matching the patient’s background, such as education level; aligning with the patient’s goals and interests; involving goal setting; including progressive difficulty levels; and promoting self-efficacy. The content features of each study were collated and classified into 3 categories: “+” for few features (2-3), “++” for medium features (4-5), and “+++” for many features (≥6).

Data Synthesis and Analysis

We conducted analyses using Review Manager (RevMan) version 5.3 software. As some studies [14,31-34] reported results in terms of the median, minimum, maximum, or IQR, we converted these to means and SDs as proposed in the study by Wan et al [35]. For studies reporting only means, SEs, *t* values, or *P* values, we computed the SDs [31,32,35]. For studies reporting only ranges or 95% CIs, we calculated the means [31,32,35]. Statistical heterogeneity for each meta-analysis was assessed using the Cochran *Q* test and the I^2 statistic. Fixed-effect models were applied when heterogeneity among trials was nonsignificant (I^2<50%), while random-effect models were used for significant heterogeneity (I^2>50%). The outcome variables included the Action Research Arm Test (ARAT), Box and Block Test (BBT), Functional Independence Measure (FIM),

XSL•FO
RenderX

Upper Extremity Fugl-Meyer Assessment (FMA-UE), and Wolf Motor Function Test (WMFT). All results were reported as mean differences (MDs) with 95% CIs. The plausible factors considered were age (with the World Health Organization defining older age as 60 years and above), total dosage (hours), trial length (weeks), duration of a session (hours/session), frequency (sessions/week), and VR content design. The cut-off value was set based on the findings of previous literature [36-39] and the principle that at least two articles must be included per subgroup. As only 15 studies were available for analysis, multiple comparisons were conducted separately for each of the 6 factors to meet this criterion. Statistical significance for the meta-analysis (whole group) was set at $P<.05$. For the subgroup analyses, the potential proliferation of type I and type II errors across the 6 comparisons was controlled by applying the Bonferroni adjustment, setting statistical significance at $P<.008$ (0.05 divided by 6).



Results

Study Selection

Details of the steps taken to select the studies are presented in the PRISMA flowchart (Figure 1; also see Multimedia Appendix 2). A total of 745 studies were retrieved from 4 databases through an electronic search. Of these, 237 studies were excluded due to duplication. An additional 303 studies were excluded after reviewing their titles and abstract contents. Full-text screening of the remaining 205 studies resulted in the exclusion of 185 studies for not meeting the inclusion criteria. Among the remaining 20 studies, 5 were further excluded for being rated below the “good” cut-offs on the PEDro and MINORS scales. The final number of studies included in the analyses was 15 [11,16,33,34,40-50], consisting of 12 RCTs and 3 non-RCTs.

Characteristics of the Included Trials

The 15 studies included a total of 28 groups, comprising 15 VR therapy (VRT) groups and 13 conventional therapy (CON) groups, with 1203 participants in total (Table 1). All studies were published between 2013 and 2022. At the total group level (14 studies), the VRT and CON groups included 411/278 and 294/177 males/females, respectively. One study did not report gender as a grouping variable and was therefore excluded from the gender analysis at the group level. The average ages of participants in the VRT groups ranged from 49.0 to 73.0 years, while those in the CON groups ranged from 53.4 to 75.6 years. The intervention durations for the VRT groups varied from 2 weeks to 3 months. Fourteen studies [11,16,33,34,40-47,49,50] involved patients with stroke secondary to ischemia or hemorrhage, while 1 study [48] included only patients with stroke secondary to ischemia.

Risk of Bias

The mean PEDro Scale score for the 12 studies with a randomized clinical trial design was 7.2 (Table 2). All these studies reported the method of randomization, baseline comparability, blinding of outcome assessors, participant dropout rates of less than 15%, between-group outcome analysis, and point estimates with variability. Most of these studies also reported adequate assignment concealment (n=7, 58%) and intention-to-treat analyses (n=4, 33%). Among the studies with a nonrandomized clinical trial design (n=3), it is noteworthy that they demonstrated clear research objectives and prospective data collection but lacked a follow-up period and did not perform sample size calculations (Table 3).

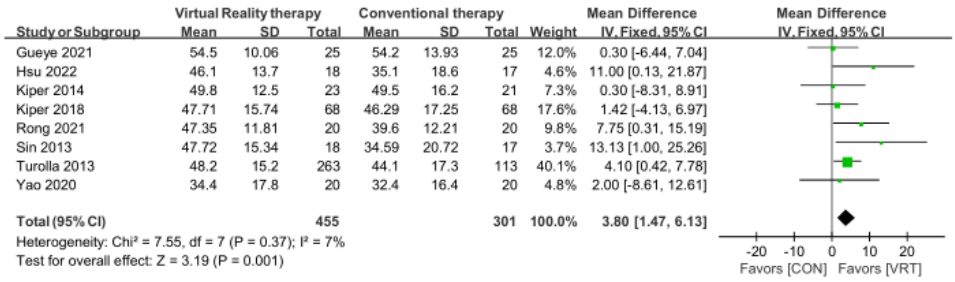
[k]Item 10: Contemporary groups.

[l]Item 11: Baseline equivalence of groups.

[m]Item 12: Adequate statistical analyses.

Meta-Analysis



Whole-Group: Upper Limb Function (FMA-UE)

Participants in the VRT group (n=455) demonstrated significantly greater improvement than those in the CON group (n=301) in FMA-UE scores (MD 3.80, 95% CI 1.47-6.13, P=.001; I^2=7%; Figure 2; see also [11,16,40-50]). Within the VRT group, participants showed significant increases in FMA-UE scores following the intervention (MD 9.95, 95% CI 6.49-13.41, P<.001; I^2=56%; Figure 3; see also [11,16,33,34,40-50]).

Figure 3. Forest plot of comparisons of within-group outcomes on upper limb function.

Whole Group: Upper Limb Activity Limitation (ARAT, FIM, WMFT, and BBT)

Participants in the VRT group showed significantly greater improvements than those in the CON group in upper limb function measured by the ARAT (MD 3.68, 95% CI 1.87-5.48, P<.001; I^2=0%; n [VRT]=102, n [CON]=98; Figure 2), independence in activities of daily living measured by the FIM (MD 4.86, 95% CI 2.92-6.81, P<.001; I^2=46%; n [VRT]=488, n [CON]=332; Figure 2), and upper limb functional capacity measured by the WMFT (MD 6.16, 95% CI 4.03-8.29, P<.001; I^2=0%; n [VRT]=78, n [CON]=74; Figure 2). However, there were no significant differences between the groups in upper limb finger dexterity measured by the BBT (MD 3.26, 95% CI –1.16 to 7.68, P=.15; I^2=0%; n [VRT]=120, n [CON]=124; Figure 2).

XSL•FO
RenderX

Among the VRT groups, participants demonstrated significant pre- and postintervention improvements in scores on the ARAT (MD 9.28, 95% CI 7.52-11.04, P<.001; I^2=0%), FIM (MD 13.60, 95% CI 9.55-17.64, P<.001; I^2=72%; or MD 9.52, 95% CI 7.02-12.02, P<.001; I^2=4% after the removal of outliers [21,25]), WMFT (MD 13.94, 95% CI 8.24-19.64, P<.001; I^2=82%), and BBT (MD 8.60, 95% CI 4.54-12.67, P<.001; I^2=21%; Figure 3).

Subgroup Analyses

Age Influencing the VR Effect

Compared with those in the CON group, younger patients (n=301, mean age 56.45 years) in the VRT group demonstrated significantly greater improvements in upper limb function measured by the FMA-UE (MD 5.34, 95% CI 2.18-8.5, P<.001; Table 4). No statistically significant heterogeneity was observed among older patients (SMD 1.96, 95% CI −1.50 to 5.41, P=.27; Table 4). Similarly, younger patients showed greater improvements in independence in activities of daily living measured by the FIM (MD 6.55, 95% CI 2.36-10.75, P=.002), while no statistically significant heterogeneity was observed among older patients (MD 2.68, 95% CI −0.47 to 5.83, P=.10; Table 5).

Dosage (Total Hours) Influencing the VR Effect

Comparisons were conducted between studies with total intervention delivery times of 15 hours or less and those exceeding 15 hours. Among studies with less than 15 hours of intervention, the VRT group did not show significant changes in upper limb function, as measured by the FMA-UE, compared with the CON group before and after the intervention (MD 0.79,

XSL•FO
RenderX

95% CI −4.90 to 6.47, *P*=.79; Table 4). By contrast, among studies with over 15 hours of intervention, the VRT group demonstrated significant improvements in upper limb function measured by the FMA-UE (MD 9.67, 95% CI 4.19-15.15, *P*<.001; Table 4).

Trial Length Influencing the VR Effect

When the trial duration was 4 weeks or longer, improvements in upper limb function measured by the FMA-UE in the VRT group were greater than those in the CON group (MD 4.02, 95% CI 1.39-6.65, *P*<.001; Table 4). For within-group comparisons, trials lasting over 4 weeks showed significant improvements in upper limb function in the VRT group measured by the ARAT (MD 9.49, 95% CI 7.69-11.29, *P*<.001; Table 6) and the BBT (MD 7.43, 95% CI 0.50-14.36, *P*=.04; Table 7). The VRT group also demonstrated improvements in upper limb function measured by the FMA-UE when the trial duration was less than 6 weeks (MD 10.88, 95% CI 6.07-15.68, *P*<.001; Table 4), but no significant improvements were observed when the trial duration was 6 weeks or longer (MD 4.15, 95% CI −1.78 to 10.09, *P*=.17; Table 4).

Duration (Hour/Session) and Frequency (Session/Week) Influencing the VR Effect

For session durations shorter than 2 hours, participants in the VRT group (mean 1.17 hours) demonstrated significantly greater improvements in upper limb function, as measured by the FMA-UE, compared with those in the CON group (mean 1.17 hours) (MD 9.67, 95% CI 4.19-15.15, *P*<.001; Table 4). For session durations equal to or longer than 2 hours (ie, ≥2 hours/session), participants in the VRT group (mean 2.0 hours) also showed significantly greater improvements in independence in activities of daily living, as measured by the FIM, compared with those in the CON group (mean 2.0 hours; MD 6.70, 95% CI 3.46-9.94, *P*<.001; Table 5).

When the frequency exceeded 4 sessions per week, improvements in upper limb function measured by the FMA-UE (MD 3.48, 95% CI 0.87-6.09, *P*<.001) and independence in activities of daily living measured by the FIM in the VRT group were greater than those in the CON group (MD 5.82, 95% CI 3.62-8.03, *P*<.001) (Tables 4 and 5). Conversely, when the frequency was 4 or fewer sessions per week, significant changes in upper limb function measured by the ARAT were observed in the VRT group (MD 9.49, 95% CI 7.69-11.29, *P*<.001), but no significant changes were found when the frequency exceeded 4 sessions per week (MD 4.32, 95% CI –4.39 to 13.04, *P*=.33; Table 6).

Content Design Influencing the VR Effect

The content design factor was defined based on the National Clinical Guideline for Stroke for the United Kingdom and Ireland (2023 edition) [19]. The number of features in the VR interventions across all studies ranged from 2 to 10. Comparisons were made between studies with a fewer number of content features (n=7, features ≤5) and those with a greater number of features (n=8, features>5; Table 8). The common outcome variable among the included studies was upper limb function measured by the FMA-UE, and thus the comparisons were based on this measure. The MDs in FMA-UE scores did not significantly differ between the fewer and greater feature subgroups (MD 3.89, 95% CI –6.40 to 1.09; effect *Z*=1.36, *P*=.16; Figure 4; see also [11,42-46,48,50]).

Discussion

Principal Findings

This study aimed to examine the influence of patients' age, delivery dosage and schedule, and content design on the outcomes of virtual reality interventions for patients with stroke. The meta-analytic results revealed that virtual reality training had significantly greater therapeutic effects than conventional training in improving upper limb function in patients with stroke. These effects included enhancements in upper limb function, as measured by the FMA-UE and ARAT, and improvements in activities of daily living, as measured by the FIM.

The demographic factor associated with more significant therapeutic effects was younger patient age compared with older age (mean 56.5 vs 65.9 years). Virtual reality training content

XSL•FO
RenderX

factors contributing to greater effects included higher training dosage (>15 hours) delivered over 4-6 weeks and shorter sessions (mean 1.2 vs 2.0 hours) scheduled 4 or more times per week. Notably, shorter sessions (mean 1.2 hours) were linked to better outcomes in upper limb function, whereas longer sessions (mean 2.0 hours) were associated with improved outcomes in activities of daily living.

Our findings on the therapeutic effects of virtual reality training are largely consistent with those reported in 4 previous meta-analytic studies [9,36,54,55]. The consistent results confirm that virtual reality, as a novel and potentially useful technology, is effective in improving upper limb function and activities of daily living compared with conventional therapy after stroke. However, an inconsistent result was observed in the nonsignificant effects of virtual reality training on improving patients' upper limb dexterity (measured by the BBT). This nonsignificant finding could be attributed to the smaller number of studies that used finger dexterity as an outcome variable (n=4) compared with those focusing on upper limb function or activities of daily living (n=8).

Younger patients with stroke demonstrated better outcomes than older patients in both upper limb function and activities of daily living. One plausible explanation is that younger patients may have been more motivated and actively engaged in the training, leading to better results. Previous studies have shown that increasing age is associated with lower participation in cognitively demanding activities [56]. Reduced participation inevitably results in lower gains from training. Spiteri et al [57] found that older adults (eg, 65-70 years) faced barriers such as mobility challenges, limited community accessibility, and insufficient guidance from health care professionals, which hindered their participation in physical activity (also see [58]). Our findings further emphasize the value of virtual reality training in poststroke rehabilitation. Addressing potential barriers, such as ensuring adequate supervision from health care professionals and improving accessibility, could enhance the effectiveness of VR-based training for older patients.

VR-based training offers immersive, imaginative, and interactive experiences [59,60] that facilitate functional recovery in patients with stroke [61,62]. These vivid experiences have been linked to participants engaging in more intensive cognitive and motor processes during training [63-66]. The cognitive processes involve bottom-up attention, which entails the encoding and processing of visual and auditory stimuli emitted in the virtual environment [67,68]. Top-down attention, by contrast, involves cognitive control, decision-making, and motor planning to produce motor responses [69,70]. The content design of virtual reality training did not significantly influence its therapeutic effects. In this study, we adhered to the principles outlined by the United Kingdom and Ireland for designing therapy aimed at promoting functional recovery in patients with stroke. The number of different features, whether fewer or more, based on these principles, did not emerge as a significant factor. However, 2 content features shared by most studies were setting individualized goals (item 2) and quantifying activities (item 3). Our findings suggest that counting repetitions of movements or responses performed by patients and setting treatment goals tailored to individual needs may be essential or sufficient features for designing effective virtual reality interventions.

The cognitive and motor processes involved in virtual reality training need to be repetitive to drive functional changes in patients with stroke. Our results suggest that more than 15 hours of training, scheduled over 4-6 weeks with 4 or more 1-hour sessions per week, can maximize improvements in upper limb function. By contrast, achieving significant gains in independence in activities of daily living appears to require a higher dosage, with 30 or more hours of training needed to produce meaningful outcomes. Repetitiveness is essential for initiating neural changes after a stroke. At the neurological level, posttraining changes in the motor cortices involve alterations in functional connectivity within neural networks, such as the prefrontal cortex and the basal ganglia [71,72]. Recovery of upper extremity function after a stroke has been linked to changes in functional connectivity between the bilateral primary motor cortex (M1) and the dorsolateral prefrontal cortex [73,74]. Additionally, repetitive training leads to the functional reorganization of the sensorimotor networks and the extrapyramidal system [75].

Limitation

This study has several limitations. First, the subgroup analyses did not include outcomes measured by the ARAT or the WMFT, limiting the generalizability of the results. Caution is therefore needed when interpreting the findings. Second, the therapeutic effects of VR-based training were derived from outcomes measured shortly after the completion of training. As such, the findings do not extend to short- or long-term posttraining effects. Evidence regarding the long-term benefits of VR-enhanced exercise training for improving upper limb function in patients with stroke remains limited. However, a study examining the long-term treatment effects of VR in cardiovascular rehabilitation found that combining VR-based therapy with conventional treatment was associated with sustained long-term effects on hemodynamic and autonomic outcomes. This suggests that VR could serve as a valuable new treatment modality when integrated with cardiovascular rehabilitation sessions [51-53,76]. Standalone VR treatment lacks sensory and proprioceptive inputs to the central nervous system, limiting the functionality of the central-peripheral loop. Future longitudinal studies should explore the combination of VR-based therapy with actual exercises, focusing on how to integrate these approaches effectively for patients with stroke.

Third, significant heterogeneity (I^2>50%) was observed in the meta-analysis. In the whole-group analysis, participants in the VRT group showed significantly greater improvement than those in the CON group, with I^2<50%, indicating that the results from the studies were consistent in favoring VRT. However, in the within-group pre- and postintervention analysis, we found that some studies had I^2>50%, such as the WMFT (I^2=82%). This could be attributed to clinical variability in intervention delivery, including factors such as dosage, trial length, and frequency. The heterogeneity of participants across the included trials likely reduced the effect sizes of the observed therapeutic effects, particularly for older patients and improvements in finger dexterity. Similarly, the relatively small number of studies

XSL•FO
RenderX

in the subgroup analyses may have reduced the power to identify training design content as a significant outcome factor. Future research should include more studies and patients with stroke in the analyses and investigate the long-term effects of virtual reality training.

Conclusions

Virtual reality training was effective in promoting upper limb function and independence in activities of daily living for patients with stroke. Patient age and the dosage and schedule of training delivery are factors that influence its therapeutic effects. Younger patients who participate in training for more than 15 hours tend to show better outcomes compared with older patients. Training content delivered in 1-hour sessions, with more than 4 sessions per week over 4-6 weeks, could further maximize the therapeutic effects. Additionally, the design of the VR content should be tailored to the individual needs of the patients and involve them in setting treatment goals.

Abstract

Background: Digital twins (DTs) are digital representations of real-world systems, enabling advanced simulations, predictive modeling, and real-time optimization in various fields, including health care. Despite growing interest, the integration of DTs in health care faces challenges such as fragmented applications, ethical concerns, and barriers to adoption.

Objective: This study systematically reviews the existing literature on DT applications in health care with three objectives: (1) to map primary applications, (2) to identify key challenges and limitations, and (3) to highlight gaps that can guide future research.

Methods: A meta-review was conducted in a systematic fashion, adhering to PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, and included 25 literature reviews published between 2021 and 2024. The search encompassed 5 databases: PubMed, CINAHL, Web of Science, Embase, and PsycINFO. Thematic synthesis was used to categorize DT applications, stakeholders, and barriers to adoption.

Results: A total of 3 primary DT applications in health care were identified: personalized medicine, operational efficiency, and medical research. While current applications, such as predictive diagnostics, patient-specific treatment simulations, and hospital resource optimization, remain in their early stages of development, they highlight the significant potential of DTs. Challenges include data quality, ethical issues, and socioeconomic barriers. This review also identified gaps in scalability, interoperability, and clinical validation.

Conclusions: DTs hold transformative potential in health care, providing individualized care, operational optimization, and accelerated research. However, their adoption is hindered by technical, ethical, and financial barriers. Addressing these issues requires interdisciplinary collaboration, standardized protocols, and inclusive implementation strategies to ensure equitable access and meaningful impact.

KEYWORDS

digital twins; meta-review; health IT; applications; challenges; healthcare innovation; personalized medicine; operational efficiency

Introduction

Digital twins (DTs) are digital replicas of physical entities, processes, or systems dynamically updated with real-time data to reflect their real-world counterparts [1-4]. They enable predictive modeling, decision support, and personalized simulations in health care. DTs are often presented as 3D models or dashboards; for example, a cardiac DT might appear as a real-time, visual simulation of a patient's heart. Clinicians can interact with the model by testing different treatment scenarios, such as adjusting medication dosages or simulating surgical interventions, and observe how the heart behaves—showing changes in function, blood flow, or potential complications in real time. This technology leverages sensors, analytics, and machine learning to enable monitoring, simulation, and predictive insights. Characterized by their ability to adapt to live data inputs, DTs facilitate real-time optimization, risk

XSL•FO
RenderX

assessment, and enhanced decision-making across industries, from manufacturing to health care.

DTs offer transformative advantages over traditional tools by providing real-time insights and predictive analytics that enhance operational efficiency and decision-making. In sectors such as aerospace, DTs have reduced development times by up to 50% and significantly improved product quality [5]. As this technology advances, the global DT market is expected to grow rapidly, reaching US $110.1 billion by 2028, with an annual growth rate of 60% [6]. In health care alone, the market is valued at US $1.6 billion in 2023 and is projected to grow to US $21.1 billion by 2028, representing nearly 20% of the total DT market [7].

Health care applications of DTs offer the potential to simulate complex patient scenarios, support predictive diagnostics, and enable real-time, personalized treatment planning based on live health data [2]. Yet, as a new technology in the biomedical field, DT research in health care encompasses a wide range of clinical and operational applications at different stages of development, spanning from theoretical models to advanced experimental stages. This diversity—from individualized patient modeling to hospital workflow optimization—creates a fragmented body of research, where theoretical concepts and experimental models vary widely in sophistication. The variability in data sources, model design, and intended goals limits consensus on best practices and implementation pathways [8]. These factors highlight the need for a systematic review to synthesize the existing research, map out the various applications of DTs, and identify the gaps and challenges that remain.

The objective of this review is threefold. First, it seeks to provide a structured overview of the field, highlighting the diverse applications of DTs in health care. Second, it identifies and examines the barriers to DT adoption, along with potential strategies to address them. Third, it pinpoints gaps in existing knowledge to guide future research. The research questions addressed are as follows: (1) What are the primary applications of DTs in health care as identified in the extant literature? (2) What are the key challenges and limitations associated with implementing DTs in health care? (3) What gaps exist in current DT research in health care, and what are the implications for future research and practice?

Methods

Study Design

This meta-review was conducted and reported following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines to ensure comprehensive reporting and methodological rigor [9]. The decision to use PRISMA-ScR reflects the emergent nature of DT research in health care, which requires a scoping approach to capture the breadth and diversity of this rapidly evolving field. Despite its emergent status, the field has already produced multiple literature reviews, indicating a growing maturity in this research stream. This apparent paradox reflects the rapid pace at which new knowledge is generated in DT research, necessitating both a broad mapping of the field and a deeper synthesis of existing findings. To address this dual need, we drew inspiration from the methodological approaches of Sarrami-Foroushani et al [10], incorporating elements of scoping meta-reviews. This hybrid approach allowed us to systematically map the literature while evaluating all existing reviews, enabling a comprehensive understanding of the field without restricting our analysis to systematic reviews alone.

Search Strategy and Selection Criteria

A comprehensive literature search was conducted across multiple electronic databases without date restrictions, retrieving all available records up to May 15, 2024. The databases included PubMed, CINAHL, Web of Science, Embase, and PsycINFO. The search strategy and database selection were developed in collaboration with a professional librarian, who also executed the searches. The protocol for this review is registered on Open Science Framework [11].

Key search terms included “digital twin,” “intelligent twin,” and “mirror twin” combined with “review,” “systematic review,” and “meta-analysis.” To ensure the inclusion of all potentially relevant studies, the reference lists of selected papers were manually reviewed (snowballing). The complete search strategy for each database is provided in Multimedia Appendix 1.

We set inclusion criteria at the start of this study, allowing for potential revisions during the process. Papers were eligible for inclusion if they met the following criteria: (1) literature review paper (any type), (2) specifically about DT, (3) in the context of health care, and (4) accessible in full text in English or French. If a paper referenced DT applications in both health care and other settings, only the health care–related applications were considered.

All references were organized and deduplicated using EndNote (Clarivate), while Covidence (Veritas Health Innovation Ltd) was used for this study selection process.

Study Selection

Two reviewers (MR and FAES) independently screened all titles and abstracts, with an initial screening of 30 references conducted to ensure a shared understanding of the selection criteria. This was followed by a full-text screening of selected studies to confirm eligibility.

The meta-review initially yielded 3377 references. After removing duplicates, we screened the titles and abstracts of 2921 references, retaining 65 for full-text review. Ultimately, 25 references were included in this review, with reasons for excluding others provided in the figure in the Results section.

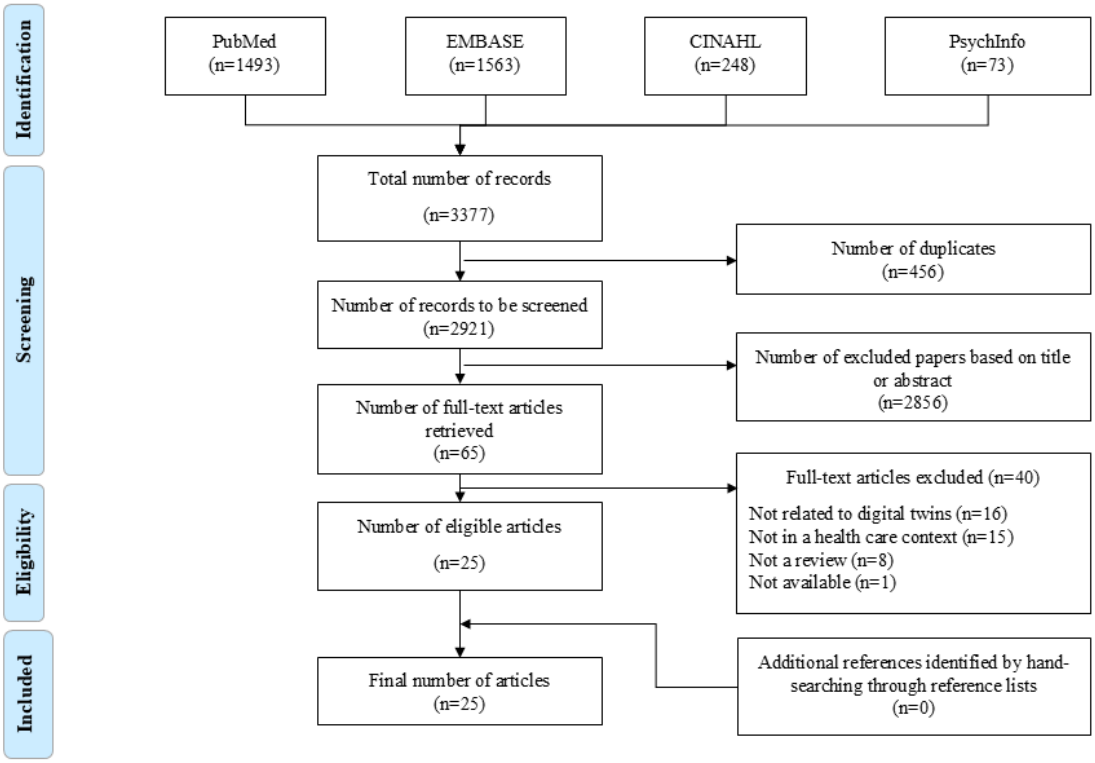
Data Extraction

Two authors (MR and FAES) independently extracted data from each of the included studies. Discrepancies were resolved through discussion. The following data were recorded: author, year, type of literature review (as reported), research questions, search period, included databases, final sample size, what DT models, DT application, potential or actual applications, DT provider, DT users, DT impacts, DT challenges, and main study results.

XSL•FO
RenderX

Data Analysis

A mixed methods approach was used, combining descriptive and thematic analysis to map the landscape of DT technology in health care. Descriptive analysis was used initially to summarize the general characteristics of the included studies, covering the range of review types, publication years, and scope of DT applications.



As most reviews did not specify the type of review conducted (eg, scoping review and narrative review), we classified all reviews based on predefined criteria [12,13]. This classification process was conducted by one reviewer (MR) and verified by a second reviewer (FAES). Any discrepancies were resolved through discussion, ensuring a consistent and accurate categorization of review types.

Results

General Characteristics of the Included Reviews

The included studies were published between 2021 and 2024 (Figure 1). Most of the reviews were categorized as scoping reviews (14/25, 56%) [1,2,14-25]. The remaining reviews included 6 narrative reviews (6/25, 24%) [26-31], 2 rapid reviews (2/25, 8%) [8,32], and 3 reviews for which a type could not be determined (3/25, 12%; see Multimedia Appendix 2 for the PRISMA-ScR checklist) [3,4,33].

Figure 1. Flow diagram.

Studied Populations and Key Users of DTs

Targeted Populations

The reviews cover various populations, defined as the individuals or groups impacted by the outcomes of the DT application. For example, a DT designed for personalized medicine would mainly benefit patients, whether or not they were diagnosed with a specific disease.

Health care providers are a key target in 48% (12/25) of the reviews [2,8,19-23,25,29,30,32,33]. Similarly, patients in general are the focus of another 48% (12/25) of the reviews [2-4,8,14,19-21,27,28,30,32], underscoring the broad potential of DTs to impact patient care across diverse contexts. Beyond these general categories, 32% (8/25) of the reviews examine the general population [2,8,14,20,21,27-29], highlighting DT applications that extend to broader public health or societal benefits. Some studies further specify particular patient populations, such as those with cardiovascular diseases (7/25, 28%) [1,2,14,17,22,30,31] or multiple sclerosis (3/25, 12%) [20,24,25], suggesting targeted applications of DTs in managing chronic or complex conditions. Lastly, a small subset of reviews (2/25, 8%) does not specify any population for particular DT uses [30,32].

Users of DTs

DTs are used by various stakeholders, each benefiting uniquely from this technology. The primary users include patients [4,22-25,28,32,33], hospital management [8,14,19,21,28-30,32], and health care professionals, including clinicians [1,3,4,14,16,17,19,22-27,29-31,33], physicians [14,20,30,32], and researchers [2-4,14-17,19,20,22-25,27,29-31,33].

For patients, DTs provide tools to actively manage health conditions. For instance, patients with migraines [32] benefit from DT systems that integrate data from wearables and health records, offering real-time monitoring and predicting potential migraine triggers. This capability empowers patients to make informed decisions about lifestyle adjustments and treatment

XSL•FO
RenderX

adherence, enhancing personal control over their condition by reducing the frequency or severity of migraine episodes.

In hospital management, DTs enhance operations across four main functions [8,14,21]. First, they improve safety by simulating emergency scenarios, allowing hospitals to identify risks and refine response protocols to protect patient well-being. Second, DTs streamline information management by consolidating real-time data from various sources, which improves communication and decision-making across departments. Third, in promoting health and well-being, DTs support personalized patient care by providing tools that adapt treatment protocols to individual data and forecast patient health trends, assisting health care professionals in delivering tailored interventions and preventive care. Lastly, DTs ensure efficient operational control by optimizing resource allocation, managing patient flow, and enabling predictive maintenance for equipment, which reduces patient wait times and enhances overall hospital efficiency.

DTs also serve as valuable tools for health care professionals, especially in supporting clinical decision-making and personalized treatment strategies. For complex cases such as cardiovascular and immune-mediated diseases, DTs enable clinicians to simulate patient-specific responses by integrating clinical, genetic, and environmental data. In cardiovascular care [1,17,19,20,30,31], DTs simulate heart function and disease progression, supporting tailored interventions based on individual patient profiles. By predicting and addressing patient-specific risks in real time, DTs enhance precision in medical practice, advancing the quality and personalization of care.

In sum, DTs support distinct user groups within health care. Patients and health care professionals, especially clinicians and physicians, benefit from DTs by providing precise, individualized care. Hospital management relies on DTs to enhance resource allocation, patient flow, and adaptability to changing demands. Clinicians and researchers leverage DTs to simulate virtual trials, advancing drug development and treatment refinement. These applications correspond to 3 main areas: personalized medicine, operational efficiency and resource management, and advancements in medical research and drug development.

Main Categories of DT Applications and Potential Benefits

DTs have emerged as a transformative tool in health care, offering tailored solutions across various applications. The following sections present 3 critical categories of DT applications, each accompanied by tables outlining the inputs, processes, and outputs relevant to each application. These tables provide a structured view of how concrete DT applications address specific health care challenges, optimize resources, and drive advancements in patient care and medical research.

Category 1: Customized Treatment and Care Optimization

One of the main applications of DTs in health care is customized treatment and care optimization (Table 1). DTs span various stages of development, from proof-of-concept models [1,8,14,17,19,20,28,30] to applications under active research and clinical testing [1,4,8,14-17,19,20,22,30-32]. Companies such as Dassault Systèmes, through their Living Heart Project [1,14,17,19,20], and Siemens [14,17,19,26] are at the forefront of these advancements. Other institutions have also developed some specific DTs, such as Medtronic with 3D cardiac maps [14,17] and Oklahoma State University with targeting tumor-only locations [14]. Some studies underscore the potential for DTs in complex areas [1,8,17,19,20,23,24,26,29,30,32], underscoring the nascent stage of this innovation in the field. Given its relative novelty, it is unsurprising that some review articles focus on potential applications while others concentrate on actual implementations.

XSL•FO
RenderX

Table 1. DT[a] applications in customized treatment and care optimization.

Problem (and root causes)	Inputs	Processes	Outputs

• Variability in patient physiology
• Delayed detection
• Limited predictive capability for disease progression
	• Data:
	  • Clinical data
	  • Genomic data
	  • Imaging data
	  • Biomarkers
	  • Lifestyle data
	  • Demographic data
	• Sources:
	  • Electronic health record systems
	  • Disease registries
	  • Laboratory reports
	  • Wearable devices
	  • Surveys and questionnaires
		• Simulation: the DT can simulate a patient's disease progression, the impact of treatment options, and various clinical scenarios, such as a sudden deterioration in condition or the patient's response to a new medication. It can also model the effects of daily changes in lifestyle, nutrition, and medication adherence
		• Optimization: based on simulation results, the DT can optimize personalized treatment plans, suggesting specific drug doses, dietary adjustments, or lifestyle interventions tailored to each patient's condition and medical history
		• Real-time decision-making: the DT can immediately alert health care providers to emerging risks such as arrhythmias or abnormal glucose levels, prompting timely interventions or adjustments in treatment
			• Real-time monitoring and prognosis
			• Improved diagnosis
			• Tailored health interventions and lifestyle guidance

[a]DT: digital twin.

The customized treatment and care optimization approach addresses key challenges in health care, including variability in patient physiology, delayed detection of disease progression, and limited predictive capabilities. By integrating diverse data inputs—such as clinical records, genomic information, imaging data, biomarkers, and lifestyle and demographic factors—sourced from electronic health record (EHR) systems, disease registries, and wearable devices [1,8,14,19,20,23,32,33], DTs enable comprehensive simulations of patient health profiles.

Through these simulations, DTs model disease progression, evaluate potential treatment options, and assess various clinical scenarios, such as predicting patient responses to new medications or lifestyle changes [1,2,4,14,17,20,22,24,28-30,32]. Beyond simulation, DTs support optimization by dynamically tailoring treatment plans to a patient's evolving condition, which may include adjusting medication dosages, recommending dietary modifications, or suggesting lifestyle changes to improve outcomes [1,2,4,8,14,19,20,22-24,30,32].

Moreover, DTs support real-time decision-making by providing health care providers with alerts about emerging risks, such as abnormal glucose levels [1,14,30] or arrhythmias [31], enabling timely interventions. The outputs of this application—real-time monitoring, improved diagnosis, and personalized health interventions—underscore the potential of DTs to enhance personalized care and responsiveness in clinical practice.

Category 2: Operational Efficiency and Resource Management

Another significant category of DT applications in health care refers to operational efficiency and resource management (Table 2). DT technology serves as a valuable tool for optimizing hospital operations across various stages, from concept development [8,32] to active deployment [4,8,14,30]. For instance, GE HealthCare has developed a Command Center leveraging DTs to simulate and enhance patient flow in hospitals, including Johns Hopkins Hospital in Baltimore [8,14]. Similarly, organizations such as BioSecure and Siemens Healthineers have implemented DT-based solutions in health care settings [2,8] to optimize supply chain processes, improve response times for critical patients, and streamline workflows. While many initiatives demonstrate tangible benefits, others remain at the conceptual or exploratory stage, showcasing the potential for future DT applications in operational efficiency and resource management [21,23,32].

XSL•FO
RenderX

Table 2. DT[a] applications in operational efficiency and resource management.

Problem (and root causes)	Inputs	Processes	Outputs

• Unpredictable patient volumes
• Difficulty in dynamically adapting workflows in high-stakes situations
• Limited real-time operational insights that lead to inefficiencies and bottlenecks
	• Data:
	  • Patient data
	  • Historical trends
	• Sources:
	  • Hospital information systems
		• Simulation: the DT can simulate hospital scenarios. By modeling these patterns, DTs can analyze how variations in patient flow affect wait times, bed availability, staffing requirements, and equipment usage, giving administrators foresight into potential bottlenecks
		• Optimization: based on simulation results, the DT can recommend ideal staffing levels, identify underused or overbooked resources, and schedule maintenance during low-demand periods
		• Real-time decision-making: the DT can suggest workflow shifts, such as rerouting noncritical cases, and improve discharge planning to free up beds efficiently
			• Optimized patient flow and resource
			• Real-time adjustments in staffing and equipment usage based on patient arrivals
			• Improved discharge planning and maintenance scheduling to ensure optimal bed availability and patient throughput
			• Efficient crisis management strategies

[a]DT: digital twin.

The operational efficiency and resource management category addresses critical challenges such as unpredictable patient volumes, the difficulty of dynamically adapting workflows in critical situations, and the lack of real-time operational insights that often result in inefficiencies and bottlenecks. By leveraging inputs such as patient data and historical trends from hospital information systems [19,23], DTs can simulate various hospital scenarios. These simulations enable administrators to analyze how changes in patient flow impact key factors such as wait times, bed availability, staffing needs, and equipment use, thereby providing foresight into potential bottlenecks [2,8,14,19,23].

Beyond simulation, DTs enable optimization by recommending staffing adjustments, identifying underused or overburdened resources, and scheduling maintenance during low-demand periods [8,14,19,23,30,32]. Furthermore, DTs support real-time decision-making by suggesting workflow modifications, such as reallocating noncritical cases or expediting discharge planning to free up bed capacity [2,4,8,14,19,23]. The outputs of this category—optimized patient flow, real-time staffing and equipment adjustments, improved discharge planning, and effective crisis management strategies—highlight the significant potential of DTs to enhance resource use and operational responsiveness in health care facilities.

Category 3: Advancements in Medical Research and Drug Development

DT technology holds immense potential to transform medical research and drug development through in silico clinical trials, encompassing both prospective initiatives [3,17,19,30] and current applications (Table 3) [2-4,14,15,17,19,30]. For instance, collaborations involving Unlearn AI, Merck, Nvidia, and the University of Florida [14,19] are using DT models to simulate patient responses and design virtual clinical trials. These efforts enable the execution of single-arm studies, which are particularly valuable in scenarios where traditional randomized controlled trials may be unethical or impractical, such as rare diseases or high-risk populations. By simulating control groups, DTs help to reduce the need for placebo arms and contribute to minimizing adverse drug reactions [14,19,30]. Other applications of DTs focus on accelerating drug discovery and optimizing drug screening processes, offering promising avenues in pharmaceutical research [2-4,15,17].

XSL•FO
RenderX

Table 3. DT[a] applications in advancements of medical research and drug development.

Problem (and root causes)	Inputs	Processes	Outputs

• High costs and time demand of physical trials
• Ethical challenges in testing on human participants, especially in vulnerable populations
• Limited ability to predict individualized responses in diverse patient populations
	• Data:
	  • Clinical data
	  • Patient data
	  • Genomic data
	  • Imaging data
	  • Physiological data
	• Sources:
	  • Electronic health records
	  • Wearable and remote monitoring devices
	  • Health databases
	  • Pharmaceutical and clinical trial data
		• Simulation: the DTs are used to simulate in silico clinical trials, allowing researchers to predict drug efficacy and safety across diverse patient profiles without the need for large-scale physical trials
		• Optimization: with data from DTs, researchers can optimize trial parameters by adjusting dosages and selecting ideal patient cohorts. This approach refines drug formulations and identifies optimal therapeutic protocols, reducing unnecessary risks and costs associated with traditional clinical trials
		• Real-time decision-making: If adverse reactions are predicted, DTs can recommend alternative treatment strategies, improving patient safety and the trial's overall effectiveness
			• Synthetic control groups to minimize physical trials and enhance safety
			• Predictive modeling of drug responses and adverse reactions, allowing for more accurate and efficient trials
			• Simulations for drug efficacy testing, reducing the need for early-stage in-person trials
			• Virtualized, patient-specific trials that allow researchers to adjust dosages and predict patient outcomes

[a]DT: digital twin.

This category of DT applications addresses critical challenges in clinical trials, including the high costs and time demands of traditional physical trials, ethical concerns related to testing on human participants—particularly in vulnerable populations—and the limited capacity to predict individualized patient responses. By integrating diverse data inputs such as clinical, genomic, imaging, and physiological data from sources such as EHRs, health databases, and pharmaceutical trial data [2,3,30], DTs enable the simulation of clinical trials in digital environments.

These simulations allow researchers to evaluate early-stage drug efficacy and safety across diverse patient profiles without the need for large-scale physical trials. This approach reduces costs and enhances safety through synthetic control groups [2-4,14,17,19]. Beyond simulation, DTs enable the optimization of trial parameters by adjusting dosages, selecting ideal patient cohorts, refining drug formulations, and identifying optimal therapeutic protocols. These capabilities help minimize unnecessary risks and costs [2-4,14,15,19].

Additionally, DTs support real-time decision-making by predicting adverse reactions and suggesting alternative treatment strategies to improve both patient safety and the trial's overall success [2,3,14,17,19]. The outputs of these applications—including synthetic control groups, predictive modeling of drug responses, and virtualized patient-specific trials—demonstrate how DTs can significantly enhance the efficiency, accuracy, and personalization of clinical trials, making them more adaptable to the needs of diverse patient populations.

Types of DT

The classification of DT technologies originates from industry practices (eg, [34]), where DTs are typically categorized based on the scale and scope of the entities they represent. This framework enables a clear distinction between DTs by their purpose and level of detail, ranging from individual components to larger systems and entire processes.

Component or part DTs represent the most granular level, simulating individual components within larger systems. Examples include specific cardiac functions, such as aortic aneurysm [19], coronary anatomy [31], and coronary vessels [17]. Additionally, they encompass representations of individual cognitive profiles [25]. Asset or product DTs replicate individual physical assets, such as organs or medical equipment, to provide insights into performance and maintenance needs. This category includes organs [1,3,14,16,17,19,20,22,24,26,30,31], such as the heart [1,14,17,19,20,30,31] or the brain [14], as well as, to a lesser extent, diseases and therapeutic equipment [14,33]. System or unit DTs focus on the interactions of multiple components within a system. Examples include models of the human body (IDs 4, 21, 22, and 25), patients in various health conditions [1-3,14,17,19-21,27-30,32], and intensive care unit systems [8,14]. Lastly, process DTs simulate entire workflows to optimize health care operations. These include broader infrastructure models such as buildings [29], health care systems [8], hospitals [8,19], and physical systems [23].

DT Implementation Challenges

The implementation of DT technology in health care organizations faces several critical challenges, which can be

XSL•FO
RenderX

grouped into 3 main categories: data and model integrity; ethical, regulatory, and governance challenges; and implementation and socioeconomic disparities.

First, data and model integrity encompasses issues related to data quality, availability, and the robustness of DT models. Limited access to high-quality data, difficulties in data integration, and privacy concerns represent significant barriers to adoption. Additionally, computational power demands and scalability challenges further complicate implementation [1,2,4,8,14-21,23,24,26,27,29,32,33]. Ensuring model validation and reproducibility remains a pressing issue, as the absence of standardized methods and randomized controlled trials undermines the clinical credibility of DTs. Moreover, the need to enhance model complexity to better capture individual patient variations highlights the current technological limitations of DTs [3,16,19,22,26,28,31].

Second, ethical, regulatory, and governance challenges address ethical considerations and the regulatory frameworks surrounding the use of DTs. Persistent concerns about bias, fairness, and data ownership highlight the risk of exacerbating existing socioeconomic disparities. Ethical dilemmas arise regarding informed consent and data ownership, particularly in the context of data sharing and potential misuse [2,4,8,14,16,17,19,20,24,29]. Furthermore, regulatory frameworks for DTs remain underdeveloped, creating uncertainties in legal governance, intellectual property protection, and alignment with existing health care regulations [4,8,17-20,24].

Third, implementation and socioeconomic disparities address the challenges of integrating DTs into clinical practice and the socioeconomic barriers to widespread adoption. Health care professionals often express concerns about trust, transparency, and the risk of job displacement, contributing to resistance against DT implementation. Additionally, there is a pressing need for enhanced education and training for both health care providers and patients to bridge the knowledge gap between clinicians and data scientists [4,14,16,17,23,30,32]. On a broader scale, the socioeconomic impacts of DTs include the potential to deepen the digital divide, limit access to advanced technologies, and enable financial barriers such as cost and reimbursement issues, which hinder broader implementation [1,18-20].

Discussion

Principal Results

This review highlights the transformative potential of DT technology across 3 critical applications in health care: personalized medicine, operational efficiency, and medical research and drug development. While these advancements present significant opportunities, they also introduce challenges that require attention to fully realize the benefits of DTs.

In personalized care, DTs leverage diverse data sources—such as clinical records, genomic information, and real-time inputs from wearable devices—to create patient-specific health simulations. These simulations serve as a foundation for predictive modeling, enabling tailored interventions and optimized treatment plans, particularly in complex domains such as cardiovascular care and immune-mediated diseases. However, many applications remain at the proof-of-concept stage, underscoring the need for further research, data standardization, and validation efforts to transition from experimentation to widespread clinical adoption.

DTs enhance health care operations by simulating patient flow, resource allocation, and emergency scenarios, offering actionable insights to improve efficiency. For instance, GE HealthCare's Command Center demonstrates how DTs can reduce bottlenecks, optimize staffing, and enhance patient experiences [13]. However, adoption remains limited due to resistance to change, significant computational demands, and challenges in integrating DTs into existing workflows. Overcoming these barriers will require targeted training and interdisciplinary collaboration to facilitate the operational implementation of DTs.

DTs are transforming medical research by facilitating digital clinical trials and predictive modeling of drug responses. These innovations can significantly reduce the cost and ethical concerns associated with traditional trials while improving trial efficiency and safety. For example, collaborations between Unlearn AI and Merck are leveraging synthetic control groups to accelerate drug development [18]. However, broader implementation in this domain is contingent upon addressing critical challenges, including ensuring data quality, achieving scalability, and navigating regulatory approval processes.

Challenges and Opportunities in Advancing DT Technology in Health Care

Overview

While our findings highlight the significant promise of DTs in health care, they also reveal that most current applications remain in their infancy, with many still at the proof-of-concept or early implementation stage. These initial deployments, though limited in scope, demonstrate promising results and lay a solid foundation for future advancements. The potential applications of DTs extend well beyond these early efforts, offering innovative solutions to address some of health care's most pressing challenges. However, overcoming key barriers is essential to making DT technology more accessible, trustworthy, and practical for health care providers, thereby paving the way for wider adoption and meaningful impact.

First, challenges related to data and model integrity represent a significant concern for DT technology in health care. Integrating large datasets from wearables, EHRs, and imaging systems involves complexities in standardization, quality control, and real-time synchronization [35]. Ensuring model accuracy and minimizing artificial intelligence biases, as a key technology supporting DTs, are critical to making DTs reliable for high-stakes health care applications [36]. Addressing these issues requires standardized frameworks and rigorous validation protocols. Legal frameworks such as the European Union's General Data Protection Regulation could serve as a model for implementing robust data governance practices within DT technology. To minimize artificial intelligence biases, validated practices established in EHRs can be leveraged to enhance data

XSL•FO
RenderX

quality and ensure patient information integrity. Further, transparent validation processes, akin to clinical trials for medical devices, would foster trust and ensure DT reliability in clinical settings.

Next, ethical, regulatory, and governance challenges present significant concerns, particularly as DTs rely on sensitive health data. Issues such as data privacy, ownership, and the potential for algorithmic bias must be addressed to avoid undermining public trust and exacerbating disparities in care [37]. Adapting regulatory frameworks from virtual reality and internet of things devices could establish standards for data ownership, informed consent, and transparency, thereby mitigating risks of unauthorized data use. Furthermore, aligning these standards with international ethical guidelines could enhance public confidence in DT technology. The establishment of independent monitoring organizations—such as the European Medicines Agency [38], or ICANN (Internet Corporation for Assigned Names and Numbers) [39]—could provide consistent oversight and accountability. Such organizations would play a critical role in ensuring the ethical and responsible deployment of DTs across health care systems.

Finally, socioeconomic barriers to DT implementation raise concerns about exacerbating existing disparities in health care [40]. The high costs of advanced technologies create substantial obstacles for low- and middle-income countries to access essential tools needed for health innovation and economic modernization [41]. Moreover, the monopolization of patents and restrictive trade agreements by Western countries limits these nations' ability to develop local solutions [42]. Dependency on international loans often shifts focus toward debt repayment instead of strategic investments in health care infrastructure, further perpetuating inequality and widening the digital divide. Lessons learned from the implementation of EHRs and connected medical devices show that cost-sharing models and collaborative funding initiatives can promote more equitable access to DT technology [43]. Open-source tools and public-private partnerships involving technology companies, health care providers, and research institutions offer additional pathways to reduce costs and enhance accessibility. Additionally, targeted training programs for health care professionals can bridge the skills gap, facilitating the successful adoption of DTs across diverse health care settings [44,45].

Future Directions for DT Technology in Health Care

Expanding DT technology in health care opens several important avenues for future research. A key challenge is the lack of a universally accepted definition, particularly in health care. While most studies define the term consistently, some variability persists, reflecting broader inconsistencies in the field. This lack of consensus complicates efforts to synthesize findings and assess the maturity of DT applications. Recognized definitions, such as those by the National Academies [46] and Drummond and Gonsard [47], emphasize the dynamic, predictive, and decision-informing attributes that distinguish DTs from other digital tools, which set them apart from other digital tools. Achieving definitional clarity is foundational for advancing practical applications, as inconsistent definitions risk undermining coherence in design, validation, and implementation. Future research should prioritize refining and standardizing DT definitions to foster alignment between research and real-world needs, enabling trust among stakeholders and paving the way for innovative, targeted health care solutions.

Future research should prioritize the practical implementation of DTs through detailed case studies and real-world applications, demonstrating their feasibility and clinical impact. Transparency and explainability are equally critical for building clinicians' trust in DT recommendations and ensuring they can effectively interpret these insights. Addressing challenges related to scalability and data standardization is essential for widespread adoption, alongside rigorous validation through real-world clinical trials to establish the accuracy, safety, and seamless integration of DT systems into health care infrastructures.

Ethical considerations, including AI biases and patient privacy, require innovative approaches to algorithm development and the refinement of data ownership and informed consent models. Moreover, research into the socioeconomic impacts of DTs and cost-effective implementation strategies is vital to ensure accessibility for underserved populations. Special attention should be given to low-resource settings, where barriers such as cost, infrastructure, and training may hinder adoption. Collaboration between private and governmental sectors can ensure DT technology benefits a diverse range of patients and institutions, paving the way for equitable and sustainable adoption.

Limitations

This review has limitations that may affect the interpretation of its findings. As a meta-review, our analysis is constrained by the scope and depth of the included studies, which may not comprehensively capture all aspects of DT applications and developments in health care. Furthermore, the rapid growth of DT research in health care, particularly with significant contributions from private industry, limits the visibility of current implementation efforts. Industrial stakeholders often hesitate to publish detailed information about their proprietary DT technologies and methodologies, a challenge also observed during the COVID-19 pandemic [48]. This restricts access to real-world data, reducing insights that could deepen our understanding of DT advancements.

Conclusions

Though still in their early-stage applications, DTs hold immense potential to revolutionize health care through personalized medicine, operational efficiency, and accelerated medical research. However, realizing this potential requires addressing key challenges related to data integrity, ethical concerns, and socioeconomic disparities. Strategic investments, supportive policies, and collaborative research initiatives are crucial to ensuring equitable development. With an inclusive approach, DTs can transition from a visionary concept to a practical and transformative tool that enhances health care outcomes for diverse populations.

Abstract

Background: Online record access (ORA) is being increasingly implemented internationally. Despite reported benefits for patients, health care professionals (HCPs) have raised concerns about potential disadvantages. To date, no review has examined the empirical evidence on whether and how documentation changes following the introduction of patients' ORA.

Objective: This scoping review aimed to examine potential subjective and objective changes in HCPs' documentation after using patients' ORA.

Methods: A scoping review was conducted using a methodological framework for scoping reviews and data from 4 electronic databases. Studies examining objective and subjective changes in clinical documentation following the implementation of ORA, specifically those related to actual use experiences (rather than previous expectations), up to July 2023, were included. We used the Mixed Methods Appraisal Tool to assess the quality of the included studies. The narrative synthesis and reporting of findings were guided by the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews).

Results: Of the 3143 papers screened, 42 (1.34%) were included in this review. The included studies mainly used qualitative methods and were predominantly published after 2016 in the United States. The included studies were conducted in different settings (inpatient and outpatient) and clinical areas (somatic, mental health, and other). In total, 8 studies analyzed clinical notes, while the remaining studies focused on the experiences of patients, HCPs, and other stakeholders with ORA. Objectively, a decrease in complexity, an increase in readability, and a change in the emotional tone of the clinical notes were observed. The length of the clinical notes was observed to change both objectively and subjectively, although the direction of this change was inconclusive. However, many HCPs also reported writing notes that were less open and more restrictive to protect sensitive or hypothetical information. While for some HCPs the implementation of ORA made the clinical notes a less efficient and valuable working tool, others perceived that ORA opened up new therapeutic opportunities through direct contact with patients.

Conclusions: The question of whether an inherently uniform clinical note can meet the diverse needs of different health care stakeholders remains unresolved, highlighting the challenges of standardizing practices in this complex sector. While ORA may

XSL•FO
RenderX

encourage HCPs to make their clinical notes more patient friendly, it may also compromise the integrity of documentation by omitting sensitive findings and expert judgment, which can put patients at risk and lead to errors that increase the risk of malpractice. Given the limitations of digital documentation in fostering trust, it is imperative to prioritize meaningful patient-HCP interactions. The use of compensatory measures, such as parallel documentation and restricted access to clinical notes, indicates systemic problems and suggests that current practices are suboptimal.

Introduction

Background

The electronic health record (EHR) has evolved over time. Initially designed as a memory aid for physicians, a communication tool among clinicians, and a system for billing and reimbursement, it has more recently been made accessible to patients [1,2]. In a growing number of countries, patients are now granted partial or full access to their EHRs [3-7]. The Nordic countries and the United States have been at the forefront of this movement [8-10]. A crucial component of patients' online record access (ORA) involves accessing the clinical free-text notes written by clinicians. Granting patients access to these notes is commonly referred to as "open notes" in the literature [3]. Patient ORA reflects the zeitgeist of greater transparency in societal institutions and health care [11]. Several benefits have been cited as motivations for this practice, including empowering patients through transparency and access to information, as well as fostering innovation within the health application economy [8,12].

While ORA fulfills patient demand for transparency in care, it also necessitates a cultural shift toward higher degrees of openness among institutions and HCPs, possibly acting as a disrupter in information management behaviors among the clinicians creating them. Previous research indicates that health care professionals (HCPs) have frequently expressed skepticism toward patients' ORA [13-15]. HCPs have voiced concerns about increased workload, changed clinical routines, and ORA impacting patient safety and privacy [1,13,14,16]. Some have expressed concerns over spending more time writing notes and addressing patient inquiries and also anticipated confusion and offense among patients, particularly regarding mental health issues [3]. In terms of documentation, many HCPs expected to alter both the content and tone of their notes when patients have ORA, indicating that the practice could potentially undermine the integrity of their records [4,5,17]. For instance, a tendency to avoid technical terminology and medical jargon to enhance patient comprehension might detrimentally affect multidisciplinary communication within the team [5,18]. Other HCPs worried that they may become less detailed or candid in their documentation, feeling the need to omit information or resort to parallel documentation (a so-called shadow record) to shield patients from potentially harmful or disruptive information [13,14,19,20]. An often-overlooked risk of ORA is that individuals considered vulnerable may be pressured into revealing their records to third parties, such as relatives or abusers, potentially leading to unauthorized access to sensitive patient information without consent [13,14,19,20]. However, it is also possible that ORA could make notes more patient friendly by encouraging clinicians to use more patient-centered, more understandable, and less stigmatizing language while stimulating communication between HCPs and patients [4,21].

Studies investigating the impact of ORA on clinical documentation have predominantly concentrated on the patient experience, with limited research examining the HCPs' perspective [22]. As noted by Blease et al [1], while these studies investigate self-reports about possible documentation changes, few studies have focused on objective changes following implementation. Where such studies exist, they appear to offer inconclusive results [4,23,24] and are frequently hindered by methodological limitations. There is a growing body of qualitative research [25], along with research using natural language processing methods to examine the language used by clinicians in their records, including the potential for stigmatizing language [22]. However, it remains unclear from these studies whether patient ORA influences or indeed enhances the quality of record keeping, given the awareness that patients may read the clinician's notes [22,26].

Objectives

As highlighted earlier, HCPs are often reluctant or critical toward granting patients ORA and anticipate an additional documentation burden upon its introduction. Therefore, this scoping review focuses exclusively on studies containing postimplementation data, encompassing the experiences of various stakeholders, such as patients, HCPs, and other health care providers, while excluding preimplementation expectations. This study seeks to (1) identify, compile, and assess reported objective and subjective changes in documentation following the implementation of ORA; (2) enhance stakeholders' knowledge of the types of documentation changes that may arise because of ORA policy implementation; (3) highlight implications for documentation practices and offer recommendations for improving future clinical practice; and (4) identify knowledge gaps warranting further research.

Methods

Scoping Review

Compared to the systematic review method, which is guided by a strongly focused research question, a scoping review aims to broaden the spectrum of the available evidence in a relatively

XSL•FO
RenderX

new field of research, allowing its breadth and depth to be clearly seen [27]. We conducted a scoping review following the framework proposed by Arksey and O'Malley [27]. Their approach consists of the following five stages: (1) identifying the research question, (2) identifying the relevant studies, (3) selecting eligible studies, (4) collecting data, and (5) summarizing data and synthesizing results. The review is reported following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Multimedia Appendix 1) [28,29]. We adhered closely to the methodological approach outlined in our published review protocol [30]. Any minor deviations are comprehensively described.

Stage 1: Identifying the Research Question

Through discussions with the research team, we decided on the following research questions: (1) Does clinical documentation change after introducing ORA for patients? and (2) If so, what objective and subjective changes arise after ORA implementation? By objective, we mean the differences that can be demonstrated by a direct, quantifiable comparison of clinical notes before and after the implementation of ORA. By subjective, we refer to clinicians' perceptions of how they write their notes after ORA implementation. In the context of this scoping review, we define ORA as any channel in which patients have electronic access to their patient records (eg, through the internet and via tethered patient portals and apps).

Stage 2: Identifying Relevant Studies

First, the research team performed a rigorous manual search to obtain a basic overview of the available evidence and to refine the scope of the review as well as the search strategy, as suggested by Popay et al [31]. The literature search was then conducted in the following 4 databases on July 31, 2023: APA PsycINFO, CINAHL, PubMed, and Web of Science Core Collection. The deduplication process was then performed. The search strategy consisted of three key concepts: (1) EHRs, (2) sharing EHRs with patients, and (3) changes in documentation, which were combined with the Boolean "AND" (Textbox 1). The search terms were adapted according to different databases. The complete search string can be found in Multimedia Appendix 2.

Textbox 1. Key concepts of the search strategy.

Search string for the electronic health record

- "inpatient portal*" OR "open notes" OR opennotes OR PAEHR OR "patient portal*" OR "patient web portal*" OR "Electronic Health Records"
- "clinic notes" OR "clinical notes" OR "progress notes" OR "doctors notes" OR EHR OR "health record*" OR "health care record*" OR "medical record*" OR "mental health notes" OR "patient record*" OR "psychiatric notes" OR "psychotherapy notes" OR "visit notes"

Search string for sharing the electronic health records with patients

- "guardian access" OR "parental access" OR "parents access" OR "patient access*" OR "patients access*" OR "patient online access" OR "patients online access" OR "proxy access" OR "shared medical record*" OR "shared health record*"

Search string for documentation changes

- "Language"[Mesh] OR "Attitude"[Mesh] OR "Comprehension"[Mesh]
- accura* OR ambigu* OR characteristics OR characters OR clarity OR content* OR completeness OR comprehend* OR comprehensibl* OR comprehension* OR correctness OR dialog* OR express* OR directness OR impression* OR inaccura* OR incomplete* OR incomprehen* OR incorrectness* OR intelligib* OR interpret* OR intuitive* OR language OR length OR linguistic* OR misconception* OR misinterpret* OR misread* OR misunderstand* OR monolog* OR negative* OR pattern* OR positive* OR pronoun* OR readab* OR style* OR simplicity OR terminolog* OR transparen* OR truthful* OR unambigu* OR understand* OR untruthful* OR veracity OR wordcount* OR words OR writing
- OR attitude* OR emotion* OR experience* OR perception* OR satisfact*
- OR adopt* OR alter* OR censor* OR change* OR changing OR difference* OR introduc* OR implement* OR modif* OR postimplement*

Stage 3: Selecting Eligible Studies

Inclusion and Exclusion Criteria

Inclusion and exclusion criteria were defined by the entire research team and were applied in the study selection process (Textbox 2). Due to the limited number of publications available on the subject, there were no restrictions on the study type. As ORA is only gradually being implemented in various countries, we refrained from any location restrictions. A wide variety of approaches exist to make clinical notes available to patients electronically [32]. We included all studies examining the actual implementation and the use of patient ORA regardless of the platform (eg, web browser or mobile apps). Studies that explored the sharing of hard copies of patients' clinical records were excluded.

During the review process, we refined the inclusion and exclusion criteria as follows: we required studies to provide empirical data on changes in clinical documentation resulting from ORA. Studies that solely focused on secure messaging between patients and clinicians were excluded.

Inclusion criteria

- Study design: all study types
- Publication: original, peer-reviewed work including empirical data published between January 1, 2005, and June 30, 2023, in English
- Study location: all medical disciplines, all health care settings, and no location restrictions
- Study participants: patients and health care professionals of all ages
- Studies that examine actual use by stakeholders and their experiences with patient-accessible electronic health records
- Studies that provide empirical data on documentation changes resulting from the use of online record access

Exclusion criteria

- Paper-based, disc, or USB sharing of patients' records
- Articles without empirical data (eg, comments, editorials, and news)
- Gray data (websites, tweets, and blogs)
- Studies that exclusively investigate expectations about patient-accessible electronic health records
- Studies on secure messaging

Study Selection Process

We used Rayyan Software (Rayyan Systems, Inc) for conducting a collaborative, single-blinded title and abstract screening following the predefined eligibility criteria [33]. All research team members participated in this process, and at least 2 people evaluated each record of the result set. Discrepancies were discussed, taking the full texts of the corresponding studies into account. In case of disagreements that could not be resolved, a third reviewer was involved and entrusted with the decision of including or excluding the study.

Stage 4: Collecting Data

After selecting the studies to include, metadata (eg, title, authors, and publication year) of the remaining records were exported and summarized in a Google Sheets (Google LLC) spreadsheet for further processing. To extract and organize relevant data from included studies, the spreadsheet was extended by the following parameters based on the studies' full text: country, study design, sample, characteristics of study participants (eg, gender, age, ethnicity, and type of stakeholder), treatment setting and medical specialty, study purpose, and relevant results (Multimedia Appendix 3). Data extraction was performed by EM-D and checked for correctness and completeness by CL. The quality and methodological rigor of the studies were assessed using the Mixed Methods Appraisal Tool (MMAT) [34]. Two reviewers (CL and EM-D) independently conducted the MMAT grading of all studies and reached consensus concerning the methodological quality of the studies (Multimedia Appendix 4). Two additional researchers (AK and JS) validated the MMAT grading for correctness.

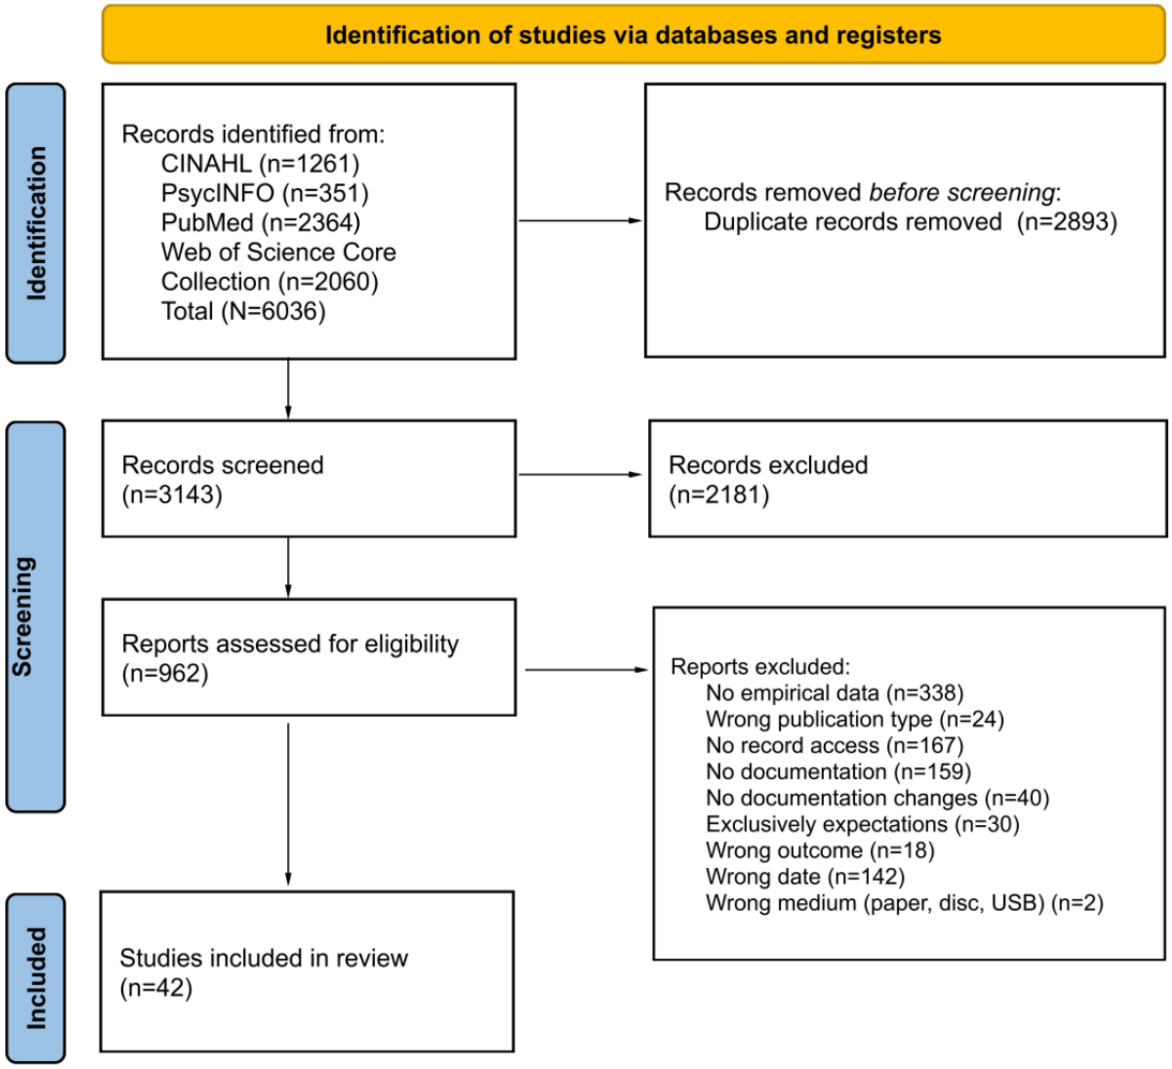
Stage 5: Summarizing Data and Synthesizing Results

Study results were extracted from the full texts by the lead author (EM-D) and summarized in (1) a reduced format within a textbox, providing an overview of the findings from all included studies; and (2) a detailed version for narrative synthesis. The latter was analyzed independently by 2 researchers (CL and EM-D) using thematic analysis [35]. Objective and subjective changes in HCPs' documentation practices after the introduction of patient ORA served as guiding deductive themes, informed by the research question. However, they were open to modifications during the analytic process. As suggested by Levac et al [28], we aimed to identify patterns and relationships within and across studies to identify potential factors influencing documentation after ORA implementation. In assessing the methodological rigor of the studies, we also envisaged the potential to identify research gaps; for example, we predicted that there may be a preponderance of survey research investigating clinicians' perceptions about documentation changes rather than studies investigating objective markers of any such documentation changes. While the former studies may be useful, they may be compromised by responder biases. Results were discussed and approved by the entire research team.

Ethical Considerations

This study did not require ethics approval, as it only used publicly available data and followed the scoping review methodology.

Results



Study Selection

A total of 6036 records were identified: 1261 (20.89%) from CINAHL, 351 (5.82%) from PsycINFO, 2364 (39.17%) from PubMed, and 2060 (34.12%) from the Web of Science Core Collection. After removing duplicates, 52.07% (3143/6036) of the records remained for title, abstract, and keyword screening. At this stage, an additional 36.41% (2198/6036) of the records were eliminated, leaving 15.66% (945/6036) of the records for full-text screening to check eligibility. During the full-text screening, 903 studies were excluded, resulting in a final selection of 42 studies that met the inclusion criteria and could be included in the review. The PRISMA (Preferred Reporting Item for Systematic Reviews and Meta-Analyses) flow diagram

XSL•FO
RenderX

(Figure 1), adapted from the study by Page et al [36], provides a detailed representation of the study selection process.

Figure 1. PRISMA (Preferred Reporting Item for Systematic Reviews and Meta-Analyses) flow diagram for study inclusion. ORA: online record access.

Basic Characteristics of the Body of Evidence

The included studies mainly used qualitative methods, but quantitative, descriptive, and mixed methods were also frequent. Of the 42 studies included, 23 (55%) were conducted in the United States, followed by Sweden with 9 studies (21%). Since 2017, the number of articles published on the topic of documentation changes following ORA implementation has remained relatively constant at 4 to 6 relevant articles per year. Only 19% (8/42) of the included studies analyzed clinical notes and reported on objective documentation changes, while most studies (34/42, 81%) investigated subjective documentation changes. A comprehensive overview of the basic parameters of the included studies can be found in Table 1.

Search Results

While several studies specifically examined documentation changes due to ORA implementation (11/42, 26%) [23,24,40,43,45-47,49,53,67,68], many more reported them as a secondary outcome (31/42, 74%). The results were divided into three groups: (1) objective changes, (2) subjective changes, and (3) influences on documentation practices. Both objective and subjective changes and a lack of changes were observed in the included studies. The categories identified for subjective changes were note characteristics, changes in content and functionality, and absence of subjective changes. Figure 2 provides a visual summary of the objective and subjective changes identified in the documentation. For documentation behaviors, the categories identified were influence on writing practices, secure information, and influence of sociodemographics.

XSL•FO

Figure 2. Graphic overview of the objective and subjective changes in documentation.

Objective Changes in Documentation

Overview

Of the 42 studies we reviewed, 8 (19%) examined clinical notes and 7 (17%) reported objective changes in documentation due to ORA. The number of notes analyzed varied notably, spanning from 200 [4] to 164,806 [53]. The studies used validated scales and tools such as Linguistic Inquiry and Word Count, Flesch-Kincaid Grade Level, Flesch Reading Ease Scores, Gunning Fog Index, Measure of Gobbledygook, Coleman-Liau Index, and Automated Readability Index as outcome measures, alongside other metrics such as the number and frequency of abbreviations, word frequencies, co-occurrences between frequent words, and note length in characters. Most studies (1/15, 7%) found changes in clinical notes after the implementation of ORA; however, there were also results where clinical notes remained unaffected, often for the same outcome measures.

Reading Ease and Complexity

In total, 3 studies examined changes in the reading ease and complexity of clinical notes [23,45,47]. Blok et al [45] and Kind et al [47] reported a decrease in reading ease and an increase in complexity, while Rahimian et al [23] found the opposite trend: a significant decrease in complexity and an increase in readability. Changes in reading ease were primarily observed in the clinical progress notes. In contrast, other note types, such as the initial notes and letters [23] or the assessment and plan sections [47], seemingly did not change.

Both reading ease and complexity are affected by the use of acronyms and clinical abbreviations [45,47]. While Blok et al [45] found no objective changes in the number and frequency of abbreviations used before and after ORA implementation, Kind et al [47] reported a significant increase in the rate of acronyms and abbreviations in clinical notes. However, the absolute rate of acronyms and abbreviations remained low at approximately 3%.

Length

When discussing the readability and complexity of the notes, studies often refer to note length as a relevant moderator. Four of the included studies [23,24,45,46] examined objective changes in note length because of ORA implementation. Two studies found a statistically significant increase in the average length of progress notes [23,45]. In contrast, Holmgren and Apathy [46] observed a brief, nonsignificant increase in note length of 27.3 characters after ORA implementation, followed by a statistically significant downward trend in note characters over the long term. These changes mainly appear to apply to unstructured visit notes and are not present in the medical history or physician's letters [23,45]. In addition, Rahimian et al [24] used n-grams to identify provider-specific variation in note length. N-grams (linguistics) are sequences of "n" items from a given sample of text or speech, where the items can be phonemes, syllables, letters, words, or base pairs, depending on the application. Rahimian et al [24] found that the number of significant n-grams remained consistent across providers.

Content and Emotional Tone

When it comes to the content of clinical notes, the objective evidence is inconclusive. Typically, only small to moderate changes in the content of clinical notes are reported when shared with patients via web-based patient portals [40,47]. Rahimian et al [24] and Jain et al [40] both use visual graphing of words used and their relatedness to analyze objective content changes in clinical notes pre- and post-ORA: Before ORA, words such as "follow," "well," and "disease" were most prominent, while after ORA, the words "old" and "well" became more prevalent [40]. According to Rahimian et al [24], the use of words such as "distress," "concerning for," and "follow-up" decreased in clinical notes post-ORA, while the word "improving" became more prevalent after ORA was implemented. According to an analysis by Alpert et al [49] using Linguistic Inquiry and Word Count, the emotional tone of the notes remained unchanged. With regard to mental health issues, an increase (pulmonology) or decrease (rheumatology) in notes mentioning mental health status was observed depending on the medical department [47].

Subjective Changes in Documentation

Overview

The included studies with qualitative survey components (ie, pure qualitative or mixed methods studies) primarily used qualitative interviews for data collection (18/26, 69%), followed by qualitative analysis of written free-text responses (3/26, 12%) to assess perceptions of changes to documentation. Some studies (3/26, 12%) conducted focus groups. In some studies (6/26, 23%), findings about documentation changes draw upon a broader dataset, while in others (20/26, 77%), they are supported only by individual quotes from practitioners. All of the studies with qualitative components (26/26, 100%) report changes in clinician-perceived note characteristics (such as length, comprehensibility, accuracy, objectivity, tone, and wording) or changes in content (candor, quality, and tacit knowledge) and functional aspects (notes as a working tool) due to ORA implementation. In contrast, in a few studies (6/26, 23%), some clinicians reported experiencing no changes in clinical documentation due to the introduction of ORA [38,49,54,55,57,61].

Linguistic Characteristics

Length

Similar to the objective changes, some clinicians reported a change in the length of their notes. In 2 studies, clinicians reported that their notes were lengthened by additional text [59] and clinically irrelevant information [42]. However, there were also reports suggesting the opposite: notes became shorter and more concise with the introduction of ORA, partly because hypothetical information was no longer included [68] (refer to the Loss of Tacit Knowledge section) and partly because of concerns about reputational risk [13] (refer to the Candor and also Influences on Documentation Practices section).

Comprehensibility

The comprehensibility of clinical notes appears to be related to their length. While a concise but accurate clinical note is easy for HCPs to understand and work with, patients often require longer explanations in clinical notes to fully understand their content. For example, Alpert et al [49] describe the challenge of composing notes that are both more comprehensible and less intimidating for patients (incorporating more paraphrases and explanations), while also limiting the number of words to ensure their usability in clinical practice. In many of the included studies, HCPs report being more aware and considerate in their writing after implementing ORA, with the goal of creating clinical notes that are more comprehensible and understandable [42,63,65,66]. To achieve this, clinicians reported writing in a clear, concise, and simple manner while avoiding ambiguous terminology [49,50,62,66-68]. Several qualitative studies reported that HCPs modified their use of medical terminology following the implementation of ORA, either by avoiding, reducing, or adapting it to make it more understandable to patients [20,42,49,62,63,68]. In addition, in 2 studies, HCPs reported a decrease in the use of abbreviations and Latin expressions [55,67]. In a recent study conducted by Keuper et al [41], 40.1% of clinicians reported adopting lay language after ORA implementation. Two studies reported a reduction in medical terminology, but HCPs expressed reluctance to completely eliminate it, recognizing its importance for communication with colleagues [66,68]. One study outlined that the described linguistic adjustments peaked shortly after the implementation of ORA but gradually decreased over time, resulting in clinicians reporting a return to their previous documentation practices [65]. Furthermore, 2 studies reported that some clinicians did not observe any effects of ORA on their writing style and continued to use medical terminology to ensure the integrity of clinical documentation [4,65].

Accuracy

Some qualitative studies (8/26, 31%) suggest that clinicians strive to document more accurately, factually, formally, precisely, and objectively when sharing clinical notes with patients [3,20,41,49,66-68], partly to mitigate potential misunderstandings with patients [20]. Other practitioners experience that the implementation of ORA leads to clinical documentation that is less accurate, less direct, and less objective, as the lack of correct medical terminology hinders the accurate communication of information to other providers while potentially introducing irrelevant clinical data [20,42,63]. Some studies (6/26, 23%) report that note accuracy after ORA implementation can be ensured by clinicians being more mindful in their documentation practices [3,20,41,49,66,68].

Mindful Tone and Wording

HCPs from 15 studies reported adjusting the tone and wording of clinical notes when patients were able to read them [3,4,14,17,39,42,49,51,52,54,55,57,58,63,66]. Many professionals reported being more careful and cautious in terms of tone and word choice when writing their clinical notes after the implementation of ORA [3,14,49,66]. They reported making efforts to write notes in a professional and respectful manner, acknowledging the patients' identity and experience [58,66]. In addition, the implementation of ORA reportedly led to perceived changes in how sensitive clinical and social information was documented [42]: some clinicians reported refraining from using language that patients might perceive as critical, provocative, or offensive to avoid upsetting or angering them [39,42,51,54,55]. For instance, clinicians reported that they avoided using subjective terms such as "troubled," "difficult," "disruptive," or "noncompliant" to describe patients' conditions [4,42]. Potentially stigmatizing or hurtful descriptions (eg, obesity and mental health issues) were often reportedly excluded from the clinical notes or paraphrased [4,42,54,55]. However, Alpert et al [57] noted that even after the implementation of ORA, derogatory terms such as "fat" were still present in the clinical notes, causing distress to the patients. In 3 studies, practitioners emphasized that the adoption of patient-friendly, sensitive documentation (after the implementation of ORA) compromised the quality of the clinical notes, as described in more detail in the following section [4,17,52].

Note Content and Functionality

Candor

In many of the included qualitative studies, clinicians reported being less candid in their documentation or omitting information

XSL•FO
RenderX

from the clinical notes. Percentages of clinicians who stated they were less candid in their documentation ranged from 15% to 52% [17,19,42,48,51,53-56,60,62,69]. Two studies showed that significantly more professionals expected to be less honest in their documentation due to ORA than they were when actually sharing their notes with patients [48,69].

Many clinicians reported becoming more selective in what they write [17,43,64], exercising greater caution in deciding what information to include [50,68], and reducing unnecessary detail in their clinical notes [14,39,60,66]. Numerous studies reported that clinicians tended to "safeguard" sensitive and potentially harmful information (eg, domestic violence) to protect patients from potential negative consequences. This may result in information being described more generally, censored, or hidden altogether from the clinical note [4,19,38,42-44,48,51,54-56,60-64,66-68]. In some cases, practitioners blocked patients' access to their clinical notes [19,38] or used parallel documentation, referred to as "shadow records." Shadow records refer to unofficial, private documentation maintained by clinicians in various formats, which is kept distinct from shared documentation [14,51]. Because of the reported changes in the level of candor, detail, and information included in the documentation, some clinicians criticized the decline in the quality and effectiveness of clinical notes [4,17,62,63].

Fewer clinicians reported that the ORA has led to more detailed and open documentation, typically to avoid patient complaints about missing information [3,65]. However, some studies suggest no change in content and candor: clinicians were already writing openly, honestly, and respectfully before ORA was implemented, perceiving that no further changes were required when records were shared with patients [3,4,58,63,68].

Loss of Tacit Knowledge

Some clinicians reported that they excluded certain information—often sensitive or not yet confirmed—from the clinical notes. Clinicians primarily avoided tentative differential diagnoses (especially in cases of suspected serious illness) [17,38,42,62,63,68]. However, they also reported withholding their own assessments and observations [17,54,62]. This included hypotheses, concerns, "gut feelings," and speculative information that might be helpful to the next clinician treating the same patient [17,20,62,68]. In doing so, clinicians may be striving to avoid causing misunderstanding and confusion [17,20,63,68] or arousing fear and offense in patients [13,42,62], especially when there is no time or opportunity to thoroughly discuss the preliminary information with the patient [20,68].

Value as a Working and Therapy Tool

The changes described in the content and structure of clinical notes resulting from the use of ORA also affect how clinical notes may be used as work and therapy tools. Some clinicians argued that the clinical notes are no longer effective as a work tool and do not adequately serve their professional purpose when shared with patients. This is attributed to the omission of preliminary or sensitive information and a shift toward more descriptive but less rigorous documentation [17,62,63]. Some studies suggested that clinicians prefer to use clinical notes primarily in the traditional sense, either as a communication tool with colleagues and other providers [4,42,67,68] or as a work tool for themselves [4,38,62]. According to several clinicians, the changes in documentation caused by ORA hinder interdisciplinary communication within the team [42,62,64] as well as the personal use of notes (eg, as a personal reminder) [4,38,62], making the clinical note a less efficient and valuable working tool [39,42,69].

Other practitioners saw the adaptation of their writing as a new opportunity to expand the function of clinical notes as a therapeutic tool. By communicating directly with the patient through clinical notes, they could better engage patients by including self-care instructions or different types of reminders [42,63], highlighting the patient's strength and progress, and reassuring the patient that their perspective is heard and understood [66]. The notes were used to emphasize important aspects of the consultation, clarify goals, and provide educational resources [66].

Influences on Documentation Practices

Two studies found that HCPs may feel uncertain or vulnerable when writing shared documentation [54,60]. Aiming to protect patients from adverse outcomes such as misunderstanding [20,49,63,66], anxiety, and confusion [17,42,63,64,68], they reported being more careful and guarded in their writing [17,49,51,63,67]. This was seemingly fueled by their desire to avoid being perceived as harsh, critical, or judgmental in their documentation [39,42,49]. In addition, clinicians were aware of the potential reputational risks, medicolegal concerns, and patient safety consequences associated with ORA, which accordingly influenced their documentation practices [13,20,60].

Finally, it should be noted that clinicians write with several target audiences in mind when ORA is available. HCPs were usually more considerate of the patient's reception of the note, while still documenting appropriately for colleagues, health insurers, billing, and other stakeholders [3,4,17,42,44,49,51,52,56,57,59-62,65,66,68]. They must also consider the possibility of the so-called secret readers, such as relatives or caregivers, who may have access to the clinical notes without the clinician's knowledge [3,42,52,60-62,64]. Therefore, the introduction of the ORA presents practitioners with the major challenge of writing a uniform note to serve multiple and sometimes conflicting needs.

Discussion

Principal Findings

This scoping review is the first to assess the potential for changes in documentation following patient ORA. Most of the included studies, which incorporated qualitative components, report changes in clinician-perceived note characteristics, such as length, comprehensibility, accuracy, objectivity, tone, and wording. In addition, these studies highlight changes in content, such as candor and quality as well as functional aspects, such as the role of notes as a working tool, following the implementation of ORA. Conversely, a minority of studies indicated that some clinicians reported no discernible changes in clinical documentation following the introduction of ORA [38,49,54,55,57,61]. Similar to the objective changes noted,

XSL•FO
RenderX

some clinicians observed alterations in the length of their notes. In 2 studies, clinicians reported that their notes were longer [42,59]. However, contrasting subjective findings indicate the opposite effect [68]. Regarding the content of free-text notes, the objective evidence remains inconclusive. Generally, only minor to moderate alterations in the content of clinical notes are reported when shared with patients via the web [40,47]. Moreover, several studies using literacy metrics investigated changes in the readability and complexity of clinical notes. While Blok et al [45] and Kind et al [47] reported an increase in complexity and a decrease in readability, Rahimian et al [23] found a significant decrease in complexity and an increase in readability.

The mixed findings reported may reflect the diverse perspectives and experiences of the different individuals involved. Just as people communicate differently, they also approach documentation in unique ways, influenced by their background, experiences, and perceptions of transparency, privacy, and integrity. Various factors, such as personal attitudes, power dynamics, and professional habits, might further contribute to the variation in documentation practices. Given this diversity, the implementation of ORA will inevitably impact health care staff's documentation practices differently. Some may view it as an opportunity to extend their caregiving beyond face-to-face interactions, using clinical notes as a therapeutic tool to better engage with patients [42,63], highlighting progress, clarifying goals, and offering reassurance through ORA [66]. Contrastingly, others grapple with ethical dilemmas regarding the inclusion or omission of certain information. Practitioners in 15 studies indicated that they modified the tone and language used in clinical notes when patients had access to them [3,4,14,17,39,42,49,51,52,54,55,57,58,63,66]. Following the introduction of ORA, numerous professionals adopted a more deliberate and cautious approach toward tone and language selection in clinical notes [3,14,49,66].

This variance in approaches underscores the need for flexibility and understanding within the health care setting. In essence, the following question arises: can a one-size-fits-all approach accommodate the diverse needs and perspectives present in health care? The answer remains uncertain, highlighting the complexities of standardizing practices across such a multifaceted sector. As the language, format, and content of clinical notes may evolve following ORA, assessing whether such changes yield benefits or pose risks is imperative.

O'Neill [70] contests the common belief that transparency and truth are inherently linked, asserting instead that they are fundamentally at odds. O'Neill [70] argues that transparency compels document writers to obscure genuine information or motives, crafting content deemed suitable for public consumption and thereby fostering deception. Worsening the argument by O'Neill [70], Nguyen [71] adds that the pressure to conform to public expectations through transparency may lead experts to compromise the integrity of their documentation, abandoning nuanced insights, tacit knowledge, and expert judgment. In several of the included qualitative studies, clinicians did express being less candid in their documentation or selectively omitting information from clinical notes due to patient access. Reported percentages of clinicians admitting to reduced candor in their documentation varied from 15% to 52% [17,19,42,48,51,53-56,60,62,69]. On the contrary, 2 studies found that more professionals expected to be less honest in their documentation due to ORA than those who actually were when sharing their notes [48,69]. Adding weight to the argument by Nguyen [71], practitioners experience that ORA implementation results in clinical documentation that is less accurate, less straightforward, and less objective; the absence of correct medical terminology hinders effective communication with other providers and possibly introduces irrelevant clinical data [20,42,63].

The increase in readability and note length following the implementation of ORA also suggests that HCPs may have started documenting in a manner they perceived to be more understandable or accessible to a broader audience, such as patients [23]. Numerous clinicians indicate increased selectiveness in their documentation [17,43,64], exercising caution in determining the information to incorporate [50,68], and trimming unnecessary details from their clinical notes [14,39,60,66]. In certain instances, practitioners went as far as to restrict patients' access to their clinical notes [19,38] or resorted to parallel documentation, also known as a "shadow record" [14,51]. Restricting patients' access to parts or all of their EHR may be justifiable in certain situations (such as suspected coercive access in the context of domestic abuse) and may therefore be acceptable clinical practice [72]. The reported changes in the level of candor, detail, and information in the documentation led some clinicians to critique a decline in the quality and effectiveness of clinical notes [4,17,62,63].

Fewer clinicians noted that ORA implementation resulted in more detailed and transparent documentation, often aiming to prevent patient complaints about missing information [3,65]. However, contrary to the theory of transparency and deception by O'Neill [70], certain studies suggest no alteration in content and candor due to ORA: clinicians had already been writing openly, honestly, and respectfully before the implementation of ORA; thus, no adjustments were deemed necessary when records were shared [3,4,58,63,68].

Numerous qualitative studies indicate that clinicians aim for greater accuracy, formality, precision, and objectivity when sharing clinical notes with patients [3,20,41,49,66-68]. In total, 6 studies indicate that clinicians can enhance note accuracy following ORA implementation by adopting more mindful documentation practices [3,20,41,49,66,68]. We can assert that ORA offers both advantages and disadvantages. They potentially enhance patient care while simultaneously posing risks regarding what information is omitted.

Extended Care Through Documentation

Patient ORA satisfies the moral argument that the information belongs to the patient. It is even argued that when patients feel in more control of their care, they will take better care of themselves [73]. While it is acknowledged that all patients, including those with mental illness, have the right to access information about their health, this raises ethical questions about the implications of transparency in health care documentation. Here lies a definite complexity in the concept of care and conducting it ethically. Can ORA completely align with the

XSL•FO
RenderX

medical "do no harm" principle? An often-overlooked risk linked to providing patients access to their medical records is the so-called secret readers—individuals other than the patients themselves who may access their medical records for both positive and negative reasons [3,42,52,59-62,64]. The possibility of secret readers may prompt physicians to self-censor in their documentation as a means of additional care and protection of patients considered vulnerable, such as children in families affected by domestic violence. Numerous studies have documented that clinicians frequently take measures to safeguard sensitive and potentially harmful information, such as instances of domestic violence, to shield patients from potential negative repercussions. Therefore, this often leads to describing information in more general terms or entirely concealing it from the clinical note [4,19,38,42-44,48,51,54-56,60-64,66-68]. Confidentiality in these fragile circumstances is paramount due to the potential escalation of abuse if a perpetrator discovers unwanted disclosure. ORA, therefore, heightens concerns about coercion and privacy breaches concerning issues of domestic violence and abuse. In established patient portals, such as the Swedish portal, safeguards have been implemented by excluding certain specifically tagged keywords, such as "risk for domestic violence," from ORA [74].

To Document or Not

When clinicians choose to exclude specific information, particularly sensitive or unconfirmed details such as provisional differential diagnoses [17,38,42,62,63,68] from shared clinical notes, it can be viewed as a form of practical care, aiming to prevent unnecessary worry or distress for the patient. Alongside these caregiving perspectives of omitting information due to ORA, a serious downside can arise when clinicians frequently refrain from including subjective assessments and observations [17,54,62]. This encompasses hypotheses, concerns, "gut feelings," and speculative information that could help the next clinician treating the same patient [17,20,62,68]. In a health care context with high staff turnover, omitting information from a shared working document, although with the best intentions of care for the patient, could inevitably put the same patient at risk. Changes to documentation that are found to cause errors and lead to patient harm could also place clinicians at increased risk of malpractice [75]. By omitting this often tacit knowledge, clinicians aim to prevent misunderstanding and confusion [17,20,63,68] as well as avoid instilling fear and offense in patients [13,42,62], particularly when there is insufficient time or opportunity to thoroughly discuss preliminary information with the patient [20,68].

Research indicates that HCPs often experience feelings of insecurity and vulnerability when composing shared documentation [54,60], striving to shield patients from potential adverse outcomes, including misunderstanding [20,63,66], anxiety, and confusion [17,42,63,68]. Consequently, they tend to be more cautious and guarded in their writing [17,51,63,67]. This caution is further fueled by their desire to avoid being perceived as overly harsh, critical, or judgmental in their documentation [39,42].

Changing Function of the EHR

The traditional function of the medical record has never been to inform, empower, or engage the patient; rather, its primary purpose has been to serve as a tool for HCPs to document clinical information. Several clinicians argue that the alterations in documentation induced by ORA hinder interdisciplinary communication within the team [42,62] and diminish the personal utility of notes (eg, as a personal reminder) [4,38,62], thereby reducing the effectiveness of clinical notes as a working tool. Certain clinicians contend that clinical notes are ineffective as a professional tool and fail to fulfill their intended purpose. This is attributed to the omission of preliminary or sensitive information and a transition toward more descriptive but less precise documentation [17,62,63]. Training on how to write clinical notes in the context of ORA could help HCPs navigate the changing role of the EHR. A recent survey of psychotherapy trainees found that 9 out of 10 believed that education on open notes should be part of the curriculum [76].

In an era of advancing digitization, ORA can be viewed as a burgeoning trend aimed at empowering patients through transparency, with medical documentation increasingly tailored for patients as one of the primary audiences. However, this shift may lead to deviations from the ethical principles that underpin patient care. It is important to recognize that not all aspects of health care can or should be shaped to be pleasing and empowering. Being a patient inherently involves vulnerability and a reliance on the expertise and trustworthiness of HCPs. Patients may feel objectified or reduced to a diagnostic label, seeking recognition of their individuality rather than being treated as a mere statistic or case study. However, in medical records, HCPs are not *describing* an individual; they are documenting a disease, which often causes confusion in a multipurpose document that is interpreted by various audiences. Research shows that clinicians opted not to use language that patients could interpret as critical, provocative, or offensive to prevent causing patients distress or frustration [39,42,51,54,55]. However, being a patient is ultimately intertwined with being vulnerable and distressed; this is essential and part of being in someone's care, which ultimately leads to the patient being forced to trust and live through that vulnerability.

While ORA can facilitate patient engagement and transparency, it also introduces new considerations regarding data privacy, accuracy, and interpretation. Consequently, it is essential to recognize the limitations of digital documentation in fostering trust and prioritize cultivating trust through meaningful patient-HCP interactions. As seen in the included research, one reason clinicians omit preliminary findings in ORAs, in particular, is the lack of time to discuss them thoroughly with the patient [20,68].

Limitations

The studies included in this scoping review have some notable limitations. The search for articles to be included in the review was conducted in the fall of 2023; therefore, the most recent evidence may not be included. Slightly less than half of the studies (19/42, 45%) were based on surveys, and it is unclear whether response bias may have affected the findings. In addition, studies reporting subjective changes in documentation

XSL•FO
RenderX

were more prevalent than objective studies. Furthermore, some studies, particularly those using qualitative interviews, had relatively small sample sizes. Both these factors may affect the generalizability of the results. However, the inclusion of qualitative studies allows a more nuanced and comprehensive understanding of the results, and the studies with small sample sizes are counterbalanced by those with larger sample sizes.

In some studies, such as those conducted by Zellmer et al [56], clinicians were able to selectively choose which notes to share with patients and which to withhold. Assuming that particularly sensitive topics might have been avoided or not shared, this may influence the extent to which the documentation changed, as such topics especially require a patient-friendly adjustment of the clinical note.

Participating clinicians volunteered to participate in the studies and thus volunteered to share their clinical notes with patients. Therefore, it can be assumed that the clinicians had a positive attitude toward ORA or were at least interested in it (self-selection bias); critical voices may be underrepresented. However, as our results show a wide variation, it can be assumed that this is not the case.

Conclusions

While there may be variations in the outcomes and attitudes among clinicians, it is evident that ORA does exert an influence on medical documentation practices. While it may not affect all health care staff uniformly, its effects are palpable for some, potentially influencing health care outcomes. Several included qualitative studies show that HCPs modify their use of medical terminology, either by avoiding, reducing, or adapting it to make it more understandable to patients [20,42,49,62,63,68]. This practical measure could indeed be seen as extended caregiving through documentation. In numerous of the included studies, professionals report being more aware and considerate in their writing after implementing ORA, with the goal of creating clinical notes that are more comprehensible and understandable [42,63,65,66]. Other patient benefits from ORA include clinicians' attempts to write notes professionally and respectfully, acknowledging the patients' identity and experience [58,66].

In contrast to the positive outcomes of documentation changes due to ORA, the presence of compensatory measures, such as parallel documentation [14,51] and restriction of patients' access to their clinical notes [19,38], indicates a systemic issue, suggesting that current practices are not yet functioning optimally. Parallel documentation in this matter refers to shadow recording including unofficial, private documentation maintained by clinicians in various formats, which is kept distinct from shared documentation. Practical compensatory measures underscore deficiencies in the current system, wherein crucial information may be omitted or obscured. If an HCP, for example, withholds information out of fear or concerns regarding reputational risks [13], this might ultimately jeopardize the safety of their colleagues and delay proper patient care. The consequences of physicians omitting information that would benefit their colleagues in differing ways, even if only practiced by a minority, can have a cascading effect on patient care. Given that patient health care journeys are collaborative efforts involving multiple professionals, the impact of 1 note being influenced by ORA extends beyond individual patients and physicians. Such practices, whether they involve avoiding gut feelings or diverting critical information to less formal channels, jeopardize patient safety.

Finally, it should be noted that clinicians must write with multiple audiences in mind when implementing ORA. Clinicians were more considerate of the patient when writing the shared note, while still documenting appropriately for colleagues, health insurers, billing, and other stakeholders [3,4,17,42,44,49,51,52,56,57,59-62,65,66,68]. Therefore, the introduction of ORA presents practitioners with the major challenge of writing a uniform note. Many clinicians expressed a desire for system-level guidance regarding optimal documentation practices to mitigate potential negative outcomes for themselves or their patients. They emphasized the importance of training in recovery-oriented and strengths-focused treatment approaches, shifting from problem-focused thinking to a collaborative relationship with clients [60].

Using ORA effectively without omitting information does present a challenge. Future research must explore practical strategies regarding how ORA can be designed to navigate the complex surroundings of such a vital and multifaceted working document, ensuring ORA does not compromise the efficiency and security of care delivery, patients, or health care staff. To this end, we expect that future scoping reviews and empirical research will focus on the use of generative artificial intelligence in documentation practices [77,78]. There is already evidence that clinicians may be using these tools to assist with writing sensitive, understandable notes that patients will read [79]. It remains unclear whether such practices effectively meet the dual requirements of preserving documentation for clinicians while making the notes more understandable and empathetic for patients [80].

Acknowledgments

The authors would like to thank Malin Barkelind, the librarian at the Uppsala University, for conducting the literature search and performing the deduplication process. BM is funded by a National Institute for Health and Care Research (NIHR) Advanced Fellowship (NIHR300887). The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files). All studies analyzed during this study are publicly available and can be found via the following databases: APA PsycINFO, CINAHL, PubMed, and Web of Science Core Collection.

Authors' Contributions

EM-D wrote the Methods, Results, and Limitations sections. EM-D created the figures and tables. CL wrote the Introduction and Discussion sections. CB and JS were responsible for the conception of the study and contributed to drafting the manuscript. CB, JS, EM-D, and MH were responsible for conceptualization; all the authors were responsible for data curation and validation; EM-D and CL (screening: all authors) were responsible for the formal analysis; EM-D and JS were responsible for methodology; JS, CB, and MH were responsible for supervision; EM-D was responsible for visualization and writing—review and editing; and EM-D and CL were responsible for writing—original draft. All authors participated in the screening process. All authors read, provided feedback, and approved the paper for submission.

Abstract

Background: older people experiencing homelessness can have mental and physical indicators of aging several decades earlier than the general population and experience premature mortality due to age-related chronic conditions. Digital interventions could positively impact the health and well-being of homeless people. However, increased reliance on digital delivery may also perpetuate digital inequalities for socially excluded groups. The potential triple disadvantage of being older, homeless, and digitally excluded creates a uniquely problematic situation warranting further research. Few studies have synthesized available literature on digital interventions for older people experiencing homelessness.

Objective: This scoping review examined the use, range, and nature of digital interventions available to older people experiencing homelessness and organizations supporting them.

Methods: The scoping review followed Arksey and O'Malley's proposed methodology, PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, and recent Joanna Briggs Institute guidelines. We searched 14 databases. Gray literature sources were searched to supplement the electronic database search. A narrative synthesis approach was conducted on the included articles, and common themes were identified inductively through thematic analysis.

Results: A total of 19,915 records were identified through database and gray literature searching. We identified 10 articles reporting on digital interventions that had a clearly defined a participant age group of >50 years or a mean participant age of >50 years. A total of 9 of 10 studies were published in the United States. The study design included descriptive studies, uncontrolled pilot studies, and pilot randomized controlled trials. No studies aimed to deliver an intervention exclusively to older people experiencing homelessness or organizations that supported them. Four types of intervention were identified: telecare for people experiencing homelessness, distributing technology to enable digital inclusion, text message reminders, and interventions delivered digitally. Interventions delivered digitally included smoking cessation support, vocational training, physical activity promotion, and cognitive behavioral therapy. Overall, the included studies demonstrated evidence for the acceptability and feasibility of digital interventions for older people experiencing homelessness, and all 10 studies reported some improvements in digital inclusion or enhanced engagement among participants. However, several barriers to digital interventions were identified, particularly aspects related to digital inclusion, such as infrastructure, digital literacy, and age. Proposed facilitators for digital interventions included organizational and peer support.

XSL•FO
RenderX

Conclusions: Our findings highlight a paucity of evaluated digital interventions targeted at older people experiencing homelessness. However, the included studies demonstrated evidence of the acceptability and feasibility of digital interventions for older people experiencing homelessness. Further research on digital interventions that provide services and support older people experiencing homelessness is required. Future interventions must address the barriers older people experiencing homelessness face when accessing digital technology with the input of those with lived experience of homelessness.

Introduction

Homelessness is a complex phenomenon, with different conceptualizations making it challenging to establish its prevalence and study its phenomenology and effects. The European Observatory on Homelessness proposed the European Typology of Homelessness and Housing Exclusion (ETHOS) states homelessness can include rooflessness (without a shelter of any kind or sleeping rough), houselessness (with a place to sleep but temporarily in institutions or shelter), living in insecure housing (threatened with severe exclusion due to insecure tenancies, eviction, or domestic violence), and living in inadequate housing (in caravans on illegal campsites, in unfit housing, or in extreme overcrowding) [1]. People experiencing homelessness are thought to encounter “accelerated ageing” relative to the general population [2].

An interplay of health and social deprivation leads to people experiencing homelessness with disproportionately high rates of chronic illness [3] and premature age-adjusted mortality rates [4-6]. In this study, older people experiencing homelessness are defined as people older than 50 years who have experienced chronic/episodic homelessness. Chronic homelessness is associated with accelerated aging that predisposes younger people to geriatric health conditions normally associated with older than 75 years in the general population [7]. Older people experiencing homelessness are largely invisible in research, policy, and practice despite the rapidly increasing rates of this population [8]. In the United States, currently, half of single homeless adults are aged 50 and older, compared with 11% in 1990 [9,10]. Further, forecasts from US cohorts project significant growth in aged homelessness in age groups of 50 years and older and 65 years and older, revealing that much of the impact of the postwar baby boom on the aged homeless population is already well underway [11]. Similarly, in Scotland in 2022, 16% of new homeless applications were made by persons older than 50 years [12]. Consequently, the rapidly growing population of older people experiencing homelessness is of critical public health concern and warrants further research.

Homelessness is inextricably linked to social exclusion as individuals are often marginalized from participating in economic, political, social, and cultural life [13]. Concurrently, older people experiencing homelessness are particularly marginalized in the health care system. Older people experiencing homelessness face multiple barriers to timely and effective care for multiple long-term conditions [14,15]. The recent COVID-19 pandemic resulted in a shift from traditional face-to-face health care delivery toward an expansion in using digital technology for service provision [16,17]. In this study, we define digital interventions as interventions that incorporate using and accessing a digital device.

Digital interventions offer promising opportunities to explore new ways of intervention in harm reduction, well-being enhancement, and health treatment of older people experiencing homelessness [18]. This expansion of digital health care is positive for many; however, it has raised issues of digital inequalities for socially excluded groups, including physical barriers in a lack of access to equipment and educational barriers in not being able to use the technology [19]. This is of particular concern to older people experiencing homelessness as evidence has demonstrated that people older than 50 years experiencing homelessness have a lower prevalence of smartphone and internet access than adults aged older than 65 years in the general public or low-income adults [20]. Paradoxically, digital interventions hold new opportunities for inclusion for older people experiencing homelessness while presenting significant barriers due to unaddressed inhibited accessibility.

Over the past decade, more digital interventions have been used within homeless populations [19,21-23]. There is some existing evidence that older people experiencing homelessness meaningfully engage with technology [20,24]. However, no efforts have been made to synthesize this literature on digital interventions specifically for older people experiencing homelessness. Therefore, we conducted a scoping review to synthesize existing primary data from digital health interventions for older people experiencing homelessness. Our main research question was: what is the use, range, and nature of digital interventions available to older people experiencing homelessness and organizations that support people experiencing homelessness? To answer this research question, our scoping review aims to achieve the following objectives: (1) examine current digital interventions (delivery, implementation characteristics, and context) for people experiencing homelessness and the organizations that support them, (2) examine the use of included digital interventions by older people experiencing homelessness and organizations that support them, and (3) identify the facilitators and barriers for older people experiencing homelessness to inclusion in digital interventions.

The scoping review method was chosen because it provides a systematic, rigorous, and transparent approach to mapping a

XSL•FO
RenderX

field of interest regarding existing research's volume, nature, and characteristics [23]. Given that digital interventions available to older people experiencing homelessness are a rapidly developing area of research, a scoping review is an important first step in informing future research and practice [25].

Methods

Overview

This scoping review used the guidelines of Joanna Briggs Institute's (JBI's) Methodology for Scoping Reviews [26] and follows the methodological framework proposed by Arksey and O'Malley [27] which consists of the following stages: (1) identifying the research question; (2) identifying relevant studies; (3) selecting studies; (4) charting the data; and (5) collating, summarizing, and reporting the results. Our review also complies with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Multimedia Appendix 1) [25]. We first developed a scoping review protocol, including a rationale for conducting the review, the main objectives, search strategy, inclusion and exclusion criteria, and methods for screening and data extraction, that was then piloted and discussed by the research team before finalizing. The final protocol was registered retrospectively in Open Science Framework on May 15, 2023.

Information Sources and Search Strategy

A systematic search strategy was developed in consultation with an expert librarian (RS). The search strategy also adhered to the Peer Review of Electronic Search Strategies (PRESS) guidelines [28]. We systematically searched 15 electronic databases from inception up to 28 July 2023: MEDLINE, Global Health, Cumulated Index to Nursing and Allied Health Literature (CINHAL), SCOPUS, APA PsycInfo, Embase, Academic Search Premier, International Bibliography of the Social Sciences (IBSS), Applied Social Sciences Index & Abstracts (ASSIA), Association for Computing Machinery Digital Library (ACMDL), Institute of Electrical and Electronics Engineers (IEEE), Web of Science, Educational Resources Information Centre (ERIC), and Cochrane library. Policy Commons was used to search for gray literature.

The systematic and comprehensive search strategy consisted of key search terms derived from existing search strings and bespoke for each electronic database. The search terms were as follows: homeless* OR temporary accommodation OR roofless OR unfit hous* OR inadequate hous* OR night shelter OR shelter* OR sofa surf* OR rough sleep* AND information communication technolog* OR cell phone* OR mobile app* OR mobile technolog* OR mobile health OR (m health OR e health OR mhealth or ehealth) OR online OR digital OR (telehealth OR tele health OR telemedicine OR tele medicine OR telecare OR tele care) OR social media OR internet OR (web based OR web-based) OR wearable* OR (Smartphone OR smart phone) OR Mobile phone OR Instant messag* OR (Email or electronic mail or e mail) OR (Smartwatch OR smart watch) OR (WhatsApp OR Instagram OR Facebook OR Telegram OR Signal OR Viber) (note: * indicates a wildcard). The results were combined using Boolean operations and adapted for each database (Multimedia Appendix 2). We also scanned references of the included articles for any relevant studies.

Study Selection

After the publications were retrieved and duplicates removed using Endnote (Clarivate), search results were imported into the Covidence software management system (Veritas Health Innovation) for additional deduplication and screening by multiple reviewers.

As advised by JBI guidelines for conducting scoping reviews [26], the population, concept, and context framework was used to define eligibility. Textbox 1 shows the inclusion and exclusion criteria in line with the population, concept, and context framework and contains additional study elements relevant to the eligibility criteria. The ETHOS definition of homelessness framed the inclusion of participants experiencing homelessness [29]. Organizations supporting older people experiencing homelessness were considered to be any health or social care services or third-sector organizations providing a service to people experiencing homelessness. Due to accelerated aging, those who are 50 and experiencing homelessness are defined as "older" in contemporary research [2,30]. Therefore, only studies that included participants with a mean age of 50 years and older or studies with a clearly defined group of participants older than 50 years were included. The nature and causal pathways of homelessness vary globally [31]. To acknowledge that interventions for people experiencing homelessness will diverge due to social and cultural structures, health systems, and the provision of emergency accommodation [32], the scope of this review will be refined to solely high-income countries as defined by the Organization for Economic Co-operation and Development. This allowed for interventions to be more appropriately compared in the analysis [2]. So as not to exclude any innovative interventions, the definition of "digital intervention" was kept intentionally broad to include digital, web-based, or mobile interventions used by people experiencing homelessness to improve social, health, or prospective outcomes.

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria detailing the population, concept, and context framework for defining eligibility criteria for scoping reviews.

Inclusion criteria

- Population: Participants currently absolutely homeless (living in shelters or on the streets) OR Participants currently in unstable housing situations (couch surfing, transiently housed) OR Organizations (health or social care services or third sector) that support the aforementioned participants AND Publications including people experiencing homelessness aged 50 years or older (mean participant age or clearly defined participant age group older than 50 years)
- Concept: Interventions are digital in delivery (web-based, mobile, applications, training, or social media)
- Context: Population in high-income nations or the Organization for Economic Co-operation and Development countries.
- Study type: Primary data presented

Exclusion criteria

- Population: Intervention not specific to homeless populations (eg, intervention for migrants or refugees)
- Concept: No digital intervention described OR Digital interventions solely designed for children or youth experiencing homelessness (younger than 18 years)
- Study type: No primary data presented

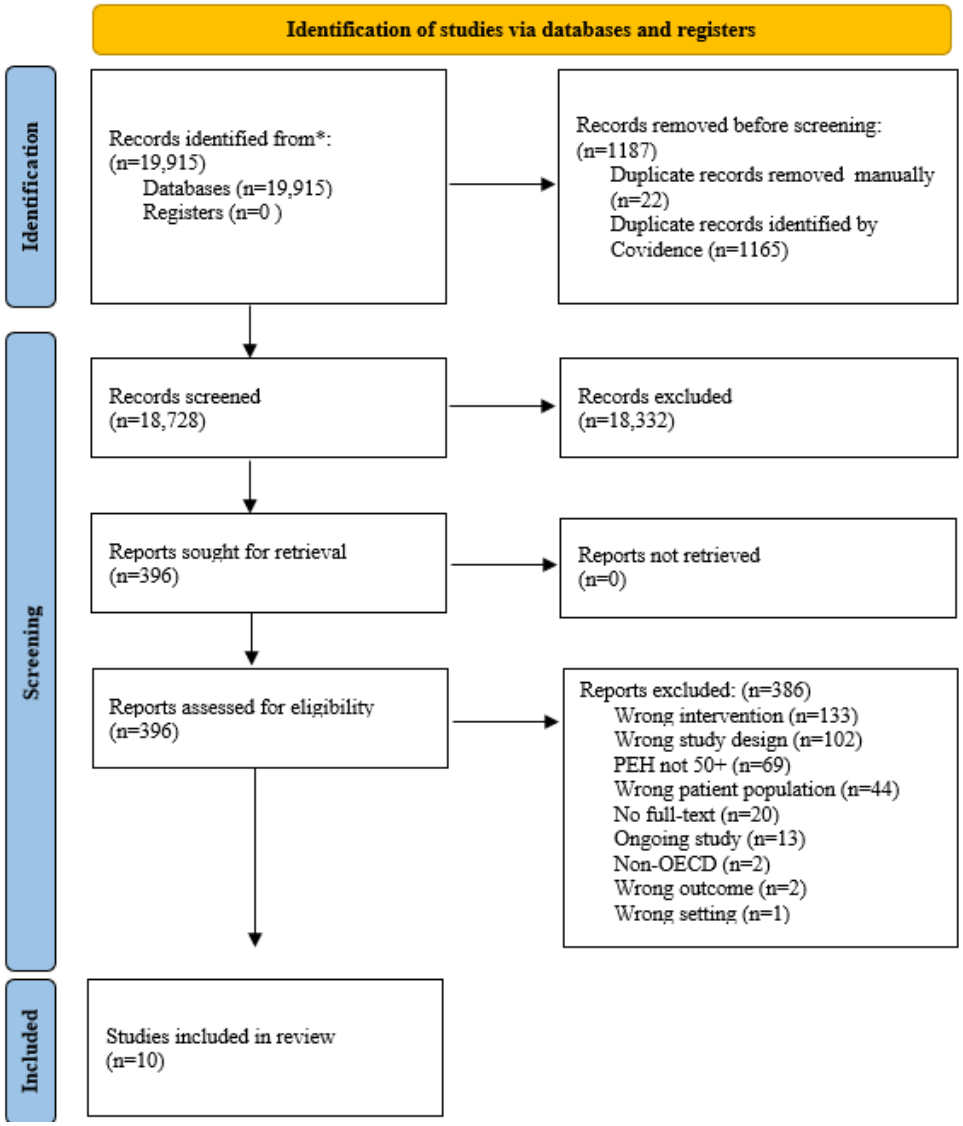
Further to the inclusion and exclusion criteria outlined in Textbox 1, throughout the review, publications were excluded for the following: (1) no full text available and (2) no English language version available.

Level 1 screening focused on inclusion criteria based on titles and abstracts, while level 2 screening involved reviewing full-text articles. Four reviewers (EA, LN, CS, and RG) independently screened all titles and abstracts. Reviewers met throughout the screening process to discuss queries and reduce uncertainties. Two reviewers (EA and LN) completed the full-text screening independently, with disagreements resolved by discussion with the reviewers and SWM.

Charting Data and Reporting Results

The selected publications were read, annotated, and entered into a Microsoft Excel spreadsheet. EA and LN piloted the data extraction sheet with 2 of the included studies and then revised it in consultation with ED and SWM. We did not critically appraise the included studies, given that this is not typically an objective of a scoping review and the large research design heterogeneity of the studies reviewed [33].

To summarize the data, where applicable, we conducted a basic numerical analysis, for example, the proportion of participants older than 50 years in each study. Meta-analysis was not feasible due to the necessary inclusion of heterogeneous studies in answering the research question. We used a narrative synthesis approach to organize and present relevant findings. Qualitative data (eg, perceptions of digital interventions, barriers to digital interventions for older people experiencing homelessness, and facilitators to digital interventions for older people experiencing homelessness) were imported to NVivo 12 software (Lumivero) for analysis by EA. This approach is characterized by textual summaries and explanations of findings, which are first synthesized by thematic analysis to explore relationships among studies. Thematic analysis in this context involved iteratively identifying, classifying, and sorting the most important themes and concepts across studies [34]. The core research team (EA, LN, SWM, ED, MW, and CS) applied Braun and Clarke's [35,36] reflexive thematic analysis approach, which involved familiarization with the data, generating initial codes, identifying and refining preliminary themes, reviewing themes collaboratively, and ultimately constructing and defining final themes. This iterative, reflexive process—guided by our own perspectives and the review's research questions—enabled a deeper interpretation of the data, resulting in us developing the reported themes.



Results

Study Characteristics

Our searches yielded 19,915 records. After removing duplicates 18,728 records were title and abstract screened (Multimedia Appendix 3). Ten articles met the inclusion criteria [37-46]. All records included in our review were peer-reviewed studies reporting on digital interventions for older people experiencing homelessness that had a clearly defined age group of participants older than 50 years or the mean participant age was older than 50 years (Figure 1 portrays the adapted PRISMA-ScR flow diagram). This screening criteria resulted in 90.5% (n=5902) of the total participants (N=6557) being older people experiencing homelessness (older than 50 years). In 6 of the studies, participants were veterans experiencing homelessness [38,39,41,42,45,46]. A total of 9 of the 10 studies were conducted in the United States [38-46], and the other was conducted in Hungary [37]. Studies were published between 2013 and 2023, with 4 published after the 2020 lockdowns of the COVID-19 pandemic [37,41,45,46]. The study design included descriptive studies [39,43], uncontrolled pilot studies [37,38,42,44,46], and pilot randomized controlled trials [40,41,45].

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram for the identification of studies via databases [25]. OECD: Organization for Economic Co-operation and Development; PEH: people experiencing homelessness.

Intervention Characteristics

The included studies were heterogeneous concerning intervention content, delivery, and reported outcomes. Tables 1 and 2 show the intervention delivery and implementation. Interventions could be categorized into implementing telecare for people experiencing homelessness [37,38], distributing technology to enable digital inclusion [39,46], text message reminder interventions [40,42], and 4 interventions delivered digitally [41,43-45] (summarized in Figure 2). Interventions delivered digitally ranged from smoking cessation support [43], vocational training [41], physical activity promotion [44], and cognitive behavioral therapy [45]. We used the broad definition of telecare used by Barlow et al [47], "the use of communications technology to provide health and social care directly to the user ('patient')" where interventions self-described as "telemedicine" [38] and "telehealth" and terms were used interchangeably.

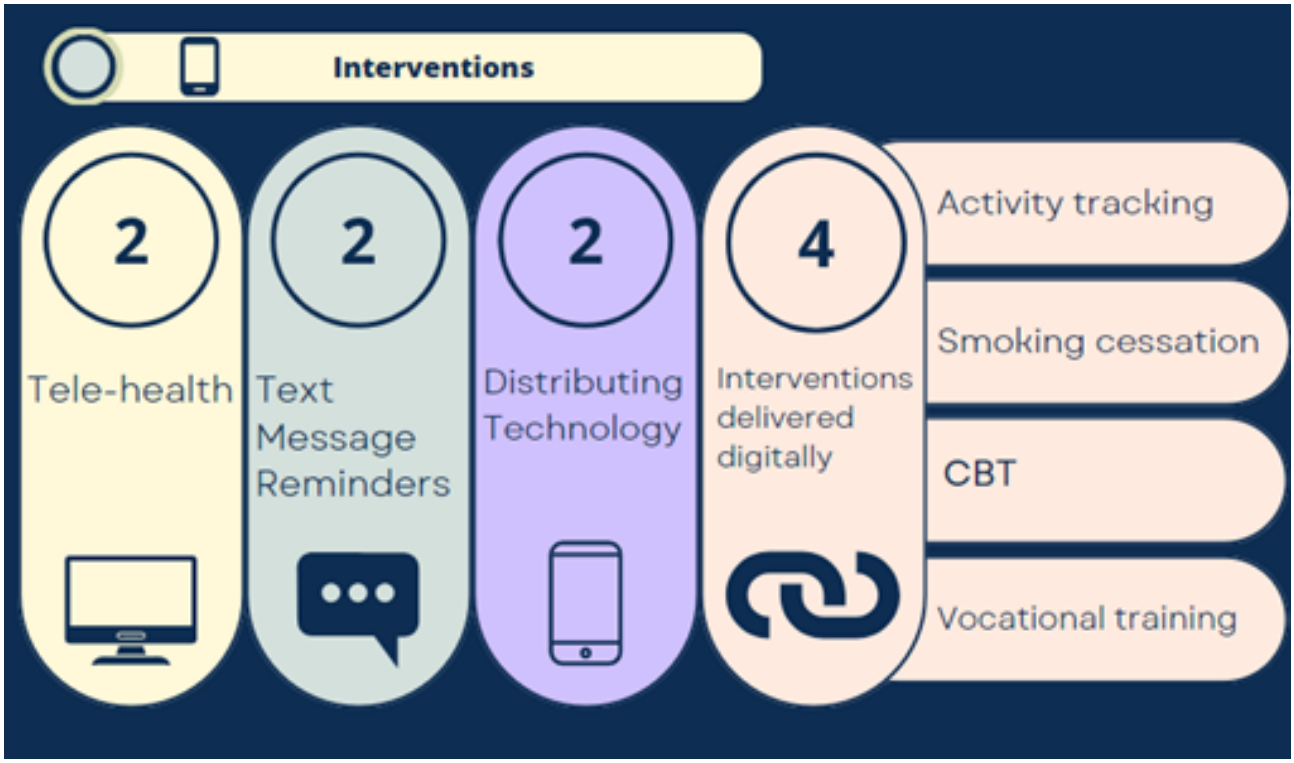
Table 1. Summary of identified study and intervention characteristics.

Author, year	Sample size (% OPEH[a], % Male)	Study design	Intervention	Intervention details
Békási et al, 2022 [37]	75 (100, 76)	Uncontrolled before and after (pre-post) pilot study	Telecare	Participants were invited to 6 web-based telecare visits bi-weekly with a focus on medical management of chronic conditions.
Gabrielian et al, 2013 [38]	14 (100, 71.4)	Uncontrolled mixed methods pilot study	Care Coordination Home Telehealth (CCHT)	CCHT used in-home messaging devices to provide health education and daily questions about clinical indicators from chronic illness care guidelines.
Garvin et al, 2021 [39]	1070 (97.1, 77.9)	Descriptive study	Tablet distribution	Veterans Association distributed tablets to access challenged veterans to be used for any clinical care that does not require physical contact (mental health therapy, medication management, primary care, palliative care, and rehabilitation care).
Kershaw et al, 2022 [40]	62 (100, 85)	Pilot randomized controlled trial (RCT)	Cell phone–based text messaging system	One-way message appointment reminders for upcoming appointments for a range of services and 2-way messages, which requested a text response, asked participants about their mood.
LePage et al, 2023 [41]	27 (81.5, 100)	Pilot developmental study and pilot RCT	Web-based vocational rehabilitation program	Manualized vocational program to aid individuals in identifying work skills, generating examples of those skills, and developing answers to typical questions one might encounter during the interview process.
McInnes et al, 2014 [42]	20 (80, 81)	Uncontrolled before and after pilot study	Text-messaging reminder intervention	Participants were sent 2 text message appointment reminders on a schedule of 5 days and 2 days before their appointment.
Reitzel et al, 2014 [43]	22 (100, 63.6)	Descriptive study	Smartphone-based Smoking cessation	The smartphone was programmed to collect latitude-longitude data via an internal GPS chip at the time the random assessment was prompted.
Rhoades et al, 2019 [44]	13 (100, 46.2)	Uncontrolled before and after pilot study	Cell phone-based physical activity intervention	Intervention to increase physical activity by encouraging walking via goal-setting and motivational text messaging, self-monitoring of walking behavior using pedometers, and providing ongoing feedback on walking performance.
Wilson et al, 2023 [45]	27 (100, 93)	RCT	Telephone-delivered cognitive behavioral therapy (CBT)	Telephone-delivered CBT, tobacco cessation pharmacotherapy, long-term incentives for abstinence-delivered counseling sessions, and optional prescribed tobacco cessation pharmacotherapy.
Wray et al, 2022 [46]	5127 (88, 87.8)	Uncontrolled before and after study	Distribution of video-enabled tablets and cell phones	Program that provided video-enabled tablets to any Veteran who was deemed to have necessary clinical services and a technological need.

[a]OPEH: older people experiencing homelessness.

XSL•FO
RenderX

Table 2. Summary of included digital intervention outcomes for older people experiencing homelessness.



Author, year	Duration (Months)	Follow-up	Outcomes measured	Main Findings
Békási et al, 2022 [37]	3	6 months post	• Feasibility • Patient experience • Medical relevance	• The study provided evidence of a feasible telecare setup in shelters for people experiencing homelessness. • Client satisfaction was high; participants reported similarly high ratings for ease of use and comfort. • Physicians reported the ability to assess the patient's condition properly and make an adequate diagnosis.
Gabrielian et al, 2013 [38]	unclear	not stated	• Program acceptability to staff and consumers • Role of peers to support illness self-management	• Participants were satisfied with CCHT[a]. • Most did not require support from peers to engage in CCHT but valued peer social assistance.
Garvin et al, 2021 [39]	6	not stated	• Tablet adoption and use	• Tablet use was more common among veterans experiencing homelessness who were younger (AOR[b]=2.77; *P*<.001); middle-aged (AOR=2.28; *P*<.001); in rural. • Use was less common among those who were Black (AOR=0.43; *P*<.001) and those with a substance use disorder (AOR=0.59; *P*<.001).
Kershaw et al, 2022 [40]	4	Immediately after (4 months)	• Number of ED encounters • Number of inpatient admissions • Appointment keeping	• No significant differences were found in ED admissions and inpatient or outpatient care between the intervention and control groups. • Appointment no-show rates were 21.0% versus 30.6% (*P*=.08).
LePage et al, 2023 [41]	7 days	6 months post	• The acceptability of the system • The impact of the system	• Veterans found the web-based program as acceptable as a hardcopy manual covering similar material. Participants randomized to the web-based system were more likely to obtain employment than people randomized to the hardcopy manual.
McInnes et al, 2014 [42]	2	Immediately after (2 months)	• Feasibility, effectiveness, and acceptability of text message reminders for people experiencing homelessness	• Participants were satisfied with the text-messaging intervention and had very few technical difficulties. • Patient canceled visits, and no-shows trended downward.
Reitzel et al, 2014 [43]	1	6 months post	• Associations between shelter proximity and real-time effects during a specific smoking quit attempt	• Closer proximity to the shelter was associated with greater negative effects only during the post-quit attempt week (*P*=.008). All participants relapsed to smoking by 1-week post-quit attempt.
Rhoades et al, 2019 [44]	1.5	12 months post	• Physical activity • Acceptability • Wellbeing	• Changes to people's physical activity levels were limited, but participants reported increased quality of life during the intervention period. Interviews revealed that the intervention was well-received and enjoyable for participants.
Wilson et al, 2023 [45]	1.5	3, 6, and 12 months post	• The effectiveness of the intervention on biochemically verified prolonged smoking abstinence	• At 6 months, participants in the mCM group were significantly more likely to meet the criteria for prolonged abstinence (AOR=3.1). Across time points, veterans in the mCM group had twice the odds of prolonged abstinence as those in the standard care group. However, by the 12-month follow-up, no statistically significant group difference in abstinence existed.
Wray et al, 2022 [46]	6	immediately (6 months post)	• Characterize device recipients • Assess in-person, telephone, and video-based engagement patterns across a variety of clinical settings	• Compared with the 6 months prior to device receipt, in the 6 months following receipt, in-person and video engagement increased by an average of 1.4 visits (8%) and 3.4 visits (125%). Tablet users had a substantially more significant increase in video-based engagement (þ3.2 visits [þ110%] vs þ0.9 [þ64%]).

[a]CCHT: Care Coordination Home Telehealth.

[b]AOR: adjusted odds ratio.

XSL•FO
RenderX

Figure 2. Summary of the 10 digital interventions included in this review. Interventions were categorized into implementing telecare for people experiencing homelessness, distributing technology to enable digital inclusion, text message reminder interventions, and 4 interventions delivered digitally. CBT: cognitive behavioral therapy.

No papers included aimed to develop or deliver interventions specifically for older people experiencing homelessness participants. Additionally, no interventions were found specifically for organizations supporting people experiencing homelessness. Thus, all included studies were developed to be used by individuals experiencing homelessness without specific considerations for older age.

Outcomes From Digital Interventions

Overview

Thematic analysis of study outcomes identified 4 themes: improved digital inclusion, enhanced service engagement and care, no significant outcomes, and unintended consequences from digital interventions (summarized in Textbox 2). Individual intervention outcomes are summarized in Table 2. Barriers and facilitators for digital interventions were synthesized from the included interventions. Finally, the thematic analysis identified the overall feasibility of the included interventions.

Textbox 2. Outcomes from included digital interventions for older people experiencing homelessness and their impact on them.

Improved digital inclusion:

- More equitable access to digital tools by improving the availability of resources [37-39,44,46]
- Improved perceptions of digital intervention [37,39]

Enhancing service engagement and care:

- Improvement in appointment attendance [40,42,46]
- Improvement in medication adherence [42]
- Improvement in perceived quality of care [37,38]

Unintended outcomes:

- Disengagement with in person services [38,46]

Improved Digital Inclusion

The outcomes of 5 included studies demonstrated more equitable access to digital tools for older people experiencing homelessness [37-39,44,46]. First, 2 studies evaluating device distribution programs concluded that tablet distribution offers a model for expanding access to health-related technology and telemedicine [39,46]. In the first study, Garvin et al [39] found that nearly half (45.9%) of veterans experiencing homelessness who received a tablet went on to use the device for video health

XSL•FO
RenderX

consultation within 6 months of receipt. The most frequent tablet use was for tele-mental health support. In bivariate analyses, homeless tablet users were also less likely to have 3 or more chronic conditions (48.7% vs 56.7%; *P*=.006) or to have substance misuse disorder (47.6% vs 58.2%) [39]. The second study was a 6-month evaluation of people experiencing homelessness as digital device recipients. Wray et al [46] found engagement characteristics were similar between those who received a tablet or a cell phone, though fewer individuals with a cell phone had video encounters after receiving a device (45.3% vs 67.4%; *P*<.001), compared with those who received a tablet.

In addition to improving the availability of resources for digital inclusion, 2 studies addressed perceptions or acceptability of the intervention within the population, promoting digital inclusivity [37,39]. For example, during a 12-week telecare pilot for people experiencing homelessness in sheltered housing, Békási et al [37] demonstrated a significant difference in openness to telecare among people experiencing homelessness participants. They found that a group of previously digitally excluded homeless persons found the telecare visits helpful and valuable [37]. Similarly, Gabrielian et al [38] found support for telecare acceptability among homeless veterans with chronic conditions.

Enhancing Service Engagement and Care

Two studies used text message appointment reminders and showed improvement in appointment attendance and medication adherence for people experiencing homelessness [40,42]. In an 8-week pilot intervention period, McInnes et al [42] compared appointment attendance in pre and postintervention periods for a text messaging reminder intervention. They found that twice-weekly text message reminders led to a significant reduction of 30% in patient-cancelled appointments, and "no-shows" (missed appointments) were reduced by 19% [42]. Similarly, when they assessed the feasibility and effectiveness of text messaging to increase outpatient care engagement and medication adherence in people experiencing homelessness in Boston, Kershaw et al [40] recorded positive comments from participants overall. Qualitative findings from the follow-up interviews with intervention group participants showed that text messages functioned as social support. In addition, text messages complemented the participant's lifestyle, and appointment reminders were helpful to ensure attendance [40].

The 2 telecare interventions demonstrated that digital delivery was acceptable to people experiencing homelessness and significantly improved the perceived quality of care [37,38]. Participants in the telecare pilot by Békási et al [37] were present at more than 90% of initially planned appointments, and almost 3-quarters of recruited clients completed the whole course of 6 web-based visits. In postintervention qualitative interviews for a Care Coordination Home Telehealth intervention, participants described telecare as user-friendly and promoted illness self-management [11]. Similarly, Wray et al [46] found that the distribution of "tablets" to veterans improved participants' access to clinical services as it facilitated telecare uptake.

Three digital interventions improved the health and well-being outcomes of people experiencing homelessness [40,44,45]. In a comparative effectiveness trial of digital smoking cessation, Wilson et al [45] reported that veterans in the digitally delivered cognitive behavioral therapy group had twice the odds of prolonged tobacco abstinence compared with the control. Similarly, Rhoades et al [44] identified text messaging and the use of pedometers as a feasible and promising option for improving health and well-being among people experiencing homelessness, as slightly more than half (54%) of participants increased their weekly steps from the beginning to the end of the intervention.

Digital Interventions Demonstrated no Significant Difference

Conversely, 2 studies could not demonstrate any significant difference between control and intervention groups in prestated outcomes for some aspects of digital interventions [40,41]. Kershaw et al [40] aimed to demonstrate outcomes in the text messaging reminders that impacted inpatient care for veterans experiencing homelessness; however, no significant differences were found in an inpatient or outpatient care engagement between the intervention and control groups. Additionally, when stratified by appointment type, there were no significant differences in appointment keeping between intervention and control groups, and estimated effect sizes were small for both appointment types. However, effect sizes for completed appointments and no-shows were slightly larger for physical health appointments than for behavioral health appointments [40]. In a randomized controlled pilot test of employment outcomes, Lepage et al [41] found that the web-based vocational rehabilitation program's control and intervention groups did not differ significantly in the number of modules completed.

Unintended Outcomes of Digital Interventions

Two studies reported unintended consequences of implementing digital interventions [38,46]. Wray et al [46] observed a "substitutive effect"—where telephone-based engagement decreased while in-person and video-based engagement increased at a commensurate rate. Further, compared with those who received a cell phone, those who received a tablet had a smaller increase in in-person (1.3 visits, 8% vs 2.1 visits, 13%) visits and a greater decrease (4.6 visits, 23% vs 1.8 visits, 12%) in telephone visits. They suggest this could negatively impact patients' willingness to engage with in-person care options [46]. This aligns with the findings of Gabrielian et al [38], which reported the unintended negative consequence of participants feeling detached from the technology by the digital delivery of telehealth. In particular, participants felt digital delivery was impersonal.

Barriers and Facilitators to Digital Interventions for Older People Experiencing Homelessness

Overview

Five studies reported age and pre-existing digital exclusion as barriers to people experiencing homelessness in the studied digital interventions [37,39,40,42,46]. Table 3 summarizes the barriers and facilitators identified in the review. Three studies found that the predominant facilitators of digital interventions for people experiencing homelessness were organizational support and peer support [37,39,44].

XSL•FO
RenderX

Table 3. Summary of the reported barriers and facilitators of digital interventions of older people experiencing homelessness.

Barriers	Facilitators
Digital literacy [40,41]	Organization support/technical assistance [37,40,44,46]
Device loss and theft [40]	Charging spots [40]
Internet connection [46]	Peer support [38]
Prohibitive cost (data and minutes) [37,42]	—[a]
Age [39]	—

[a]Not applicable.

Barrier: Digital Exclusionary Factors for People Experiencing Homelessness

Three studies noted participants' difficulties in operating devices and a need for supporting digital literacy. Kershaw et al [40] highlighted digital literacy problems, with 31% (n=19) of participants reporting some technical difficulty, confusion, and usability problems when operating flip phones. Furthermore, Kershaw et al [40] reported loss and theft of mobile devices frequently during the study, requiring numerous replacements given the population is at elevated risk of experiencing theft and limited ability to store devices securely. In distributing tablets to people experiencing homelessness, Wray et al [46] highlighted challenges in maintaining connectivity to the internet and digital literacy problems as factors negatively impacting their experience of such tools. Similarly, McInnes et al [42] noted financial barriers to mobile phone use (eg, running out of minutes).

Barrier: Age

One study reported age as a barrier to the tablet adoption intervention. Following distribution, tablet use was more common among veterans experiencing homelessness who were younger (adjusted odds ratio 2.77; $P<.001$). Garvin et al [39] suggest that older veterans would benefit from simplified user interface designs and digital literacy training to increase comfort, confidence, and willingness to use.

Facilitator: Organizational Support Required

No studies identified in the review focused their intervention on organizations supporting people experiencing homelessness. However, 4 studies note that assistance from support staff or research teams was required in the set-up or duration of the intervention [37,40,44,46]. In the telecare intervention of Békási et al [37], the presence of on-site assistants served as technical support and prevented any misunderstandings regarding medication or referral issues. Rhoades et al [44] gave participants one-on-one assistance with using text messaging as needed. Wray et al [46] preconfigured devices and loaded them with videoconferencing software and mobile apps for participant ease. Kershaw et al [40] conclude that making charging more readily available where homeless persons spend their time could also help reduce theft, such as near bedsides in shelters (inside lockers) and more widely available in libraries, health clinics, food banks, and soup kitchens.

Facilitator: Peer Support

Two studies suggested implementing peer support to enhance adherence and troubleshoot utility issues [38,45]. Gabrielian et al [38] employed peer mentors to conduct visits with veterans to assess relevant psychosocial circumstances and report back to researchers on any equipment/medical concerns. They suggested that peers could significantly break down patient-level barriers to participation in telecare management. Nevertheless, institutional obstacles prevented peer contact with veterans-with 10 of 14 participants opting for adjunctive peer support [38]. Similarly, Wilson et al [45] suggest approaches that integrate peer support into smoking cessation intervention sessions/groups might be beneficial, given previous research indicating that knowing 5 quitters was associated with greater odds of achieving smoking abstinence among homeless smokers.

Potential Viability of Digital Interventions for Older People Experiencing Homelessness

Three included studies concluded that the intervention demonstrated the viability of digital delivery for older people experiencing homelessness [37,39,42]. There was evidence of a feasible telecare setup in shelters offering accommodation to people experiencing homelessness that might support the planning of future telecare services for vulnerable populations [37]. McInnes et al [42] proposed that text messages are a feasible digital intervention as they are an unobtrusive connection to patients, and mobile phones are one of the few communication tools that people experiencing homelessness can attain. Further, they concluded that appointment reminders are greatly needed for this population because they frequently lack the tools that nonhomeless take for granted: reliable mailing addresses, landline phones, wall or computerized calendars, and social supports to remind them of appointments [42].

Discussion

Principal Findings

The scoping review examined the range, nature, and use of digital interventions available to older people experiencing homelessness and organizations that support older people experiencing homelessness. We identified only concerned studies within an Organization for Economic Co-operation and Development context detailing digital interventions with participants who were older and experiencing homelessness. The nature of interventions included digitally delivered primary health care (telecare) [37,39], appointment reminders [40,42], technology distribution [39,46], and well-being interventions

XSL•FO
RenderX

delivered in a digital format [41,43-45]. Included interventions found that common barriers were existing digital exclusion factors for older people experiencing homelessness, such as digital literacy, absence of safe storage for technology, and inconsistent internet connectivity. Suggested facilitators for older people experiencing homelessness in digital interventions were organizational and peer support. The searches found no interventions designed for adoption by support services (as opposed to the older people experiencing homelessness user). Further, it should be noted there was a lack of studies reporting on other dimensions of exclusion (ethnicity, gender, etc) for older people experiencing homelessness. Finally, no included interventions were intended for sole use by a cohort of older homeless adults; subsequently, there were no specific considerations for older people in the intervention design. Therefore, this review highlights the paucity of digital interventions designed for and delivered to older people experiencing homelessness.

Older People Experiencing Homelessness and Digital Engagement

This review demonstrates evidence that digital interventions could benefit older people experiencing homelessness. Consequently, it is crucial to understand the prevalence and use of technology among older people experiencing homelessness to implement digital interventions effectively. People experiencing homelessness access to mobile devices varies greatly. One study showed that as many as 95% had a mobile phone, and 77% reported having a smartphone [48]. However, participants from an ongoing clinical trial at a homeless shelter in Texas reported lower (28.4%) access to an active cell phone. However, 88.6% of participants reported at least weekly internet use, and 77.2% used email [49]. It is well established that older adults in the general population use technological solutions at lower rates than younger adults [50]. In addition, little is known about access to and use of the internet and mobile phones by older homeless adults. Raven et al [20] make one of the only attempts to describe the access to and use of mobile phones, computers, and the internet among 350 homeless adults older than 50 years. They found that most (72.3%) participants owned or had mobile phone access. Participants used phones and the internet to communicate with medical personnel (64.6%), search for housing and employment (30.7%), and to contact their families (82.3%). They concluded that participants had a lower prevalence of smartphone and internet access than adults aged older than 65 years in the general public or low-income adults. Participants faced barriers to mobile phone and internet use, including financial barriers and functional and cognitive impairments [20].

Only one included intervention analyzed age as a variable for use, where tablet use was less likely for older participants [39]. Similarly, in a sample of homeless-experienced adults aged 50 years and older, Raven et al [20] found that almost 3-quarters of participants had current access to a mobile phone. However, participants had a lower prevalence of smartphone and internet access than adults older than 65 years in the general public or low-income adults [20]. This demonstrates that premature aging and complex social challenges that are attributed to homelessness are significant factors in digital exclusion. Concurrently, in the literature, there are significantly more evaluated digital interventions for youth experiencing homelessness (YEH) than those retrieved for this review [49,51-61]. The disparity in tailored interventions for YEH and older people experiencing homelessness further illustrates the widening digital divide for older people experiencing homelessness.

Digital Exclusion as a Barrier

Three included studies highlighted exclusionary factors associated with homelessness, causing barriers for digital interventions [40,42,46]. Technological competency, limited safe storage, and lack of internet connectivity were all referenced in this review as barriers to digital interventions for individuals experiencing homelessness [40,46]. Sieck et al [62] state that digital literacies and internet connectivity have been called the “super social determinants of health” because they address all other social determinants of health. For example, applications for employment, housing, and other assistance programs, are increasingly, and sometimes exclusively, accessible via the web [62]. In their systematic review of technology for people experiencing homelessness, Heaslip et al [19] found that older people experiencing homelessness felt further marginalized by the modern benefits system that “assumes” digital competence and confidence. As participation in most included studies was voluntary, older people experiencing homelessness with a more positive attitude and openness toward telecare might have been overrepresented in the sample, skewing the sample to those more digitally literate [37]. “Access instability” is a term used by Galperin et al [63] to describe their findings that reliable access to electrical power represents a fundamental yet understudied barrier to mobile use. Lacking a safe and reliable place to charge devices, the unstably housed must activate coping strategies that limit digital engagement and constrain use [63]. Overall, this suggests that while digital interventions have the potential to expand inclusion, existing literacy and connectivity barriers must be addressed in tandem with implementation.

Facilitators of Digital Interventions

Despite those barriers, digital interventions can also facilitate access to care. In this review, Garvin et al [39] suggest older veterans would benefit from simplified computer app designs and digital literacy training to increase comfort, confidence, and willingness to engage in their tablet adoption intervention. Concurrently, Sieck et al [62] posit that improving digital literacy skills to access valuable digital tools is key to reducing disparities. In a digital access survey for people experiencing homelessness, Sturman et al [64] found that digital literacy was positively associated with uptake in digital health interventions. Relatedly, Van den Berk-Clark and McGuire [65] argue that the issue of trust between people experiencing homelessness and support services is multifaceted and is influenced by technical competence and the degree to which the individual is made to feel welcome. A study of video consultation suggested that clinicians interacting with homeless-experienced older adults should prioritize addressing the potential skepticism of video calls. Further, it is proposed that clinicians should assess

XSL•FO
RenderX

their access to and knowledge of video conferencing technology [66].

Similarly, 4 studies found that organizational or research team support facilitated the engagement of people experiencing homelessness with digital interventions. Furthermore, the authors identified peer support as a key contributor to participants' comfort with digital interventions [37,40,44,46]. However, Gabrielian et al [38] stated that most participants did not use peer support and highlighted that fostering trust with those providing technology assistance was of primary importance. Similarly, Glover et al [54] found that YEH preferred automated mobile phone functions that avoided interaction with professionals and peers.

This review included 6 studies with interventions conducted with veterans in the United States [38,39,41,42,45,46]. The interventions benefited from the support and infrastructure of the US Department of Veterans Affairs (VA) [67]. It can be assumed that the integration of VA into the health system facilitated the implementation of the interventions. However, additional evaluative research on the context of the implementation is required to determine if internal process barriers nullify any potential facilitatory effects [68].

Implications for Policy and Practice and Future Research

This scoping review highlights several research gaps, upon which we base the following recommendations:

1. The review demonstrated a largely positive view of older people experiencing homelessness's digital interventions however, this needs to be supported by additional empirical evidence of the health and well-being benefits.
2. Additional research is needed to examine older people experiencing homelessness's access to and use of digital tools and interventions.
3. More research is needed on the digital health literacy skills of older people experiencing homelessness and their experiences of using technology to search for and access information and services.
4. Additional evaluation of the implementation infrastructure, for example, the health system deploying a telecare initiative, on the efficacy of an intervention for older people experiencing homelessness
5. Finally, future research should also focus on developing and evaluating digital interventions for older people experiencing homelessness.

The use of digital interventions is a rapidly developing area of practice for professionals with several elements to consider, including:

1. increasing access to technology
2. optimizing technology-based infrastructure,
3. providing training for community outreach and practitioners,
4. engaging service users in the co-design of diverse and contextually sensitive interventions

Due to longstanding digital barriers, implementing digital interventions without addressing older people experiencing homelessness's digital exclusion will likely further damage trust and perpetuate existing poor support service access. As such, services should:

5. systematically assess individual patients' digital literacies,
6. learn about their internet access, and
7. work to address their needs.
8. Partner with community-based organizations with expertise in digital literacy training to address comfortability.

Policy for digital inclusion of older people experiencing homelessness should prioritize free and accessible technology in public settings (eg, shelters, community centers, libraries, and harm reduction centers) and free access to mobile devices. Action is needed across government, public, private, and third-sector organizations to ensure capitalization on the potential for digital interventions to address health and well-being while minimizing the risk of exacerbating existing health inequalities.

Strengths and Limitations

This scoping review has several strengths. To the best of our knowledge, it is the first scoping review to describe the digital interventions for older people experiencing homelessness. We followed the JBI guidance for scoping reviews [33] and our database searching, handling of data, and reporting adhered to published guidelines for undertaking a robust standard scoping review [25,27].

Several limitations should be highlighted. Given the heterogeneity of study methods, we did not systematically assess the quality of studies. Similarly, only English language publications were included due to time and human resources. As there was inconsistency in how papers reported participant age, either a subgroup of participants was clearly defined as older than 50 years or the entire participant group's mean age was older than 50 years. We acknowledge that this inclusion method may generate an incomplete picture of available interventions for older people experiencing homelessness. Most participants in the included studies are veterans based in the United States; therefore, any attempt to generalize these results should be undertaken with caution.

Finally, as this study is not a formal meta-analysis, we did not use more complex statistical pooling methods or analyze the heterogeneity in outcomes reported; as such, our results should be interpreted with these considerations in mind.

Conclusion

Our findings demonstrate the paucity of bespoke digital interventions for older people experiencing homelessness. However, the included studies demonstrate some evidence for the acceptability and feasibility of digital interventions for older people experiencing homelessness. To leverage the potential benefits of digital interventions for older people experiencing homelessness, implementing such interventions will require additional consideration of the multiple exclusionary factors experienced by older people experiencing homelessness. The anticipated increase in the number of older people experiencing homelessness warrants further research on the impact of digital interventions for this vulnerable population.

Acknowledgments

We want to thank Rowena Stewart, academic support librarian at the University of Edinburgh Library, for her contribution to the literature search. We are also grateful for David Henderson's initial contribution to this scoping review, who reviewed the protocol prior to registration. Finally, thanks to Victoria Barber Fleming, who supported the pilot screening. This research was funded by the Legal & General Group (a research grant to establish the independent Advanced Care Research Centre at the University of Edinburgh). The funder had no role in the conduct of the study, interpretation, or the decision to submit for publication. The views expressed are those of the authors and not necessarily those of Legal & General.

Authors' Contributions

EA conceptualized this research, and SWM, ED, CS, and MW contributed to the study design. Search Strategy and searches were completed by EA in consultation with RS. The title and abstract screening were conducted by EA, LN, RG, and CSJ, and full-text screening and data extraction were carried out by EA and LN. The manuscript was drafted by EA. A critical review of the manuscript was undertaken by SWM, ED, CS, and MW. EA is the guarantor, accepts full responsibility for the finished work and the conduct of the study, and has access to the data. All authors approved the final manuscript**.**

Abstract

Background: Mental health plays a key role across the cancer care continuum, from prognosis and active treatment to survivorship and palliative care. Digital health technologies offer an appealing, cost-effective tool to address psychological needs.

Objective: This umbrella review aims to summarize and evaluate the available evidence on the efficacy of digital health interventions for improving mental health and psychosocial outcomes for populations with cancer.

Methods: Literature searches were conducted in Embase, PsycINFO, PubMed, CINAHL, the Cochrane Library, and Web of Science from their inception to February 4, 2024. Systematic reviews (with or without meta-analysis) investigating the efficacy of digital health interventions for psychosocial variables in patients with cancer were included. Quality was assessed using the Assessing the Methodological Quality of Systematic Reviews-2 tool.

Results: In total, 78 systematic reviews were included in this review. Among diverse delivery modalities and types of digital interventions, websites and smartphone apps were the most commonly used. Depression was the most frequently addressed, followed by quality of life, anxiety, fatigue, and distress. The qualities of the reviews ranged from critically low to high. Generally, despite great heterogeneity in the strength and credibility of the evidence, digital health interventions were shown to be effective for mental health in patients with cancer.

Conclusions: Taken together, digital health interventions show benefits for patients with cancer in improving mental health. Various gaps were identified, such as little research specifically focusing on older adult patients with cancer, a scarcity of reporting high-precision emotion management, and insufficient attention to other certain mood indicators. Further exploration of studies with standardized and rigorous approaches is required to inform practice.

Introduction

Global cancer statistics for 2022 released by the International Agency for Research on Cancer of the World Health Organization indicate that there will be almost 20 million new cases of cancer and approximately 10 million cancer deaths in 2022, and the annual number of new cases of cancer will reach 35 million by 2050, a 77% increase from the 2022 level [1]. Patients of all ages may experience psychological distress at any stage of the cancer continuum, from diagnosis and active treatment to survivorship and palliative care [2-4]. The financial burden, and fear of death, together with prognostic uncertainty,

XSL•FO
RenderX

cause patients to suffer a series of negative emotional experiences [5,6]. The prevalence of psychological distress in patients with cancer (20%) was approximately twice as high as in healthy controls (10.63%) [7]. A meta-analysis of 94 interview-based studies showed that the prevalence of mood disorders in patients with cancer attained 38.2% in the first 5 years after diagnosis, with depression and anxiety being more common, affecting up to 20% and 10% of patients with cancer respectively [8]. What is worse, these symptoms persist despite recovery from cancer [9,10]. Psychological distress has been identified as the sixth vital sign in cancer care [11]. Unmet psychological support needs could adversely affect cancer prognosis, which has been negatively associated with treatment adherence, quality of life, and even impact survival rates [12-14]. However, in traditional health care practice, health care providers often focus on the progression of medical and physical symptoms, while frequently overlooking the psychological needs of patients [7,15]. Moreover, due to the constraints in time, location, and economic costs, in-person psychosocial support is difficult to consistently reach the majority of people in need [16]. Accordingly, there is an urgent need for more accessible, cost-effective, and widespread approaches to the early identification and treatment of psychological distress in patients with cancer [17].

Recently, clinicians and patients have been increasingly inclined to opt for digital delivery models [18]. Notably, the transformation of health services during the COVID-19 pandemic activated the promotion and application of digital health in cancer care, in parallel with the acceleration of the interest and investment of health systems in remote care and digital technologies [19,20]. Compared to the traditional face-to-face delivery model, digital delivery technology is perceived to offer several advantages. In addition to high scalability, low access thresholds, and availability, natural anonymity provides a more private and stigma-free environment, which helps overcome some limitations of in-person psychological support for patients with cancer [21].

In recent years, the growing interest in digital health interventions for mental health management in cancer care has led to numerous systematic reviews and meta-analyses. These studies cover a variety of interventions (ie, internet cognitive behavioral therapy [iCBT] [22,23], "web-based" mindfulness-based cognitive behavioral therapy [24,25], and music therapy [26]). Though several current systematic reviews have examined the efficacy of digital health interventions on specific indicators of mood disorders (ie, anxiety [23,27-30], depression [23,27-31], and fear of recurrence [32,33]) in patients with cancer, mental health is a complex and integrated concept, which is hard to comprehensively embrace and assess by a single systematic review or meta-analysis. Furthermore, the current evidence is extensive and scattered, inconsistent conclusions and varied interventions make it difficult to use a similar metric and methodological framework to appraise it. In this context, umbrella review has emerged as a more integrated research methodology. Nevertheless, published umbrella reviews in the field of digital health care focused on physical activity [34] or other individuals [35], lacking research on mental health aspects.

Given the earlier findings, this umbrella review aims to comprehensively summarize and appraise the available evidence on the efficacy of digital health interventions for alleviating psychological symptoms among patients with cancer.

Methods

Overview

We conducted an umbrella review, in which all currently available evidence from previously published multiple systematic reviews and meta-analyses was systematically collected and assessed, and it could provide an overall picture of the digital health care area on mental health management for patients with cancer and highlight whether the evidence base is consistent or contradictory [36-38]. It adheres to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [39,40] and was conducted according to the recommendations for umbrella reviews to report findings [41]. The protocol was registered on PROSPERO (CRD42024565084).

Search Strategy and Inclusion or Exclusion Criteria

Six databases were searched from their inception to February 4, 2024: Embase, PsycINFO, PubMed, CINAHL, the Cochrane Library, and Web of Science. Our search strategy used the following terms: (1) neoplasm* OR cancer OR oncology* OR tumor? OR "secondary cancer" OR malignancy, (2) "web-based" OR "internet-based" OR "technology-based" OR "ehealth" OR "mhealth" OR "connected health" OR "telehealth" OR online OR digital OR mobile OR "text messag*" OR "social media" OR "internet-based cognitive behavioral therapy" OR "ICBT" OR "online mindfulness-based cognitive behavioral therapy," (3) intervention OR "self-management" OR "support care" OR program* and (4) mental health OR mental OR psycho* OR depression OR anxiety OR distress OR mood OR fatigue. The complete list of search terms is presented in Multimedia Appendix 1. The reference lists and citations of relevant studies were manually examined to identify additional publications. We did not pursue unpublished and gray literature and key journals. The eligibility criteria were structured using the Population, Intervention, Comparison, Outcome, and Study (PICOS) framework (Textbox 1) [42].

XSL•FO
RenderX

Textbox 1. Inclusion and exclusion criteria for this umbrella review.

Inclusion criteria

- Population: (1) The population of interest comprised patients with cancer, regardless of age, any type, and stage throughout the entire cancer continuum, from diagnosis to survivorship; and (2) focused on diverse health conditions but included cancer groups, and from which relevant data could be independently extracted.
- Intervention: Our operational definition of digital health comprises eHealth, mHealth, telehealth, virtual reality, and telemedicine and (2) any type of digital health intervention, whether psychological, physical, or supportive care interventions provided by any form of digital technology (eg, website, telephone, smartphone app, and videoconference).
- Comparison: No restrictions.
- Outcome: (1) The outcome of interest was mental health, which is defined as a state of well-being that allows individuals to cope with the normal stresses of life and function productively, with several core domains encompassing mental health literacy, self-perceptions, values, cognitive skills, emotions, self-management strategies, and quality of life [43], including but not limited to indicators of psychological well-being and any varying levels of psychological distress; and (2) other indicators and precursors of mental health, such as self-efficacy, social support, mindfulness, sleep problems, resilience, rumination, perceived stress, posttraumatic stress, or problems were also considered [44,45].
- Study design: (1) Systematic review (with or without meta-analysis); (2) published in peer-reviewed journals; and (3) written in English.

Exclusion criteria

- Population: (1) Did not exclusively consider patients with cancer and (2) all studies particularly focused on a specific area or race.
- Intervention: Did not mainly relate to digital health interventions.
- Comparison: No restrictions.
- Outcome: Did not focus on mental health.
- Study design: Other wrong study designs (such as scoping reviews, literature reviews, or primary research).

Selection and Screening Process

We imported all retrieved records into Zotero (Corporation for Digital Scholarship) for the removal of duplicates and management and for title, abstract, and full-text screening. Before the selection phases, standard training was created for each reviewer to identify the review qualification. The full text of relevant reviews was independently evaluated by 2 reviewers to finalize its eligibility (CH and JC). Disagreements were resolved by a consensus session with another reviewer (YW).

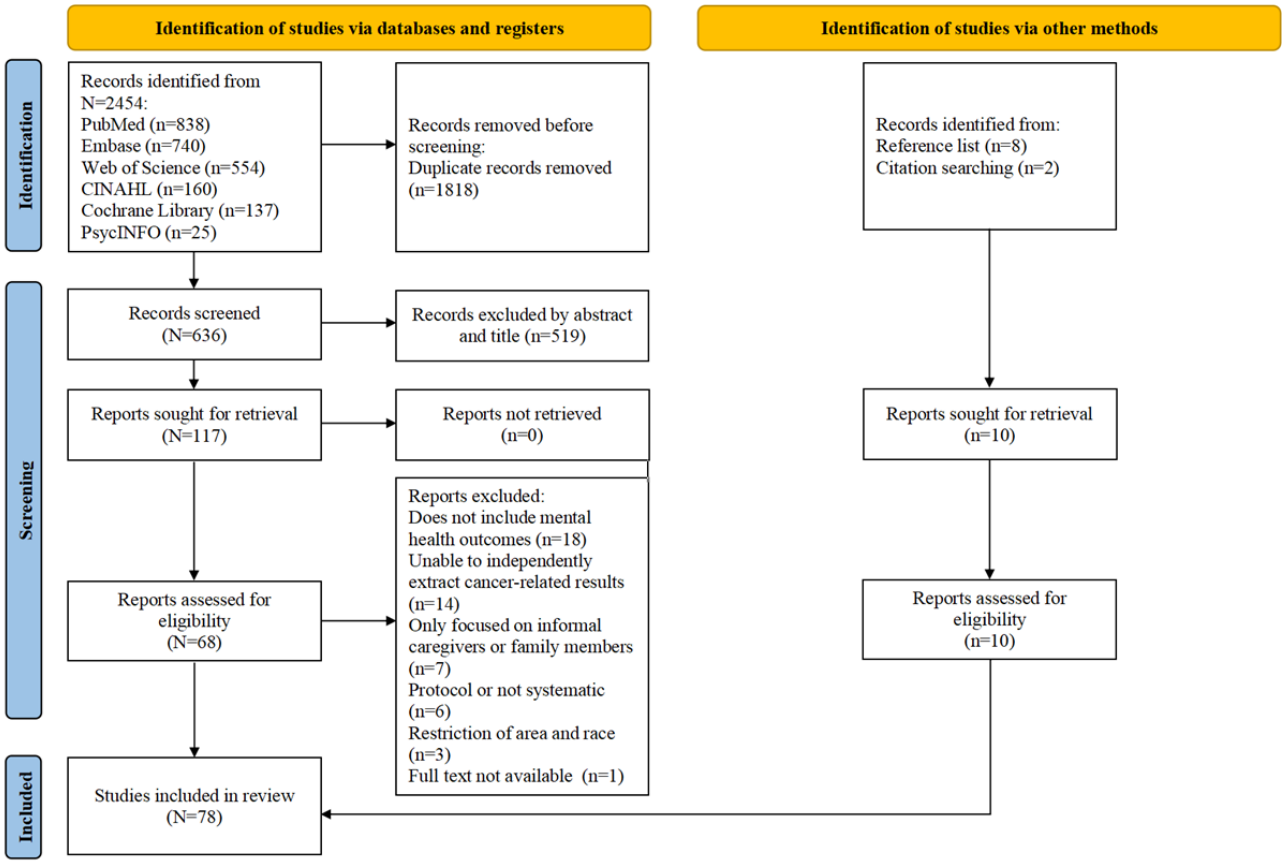
Data Extraction and Synthesis

To minimize the risk of error and bias, a predefined Microsoft Excel spreadsheet was developed and pilot-tested on 8 randomly selected reviews and then refined accordingly. Data were independently extracted by 2 authors (CH and JC; Multimedia Appendix 2).

Two reviewers (CH and JC) independently evaluated the methodological quality of the included reviews using the Assessing the Methodological Quality of Systematic Reviews-2 tool [46], a strict, validated, and reliable appraisal tool used for systematic reviews and meta-analyses on health care interventions. It consists of 16 items and rating overall confidence in the results of the review as 4 grades: high, moderate, low, or critically low. Any disagreements and conflicts were resolved through discussion by the review team until a consensus was reached.

Due to the great heterogeneity of interventions and delivery technology and the inconsistency of measured outcomes, evidence was analyzed by narrative synthesis.

Results



Study Selection

In total, 2454 records were retrieved from 6 electronic databases of which 636 studies were retained after removing 1818 duplicate records. Screened by abstracts and title, 519 records were excluded. We reviewed the full texts of the remaining 117 studies and excluded 49 studies because of the following reasons: not include mental health outcomes (n=18, 37%), unable to independently extract cancer-related results (n=14, 29%), only focused on informal caregivers or family members (n=7, 14%), protocol or not systematic (n=6, 12%), restriction of area and race (n=3, 6%), and not available full text (n=1, 2%). A hand search was conducted for references and citations, and an additional 10 records were identified for eligibility. Finally, 78 reviews were included, of which 45 (58%) reviews were meta-analyses, and 33 (42%) reviews were systematic reviews for narrative synthesis. Figure 1 illustrates the selection process flowchart according to the PRISMA guidelines.

The PRISMA checklist is found in Multimedia Appendix 3. A full list of excluded studies from the full-text review with reasons for exclusion can be found in Multimedia Appendix 4.

Study Characteristics

Overview

The included reviews were published between 2015 and 2024, and it is worth mentioning that 58 (74%) reviews were published after 2019. Sixty-eight (87%) reviews reported geography information to ensure diversity, with research mainly performed in the United States, Europe, and Asia Pacific, while countries in low or middle-income areas like Africa and South America were less common. The number of studies and sample size varied from 4/374 to 68/13,125. Sixty-two (80%) reviews reported the range of duration of interventions, and 36 (41%) reviews reported the follow-up period. Twenty-seven (35%) reviews included interventions that did not report explicit providers, and 29 (37%) reviews included automatic feedback or self-guided interventions, while 32 (41%) reviews included interventions that were provided by health care professionals, which consisted of mainly nurses, physicians, or psychologists, in addition to dietitians, and information engineers. A framework was developed based on this umbrella review showing how digital health interventions have been used to improve mental health in patients with cancer. Our represented framework (Figure 2) consists of 4 layers: individual, technology, involvement, and intervention, and each layer contains the corresponding aspects categories. The top layer is the main content involved in digital health interventions on mental health. The second layer is the participants required for the intervention. The third layer is the involved digital technologies and delivery platforms. The fourth layer is the target population. Extracted study information is presented in Table 1.

Target Population

Of 78 included reviews, 39 (50%) mainly addressed patient-level interventions, 16 (21%) exclusively addressed survivor-level interventions, and 18 (23%) both focused on patients and survivors. The remaining 5 reviews (6%) featured patient and caregiver-level interventions [47-51], and two of them were in the form of dyads (1 review was a patient-caregiver dyad [49] and the other review was a survivor-caregiver dyad [51]), which aimed at exploring specific characteristics on web-based dyadic interventions.

25 reviews (32%) restricted participants based on cancer type, with breast cancer being the most common focus in 18 (23%) reviews, of which 6 reviews restricted inclusion criteria for only women. Two reviews each targeted colorectal cancer [52,53], and head and neck cancer [54,55], while 1 review targeted lung cancer [56], 1 review targeted prostate cancer [28], and 1 review targeted gynecological cancer [30]. The remaining 53 (67.9%) reviews included one or more specific cancer types, with 1 review exclusively focused on advanced cancer [57]. Six reviews (8%) focused on pediatric, adolescent, or young adult individuals with cancer or their caregivers. Of these, 3 reviews focused on pediatric, adolescent, or young adult patients with cancer [58-60], 2 on adolescent, or young adult patients with cancer [61,62], and 1 focused on children and adolescents and their parents with cancer [63]. No reviews mentioned older adult patients with cancer or people who have survived cancer. Because cancer type was most frequently and clearly reported across reviews, we additionally used it to stratify our synthesis results (Figure S1 in Multimedia Appendix 5).

Delivery and Type of Intervention

Rather than focus on a single intervention delivery platform, reviews were more interested in including studies of contained interventions that entirely or in part provided multiple asynchronous or synchronous delivery platforms. It should be emphasized that some in-person elements could be used as additional supplementary components (eg, printed material, educational brochures, face-to-face consultations) at the same time.

Of the multiple included delivery technologies or platforms, website (n=57, 73%) is the most frequently selected platform, smartphone app was followed by (n=45, 58%), and other common technologies are telephone (n=28, 36%), telehealth messaging services (n=21, 27%), videoconference (n=15, 19%), electronic devices (n=13, 17%), and audiovisual resource (n=8, 10%). Admittedly, the use of gamification and new technologies such as virtual reality (n=12, 15%), artificial intelligence (AI) systems (n=1), and communicative chatbots or humanoid robots (n=5, 6%) were not in the minority. As shown in Table 1, the delivery methods based on websites and smartphone apps are the most common. Therefore, we conducted a subgroup narrative synthesis for these two approaches (Figures S2 and S3 in Multimedia Appendix 5). The impact of each platform on various outcomes is represented by the number of studies conducted. Combinations of delivery platforms show a broader coverage of outcomes, indicating that multi-platform combined interventions can provide more comprehensive support.

Similarly, the included interventions were diverse. Eighteen reviews (23%) included studies that were not specifically detailed in their intervention methods or were too broad to be classified. Among the remaining 60 reviews (77%), due to a large variation in reported intervention components, we have categorized them into five dimensions: (1) psychosocial and emotional enhancement; (2) behavior and lifestyle change management; (3) education and information support; (4) counseling and ope communication; and (5) symptom detection and self-management. The first dimension is the most predominant (62%) of included reviews and commonly involves psychological interventions, psychoeducation, and social or peer support. Of the more than a dozen digital psychological interventions included, the most reported type of intervention was iCBT, which a total of 24 (31%) reviews investigated. All interventions were designed based on CBT theory, involving various elements (eg, cognitive restructuring, problem-solving strategy, coping skill training). Certainly, the structure and content of the iCBT were diverse. For instance, 3 reviews included studies that used web-based specified or tailorable CBT training modules [22,23,64], which could be completed with therapist support or with self-guidance. In general, the self-guided method is generally realized by the corresponding modules of intervention independently completed by patients. The therapist-guided method is conducted by therapists providing feedback and support, conducting intervention sessions, or monitoring symptoms via digital technology platforms (eg, email, videoconference, telephone) or internet-based interaction with groups of other patients. Four reviews reported that compared to self-guided interventions, therapist-guided interventions were more efficacious in engagement, improvement of quality of life (QoL), and

XSL•FO
RenderX

adjustment of some negative emotions [22,65,66]. In addition, 19 (24%) reviews mentioned mindfulness-based interventions, including mindfulness-based cognitive therapy (MBCT) [25,33,67,68], mindfulness-based stress reduction [25,69], mindfulness-based cancer recovery [70], and mindfulness self-compassion [32,71]. Other common psychological interventions included acceptance and commitment therapy [32,33,52,70], problem-solving therapy [24,32,65,71,72], and cognitive rehabilitation therapy [62,72]. Gratitude intervention [33], supportive expressive therapy [24], narrative therapy [24], and music therapy [26] were less commonly included. Fourteen (18%) reviews reported psychoeducation. Sixteen (20.5%) reviews reported components of social support or peer support, which adopt various formats (eg, web-based workshops, portals, or discussion forums). McCaughan et al [73] assessed the effects of online support groups on negative emotions and QoL of female patients with breast cancer.

Second, 23 reviews (30%) reported interventions related to behavior and lifestyle change, generally consisting of physical activity intervention, dietary and nutrition intervention, and exercise prescriptions. Third, 24 reviews (31%) reported information support interventions, the majority provided knowledge of cancer disease and treatment, available medical resources or health care service information, self-management strategies for emotional and physical symptoms, and so on. One review mentioned culture-related specific educational information particularly [67]. Qin et al [74] reported a pattern that based on predesigned personalized code and program, the app generates automated feedback and feeds hyper-relevant and tailored suggestions. Fourthly, 30 reviews (39%) reported symptom management interventions, including forms of skills training (eg, coping, rehabilitation), stress management, meditation adherence management, self-assessment, and symptom monitoring. Of the 3 reviews, distraction therapy was used for attention management to alleviate negative emotions in patients with cancer [24,63,75]. Finally, 17 reviews (22%) reported counseling and open communication. The main form is that patients could directly contact or consult with experts. Horn et al [54] found that nurses may be the bridge and activator to facilitate survivors to obtain more information from physicians.

Comparison

45 reviews (57.7%) included a meta-analysis of all or a subset of their included studies. In the control groups of 45 meta-analyses, 8 (18%) reviews conducted usual or conventional care and standard care to participants, and the remaining reviews were compared with any comparator (eg, waitlist control, active control, attention control, no intervention control, placebo control). In addition, 3 reviews reported that the effectiveness of digital interventions in reducing fatigue, fear of recurrence, and psychological distress was similar to face‐to‐face interventions [32,51,76]. Moreover, Chen et al [51] examined the efficacy of eHealth interventions in cancer survivorship care and found that compared with traditional face-to-face dyadic interventions, web-based dyadic interventions can break the constraints of time and space and may better address needs during post-treatment survivorship.

Implement Outcome

Neither statistical pooling of the results nor a meta‐analysis was performed because of the high heterogeneity of the included reviews. The reported targeted variable was considered positive when at least half of the studies included in the narrative synthesis showed positive results, or when the meta-analysis showed a significant effect.

Across 45 meta-analyses, the most examined outcome was depression, 29 (64.4%) of which reported positive effects of interventions relative to control, and 6 reported null findings. Followed by QoL (29 positive effects and 3 null effects), and anxiety (25 positive effects and 7 null effects). Other commonly reported outcomes include cancer-related fatigue (13 positive effects, 5 null effects), distress (10 positive effects, 3 null effects), self-efficacy (8 positive effects and 1 null effect), sleep-related problems (6 positive effects and no null effects), fear of recurrence (3 positive effects and 2 null effects), and well-being (2 positive effects, no null effects. Of the remaining 33 systematic reviews, not surprisingly, the most concerned outcomes were still QoL, depression, and anxiety, which also showed promising trends. The global positive effect of the interventions is depicted in Figure 3.

Social support	0	0	3/4

Meta-analyses		Narrative syntheses	
Direction of effect		n/N	
	Positive	Numerator	Number of studies with effect
	No effect	Denominator	Total studies
	No data		

Quality Assessment

The majority of included reviews had critical weaknesses and were rated as critically low (n=42, 53.8%) or low (n=19; 24.4%) confidence. Only 4 reviews were rated as high confidence (5.1%), and 13 (16.7%) were rated as moderate confidence. Common methodological weaknesses were failure to report on the sources of funding for the studies included in the review and failure to provide a full list of excluded studies (only 3.8% successfully met this criterion). Due to space limitations, the full results are found in Multimedia Appendix 6.

Discussion

Principal Findings

To our knowledge, this is the first umbrella review to extensively summarize and evaluate the scientific evidence on distinct digital health interventions in improving mental health issues for patients with cancer. It provides an overview of the current state of this domain and identifies gaps regarding delivery modalities, intervention methods, and targeted psychological indicators. Notably, the majority of literature published after 2019, emphasizes the trend to integrate technology into psychological distress management for patients with cancer, highlighting the growing importance of digital interventions in oncology care. Furthermore, the variety of delivery platforms caters to diverse patient preferences and demonstrates the adaptability of interventions for different backgrounds and populations.

XSL•FO
RenderX

The majority of reviews primarily focused on adult patients with cancers or people who have survived cancer while a minority referred to pediatric, adolescent, and young groups. However, none of them focused on older patients with cancer, which conflicts with the staggering discovery that more than 50% of new cases and nearly 70% of death cases are diagnosed with cancer aged 65 years and older [77]. Cheng et al [78] acknowledged the prevalence of spiritual needs among older adults with cancer and highlighted that psychological care should be an indispensable part of daily care. Other research showed that remote health care in older adults contributed to the QoL, level of depression, anxiety, and prognosis, as well as more favorable psychological outcomes [79-82]. Although it is often assumed that digital health interventions may not be appropriate for older adults because of several barriers such as lack of usability and perceived usefulness [83,84]. A study of patients with genitourinary cancer suggests that high engagement and interest in digital technologies were observed among older patients [85]. Moreover, older patients with cancer usually have unique preferences regarding digital health interventions [86]. In contrast to the stimulating sensory experiences and diverse games offered by complex interfaces, older adult patients with cancer prefer clear and concise user instructions, which allows those with no prior experience or nonprofessionals to also get started easily [86-88]. Future research should explore the development of personalized digital interventions for older adult patients with cancer [82,89]. Considering factors like social isolation and cognitive decline [90,91], efforts should focus on enhancing feasibility, convenience, and user engagement to achieve better outcomes [83,92,93].

Within the extensive scope of digital health technologies covered in this study, websites and smartphone apps are particularly widely used in cancer care. This widespread use is due to their advantages in accessibility and functionality compared to other delivery formats. Given the characteristics of web browsers on popularization and no need to download, web-based platforms are often easier to access, making them a preferred choice for patients who use older or insufficient memory usage devices. Even so, they may lack the immediacy and interactivity that smartphone apps provide. Whereas smartphone apps offer distinct advantages in personalized design, real-time monitoring and feedback, and the capacity for big data delivery [94,95]. By offering vivid and comprehensible materials, it bridges the gap between patients and substantial evidence-based educational resources, which can alleviate to some extent patients' anxiety due to lack of knowledge [96,97]. The capabilities of push notifications and real-time data tracking that smartphone apps have led to increased user engagement and adherence to interventions [98,99]. Likewise, tailored user interfaces and digital features can significantly increase patient satisfaction [100], which demonstrates the importance of optimizing digital health interventions to meet patient preferences and needs. In other words, the effectiveness of these interventions depends on their ability to seamlessly integrate into the user's daily life, providing personalized and timely support that meets the user's emotional and psychological needs. We agree with Kamalumpundi et al [57] that effective web-based emotion regulation interventions are far more intricate than merely offering individuals a range of app features.

The design of apps in this study mostly focuses on patient education, disease self-management, and remote monitoring of symptoms [18], but lacks highly tailored symptom management interventions for certain emotional conditions. One plausible explanation was as Krueger and Eaton [101] stated, among different diseases, there may exist shared subthreshold disorder manifestations, which could be associated with significant distress and functional impairment. This indicates that categorical diagnoses may fail to capture the underlying dimensions of mental disorders and emphasize the loss of information when complex constellations of signs and symptoms are simplified into an "either/or" binary framework. Furthermore, it helps explain why specific psychotherapeutic approaches are purportedly effective across a range of ostensibly distinct emotional states. In addition to the more concerned anxiety and depression, many other specific emotional states affect patients such as self-doubt [102], guilt [103], anger [104], and self-esteem [105], which received insufficient attention. To address this complexity, future research should focus on developing high-precision emotion recognition and decision-making applications. Advanced algorithms and machine learning techniques could be conducted to accurately identify and classify emotional states. For instance, ecological momentary assessments could be used for daily monitoring of mental health care [106]. Combined with wearable devices with social media data, real-time emotion tracking was conducted to provide tailored feedback and interventions. Furthermore, the implementation of evidence-based interventions that correspond to specific emotional categories could enhance the effectiveness of emotional management strategies [107]. Individuals experiencing anxiety may benefit from cognitive behavioral techniques and mindfulness exercises, while those with depression might require mood monitoring and behavioral activation strategies [108,109]. By integrating these tailored interventions into digital platforms, we can offer precise, individualized emotional support.

Although a few reviews included interventions with gamification (eg, active games, virtual reality) or new technologies (eg, AI systems, humanoid chatbots), which progress swiftly and as a highly promising trend to solve several limitations of current situations. The results of a scoping review by Poliani et al [110] show that gamification seems to improve QoL and reduce anxiety levels in patients with cancer, which was consistent with other findings [94,95,111,112], and broader exploration of other health-related outcomes, indicating that gamification also had a significant effect on anxiety, distress, and cognitive function. However, all gamified interventions included in the studies were ordinary commercial apps for the universal population and were not specifically developed for patients with cancer. Additionally, designing gamified interventions tailored to older patients is crucial. As the aging population grows, there is a need for age-appropriate gamification strategies that can address the unique challenges faced by older adult patients [113,114]. Simplified interfaces, cognitive training games, and physical activity-based interventions are all worthwhile options. After all, digital health interventions should be more inclusive, effectively supporting patients with cancer of all ages. Furthermore, large language models have found diverse applications in clinical practice, including supporting clinical

XSL•FO
RenderX

decision-making, intelligent question answering, generating medical documents, and assisting therapy through chatbots [115,116]. Future advances aim to explore further integration of AI technologies into mobile emotion management. This involves implementing scientific frameworks to facilitate their adoption and usage within mental health care systems, to enhance its accessibility and scalability, implementing scientific frameworks may be a proper choice for facilitating their adoption and use.

Variations in reported intervention effects across outcome measures were observed in the results [24,64,66,70,74,117]. This variability may be explained by conceptual ambiguities among studies regarding specific indicators, leading to differences in measurement tools and assessment methods. Moreover, the heterogeneity in study designs, intervention components, and outcome measurement methods, makes it hard to give a rigorous and accurate report on which of them are associated with the best efficacy.

It is mentioned that although the objective of this umbrella review was to systematically synthesize the effectiveness of digital interventions on the mental health of all patients with cancer, the majority of the patients with cancer included in the studies originate from high-income countries and regions, with limited racial representation. Consequently, it cannot draw convincing conclusions for vulnerable cancer groups such as patients from middle- and low-income backgrounds and ethnic minorities. We must acknowledge the disparity in digital health equity [118]. Typically, high-income and middle-income individuals have greater access to technology and health care facilities than the low-income group, who may also have fewer opportunities to obtain medical care [119]. A multiclinic study targeting ethnic minorities has indicated that the lack of broadband access is likely one of the significant factors affecting the adoption of telemedicine by these minority groups [120]. Furthermore, healthy digital literacy is a crucial element in being able to process complex health information and effectively absorb and use it. Generally, the health literacy levels of vulnerable groups are already low, and there are notable differences in the social, economic, or environmental contexts of health, which make it challenging for these groups to cope with and depend on complex technologies to search for information [121]. With the increasing implementation of digital health services, we must recognize the limitations of these tools and implement them in a manner that promotes optimal functionality, accessibility, and usability. Future research should consider multiple levels and perspectives to reduce health literacy barriers and enhance the acceptance of technology among specific groups.

Limitations

While this comprehensive umbrella review provides valuable insights, several limitations need consideration. First, due to heterogeneity in outcome measures, intervention components, and methods of outcome assessment, we did a narrative synthesis and were unable to check for overlap of included individual studies statistically. Moreover, it is impossible to systematically characterize the heterogeneity in the included reviews and assess the potential publication bias. Second, unclear conceptual definitions are commonly encountered. Indeed, digital health interventions constitute a relatively ambiguous concept in literature, where descriptions of intervention measures may be confusing, and there is considerable overlap between similar digital intervention definitions. Similar problems exist in the evaluation of outcome measures related to mental health. Hence, with the increasing prevalence of digital mental health services based on technologies such as the internet, big data, and AI, stricter descriptions and definitions of relevant concepts seem crucial. Third, the general demographics information collected in the included reviews most focuses on factors such as age, sex, and region, neglecting other factors like income and ethnicity, which makes it difficult to adequately consider the needs of other underrepresented groups. The priority in future research should be to fully understand these existing problems and strive to resolve them through more rigorous and cautious research.

Conclusions

In general, the review identified that various interventions delivered by digital technologies, a feasible and available approach, can facilitate subjectively assessed levels of more than a dozen emotional parameters in patients with cancer. There are also some limitations to these results. The great heterogeneity observed in the studies makes it difficult to have a quantitative synthesis of results, and several reviews have not followed the methodological requirements for reporting results. Further research is needed to develop rigorous methodological interventions allowing for scrupulous testing to determine the effective types of interventions and their exact effects. More precise and sensitive emotional measurement tools and identification systems are needed to capture subtle changes in patient's psychological needs and preferences, enhancing the targeted nature of interventions. Additionally, integrating evidence-based intervention measures into standard oncological care forms multidimensional, multilevel support strategies. This integration can provide more effective support and guidance for clinical practice and policy-making, thereby offering comprehensive and personalized psychological support and care for patients with cancer. Ultimately, this approach aims to enhance the psychosocial health and QoL of patients with cancer globally.

Acknowledgments

The authors thank all researchers who participated in this study. This study is supported by the National Natural Science Foundation of China (grant 72304131), the Outstanding Youths Development Scheme of Nanfang Hospital, Southern Medical University (2023J005), and the National Natural Science Foundation of China (72101107).

Abstract

Background: The surge in artificial intelligence (AI) interventions in primary care trials lacks a study on reporting quality.

Objective: This study aimed to systematically evaluate the reporting quality of both published randomized controlled trials (RCTs) and protocols for RCTs that investigated AI interventions in primary care.

Methods: PubMed, Embase, Cochrane Library, MEDLINE, Web of Science, and CINAHL databases were searched for RCTs and protocols on AI interventions in primary care until November 2024. Eligible studies were published RCTs or full protocols for RCTs exploring AI interventions in primary care. The reporting quality was assessed using CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) and SPIRIT-AI (Standard Protocol Items: Recommendations for Interventional Trials–Artificial Intelligence) checklists, focusing on AI intervention–related items.

Results: A total of 11,711 records were identified. In total, 19 published RCTs and 21 RCT protocols for 35 trials were included. The overall proportion of adequately reported items was 65% (172/266; 95% CI 59%-70%) and 68% (214/315; 95% CI 62%-73%) for RCTs and protocols, respectively. The percentage of RCTs and protocols that reported a specific item ranged from 11% (2/19) to 100% (19/19) and from 10% (2/21) to 100% (21/21), respectively. The reporting of both RCTs and protocols exhibited similar characteristics and trends. They both lack transparency and completeness, which can be summarized in three aspects: without providing adequate information regarding the input data, without mentioning the methods for identifying and analyzing performance errors, and without stating whether and how the AI intervention and its code can be accessed.

Conclusions: The reporting quality could be improved in both RCTs and protocols. This study helps promote the transparent and complete reporting of trials with AI interventions in primary care.

KEYWORDS

artificial intelligence; randomized controlled trial; reporting quality; primary care; meta-epidemiological study

Introduction

Primary care provides a large health care delivery platform for primary care physicians to offer person-centered services for a vast patient population [1]. The practice of primary care generates substantial digital data that can be leveraged for primary care research [2,3]. The growing resources of big data, mainly consisting of electronic health records, electronic medical data, patient self-reported data, and wearable device data, have paved the way for the advancement of artificial intelligence (AI) in deep machine learning (ML) technology and natural language processing to explore AI- or ML-driven clinical tools dedicated to the improvement of clinical decision-making in the disease screening, diagnosis, prognosis, and management

XSL•FO
RenderX

[4-6]. For example, several studies in primary care have developed the prediction tool for patients presenting with acute cough, the prediction score for head and neck cancer referrals, and the prediction model for asthma exacerbation [7-9]. Nevertheless, in practice, a significant proportion of these tools have not undergone validation through a robust clinical trial, although the majority of these studies use performance indicators to showcase their superiority [10,11].

Randomized controlled trials (RCTs) are widely recognized as the gold standard for evaluating interventions [12]. Many clinical studies that investigate AI- or ML-driven clinical tools as a clinical intervention conduct a confirmatory RCT, aiming to demonstrate the clinical significance [13-15]. Transparency and explainability are essential for the widespread integration of AI systems into clinical practice, as an inaccurate prediction could result in severe consequences [16]. Given the inherent complexity of AI interventions, it is critical for RCT reporting to be comprehensive and transparent. Adhering to reporting guidelines for AI in clinical trials and transparently reporting AI interventions in RCTs are important steps toward improving research quality, fostering scientific discourse, and establishing more reliable foundations for clinical practice and decision-making [17-19].

The CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) extension [17] and SPIRIT-AI (Standard Protocol Items: Recommendations for Interventional Trials–Artificial Intelligence) extension [18] are newly developed reporting guidelines specifically focusing on AI intervention in trials. CONSORT-AI focuses more on trial results and reporting completeness, while SPIRIT-AI emphasizes pretrial elements, such as trial design and ethical considerations. The relative items in the guidelines should be transparently and completely reported, and qualified reporting is essential for independently evaluating and replicating the trial. However, there is no systematic review and critical appraisal of RCTs for examining AI interventions in primary care, leaving the clarity of their reporting quality uncertain.

This systematic review and meta-epidemiological study aims to evaluate the reporting quality of AI interventions in published RCTs and protocols for RCTs in primary care. The assessment was based on the CONSORT-AI extension and SPIRIT-AI extension guidelines.

Methods

Study Design

This study was reported in accordance with the guidelines for reporting meta-epidemiological methodology research [20] and PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) reporting guidelines (Multimedia Appendix 1). The protocol for this study has been registered on PROSPERO (ID: CRD42023427694).

Search Strategy

The searches of PubMed, Embase, and Cochrane Library were conducted up to November 30, 2024. To ensure a comprehensive literature search, we further referenced a previously published study strategy [3], ensuring the completeness and accuracy of the process of collecting RCTs. This further search was applied across MEDLINE, Web of Science, and CINAHL. There were no restrictions on the year of publication or language. The detailed search strategies are listed in Multimedia Appendix 2.

Study Selection

Overview

To be included in this study, articles had to meet the following criteria: (1) RCTs or protocols for RCTs that used AI interventions or AI-assisted tools to guide a randomized intervention and (2) studies that belonged to primary care research. Based on the 1996 report of the US Institute of Medicine, primary care was defined as “the provision of integrated, accessible health care services by clinicians who are accountable for addressing a large majority of personal health care needs, developing a sustained partnership with patients, and practicing in the context of family and community” [21]. Primary care research was defined as “Research done in a primary care context” [22]. Only published RCTs and published, full RCT protocols were included. We excluded (1) studies with abstracts only; (2) commentaries, letters, editorials, or reviews; and (3) animals or preclinical studies.

Stage 1: Title and Abstract Screening

The retrieved records were imported into EndNote 20 (Clarivate). Two independent reviewers (JZ and TZ) conducted the screening of titles and abstracts to identify studies potentially meeting the inclusion criteria. Any discrepancies were resolved through discussion.

Stage 2: Full-Text Screening

Using EndNote 20, the reviewers (JZ and TZ) independently assessed the full-text articles identified at stage 1 for eligibility. Any discrepancies were discussed and resolved by consulting the third researcher (YH), and consensus was reached through discussion. Studies meeting the eligibility criteria were included for data extraction.

Data Extraction Process and Data Items

Two researchers (JZ and TZ) independently extracted data from each article by using a standardized data extraction form. Discrepancies in data extraction were discussed between JZ and TZ and the remaining conflicts were resolved by YH.

Data were collected on (1) trial name, (2) trial registration identifier assigned to clinical trials registered in the database, (3) first author’s name, (4) published article name, (5) journal name, (6) publication year, (7) research topic, (8) study design (sample size, blinding, and type of comparator arm), (9) primary outcome, (10) classification of primary outcomes by result status (positive or negative), (11) type of AI model (large language model [LLM], ML, deep learning, clinical decision support system [CDSS], or risk prediction model), and (12) deployment context (clinician-assisted decision support, fully automated diagnostic systems, or patient self-management tools).

The reporting quality of included studies was assessed using the CONSORT-AI and SPIRIT-AI checklists. Each checklist consists of two components: (1) the original CONSORT 2010/SPIRIT 2013 items and (2) the AI-specific elaborations

XSL•FO
RenderX

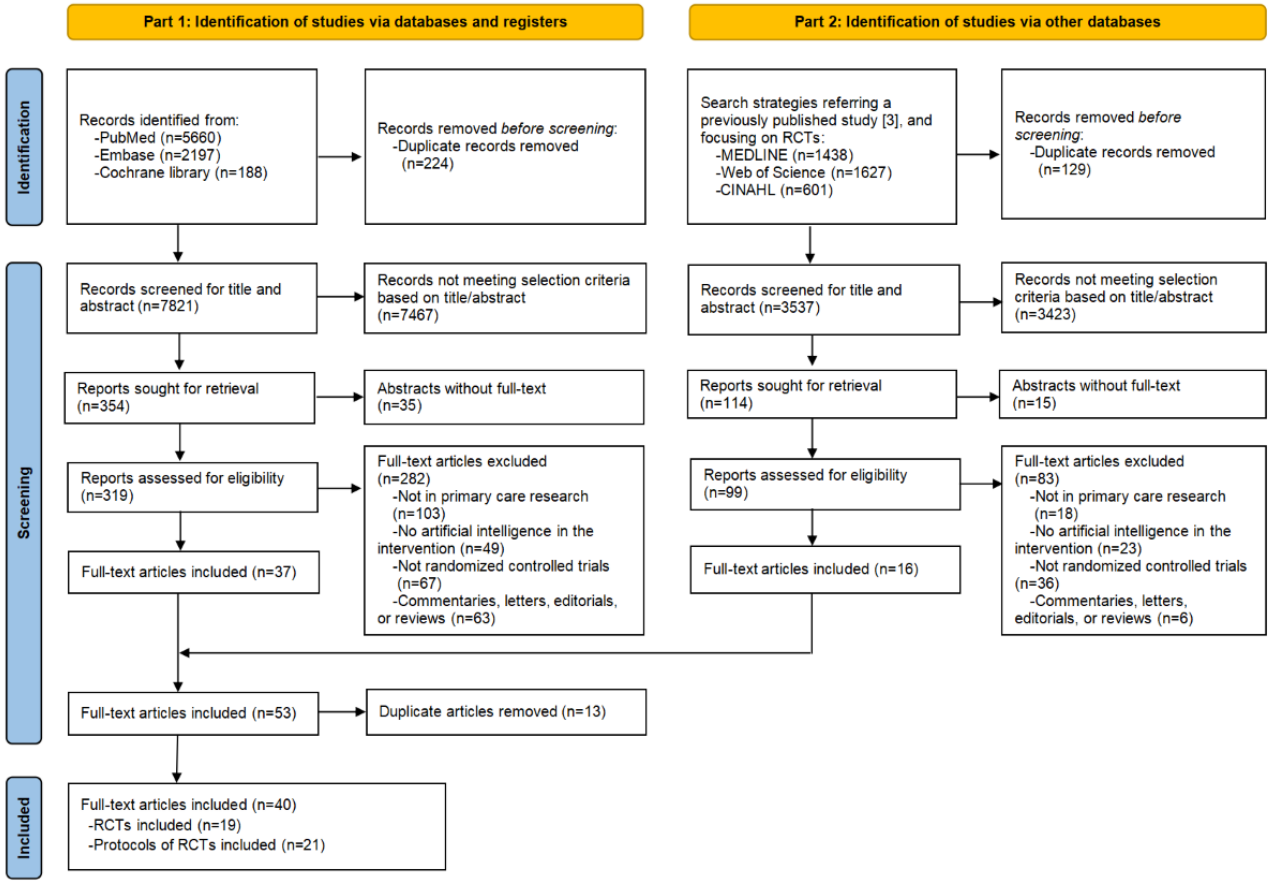
and extension items. This study focused on evaluating the AI-related reporting quality. Only items that are separately elaborated or extended in the CONSORT-AI (14 items) and SPIRIT-AI (15 items) checklists were appraised. These items ensure that critical aspects of AI-supported interventions such as input-data setting are transparently and completely reported. Each item was assessed in all included published articles, as "Yes" or "No."

Outcomes

The primary outcomes were as follows: (1) the proportion of adequately reported items, calculated by dividing the number of adequately reported items by the total number of items in each article—high proportions would indicate high reproducibility and quality of the RCTs and protocols for RCTs—and (2) the percentage of articles adequately reporting each item, calculated by dividing the number of articles that adequately reported the item by the total number of articles evaluated for that particular item. Independent analysis was conducted for CONSORT-AI (14 items) and SPIRIT-AI (15 items) checklists based on the primary outcomes described above. Since CONSORT-AI focuses on reporting completed trials and SPIRIT-AI on trial protocol standards, analyzing them separately ensures more precise adherence to each guideline. The secondary outcomes focused on CONSORT-AI included (1) the association between primary outcome status and the reporting quality of each CONSORT-AI item, and (2) factors influencing the percentage of adequately reported items in CONSORT-AI.

Data Synthesis and Analysis

Descriptive statistical methods were used and presented as frequencies, median percentages, and IQRs. The proportion of adequately reported items and the percentage of articles adequately reporting each specific item was reported, with its corresponding 95% CI calculated using the Clopper-Person method. The analyses were performed using Microsoft Excel 2021 and OriginPro 2022 (OriginLab Corporation). The association between primary outcome result status (positive or negative) and the reporting quality of each item was examined using the Fisher exact test. The percentage of adequately reported items was compared across RCT characteristics such as type of disease using the Mann-Whitney *U* test. To assess the main effects and interaction effects between the primary outcome result status and various RCT characteristics on the percentage of adequately reported items, the Scheirer-Ray-Hare test was used. All *P* values were derived from 2-sided tests, with significance defined as $P<.05$ (R, version 4.4.2; R Foundation for Statistical Computing).



Results

Overview

The search strategies retrieved a total of 11,711 records. After screening, 40 articles finally met the inclusion criteria. These 40 full-text articles corresponded to 35 trials, including 19 RCTs and 21 protocols for RCTs (Figure 1 and Multimedia Appendix 3 [23-62]).

RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) flow diagram of the selection procedure. RCT: randomized controlled trial.

Characteristics of Included Articles

Table 1 summarizes the characteristics of the included articles. Among the 19 RCTs, 8 (42%) used LLMs, 10 (53%) were conducted in the context of clinician-assisted decision support, and 11 (58%) reported positive primary outcome results. In total, 21% (4/19) focused on cardiovascular topics. The median sample size for these RCTs was 335 (IQR 133-487) participants. Among the 21 protocols, 6 (29%) incorporated LLMs, 11 (52%) involved clinician-assisted decision support, and 6 (29%) focused on cardiovascular topics (Table 1).

Proportion of Adequately Reported Items

In the 19 RCTs included in this review, the overall proportion of adequately reported items was 65% (172/266; 95% CI 59%-70%). Only 2 RCTs had more than 90% of items reported adequately. In the 21 protocols for RCTs, the overall proportion of adequately reported items was 68% (214/315; 95% CI 62%-73%). Two protocols of RCTs had more than 85% of items reported adequately (Multimedia Appendix 3).

Percentage of Articles Adequately Reporting Each Specific Item

The complete list of the 14 items of the CONSORT-AI extension is shown in Table 2. The percentage of RCTs that reported a specific item ranged from 11% to 100%. The best-reported sections were the title and abstract [item 1a and item b(ii)], background and objective [item 2a(i)], and participants (item 4b), all being reported in 100% (19/19) of RCTs. The poorly reported sections were intervention [item 5(i), item 5(ii), and item 5(iii)], participants [item 4a(ii)], harms (item 19), and funding (item 25). Among these poorly reported items, 4a(ii), 5(ii), and 5(iii) were related to providing the information for input data (Figure 2 and Table 2). The reporting quality increases as it approaches the outer edges of the radar chart—1a, b(i), 1a,b(ii): title; 2a(i): background and objectives; 4a(i), 4a(ii), 4b: participants; 5(i)-5(iv): intervention; 19: harms; and 25: funding.

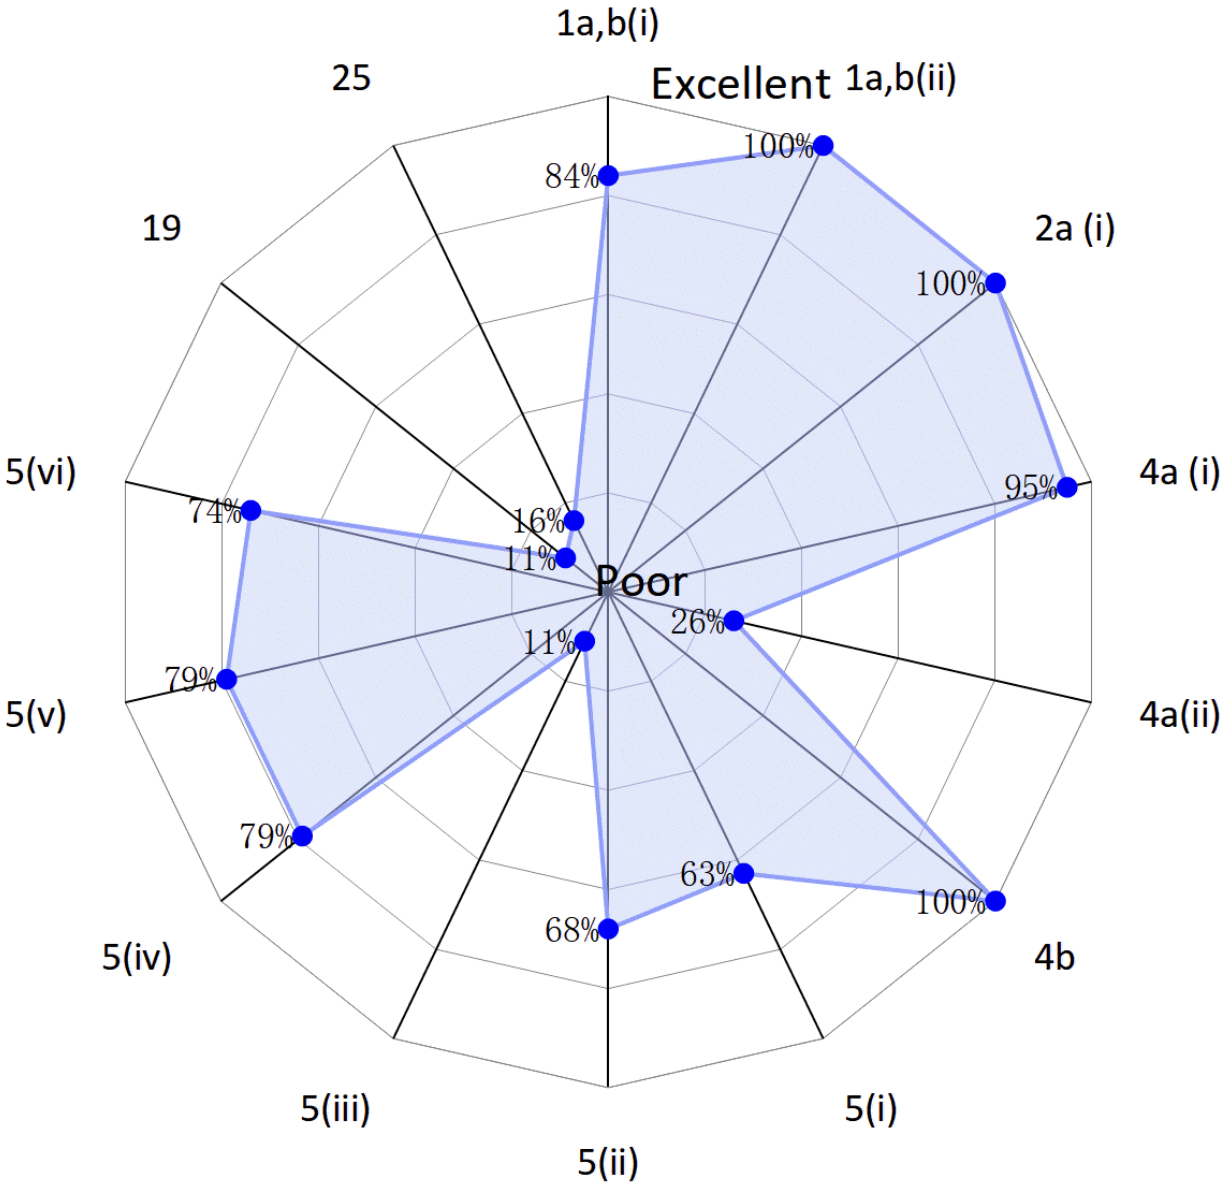

Table 2. Adherence to CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) extension items.

Item	Item description	Total (n=19), n (%; 95%CI)
CONSORT-AI 1a Elaboration	Indicate that the intervention involves artificial intelligence or machine learning in the title and abstract and specify the type of model.	16 (84; 60-97)
CONSORT-AI 1b(ii) Elaboration	State the intended use of the AI[a] intervention within the trial in the title and abstract.	19 (100; 82-100)
CONSORT-AI 2a(i) Extension	Explain the intended use of the AI intervention in the context of the clinical pathway, including its purpose and its intended users (eg, health care professionals, patients, public).	19 (100; 82-100)
CONSORT-AI 4a(i) Elaboration	State the inclusion and exclusion criteria at the level of participants	18 (95; 74-100)
CONSORT-AI 4a(ii) Extension	State the inclusion and exclusion criteria at the level of the input data.	5 (26; 9-51)
CONSORT-AI 4b Extension	Describe how the AI intervention was integrated into the trial setting, including any onsite or offsite requirements.	19 (100; 82-100)
CONSORT-AI 5(i) Extension	State which version of the AI algorithm was used.	12 (63; 38-84)
CONSORT-AI 5(ii) Extension	Describe how the input data were acquired and selected for the AI intervention.	13 (68; 43-87)
CONSORT-AI 5(iii) Extension	Describe how poor quality or unavailable input data were assessed and handled.	2 (11; 1-33)
CONSORT-AI 5(iv) Extension	Specify whether there was human-AI interaction in the handling of the input data, and what level of expertise was required of users.	15 (79; 54-94)
CONSORT-AI 5(v) Extension	Specify the output of the AI intervention.	15 (79; 54-94)
CONSORT-AI 5(vi) Extension	Explain how the AI intervention's outputs contributed to decision-making or other elements of clinical practice.	14 (74; 49-91)
CONSORT-AI 19 Extension	Describe results of any analysis of performance errors and how errors were identified, where applicable. If no such analysis was planned or done, justify why not.	2 (11; 1-33)
CONSORT-AI 25 Extension	State whether and how the AI intervention and/or its code can be accessed, including any restrictions to access or re-use.	3 (16; 3-40)

[a]AI: artificial intelligence.

XSL•FO
RenderX

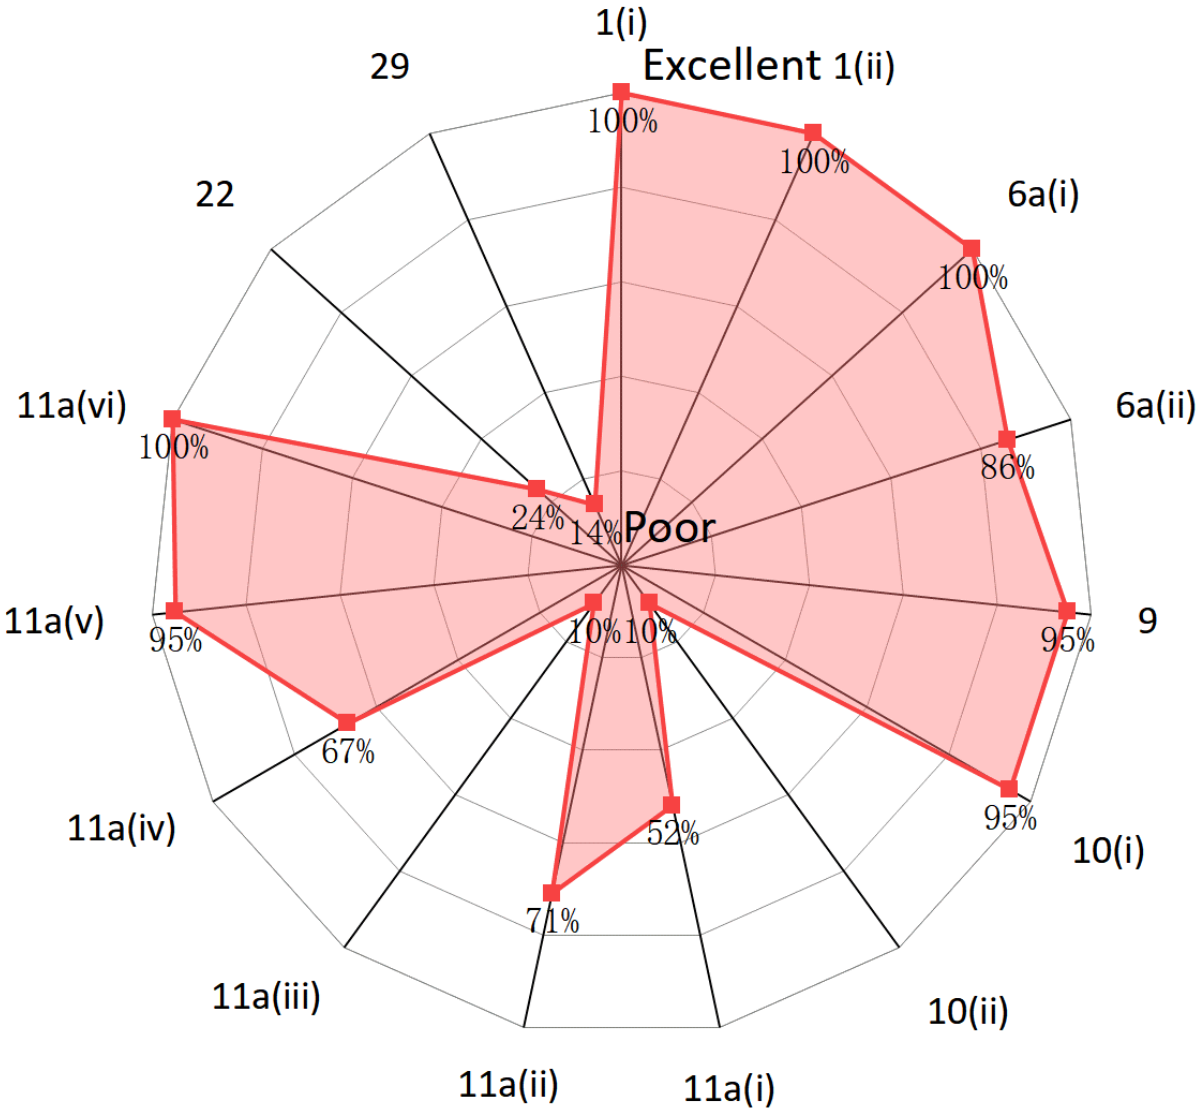

Figure 2. Radar chart to show the adequately reported percentage for each CONSORT-AI (Consolidated Standards of Reporting Trials–Artificial Intelligence) item.

The complete list of the 15 items of the SPIRIT-AI extension is shown in Table 3. The percentage of protocols for RCTs that reported a specific item ranged from 10% to 100%. The best-reported sections were title and abstract [item 1(i) and item 1(ii)], background and rationale [item 6a(i)], and intervention [item 11a(vi)] all being reported in 100% of protocols. The poorly reported sections were intervention [item 11a(i), item 11a(iii), and item 11a(iv)], eligibility [item 10(ii)], harms (item 22), and access to data (item 29). Among these poorly reported items, 10(ii), 11a(iii), and 11a(iv) were related to providing the information for input data (Figure 3 and Table 3). The reporting quality increases as it approaches the outer edges of the radar chart—1(i), 1(ii): title; 6a(i), 6a(ii): background and rationale; 9: study setting; 10(i), 10(ii): eligibility criteria; 11a(i)-11a(vi): interventions; 22: harms; and 29: access to data.

XSL•FO
RenderX

Table 3. Adherence to SPIRIT-AI (Standard Protocol Items: Recommendations for Interventional Trials—Artificial Intelligence) extension items.

Item	Item description	Total (n=21), n (%; 95% CI)
SPIRIT-AI 1(i) Elaboration	Indicate that the intervention involves artificial intelligence or machine learning and specify the type of model.	21 (100; 84-100)
SPIRIT-AI 1(ii) Elaboration	Specify the intended use of the AI[a] intervention.	21 (100; 84-100)
SPIRIT-AI 6a(i) Extension	Explain the intended use of the AI intervention in the context of the clinical pathway, including its purpose and its intended users (eg, health care professionals, patients, public).	21 (100; 84-100)
SPIRIT-AI 6a(ii) Extension	Describe any pre-existing evidence for the AI intervention.	18 (86; 64-97)
SPIRIT-AI 9 Extension	Describe the onsite and offsite requirements needed to integrate the AI intervention into the trial setting.	20 (95; 76-100)
SPIRIT-AI 10(i) Elaboration	State the inclusion and exclusion criteria at the level of participants.	20 (95; 76-100)
SPIRIT-AI 10(ii) Extension	State the inclusion and exclusion criteria at the level of the input data.	2 (10; 1-30)
SPIRIT-AI 11a(i) Extension	State which version of the AI algorithm will be used.	11 (52; 30-74)
SPIRIT-AI 11a(ii) Extension	Specify the procedure for acquiring and selecting the input data for the AI intervention.	15 (71; 48-89)
SPIRIT-AI 11a(iii) Extension	Specify the procedure for assessing and handling poor quality or unavailable input data.	2 (10; 1-30)
SPIRIT-AI 11a(iv) Extension	Specify whether there is human-AI interaction in the handling of the input data, and what level of expertise is required for users.	14 (67; 43-85)
SPIRIT-AI 11a(v) Extension	Specify the output of the AI intervention.	20 (95; 76-100)
SPIRIT-AI 11a(vi) Extension	Explain the procedure for how the AI intervention's output will contribute to decision-making or other elements of clinical practice.	21 (100; 84-100)
SPIRIT-AI 22 Extension	Specify any plans to identify and analyze performance errors. If there are no plans for this, explain why not.	5 (24; 8-47)
SPIRIT-AI 29 Extension	State whether and how the AI intervention and/or its code can be accessed, including any restrictions to access or re-use.	3 (14; 3-36)

[a]AI: artificial intelligence.

Association Between Primary Outcome Result Status and the Reporting Quality of Each Item

Multimedia Appendix 4 shows the association between the primary outcome result status in RCTs and the reporting quality of each item. Fisher exact test results indicate no significant association between positive outcomes and higher reporting quality (all $P>.05$).

Factors Associated With the Percentage of Adequately Reported Items

To further explore potential differences resulting from RCT characteristics, we compared the percentage of adequately reported items by year of publication, blinding, type of AI model, deployment context, primary outcome result status, and disease type (Multimedia Appendix 5). Trials of cardiovascular disease showed a higher percentage of adequately reported items ($P=.02$). The Scheirer-Ray-Hare test did not detect statistical significance for the interaction effects between primary outcome result status and various RCT characteristics on the percentage of adequately reported items (all $P>.05$; Multimedia Appendix 5).

Discussion

Principal Results

In this study, we assessed the RCT reporting quality in published 19 RCTs and 21 RCT protocols involved in 35 trials, with 5 trials having both published RCTs and corresponding protocols. This study found the reporting quality in both RCTs and protocols for RCTs of AI intervention could be improved in 3 aspects. The first aspect concerns providing enough information for the input data, which was detailed in CONSORT-AI guidelines [items 4a(ii), 5(ii), and 5(iii)] and SPIRIT-AI guidelines [items 10(ii), 11a(iii), and 11a(iv)]. The second aspect involves the lack of information on how to identify and analyze performance errors, which was demanded by the harm section of CONSORT-AI guidelines (item 19) and SPIRIT-AI guidelines (item 22), respectively. The third aspect involves neglecting to specify whether and how the AI intervention or its code can be accessed, which was needed in CONSORT-AI guidelines (item 25) and SPIRIT-AI guidelines (item 29), respectively. Based on the evaluation of the reporting of 35 trials, our findings revealed a consistent lack of information across these three aspects across both protocols and RCTs, highlighting a widespread gap in adhering to the reporting standards recommended by these guidelines.

XSL•FO
RenderX

Strength and Limitations

This is the first study focused on the field of AI application in primary care, providing a first systematic review into the existing landscape of RCTs using AI interventions within primary care. This review not only included RCTs of AI interventions in primary care but also covered protocols, providing a more comprehensive survey in this field.

This study has 2 limitations. First, the majority of studies were conducted in the United States, which may lead to a lack of representation for other countries. Second, this study assessed the reporting quality of AI intervention–related items for RCTs. General reporting items from the original CONSORT 2010 and SPIRIT 2013 checklists were not assessed.

Comparison With Previous Work

We are aware of only one published systematic scoping review on the application of AI in community-based primary health care [3]. The authors highlighted a gap in the development and implementation of AI in primary care. However, reporting quality was not assessed previous study [3]. This systematic review is the first focusing on primary care and indicating the need for more transparent design, conduct, and analysis of AI interventions in primary care.

Implications for Research and Practice

To apply AI interventions in primary care, accurate and sufficient information is essential to guide the standardized performance of clinical treatment. The findings of this study have several implications for clinical research and practice, concerning AI safety, reliability, and reproducibility, as outlined below.

First, reporting on AI performance errors needs to be improved. As software, AI systems are likely to undergo multiple iterations and updates [10]. For example, although LLMs have successfully answered medical licensing exam questions [63], they still produce errors when stating facts or synthesizing data from medical literature [64]. Since LLMs still have many flaws, performance error reporting is essential for continuous updating. The lack of performance error reporting may lead to misdiagnosis or incorrect treatment recommendations, ultimately jeopardizing patient safety [65]. It is crucial to specify the types of performance errors, the process of identifying them, and how updated versions correct these errors during the trial.

Second, the reporting on the section of input-data setting deserves special attention. AI interventions applied to primary care should provide comprehensive information for input-data settings, including parameter selection and preprocessing before analysis by the AI system. Moreover, during the input-data setting, the inclusion and exclusion criteria should be clearly defined, along with an adequate investigation of patient characteristics relevant to the disease type. It is necessary to report these items completely to ensure the replicability of the intervention beyond the trials in real-world circumstances [19]. It also supports investigators in identifying whether input-data-handling procedures were standardized across trial sites [17]. Overall, the AI system should establish an optimal input set that includes a wide range of parameters and attribute combinations [66]. For example, ML prediction models can only accurately predict the specific outcomes after knee arthroplasty while the ability to predict more complex outcomes remains inaccuracy [67]. Thus, ML requires comprehensive patient-related indicators and the identification of specific patterns that are suitable for ML analysis. This underscores the importance of high-quality input data setting as a fundamental prerequisite for optimizing ML capabilities in clinical applications. Finally, trials should report the prespecified conditions, particularly if minimum requirements for input data are not met. Failing to transparently report how input data were acquired and selected can compromise the representativeness and generalizability of the AI model, potentially leading to critical errors in AI-driven decision-making, which may adversely affect patient safety and clinical outcomes.[17]

In particular, reporting on assessment and handling of input data needs to be improved. The reporting of AI intervention should mention the amount of poor-quality input data, as well as how this was identified and handled [17]. Poor-quality or unavailable input data can negatively impact the success of AI algorithms and the AI's performance and effectiveness. It is essential to have a plan in place for handling such scenarios, such as implementing data cleaning techniques, using data imputation methods, or seeking alternative data sources.[10] A study on cardiovascular imaging pointed out that the quality and preprocessing of input data such as echocardiography, cardiac magnetic resonance imaging, and cardiac computed tomography should be evaluated before a model can be trained using deep learning techniques [68]. Otherwise, the black-box nature of AI models may lead to a lack of trust among clinicians and sponsors [69,70].

Finally, reporting regarding access to and reuse of AI intervention and its code needs to be specified. Human-AI interaction promotes the capabilities of AI systems, as it leverages human expertise to ensure the practical application of AI models. A review on ML highlights three reasons for the necessity of human involvement: real-world problems are inherently complex, ML methods often lack explainability, and AI outputs may not always align with clinical expectations or disease judgment [71]. It is imperative that health care professionals can validate and refine AI methodologies to ensure they are clinically applicable [72,73]. Therefore, specifying whether and how the AI intervention and its underlying code can be accessed by designated health care professionals is crucial. Clear reporting on the accessibility and transparency of AI systems further helps clinicians understand their functionality, enhancing trust in their outputs and fostering the development of user-friendly interfaces, and ensuring the safe and effective use of AI in clinical practice.

Conclusion

Our study focused on AI intervention in primary care, providing a first systematic review of qualified reporting of RCTs using AI interventions. This study indicated significant gaps between the reporting guidelines and published articles and underscored the crucial items and aspects that were frequently overlooked in the reporting framework. It is said that the whole of medicine depends on the transparent reporting of clinical trials [74]. Our

XSL•FO
RenderX

findings may contribute to the enhancement of quality standards in AI research in primary care trials and help future clinical AI investigators to design, conduct, and analysis of higher-quality AI interventions for primary care.

Abstract

Background: The digital information environment poses challenges for pregnant women and other people seeking care, as well as for their midwives and other health care professionals (HCPs). They can encounter questions, concerns, information gaps, and misinformation, which can influence health care decisions.

Objective: This scoping review examines how HCPs are affected by the modern digital information environment including health misinformation, its effects on the women and people they care for, and its implications for care provision.

Methods: English-language peer-reviewed literature, published from January 1, 2020, to May 31, 2024, with keywords related to midwifery, misinformation, and health equity collected and analyzed by a team of midwives and maternal care professionals and mapped onto a patient-centered conceptual model.

Results: A total of 105 studies were ultimately included. Further, 95 papers identified specific digital information environment issues that affected clients; 58 specifically highlighted digital information environment issues impacting HCPs; 91 papers identified specific topics of common questions, concerns, misinformation, information voids, or narratives; 57 papers identified patient or population vulnerability; and 75 included mentions of solutions or recommendations for addressing a digital information environment issue around clients seeking care from midwives and other HCPs. When mapped onto the Journey to Health model, the most prominent barrier was access to care and information. Individual-level issues dominate the step related to knowledge, awareness, and belief, with more social norms and wider engagement appearing at steps related to intent. Client-specific themes dominate the left-hand side of the model and provider-specific issues dominate the right-hand side of the model.

Conclusions: Misinformation, information voids, unaddressed questions and concerns, and lack of access to high-quality health information are worldwide prevalent barriers that affect both patients and HCPs. We identified individual, provider-level, health systems, and societal-level strategies that can be used to promote healthier digital information environments.

KEYWORDS

digital health; midwifery; misinformation; information-seeking midwifery; health information seeking; social media; medical misinformation

Introduction

Background

Pregnant women and parents-to-be are often exposed to a flood of information and advice not only from health care professionals (HCPs), but also from family, friends, and increasingly from various online sources [1]. However, not all of this online information is accurate and some might be deceptive [2], making it challenging for people to identify reliable sources of health information and to filter and act on reliable guidance regarding pregnancy, maternity, reproductive health, and other health topics [3]. The digital information environment—encompassing mobile phones, apps, social media, and websites—has profoundly influenced how people, including women and their partners in the perinatal period [4], seek and process health information. Inequities in access to health care and health information [5,6], influenced by social and commercial determinants of health [7], also affect how people's health is affected by the digital information environment [8].

Midwives and other maternal HCPs need to better understand how the people they care for seek information online, including common questions, concerns, misinformation, and narratives that may be encountered. Although information about sexuality, reproductive health, and pregnancy may come from many sources, and people may seek offline information and care from other professionals and are influenced by social and support networks [9], the digital environment is now a leading source of information [10,11]. This understanding is critical, as it can impact the HCP-client relationship [12] and is especially critical for midwives.

Midwives strive to provide woman-centered care, with respect for autonomy, choice, and control. The midwife-woman relationship has trust as its foundational basis. Evidence-based midwifery provides for deliberative exchanges for shared decision-making to establish the wishes, needs, and preferences of women, and to develop care plans that can address the needs of women, ultimately empowering them, ensuring quality care for women and newborns, and safeguarding their health and well-being [13]. The digital information environment can influence all aspects of the unique relationship between midwife and woman and can influence downstream effects of health-seeking behaviors and decision-making and how women navigate maternity care systems; in addition, it can positively or adversely affect health outcomes [14].

It is particularly important to consider that the health care relationship in the perinatal period covers the years before, during, and after pregnancy, and often multiple sequential pregnancies can result in many years of almost continuous interaction. This is a period of change as the person becomes pregnant and a parent, and develops new identities and behaviors that last a lifetime and affect all health decisions for children, mothers, and entire families [15]. Midwifery-led care, according to the International Council of Midwives [16], includes the core competency to "adapt to and adopt new and emerging technologies that have been proven to enhance midwifery practice and care." Understanding the modern digital information environment is essential to fulfilling this competency, and as the world becomes more digitally connected, its impact on people seeking care and their midwives and other maternal HCPs will only grow.

In this review, we catalog and describe how midwives and other maternal HCPs are affected by the modern digital information environment, including health misinformation, its effects on their clients, and the implications it has on care provision. The digital information environment affects both HCPs and their patients [17,18], but has differing effects on each and influences the care providers give, which is why understanding these interactions holistically is essential for improving health care. Therefore, we will use a model that encompasses the patient experience and the social and digital information landscape, as well as health care access in the review. The review also includes research that is focused on maternal HCPs beyond midwives to reflect the maturing nature of research in this field.

Based on previous literature on social media [19], digital ecosystems in health care, and the information environment in the context of health [20], we define the digital information environment as the online spaces where information—including news, social media content, and other digital material—is produced, curated, shared, discussed, and amplified across digital platforms and devices. However, access to both information and health care is not equitable for all. This review also focuses on vulnerable populations, or people who experience inequities in accessing health care, including migrants, people living in poverty, individuals with disabilities, and those with low literacy, to better understand how these groups are affected by health misinformation and the challenges within the digital information environment. Given that different HCPs have different terminology for people under their care—such as clients, patients, or parents-to-be—and this review includes papers from many medical and health disciplines, terms may be used interchangeably.

Why Focus on Midwives and Their Relationship to Their Clients?

This review will map available evidence and help inform the development of strategies for midwives to help their clients better cope with the modern digital information environment, promote inclusive communication, build trust, and more successfully encourage clients to follow health care advice, therefore improving client health outcomes. Developing a more trusting and effective midwife-client relationship can also help the clients maintain seeking health services for themselves and their children beyond the perinatal period.

The underpinning philosophy of the interaction between midwives and patients in the digital information landscape is based on trust, enabling effective collaboration in navigating

XSL•FO
RenderX

modern health care challenges [21]. Both groups operate within the same digital ecosystem, but the ways they engage with and are impacted by information and disinformation differ significantly.

Women, often the primary consumers of digital health information, increasingly rely on tools such as websites, social media, and apps to seek knowledge about their health. While this access can empower them to take a more active role in their care, it also exposes them to misinformation, conflicting advice, and volumes of iatrogenic content. The result can be confusion, anxiety, and even decisions based on unreliable sources [22].

Midwives, on the other hand, engage with the same ecosystem as intermediaries and guides. They must stay informed about the evolving digital health landscape to effectively filter, interpret, and contextualize the information women encounter [23]. Their role is to identify credible resources, dispel misinformation, and integrate digital health content into evidence-based midwifery care. This dual role of interpreter and gatekeeper reinforces trust between midwives and women, as midwives ensure that the information women rely on is accurate and applicable to their individual needs.

Moreover, the way digital information impacts midwives and women is shaped by their priorities and capabilities. For women, digital tools often serve as an entry point to health education, providing a sense of autonomy but also raising questions and concerns [24]. For midwives, these tools are professional tools [25], used to enhance shared decision-making and to address women's concerns in a way that fosters trust and collaboration. While women may experience information as fragmented or overwhelming, midwives transform the digital landscape into a resource for empowerment.

Disinformation poses a unique challenge in this ecosystem. Women may encounter intentionally misleading content that exacerbates mistrust or undermines their confidence in professional advice [26]. For midwives, disinformation adds complexity to their role, requiring them to not only correct falsehoods but also rebuild trust when it has been eroded by inaccurate digital narratives. This dynamic underscores the critical importance of midwives as trusted navigators in the health care journey.

Trust extends beyond individual interactions to midwives' broader advocacy for equitable access to credible digital resources. Systemic challenges, such as the digital divide and disparities in digital literacy, disproportionately affect women, especially those from underserved populations such as migrant mothers. Midwives address these inequities by guiding women toward accessible, understandable, and reliable health information. This advocacy, combined with evidence-based midwifery practices and critical thinking skills fostered through midwifery education, further equips midwives to support women effectively in the digital era [27].

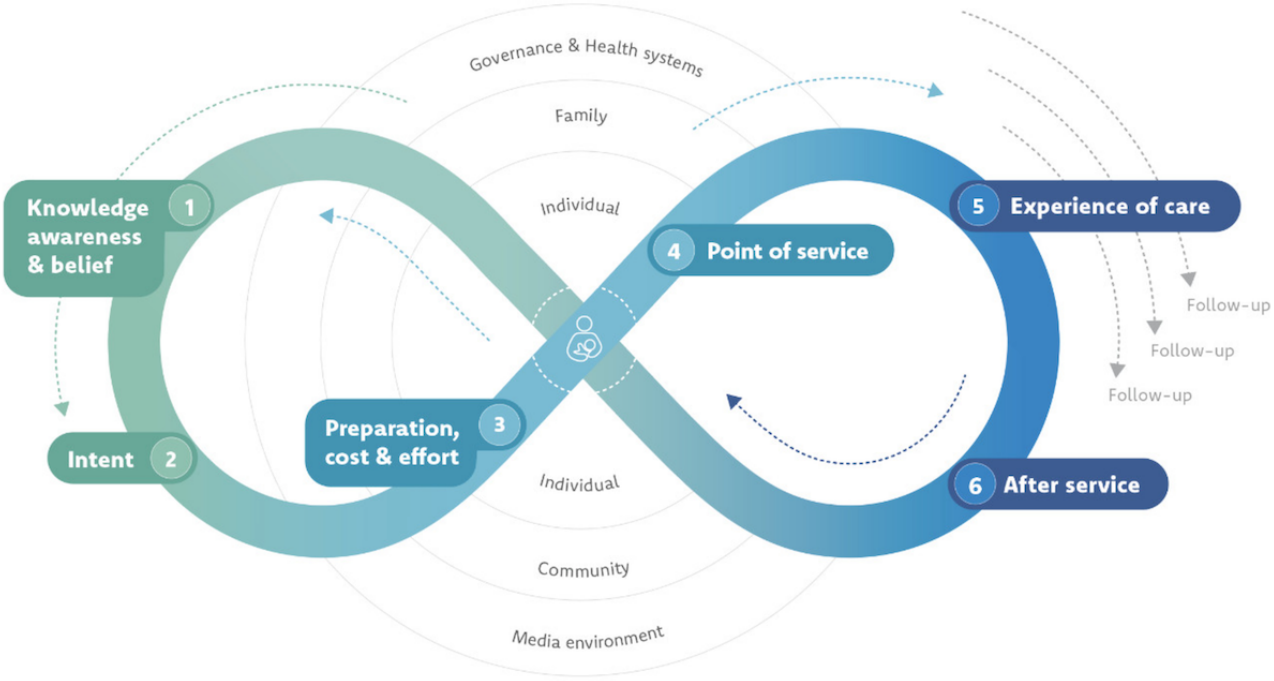
Ultimately, the differentiated dynamics between midwives and women in the digital information ecosystem highlight the complementary roles they play. By synthesizing digital information, midwifery expertise, and trust, midwives ensure that women feel supported, informed, and confident as they navigate their health care journey [28].

Review Questions

This review aims to identify the facilitators and barriers that the modern digital information environment presents to midwives and the care they provide to their clients.

The key questions to answer in this review are: (1) How has the modern digital information environment affected midwives? (2) What common types of health misinformation are midwives asked to address? (3) How has the digital information environment affected clients' information and health-seeking behaviors?

Methods



Framework for Search and Analysis

This review adapted the UNICEF (United Nations International Children's Emergency Fund) Journey to Health model to map factors specific to HCPs and clients that surface in the review's included papers [20]. This framework is used to conceptualize the health care–seeking journey of individuals and the care provision journey of HCPs. These factors are linked to the digital information environment, including health misinformation, which may influence health information-seeking behaviors, care-seeking, and health care provision.

As shown in Figure 1, the model imagines the journey a patient or client undertakes to seek health care [29], and conversely, the HCP's own journey in providing care, with individual-level and informational attributes on the left side of the diagram and more health service and care provision aspects found on the right side. For a patient or client to fully complete a course of recommended care, such as antenatal visits, they need to complete this journey many times but may encounter barriers that can make this journey harder, or enablers that make it easier. HCPs are also situated along this journey on the right-hand side at the point of service and heavily influence the experience of care and after-service for clients. This model also allows for the digital information environment effects on the HCP and the individual to be captured in the context of larger systems that shape their interactions. Any intervention or strategy—individual, community, health system, societal, or systemic—identified to manage the digital information environment would be included and mapped on the model.

XSL•FO

Figure 1. UNICEF's Journey to Health model, which illustrates the 6 steps a patient or client takes in seeking health care and the multilevel factors that influence this journey. This review maps data extracted from included papers onto this model. The Journey to Health is licensed under the Creative Commons Attribution-NonCommercial-ShareAlike 3.0 IGO (CC BY-NC-SA 3.0 IGO) license. UNICEF: United Nations International Children's Emergency Fund.

The domains of inquiry during the analysis process, aligned with this framework, include themes of digital information environment barriers and enablers to clients seeking health care, midwives, and other HCPs in providing care, and what strategies or interventions were mentioned to overcome the identified digital information environment issue.

Search Strategy

The domain being studied is digital information environment components, particularly health information, questions, concerns, information voids, narratives, health misinformation, and disinformation in online spaces [30], which can affect a person's perceptions and health care decisions. In this review, the focus was on midwives but aimed to broaden the scope also to those HCPs who provided maternal health care, people in the perinatal period, and equity considerations.

Peer-reviewed papers were identified through databases including PubMed, Scopus, Web of Science, Science Direct, Cochrane Library, Embase, and Google Scholar (specifically review papers).

The search strategy was developed by identifying keywords from relevant recent publications and identifying additional terms associated with midwives and misinformation, social media, information environment, digital health, health information, health equity, and other related Medical Subject Headings (MeSH) keywords. Search using such an approach yielded very few papers, likely due to inconsistent coding of concepts related to misinformation, information environment, and interpersonal communication challenges in a health care setting. Therefore, the keyword string was reduced to broaden the search and cast a wider net for potentially applicable papers from the information environment point of view. At the same time, terms related to midwives and pregnancy were introduced to focus the search results on midwives and their clients and reduce the number of results that were not relevant to this setting and were being returned when we used broader terms referring to HCPs. This exercise resulted in the search string provided in the following paragraph and uncovered a more diverse array of relevant papers from health care journals, social science, social media, the internet, and technology.

The final search string was modified to fit the parameters of each scientific literature database: ((pregnancy) AND (midwife) AND (misinformation) AND (communication OR question* OR concern*)) AND equity.

To be included, papers were required to be published in peer-reviewed journals in English between January 1, 2020, to May 31, 2024, in addition to other criteria (Table 1). This timeframe was chosen due to the rapidly changing digital information environment, especially during and shortly following the global COVID-19 pandemic, which saw major social media platforms weaken content moderation against health misinformation [31], TikTok grow as a leading source of health information for women [32], health care provision shift to include telehealth and increase in health information-seeking online [33,34], and misinformation identified as a growing public health concern worldwide [35,36].

Table 1. Summary of inclusion and exclusion criteria for papers in this scoping review focused on midwives, the people they care for, and the modern information environment.

	Included	Excluded
Article type	Original research, reviews, meta-analyses, or case reports published in peer-reviewed research journals	Opinions and commentaries, gray literature, preprints, duplicates, or book chapters
Methodology	Can include any methodology or type of research (qualitative and quantitative)	N/A[a]
Geography	Any country or region	N/A
Language	English	Not in English
Publication date range	January 1, 2020, to May 31, 2024	Outside of January 1, 2020, to May 31, 2024
Full text available?	Yes	No
Related to digital information environment? (eg, includes social media, apps, and internet)	Yes	No
Relevant to maternal health professionals? (eg, includes midwives or OB-GYNs[b] as health providers or pregnant women as the focus population)	Yes	No
Related to health equity? (eg, discusses disparities in information or health care access and use for different populations)	Yes	No

[a]N/A: not applicable.

[b]OB-GYN: obstetrics and gynecology.

Analysis Team Setup

The screening and analysis process was undertaken by a multidisciplinary, multinational team of health care and public health–focused academics and professionals, including several midwives. This ensured that the review of the literature to inform midwifery-led care was also led by midwives and that the extracted data and conclusions were correctly interpreted from a health care lens. A standard operating procedure (SOP) was developed and the team was trained on processes and tools to follow SOPs. The team collaborated at every stage, including screening, data extraction, analysis, and synthesis, conducting weekly check-in meetings discussing results, reviewing all entries and reconciling disparate judgments on particular papers, spot-checking one another's work, and updating SOPs and definitions to ensure consistency of screening and analysis processes.

Screening

Searches for papers for inclusion in the review were conducted in all identified peer-reviewed literature databases in English using defined date ranges and MeSH search terms. These papers (n=895) were then exported into Paperpile where some records were removed before screening, including duplicate records (n=29), non-English ones, those outside of the desired date range, or those initially flagged as not from a peer-reviewed journal (n=297). The remaining records (n=523) were screened, of which, 25 reports were not retrieved, and 498 were assessed for eligibility. Based on a full review of each paper, reports were then excluded for not being peer-reviewed (n=78), not being published within the defined date range (n=17), not being relevant to midwives (n=99), and not including an aspect of digital information environment (n=350). Ultimately, 105 papers were included in the review.

Data Extraction and Thematic Analysis

After the final list of studies to be included for review was compiled, they were loaded into a shared spreadsheet. The analysis team members then received randomized selections of the papers for further data extraction, coding, and thematic analysis. Each assigned paper was thoroughly read, reviewed, and discussed by the team. Any disagreements in judgments were resolved collaboratively before proceeding to the next stage. Papers were assessed for quality and qualitative papers were scored using a modified RATS (relevance, appropriateness, transparency, soundness) scoring framework.

In the data extraction phase, a PICO (population, intervention, comparison, and outcome) framework was used to extract and record the following information for each paper: (1) primary population of focus (HCPs), (2) stage of reproductive journey, (3) status and identities of population of focus that impact health equity, (4) country, (5) type of study, (6) link with COVID-19, (7) aspect of digital information environment investigated, (8) (if included) interventions or strategies to address digital information issue, and (9) intervention effects.

For the field (7) aspect of digital information environment investigated, the codes were developed based on a preparatory literature search and the papers analyzed: information-seeking, coping or support-seeking, community-seeking, information overload, information or news exposure, misinformation (inaccurate information on products, service, health information, or health guidance), disinformation (deliberately created inaccurate information on products, service, health information, or health guidance spread for political or financial gain),

XSL•FO
RenderX

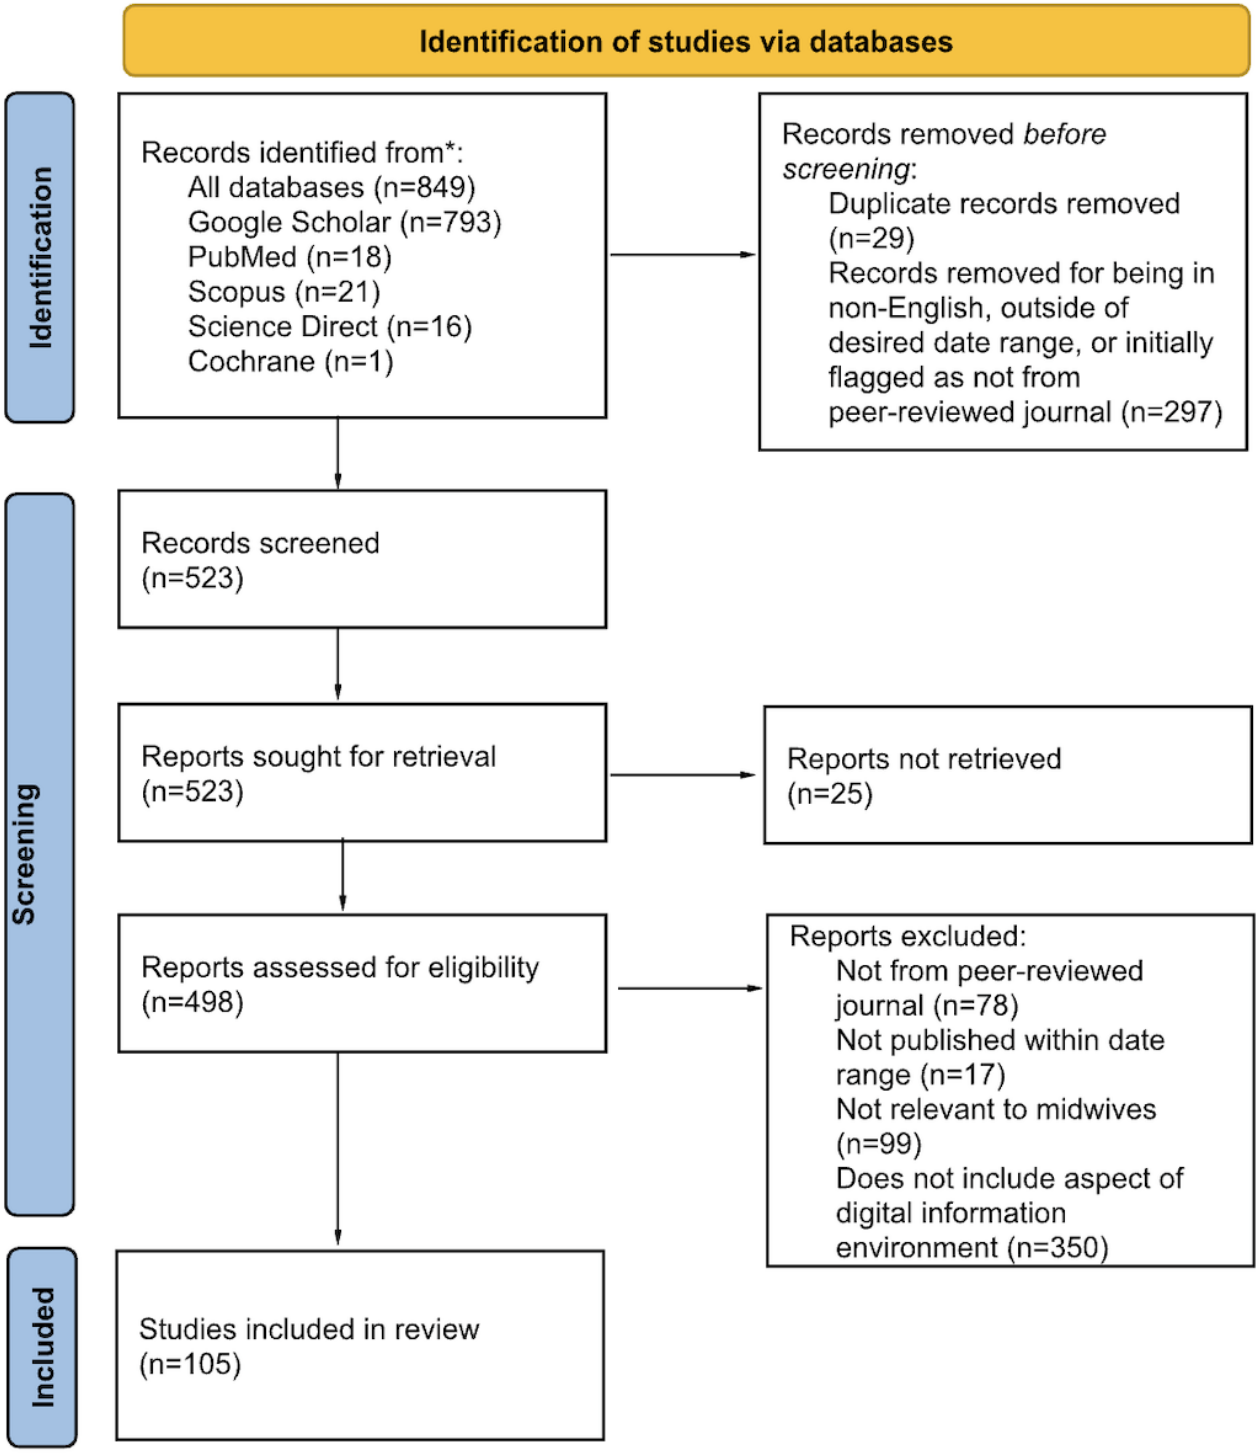
expressing questions or concerns, digital-mediated social issues (eg, bullying, harassment, stigma, or doxxing), social media use, app use, social media content (eg, memes, hashtags, videos, or images), deceptive marketing or advertising, communication with HCP, infodemic, and other.

Coding Process Across Domains

In the coding stage, the papers were coded for specific domains, with key information from relevant sections of papers extracted and added to the spreadsheet. These domains included: how the identified digital information environment issue affected clients, how it affects HCPs, and topics of common questions, concerns, misinformation, information voids, or narratives identified. Considerations related to patient or population vulnerability and any recommendations or recommended solutions to address the infodemic environment issue were also captured and coded.

Synthesis of Results

In this phase, analysts reviewed all 105 papers according to the domains listed above. To facilitate thematic grouping and visualization, the data were transferred to Miro, a digital whiteboard, where sticky notes were created, shared, discussed, and organized into themes during videoconference calls. Identifying new themes came from grouping similar ideas together [37] and identifying visually what ideas were on their own (or outliers) and placing similar groupings of ideas close to one another or between 2 different ideas that are linked. For example, COVID-19 as a theme is often related to the vaccines theme and fertility theme. Then, after the group discussion and organization of ideas on sticky notes, a template was used to help consolidate observations for each domain. Themes were then mapped on the Journey to Health model to provide a visual perspective on where along the journey the theme fits best and discussed with the analysis team to inform implications for HCP practice.



Results

Papers by the Numbers

The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist is available in Multimedia Appendix 1. Of 105 papers (Figure 2) included in the review, 28 papers were a type of review, systematic reviews, or meta-analyses, 91 papers discussed a vulnerability or aspect of health equity, 74 papers included multiple countries, 37 were COVID-19–focused, 46 included misinformation as the major digital information environment issue, 48 had suggested interventions or solutions with no papers including intervention effects, 75 had related recommendations or solutions, and 91 included topics of common questions, concerns or misinformation identified. Only 3 papers were solely focused on midwives versus broader categories of maternal HCPs. Additional information about included papers is summarized in Table 2.

XSL•FO
RenderX

Figure 2. Identification of studies via databases included in this review focusing on midwives, their clients, and health misinformation and related digital information environment issues, adapted from the PRISMA 2020 flow diagram. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

RenderX

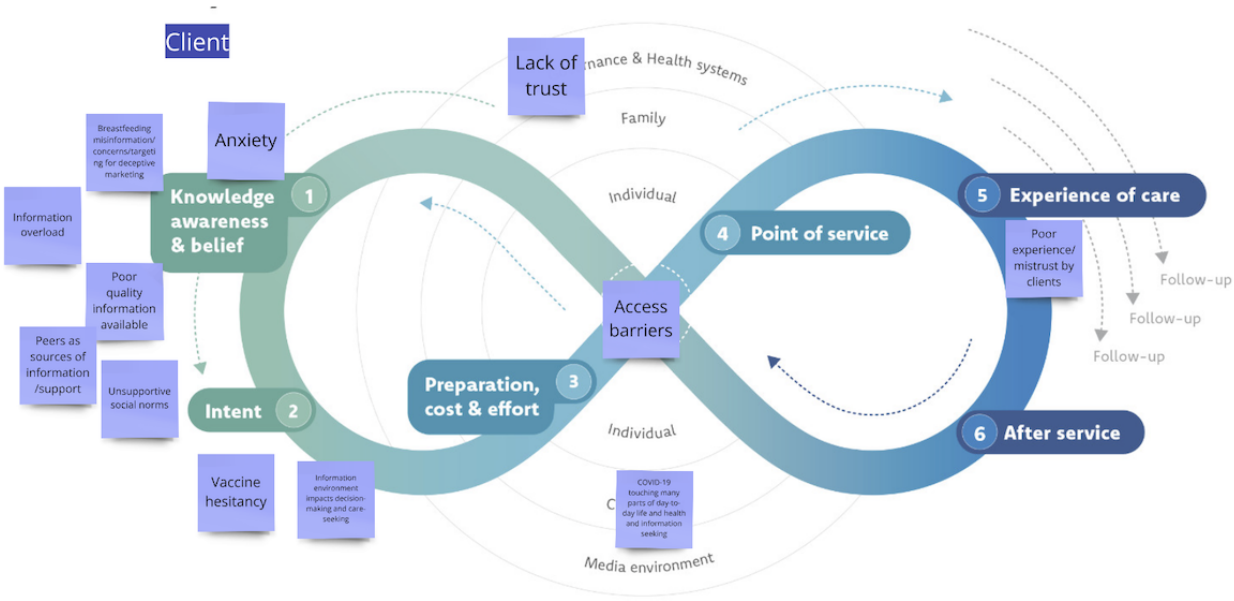
Table 2. Selected characteristics of included papers in this scoping review focused on midwives, their clients, and digital information environment challenges.

Specific characteristic	Number of papers (of 105 papers included in review), n (%)
Paper a review (eg, review, systematic review, or meta-analysis)	28 (26)
Paper related to a health vulnerability or health equity issue	91 (86)
Papers included multiple countries	74 (70)
Papers that were COVID-19–focused	37 (35)
Papers that included misinformation as a major digital information environment issue	46 (43)
Papers that included specific interventions or strategies to address digital information environment issue	48 (45)
Papers that included intervention effects	0 (0)
Papers that included recommendations or solutions to address digital information environment issue	75 (71)
Papers that included topics of common questions, concerns, or misinformation identified	91 (85)
Papers that were specific to midwives compared to other HCP[a] types or non-HCP audience	3 (2)

[a]HCP: health care professional.

Results by Domain

How Identified Digital Information Environment Issues Affected Clients



Of 105 papers, 95 papers identified specific digital information environment issues that affected clients. The most common topics were COVID-19, vaccine hesitancy, access, decision-making and care-seeking, breastfeeding, experience of care or HCP relationship, poor quality information, social norms, lack of trust, information overload, anxiety, peers, gender, and self-esteem or body image.

Several common and cross-cutting themes emerged for this domain. These included mental and cognitive barriers where clients expressed anxiety, experienced information overload, and had difficulty determining information quality and distinguishing between accurate and inaccurate information. Information voids also featured, where clients could not find the information that they were looking for from online resources or found the messaging confusing or mixed. This sometimes led to reliance on lower quality available information or misinformation. Informational barriers, such as lack of access to health information, including internet access and information available in appropriate formats, language, and cultural relevance could make people more prone to misinformation. Negative effects on behavior were also documented, where misinformation exposure can lead to attitudes and behaviors that put clients' health at risk. Finally, trust in HCPs was a barrier where poor health care encounters and stigmatizing experiences aggravated clients' mistrust in HCPs who then sought information and care elsewhere, especially from online spaces where they felt more socially connected and supported.

As shown in Figure 3, on the Journey to Health model, the clustering of themes in earlier stages of the journey highlights individual-level factors, information environment issues affecting knowledge and decision-making about health, and therefore making the rest of the journey and advancing to (3) preparation, cost, and effort and beyond more difficult. Digital information environment challenges can place informational barriers in the way of health care seeking. Access barriers further hindered the client journey, suggesting that some people who need care are not able to obtain it, and for those who do—for (5) experience of care—poor-quality interactions with HCPs by clients make it less likely they will trust them further or return.

XSL•FO
RenderX

Figure 3. Sample screenshot of Journey to Health with major themes related to client barriers and enablers related to digital information environment challenges mapped, clustering around the (1) knowledge, awareness, and belief and (2) intent stages, which can influence care seeking in later steps of the journey.

At a higher level of the socioecological diagram encompassing the journey, trust, or lack thereof, played a prominent role in influencing client attitudes toward health providers, their advice, and larger health care systems. COVID-19 also played a disruptive role, affecting the information environment and how care was offered, resulting in a chaotic information environment often seeding confusing information, providing mixed messaging, and making it difficult to communicate with HCPs.

How the Identified Digital Information Environment Issue Affected HCPs

Of the 105 papers reviewed, 58 specifically highlighted digital information environment issues impacting HCPs.

The most common topics identified included poor provision of care, stigma, the impacts of COVID-19, HCPs as both a source of misinformation and as a means of addressing it, lack of accurate guidance for HCPs, communication challenges, alternative information-seeking behaviors where clients circumvented their HCP, trust, the role of digital apps, and direct negative impacts on HCPs.

Across papers mentioning HCP-side challenges, several themes emerged. HCPs had dual-sided roles in information provision, some actively promoting misinformation and others addressing misinformation on a variety of topics, especially during the COVID-19 pandemic. COVID-19 also was the catalyst for the rapidly changing digital information environment, significantly accelerating challenges within the digital information environment for HCPs, driving greater digitization, the growth of telehealth and mobile health (mHealth), and changing client expectations around addressing misinformation. HCPs reported that misinformation was not only a challenge to providing health care but also a factor that affected their clients' attitudes and decision-making. HCPs also reported a lack of training or professional guidance on how to address misinformation and other challenges within the digital information environment, including improving their own digital literacy and evaluating mHealth apps used by clients. Misinformation contributed to less emphatic care where HCPs stigmatized or discriminated against clients based on misinformation. When clients lack access to or mistrust HCPs, they will seek and act on health information elsewhere, which can make it difficult for HPCs to understand what health information (or misinformation) influenced their clients and their resulting health decisions.

Themes were mapped onto the Journey to Health model, spanning most stages from (1) knowledge, awareness, and belief to (2) intent; (3) preparation, cost, and effort; (4) point of service; and (5) experience of care. Several themes clustered about the point of service and experience of care, indicating that digital information environment challenges such as misinformation affected health care provision. Larger social and systems forces related to the information environment and mistrust in HCPs and health systems by patients and COVID-19 as a major event disrupting health care also played a role in changing how care was provided.

Topics of Common Questions, Concerns, Misinformation, Information Voids, or Narratives Identified

Of 105 papers, 91 papers identified specific topics of common questions, concerns, misinformation, information voids, or narratives identified.

Common topics included COVID-19, vaccines, reproductive health, pregnancy, breastfeeding, family planning, LGBTQ+ (lesbian, gay, bisexual, transgender, queer, and other identities), baby, labor and birth, nutrition, obesity, and stereotypes about groups of people and mental health. These topics were not just misinformation but also reflected topics where there was confusion, lack of information, misperceptions, or questions and concerns. These are topics that patients expected their

XSL•FO
RenderX

providers to be able to address but reported feeling unsatisfied with given HCP-provided information and advice.

There were only two themes that emerged beyond specific topics, including issues related to information seeking between (1) knowledge, awareness, and belief and (2) intent and lack of access before (4) point of service on the Journey to Health. Both are about seeking information and health care, while the topical items were not specific to any stage of the journey.

Considerations Related to Patient or Population Vulnerability

Of 105 papers, 57 papers identified patient or population vulnerability.

The types of vulnerability discussed included multiple vulnerabilities, migration or refugee status, religious or ethnic minority status, adolescence, mental health vulnerabilities, disability, poverty, LGBTQ+ status, and adverse life experiences, among others. COVID-19 also highlighted the vulnerabilities of specific groups, including those with pre-existing health conditions and pregnant people.

The most common topics were access, information seeking, trust, social marginalization and stigma, literacy, and risk perception.

Emerging themes included access barriers, which included legal or policy, social, cultural, and physical access challenges to health information and care. Access to care is made more difficult if someone has a vulnerability or comes from a vulnerable population. Information seeking, shaped by literacy, identity, and access also featured as a theme. People will seek health information from sources they trust, which often includes family, friends, and larger peer groups where they share identity and community.

Themes mapped onto the Journey to Health around vulnerabilities clustered around (1) knowledge, awareness, and belief and (2) intent. Vulnerabilities can affect individual-level and social processes and barriers in earlier stages of the journey can limit access to care.

Recommendations or Solutions Are Presented to Address Digital Information Environment Issues

Of 105 papers, 75 included mentions of solutions or recommendations for addressing a digital information environment issue around clients seeking care from midwives and other HCPs. These focused on system-side interventions or solutions compared to more general societal or government-level interventions, such as technology platform regulation, content moderation, or fact-checking, which are well documented in the literature elsewhere [38,39].

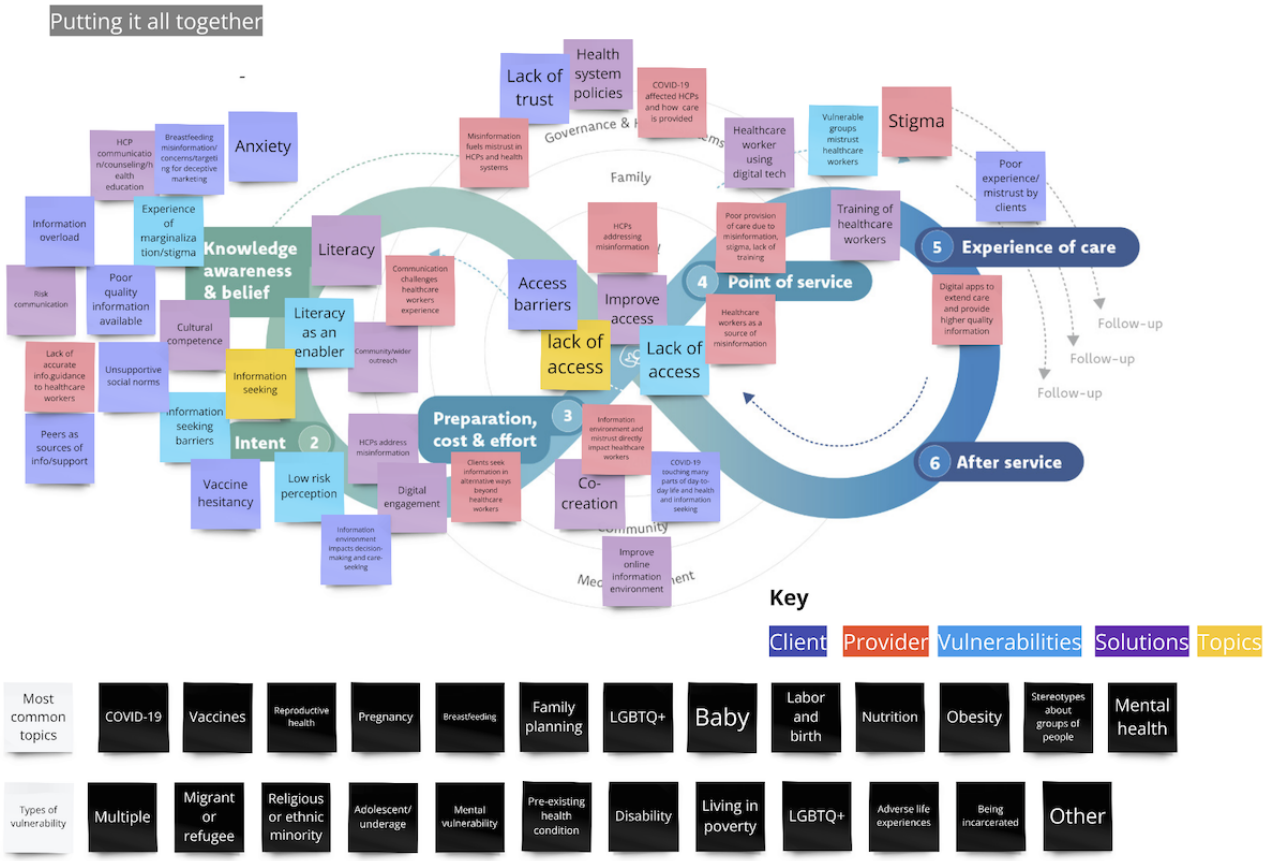
Cross-cutting themes focused on addressing skills and performance gaps by HCPs. This included improving HCP communication with strategies such as health education and counseling. Solutions were often designed to improve the quality of communication, language clarity, and inclusiveness, especially for populations that have experienced stigma or discrimination, such as people with disabilities, migrants or refugees, and LGBTQ+ people. Improving knowledge and communication on related topics, such as nutrition, can also address patient concerns. Training HCPs was also a common theme, with suggested topics on how to address misinformation, communicate more clearly, and receive training to better address vaccine hesitancy. HCPs should also be trained to give more inclusive and emphatic care to LGTBQ+ people. HCPs can also address health misinformation, using techniques such as prebunking, improving resilience and health literacy in clients, and training HCPs to address misinformation successfully.

At the systems level, more work can be done to improve risk communication by improving communication by health authorities and within families, During emergencies, it is important to evolve messaging as more information becomes known, especially for pregnant women and people in the perinatal period. Several papers suggested clarifying health systems policies such as by formalizing how HCPs are trained or expected to address misinformation, encouraging more research on health information, digital environment, and patient decision-making, and ensuring that health professionals adhere to ethics regarding product marketing and sponsorship. Improving access to health care through improved access to information could be accomplished by increasing the availability of information and enhancing access to information tools and technologies (eg, mHealth apps), particularly for patients who have historically faced inequitable health care access. Strengthening digital engagement was also recommended by promoting HCPs to use digital spaces to educate and connect with clients as trusted voices and improve the quality of available health-related social media content.

Additional themes focused on community-level strategies. Increasing community outreach, participation, and cocreation could help address the lack of tailored information or services and help enhance patient communication and care. This can be carried out by improving health system–community linkages and strengthening communications beyond pregnant women, including their communities and networks as well. Mainstreaming culturally competent communication and care by HCPs could be accomplished by policies and training to improve HCP cultural competency to better care for diverse populations. This could provide more culturally appropriate health information and support midwives and HCPs in reducing stigma by providing trauma-informed care. Finally, at the individual level, health and digital literacy could be improved through health education programs for the public and via HCP in appointments with clients.

When mapped onto the Journey to Health model, recommendations and solutions predominantly cluster on the left side, associated with individual-level knowledge, awareness, and intent. However, the solutions and recommendations cut across individual-level, provider-level, societal, health systems, and government or policy levels in recognition that the complex information environment's effects may need to be addressed through multiple levels.

Putting It All Together: Mapping Across All Domains and Themes



After each domain and major theme were mapped on the Journey to Health, all themes, still color-coded, were mapped

XSL•FO
RenderX

onto the model (Figure 4). Themes were heavily clustered in steps 1-5, with access (or lack thereof) appearing consistently for all themes except for the provider. Individual-level issues dominate at step (1) knowledge, awareness, and belief, with more social norms and wider engagement appearing at step (2) intent. Client-specific themes dominate the left-hand side and provider-specific issues dominate the right-hand side.

Screenshots of the Miro whiteboard with details of the analysis of all domains are available in Multimedia Appendix 2.

Figure 4. Screenshot of Journey to Health with major themes, common topics, and vulnerabilities mapped to address digital information environment issues.

Discussion

Principal Findings

The COVID-19 pandemic, which occurred during the period of data collection for this review, featured heavily in the included papers, where 35% (37/105) were directly related to the virus and its impacts on health systems and societies. Concepts such as “infodemic” [40] emerged and gained prominence, as did the role of misinformation in affecting health care provision and health care seeking worldwide [41]. Telehealth and digital communication to provide care became more common, and in the context of mobility restrictions, people sought more information via their mobile devices. As a result, the digital divide and inequitable access to health care for some vulnerable groups became prominent. These inequities predated COVID-19 but the pandemic highlighted new concerning dimensions where inequitable access to credible, accurate health information in the digital information environment adversely impacted health.

The review illustrates that the digital information environment exacerbates existing inequalities in access for clients and patients. HCPs struggle to overcome these challenges, particularly due to a lack of training or supportive workplace policies. Access to health care is often the first barrier faced by vulnerable populations, but even when access is attained, it does not guarantee that empathetic, culturally competent care will be provided. HCPs can struggle to adequately address patient questions, concerns, or misinformation effectively.

Individuals experiencing vulnerabilities have to deal with the dual challenges of limited access to care and credible health information. This can make them more vulnerable to exposure to low-quality information or misinformation that could negatively influence their perceptions or health behaviors. The COVID-19 pandemic provided many examples, including vaccine hesitancy among pregnant people based on mixed messaging and misinformation [42], some communities such as migrants, refugees, and other minority ethnic groups not seeking health advice reflecting their information needs, language, or values [43]. HCPs did not always meet these information needs, nor did wider health systems [44].

Some HCPs are actively addressing misinformation while others spread it, reflecting a lack of consistency in standards, training, and expectations of HCPs by health systems. However, HCPs report that since the COVID-19 pandemic, misinformation is

XSL•FO
RenderX

affecting how they provide care, and that it is no longer just an inconvenient side effect of living in the modern age.

Health misinformation is widespread on a large variety of topics of interest to people in the perinatal period [45]. How people sought it was based on who they trusted and what information sources they had access to, including HCPs. In communities that did not trust HCPs or had limited access to them, people sought out information from trusted networks including family, friends, and online support groups to help them cope, and find community and information that they could not easily obtain elsewhere. For some vulnerable groups, such as LGBTQ+ people, health information was sometimes entirely missing. This information void also affects HCPs, who may provide misinformation or provide poor, nonaffirming care to their clients.

HCPs need to broaden their knowledge of the related and trending topics their clients may have questions and concerns about and not assume that clients are operating only on credible information sources on which to base their health decisions. HCPs also should recognize that they compete for their patients' attention and trust against more emotionally compelling, slickly packaged, and immediately accessible social media content.

Health literacy emerged as a meta-theme based on numerous themes about information quality, culture, accessibility, and format—ideas that surfaced for every domain. Specifically, components of literacy [46] appeared on the individual level for clients about context, skills, knowledge, and psychological factors. Importantly, lack of digital literacy skills was not simply a challenge identified among patients, but also among HCPs, where lack of formal training or unclear workplace norms exacerbate this skills gap.

However, effective communication with patients takes more than a connection and literacy skills. Dozens of papers highlight issues of racism, stigma, discrimination, poor care, or care that even aggravates pre-existing trauma that HCPs can project onto their patients. Patients who already experience multiple vulnerabilities also face much higher hurdles to arrive at an HCP's office, if misinformation and access issues have not dissuaded them from trying to seek access. Treating them with care and respectful communication is a critical factor for them to follow health care advice and seek care in the future.

Intercultural competence and understanding the digital information environment and how it affects their patients are no longer optional for HCPs. Better interventions could be cocreated with patients, communities, and providers to address digital information environment challenges effectively. Such intervention could be better keyed to the information needs of vulnerable groups and take into account the complex web of information and social networks in digital spaces that are beyond the typical scope of HCPs. Given the widespread nature of health misinformation and other digital challenges, addressing them will require community-oriented solutions. Community-based solutions to combat misinformation could include cocreated interventions involving HCPs, patients, and community leaders, aimed at developing digital health literacy programs tailored to the specific needs of vulnerable groups, ensuring culturally relevant and accessible content.

Strengths and Limitations

The strength of this scoping review is its systematic approach, providing a snapshot of current digital information environment challenges and how they relate to midwives, maternal HCPs, and clients, including during the COVID-19 pandemic. However, this review is not exhaustive and did not include languages other than English, additional scientific databases, or gray literature. In future reviews, the inclusion of non-English language studies and gray literature could enrich the analysis, offering a broader, more international perspective on how different countries and cultures are addressing digital misinformation in health care. Additionally, as MeSH terms related to misinformation are largely categorized under communication rather than medical or public health topics, there is a risk that some relevant papers may have been overlooked. In the initial development of search strings, the terms "midwife" and "pregnancy" were included to focus on the health professional type in focus and the health state in focus for this paper; however, the search terms also led to the inclusion of broader maternal health care provider categories, which led to the inclusion of papers that did not specifically target midwives but were potentially relevant to them. This synthesis acknowledges limitations in the assessment of quality and access to digital information. A scoping review approach was used to map out the current landscape, ensuring the inclusion of diverse perspectives while recognizing gaps in data. Future work should focus on addressing disparities in access to technology and digital literacy among different populations.

Conclusion and Implications for Practice

The challenges presented by the digital information environment—misinformation, information voids, unaddressed questions and concerns, and lack of access to high-quality health information—are global issues. These barriers to optimal health are particularly detrimental for individuals seeking maternal health services, especially for those facing social, economic, or health vulnerabilities. Some barriers affect both patients and HCPs in achieving a healthier digital information environment that would promote accurate, accessible health information that people trust.

Despite these challenges, HCPs, especially midwives, are well-positioned to address misinformation and other information environment challenges. This is because HCPs are trusted sources of health information, including online. They also have pre-existing relationships with clients and communities and can extend relationships and continuity of care in digital spaces. HCPs can translate health guidance and evidence through more mediums, especially when digital "work" and tools are mainstreamed into care. HCPs can also empower clients with health education and promote digital health literacy. HCPs can also provide empathetic care with enhanced intercultural competencies through updated training.

However, to enable midwives and other HCPs to effectively address digital information environment challenges, more policy and health systems–level shifts are needed. HCPs should receive improved training in digital literacy, cultural competency, and caring for populations with specific vulnerabilities. Similar to how an HCP may ask questions related to identifying risk for

XSL•FO
RenderX

intimate partner violence or about nutrition and dietary habits and tailor their advice and care accordingly, understanding how the digital information environment is affecting their patients may be a new type of risk assessment offered. All HCPs should also benefit from work environments that promote mental health, and provide needed training and additional informational support for serving diverse patient populations.

The digital information environment will continue to grow in influence and impact health care delivery and information-seeking behaviors. Therefore, HCPs should be better supported through training and inclusion in health visits to address misinformation and other related issues. Health systems must improve their communication strategies, particularly in digital spaces, to provide accurate, timely, and culturally relevant health information to diverse audiences. One promising approach is to encourage HCPs to play an active role in digital spaces, leveraging the trust patients place in them to educate the public, engage with specific communities, and address misinformation in online communities where official health communication might not reach. Furthermore, health systems must prioritize the development of digital literacy training for both patients and HCPs, and adopt policies that support culturally competent, empathetic, and inclusive care.

Although most papers included in this review focused on general groups of maternal HCPs rather than specifically midwives, there are key insights particularly relevant to midwives. Midwives have long-term relationships with their pregnant clients while also addressing the sexual and reproductive health needs of many groups of people, from adolescents to refugees to LGBTQ+ people. Midwives are well-positioned at the client level and community level to listen, educate, and engage in offline and offline spaces, and play a crucial role in addressing health-related questions, concerns, and misinformation. It is imperative to include digital literacy, social media, cultural competency, and interpersonal communication training more firmly into midwifery education and extending midwifery practices into digital spaces. This would help midwives promote the values of empowerment, respect, and collaboration in this new digital frontier and can help them better serve the needs of clients who are increasingly online and navigating complex digital health landscapes.

Acknowledgments

EW conceptualized and implemented the work, managed the data, coordinated the coding and analysis, and drafted this paper. VV, JC-A, EP, and TDP conceptualized this research and reviewed the coding, analysis, and results. MT, PG, ET, EA, and FA coded and analyzed the data. All authors discussed the results and contributed to the final paper. No large language models such as ChatGPT, Claude, or Copilot were used in the preparation and writing of this paper.

Abstract

Background: A dramatic increase in the use of videoconferencing occurred as a response to the COVID-19 pandemic, including delivery of chronic disease management programs. With this increase, clients' openness to and confidence in receiving any type of telehealth care has dramatically improved. However, the rapidity of the response was accomplished with little time to learn from existing knowledge and research.

Objective: The purpose of this scoping review was to identify features, barriers, and facilitators of synchronous videoconference interventions that actively engage clients in the management of chronic conditions.

Methods: Using scoping review methodology, MEDLINE, CINAHL, and 6 other databases were searched from 2003 onward. The included studies reported on structured, one-on-one, synchronous videoconferencing interventions that actively engaged adults in the management of their chronic conditions at home. Studies reporting assessment or routine care were excluded. Extracted text data were analyzed using thematic analysis and published taxonomies.

Results: The 33 included articles reported on 25 distinct programs. Most programs targeted people with neurological conditions (10/25, 40%) or cancer (7/25, 28%). Analysis using the Taxonomy of Every Day Self-Management Strategies and the Behavior Change Technique Taxonomy version 1 identified common program content and behavior change strategies. However, distinct differences were evident based on whether program objectives were to improve physical activity or function (7/25, 28%) or mental health (7/25, 28%). Incorporating healthy behaviors was addressed in all programs designed to improve physical activity or function, whereas only 14% (1/7) of the programs targeting mental health covered content about healthy lifestyles. Managing emotional distress and social interaction were commonly discussed in programs with objectives of improving mental health (6/25, 24% and 4/25, 16%, respectively) but not in programs aiming at physical function (2/25, 8% and 0%, respectively). In total, 13

XSL•FO
RenderX

types of behavior change strategies were identified in the 25 programs. The top 3 types of strategies applied in programs intent on improving physical activity or function were feedback and monitoring, goals and planning, and social support, in contrast to shaping knowledge, regulation, and identity in programs with the goal of improving mental health. The findings suggest that chronic condition interventions continue to neglect evidence that exercise and strong relationships improve both physical and mental health. Videoconference interventions were seen as feasible and acceptable to clients. Challenges were mostly technology related: clients' comfort, technology literacy, access to hardware and the internet, and technical breakdowns and issues. Only 15% (5/33) of the studies explicitly described compliance with health information or privacy protection regulations.

Conclusions: Videoconferencing is a feasible and acceptable delivery format to engage clients in managing their conditions at home. Future program development could reduce siloed approaches by adding less used content and behavior change strategies. Addressing client privacy and technology issues should be priorities.

Introduction

Background

With the rise in popularity and availability of technology and the restrictions imposed by the COVID-19 pandemic, many health care providers have turned to telehealth care as an alternative, enhancement, or complement to face-to-face health care delivery [1]. Telehealth care refers to any remote communication or IT between clients and health care providers (eg, phone calls, SMS text messages, emails, and videoconferencing). In the United States, the use of telehealth care increased close to 30 times between September 2019 and September 2020, with many clients becoming first-time users during the pandemic [1]. As such, clients' openness to and confidence in receiving any type of telehealth care has dramatically improved. For example, approximately 80% of clients report being satisfied with telehealth care, and 75% wish it to continue as a regular part of their care. However, the pandemic-driven shift to telehealth care was rapid and reactive to public health measures introduced to control the spread of the disease. For this reason, knowledge about effective practices, facilitators, and barriers to using telehealth care to support adults with chronic conditions is limited or incomplete. Without this knowledge, the integration of telehealth care into regular care will continue to be fragmented and reactive.

Synchronous videoconferencing has been proposed as "a viable alternative to face-to-face [health and medical] appointments" [2]. Using an internet-based platform, bidirectional audio and video signal is exchanged in real time (ie, synchronously) enabling verbal, nonverbal, and typewritten communication between health care providers and clients. A scoping review published in 2014 identified >500 studies using synchronous videoconferencing in client care between 2002 and 2012, with a steep upward increase in publications at the end of this period [3]. The review revealed that videoconferencing was used by a wide variety of health care professionals to make diagnoses, provide consultation, monitor client compliance or progress, and support clients in managing both acute and chronic physical and mental conditions. While this review provided a broad picture of how videoconferencing was being used, it did not distinguish between routine care visits and chronic condition management programs, nor did it investigate the content or active ingredients in the interactions or report the facilitators and barriers afforded by this format of service delivery. In-depth reviews in focused areas of clinical care are needed to inform optimal practice.

The Centers for Disease Control and Prevention reports that 60% of adults in the United States live with one or more chronic conditions, making chronic conditions the leading cause of death and disability and a key driver of annual health care costs [4]. Living with chronic conditions requires active engagement in ongoing medical, role, and emotional management [4,5]. This work, commonly termed self-management, includes seeking support, making decisions, and altering behaviors in the context of everyday life [6-8]. In contrast to passive receipt of educational information, active client participation is a hallmark of "informed, activated patients" described in the widely endorsed chronic care model [9,10]. The active involvement of individuals in these interventions sets them apart from many other medical interventions and warrants specific investigation.

Objectives

Preventing chronic conditions by promoting and enabling self-management is now widely regarded as critical to improving client outcomes and reducing demands on health systems [6,7]. Therefore, in-person chronic disease management and self-management programs have proliferated. Many, particularly those for older adults, who are the most likely to have chronic conditions, are condition specific and have structured content that is delivered in a 6- to 8-week period, usually consisting of weekly sessions [11]. Self-management programs are known to effectively improve health outcomes and reduce health system demands [6,7]. As such, they have become a primary focus of health service policy, redesign, and research [9,12], with delivery both in person and via telehealth care. The purpose of this scoping review was to examine how videoconferencing has been used to deliver structured, synchronous, one-to-one interventions to clients in their own homes and actively engage them in the prevention and management of their chronic conditions.

XSL•FO
RenderX

Methods

Design

A scoping review is "a form of knowledge synthesis that addresses an exploratory research question aimed at mapping key concepts, types of evidence, and gaps in research related to a defined area or field" [13]. This methodology was selected specifically because the features of videoconferencing interventions to support adults with chronic conditions remain unclear. The 5-stage methodological framework by Arksey and O'Malley [14] was followed with augmentation consistent with recent evolutions of the scoping review methodology [15,16]. Focused on conceptual knowledge synthesis, scoping reviews do not typically assess the quality of the studies, nor are they intended to assess effectiveness. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist [17] proposed by the Enhancing the Quality and Transparency of Health Research Network was used to guide reporting of study conduct and findings (Multimedia Appendix 1). The protocol was developed and registered on the Open Science Framework [18]. Ethics approval was not sought or required for this review article.

Identifying the Research Question

The research question was discussed and defined by an international research team comprising occupational therapists or researchers with expertise in chronic disease management. The agreed upon question—"What is known about the theoretical foundation, purpose and contents, active ingredients, program structure, technology, and facilitators and barriers of structured, synchronous, one-on-one videoconference interventions that actively engage clients who are living at home in the management of their chronic conditions?"—reflects the intent to help researchers and clinicians create, tailor, or transfer in-person interventions to internet-based delivery. The focus on structured, synchronous, one-on-one videoconferencing interventions was chosen because they most closely imitate in-person chronic disease interventions. Client location during the videoconference was restricted to their home.

Chronic conditions are defined broadly as "conditions that last one year or more and require ongoing medical attention or limit activities of daily living or both" [4]. In this review, we interpreted this to include populations medically at risk, such as people with obesity or frailty or requiring common interventions such as knee arthroplasty. Features such as program structure, asynchronous activities, videoconferencing technology, and program feasibility and acceptability were operationalized a priori (Textbox 1). An existing taxonomy and an existing framework were adopted to describe and categorize program content and behavior change strategies. The Taxonomy of Every Day Self-Management Strategies (TEDSS) [19] was used to operationalize program content. Active ingredients or strategies facilitating behavior change were operationalized using the Behavior Change Technique Taxonomy version 1 (BCT Taxonomy v1) hierarchical clusters [20] (see the Collating, Summarizing, and Reporting the Results section for details of each). Program purpose and theoretical foundation were not defined a priori, relying instead on the descriptions provided by each author. Similarly, barriers and facilitators were identified based on those reported in the text or quantitative reports of client satisfaction found in the study results.

Textbox 1. A priori operational definitions of key terms.

Term and operational definition or selected taxonomy
• Chronic conditions: "conditions that last one year or more and require ongoing medical attention or limit activities of daily living or both" [4]
• Program structure: intervention duration, frequency, and asynchronous activities
• Asynchronous activities: activities undertaken outside or between the videoconferencing sessions, such as homework or symptom or activity monitoring
• Videoconferencing technology: software and hardware used or supplied, compatibility and connectivity requirements, data security, and any efforts made to set up or train clients to use the technology at home
• Program content: the Taxonomy of Every Day Self-Management Strategies framework [19]
• Active ingredients and behavior change strategies: Behavior Change Techniques taxonomy version 1 hierarchical clusters [20]
• Feasibility and acceptability: retention, attrition, and attendance rates

Identifying Relevant Studies

The search strategy was developed and supported by a medical librarian with expertise in systematic and scoping reviews. Electronic databases in the field of health science and education (MEDLINE, PubMed, CINAHL, Embase, PsycINFO, OTseeker, PEDro, Cochrane, and ERIC) were searched using the following keywords—"videoconferencing," "teleconferencing," "virtual care," "skype," "teleconsultation," "video call," "telerehab," "ehealth," and "digital"—to identify videoconference interventions. These keywords reflect the wide array of terminology used to describe videoconferencing in health care interventions and client education. Because PsycINFO and ERIC often include healthy samples or populations, the keywords "patients," "illness," and "disease" were added to those searches. Keywords related to self-management were deliberately not included in the search strategies. Review of preliminary searches revealed that many interventions meeting the criteria of active engagement and self-management of chronic conditions were excluded when these keywords were added. Because their addition greatly reduced the number of studies found, selection based on active engagement was conducted during the title, abstract, and full-text screening processes. The search was limited to articles published in

XSL•FO
RenderX

English. The initial search took place on June 3, 2020. In response to the proliferation of published literature, the search was repeated on January 25, 2023, adding the period from January 2020 to January 2023. The combined searches included articles reporting on adult samples published within the 20-year period between January 2003 and January 2023. Studies published before 2003 were excluded due to the limited currency of videoconferencing technology at that time. Detailed search strategies for each database and the number of hits from each are presented in Multimedia Appendix 2.

Study Selection

Article inclusion and exclusion criteria were defined for (1) participants, (2) intervention program technology and format, and (3) intervention content and features (Table 1). Review studies and protocol papers were included. Review studies were further checked to identify missing articles fitting the selection criteria. Because protocol papers often provide rich information about program content, they were included to help map intervention structure, content, and active ingredients, recognizing that there would be no extractable data on facilitators and barriers. Routine care, defined as having regular meetings to diagnose or monitor clients' conditions; compliance with a treatment or medication regime; or treatment without a predefined structure, topics, or modules during videoconferencing were excluded.

Table 1. Inclusion and exclusion criteria for the studies—videoconference interventions for people with chronic conditions.

Category and subcategory	Inclusion criteria	Exclusion criteria
Participants		
Adults aged ≥18 years	• Adults aged ≥18 years	• Dyads of parents and children aged <18 years
Community dwelling	• Community dwelling (eg, private home, supported housing, or group homes)	• Individuals living in a hospital, long-term care facilities, or mental health facilities
One or more chronic conditions	• Having at least one chronic or medically at-risk condition requiring ongoing medical attention for >1 year; the condition must impact activities of daily living (eg, heart condition, diabetes, obesity, or knee arthroplasty)	• Caregivers as the focus of the intervention • Health professionals or trainees as the focus of the intervention • No indication of chronic conditions (eg, inactive adults, people seeking psychological consultations, smokers, and veterans)
Program technology and format		
One-on-one	• Individual meeting in which the service provider saw 1 client or 1 client with their adult companion or caregiver	• Group videoconference or one videoconference with multiple individuals at the same time (eg, educational session for multiple people)
Synchronous	• Concurrent presence of the client or client and adult companion or caregiver and service provider in real time	• Programs delivered completely asynchronously
Videoconferencing at home	• Internet-based communication through transmitted audio and video signals; the client is located at home (for RCTs[a], at least one arm had to meet this criterion)	• Communication via telephone call only or combining telephone call and videoconferencing • Videoconferencing outside the client's home (eg, community center or clinics) • Information transmission through virtual reality, robotic interventions, or platforms without interaction (eg, electronic monitoring system or automatic graphical feedback)
Intervention program content and features		
Structured program	• Interventions with a stated goal or purpose and a structure (topics, modules, frequency, and duration of sessions)	• Diagnostic and assessment-focused studies • Routine care or follow-up sessions without structured intervention modules
Active client participation	• Evidence of active client participation (eg, verbal, physical, or cognitive), including coaching and healthy behavior monitoring	• Studies that only asked participants to listen to a lecture or read study materials (passive educational approach)

[a]RCT: randomized controlled trial.

Study selection protocols for the initial search (June 2020) are described in detail. The protocols for the updated search (January 2023) were identical unless otherwise noted. At each time point, search results were imported into the Covidence platform (Veritas Health Innovation Ltd) for screening and selection. Covidence automatically removed duplicate articles.

XSL•FO
RenderX

A total of 8 researchers participated in the review process (Multimedia Appendix 3). The lead reviewers (reviewers 3 and 6) together with reviewers 2, 4, and 5 were involved throughout both the initial and updated searches. Reviewers 1 and 2 were involved in the initial search. Reviewers 7 and 8 were involved in the updated search.

Before the initial title and abstract screening, interrater reliability trials were completed to ensure that reviewers were consistent in their selection. Reviewers 1 to 6 read the same 5 articles, independently deciding whether they met the inclusion and exclusion criteria. Conflicts were discussed, and operational definitions of the eligibility criteria were refined. This process was repeated until the κ interrater agreement level reached 0.8 [13,21]. With strong interrater reliability confirmed, title and abstract searches were completed by 1 of 5 reviewers (reviewers 2 to 6). Reviewers 3, 5, and 6 were joined by reviewers 7 and 8 to complete the updated title and abstract screening. New reviewers were provided with the written operational definitions and extensively oriented before commencing their reviews.

The full texts of retained studies were downloaded or ordered through interlibrary loan and imported into Covidence. All identified articles were located and retrieved. As with the initial title and abstract search, interrater reliability testing achieved a κ agreement of at least 0.8 before beginning the final selection of articles. In total, 2 reviewers independently screened each full-text article. For both the original and updated searches, conflicts were discussed and resolved by a full professor (reviewer 6) and a postdoctoral fellow (reviewer 3); for the updated search, conflicts were resolved by the same professor and an experienced research occupational therapist (reviewer 7).

A total of 94 studies met the inclusion criteria after the first full-text screening. Close examination revealed three distinct intervention types: (1) interventions specifically designed for individuals with mental health conditions (eg, depression, anxiety, and posttraumatic stress disorder), (2) solely exercise-based or repetitive learning interventions (eg, motor learning approach, muscle-strengthening exercises, and word-finding therapy) with no evidence of active client decision-making, and (3) interventions intended to support participants to actively and deliberately manage everyday life with a chronic condition. Exercise, activity-based, or repetitive interventions that explicitly included components to manage everyday life (eg, problem-solving, information seeking, and decision-making) were included in the third group. Given that existing reviews have reported on mental health populations [22-26] and exercise-based or repetitive interventions [27-29], this manuscript reports an analysis of the third group of interventions, for which there is less evidence.

During the original search, assignment of articles to the 3 intervention types was first completed by a single, consistent reviewer (reviewer 3); 4 other reviewers each assessed one-quarter of the articles, meaning that all articles were assigned by a consistent reviewer and one other. Conflicts were resolved by the lead reviewers. When the search was updated, reviewers 3 and 6 both assigned all articles to an intervention type and resolved conflicts through discussion.

Charting the Data

Data extraction was completed in Covidence using extraction template 2.0. The extraction form was developed based on the research question and then pilot-tested by the lead reviewers, who independently extracted data from 2 of the included articles. The data extracted included general article information, research objectives, study design, participants (clients or recipients and clinicians or service providers), intervention purpose, content and features, videoconference technology and logistics, and facilitators of and barriers to delivering or receiving interventions using videoconference. A 2-hour workshop was held to familiarize team members with the data extraction process in Covidence. The 2 reviewers included for the updated search were similarly oriented. Double data extraction by 2 of 7 reviewers was then completed. The extracted data were checked, selected, or combined by 2 consistent reviewers for each search, resulting in comprehensive and rich data available for collation. Finally, the results were exported from Covidence to a CSV file and imported into Microsoft Excel for data analysis.

Collating, Summarizing, and Reporting the Results

Extracted data were managed using Microsoft Excel. Categorical data (eg, study country, type of study design, and software and hardware selected) were analyzed using descriptive analysis. Text-based data were analyzed using either a known theoretical framework or thematic analysis. Intervention content and active ingredients were analyzed using the TEDSS framework [19] and the BCT Taxonomy v1 hierarchical clusters [20], respectively. The TEDSS framework, derived from the literature and interviews with 117 individuals living with chronic neurological conditions, was chosen for its robust and comprehensive categorization of strategies commonly used and considered important by people living with chronic conditions [19,30,31]. The 7 distinctive TEDSS domains (Textbox 2) have been used to successfully identify and describe content in self-management interventions [32,33], including in scoping reviews [11,34].

XSL•FO
RenderX

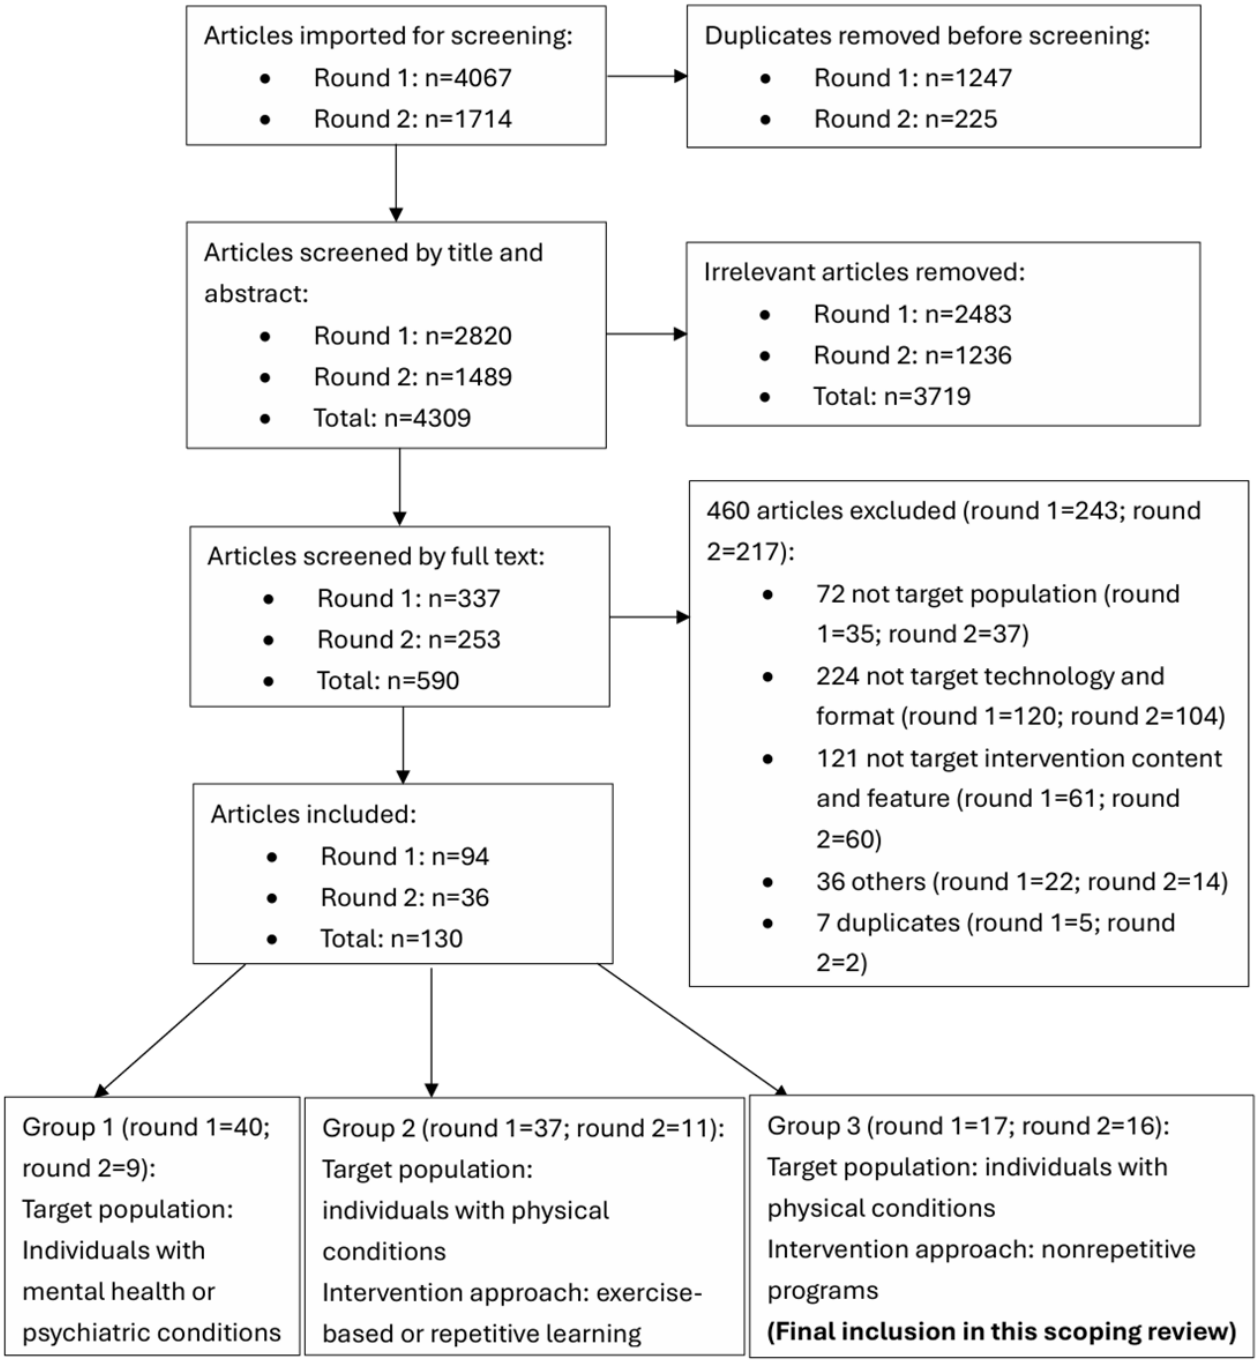
Textbox 2. Domain definitions—Taxonomy of Every Day Self-Management Strategies (TEDSS).

TEDSS domain and definition

- Process strategies: strategies used to be well informed and make good decisions; often used to support use of other, nonprocess strategies
- Resource strategies: proactively seeking, pursuing, or managing needed formal or informal supports and resources
- Activity strategies: finding ways to participate in everyday activities (leisure activities, work activities, and household chores) despite problems such as fatigue, pain, memory loss, or disability
- Internal strategies: preventing and managing stress, negative emotions, and internal distress; creating inner calm
- Social interaction strategies: managing social interactions and relationships to be able to participate without exposure to negative reactions
- Health behavior strategies: maintaining a healthy lifestyle to enhance health and limit the risk of lifestyle-related illness
- Disease-controlling strategies: preventing, controlling, and limiting symptoms, complications, or disease progression

The BCT Taxonomy v1 [20] was used to categorize "observable, replicable, and irreducible component(s) of intervention[s] designed to alter or redirect causal processes that regulate behavior; that is, a technique proposed to be an 'active ingredient'" [20]. The BCT Taxonomy v1 is a well-known taxonomy used to describe behavior change interventions. In this review, we used the 16-cluster definition developed by the BCT Taxonomy v1 authors to code the strategies used to facilitate clients' behavior change [35].

All other text data (eg, theoretical foundation, intervention purpose, facilitators, and barriers) were coded and analyzed using thematic analysis. Keywords from the extracted text were first highlighted independently by 2 reviewers. Keywords were compared to generate themes before all extracted data were recoded using these themes. The extracted data (eg, intervention purpose, theoretical background, contents, and active ingredients) were cross-referenced to ensure that all the available data were included in the analysis. Data from both searches were combined before the number and percentage of programs assigned to each theme were calculated.



Results

Overview

The search of eligible articles from multiple databases generated 4067 potential articles in the initial search, with a further 1714 in the updated search. After removing duplicates, 4309 articles were screened by title and abstract, and 590 (13.69%) underwent full-text review. Of a total of 130 articles included after the full-text review, 33 (25.4%) [36-68] reported on self-management interventions for individuals with physical or cognitive impairments (ie, not solely exercise based or repetitive in nature or designed specifically for clients with a mental health diagnosis) and were included for final review (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.

A total of 48% (16/33) of the studies were conducted or designed in the United States (Table 2). In total, 18% (6/33) of the studies were conducted in Australia and Canada each, with the remaining conducted in Israel (3/33, 9%) and the United Kingdom and Ireland (1/33, 3% each). Over half of the papers reported randomized controlled trials (12/33, 36%) or were protocol papers (8/33, 24%), and a further 18% (6/33) were pilot or feasibility studies. Other designs were less well represented (Table 2). All the included studies (33/33, 100%) were published after 2012, with 85% (28/33) published after 2018. The 33 studies reported on 25 unique intervention programs (Table 3).

[k]EVO: Elements Vital to Treat Obesity.

[l]SC: supported conversation.

[m]PCST: Pain Coping Skill Training.

[n]MCPC: Meaning-Centered Pain Coping Skills Training.

[o]CO-OP: Cognitive Orientation to Daily Occupational Performance.

[p]A total of 12% (4/33) of the studies tested the same intervention and delivered it on both a weekly and nonweekly schedule.

[q]SIT: self-instructional training.

[r]VYV: Voice Your Values.

[s]ONBOARD: Overcoming Barriers and Obstacles to Adopting Diabetes Devices.

[t]CBT-I: CBT for insomnia.

[u]CBT-SF: CBT for sleep disturbance and fatigue.

Technology

Technology differed across the studies, even those reporting the same intervention program. The most common device used for videoconferencing was an iPad or tablet (12/33, 36%). Computers (6/33, 18%), any available device (3/33, 9%), and smartphones (3/33, 9%) were less common. Skype (9/33, 27%) and Zoom (9/33, 27%) were the most frequently used commercial platforms, with a variety of other commercial and custom-designed platforms reported (Multimedia Appendix 4 [36-68]).

Device source and ownership varied. Researchers provided all devices in some studies (9/33, 27%), whereas participants used their own devices in others (5/33, 15%). Finally, in some studies (4/33, 12%), researchers provided devices only if required. A total of 36% (12/33) of the studies did not report device type, and 45% (15/33) did not provide information on device ownership. Interestingly, 55% (18/33) of the studies stated that lack of access to a device, the internet, or a videoconference platform was a reason for exclusion. In total, 45% (15/33) included only participants who owned or had access to compatible devices and a reliable internet connection, excluding those without. A total of 24% (8/33) of the studies excluded participants who were unable to set up or log into the videoconference system independently or with assistance from family or friends.

In total, 15% (5/33) of the studies reported that the platform or software used was compliant with national or provincial personal and health information regulations, such as Health Insurance Portability and Accountability Act (HIPAA) or the Personal Information Protection and Electronic Documents Act (PIPEDA). A total of 27% (9/33) of the studies [36,37,39,41,45,55,62,64,68] reported strategies to enhance data security (eg, password-protected log-in procedures and encrypted data access), and 9% (3/33) [58,60,62] reported how participants were informed of data security and consented to any potential risk.

XSL•FO
RenderX

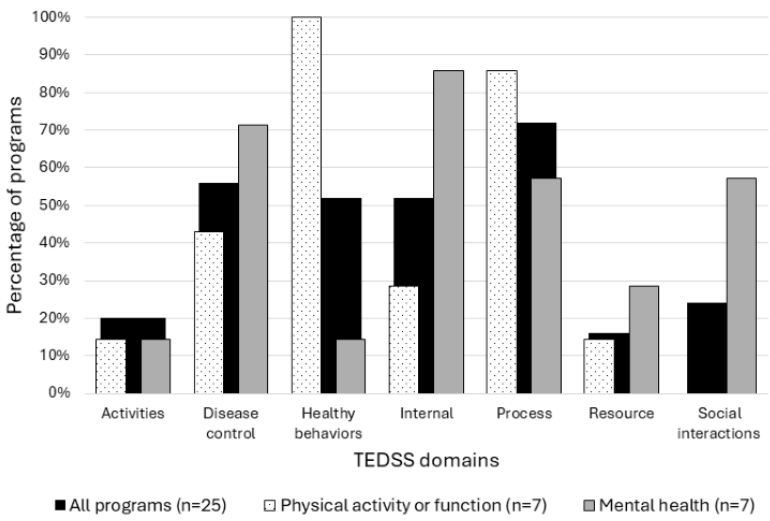
In total, 39% (13/33) of the studies confirmed participant device videoconference compatibility and internet strength. Training sessions (10/33, 30%) [37,40,41,45,48,52,55,56,65,68], securing family supports (4/33, 12%) [36,43,55,56], providing manuals (5/33, 15%) [38,45,55,58,63], home visits (2/33, 6%) [41,43], and email instructions (3/33, 9%) [45,58,68] were reported as ways to prepare and educate participants.

Intervention Programs

A total of 33 studies met the inclusion criteria and reported on 25 unique intervention programs. Therefore, program data were aggregated and are presented by program rather than by study in this section.

Programs were delivered by various health care professionals, with psychologists (9/25, 36%) being the most common, followed by multidisciplinary health care teams and nurses (3/25, 12% each) and speech-language pathologists and occupational therapists (2/25, 8% each; Table 2). Participants were people with neurological conditions (10/25, 40%); cancer (7/25, 28%); musculoskeletal conditions (3/25, 12%); or inflammatory bowel disease, obesity, and diabetes (2/25, 8% each). One intervention was delivered to participants with both neurological *and* musculoskeletal conditions. A total of 32% (8/25) of the programs required a companion to join the videoconference to practice communication skills, facilitate family support and relationships, or promote activity engagement [43,45,48,53,55,56,58,59,62,65].

The number of sessions was almost evenly divided between 3 categories. In total, 36% (9/25) of the programs were delivered in ≥10 sessions, and another 36% (9/25) spanned 5 to 9 sessions. A total of 28% (7/25) of the programs had ≤4 sessions (Table 3). Weekly meetings for ≤1 hour were the most common arrangement (9/25, 36%). Only 16% (4/25) of the programs had videoconferencing sessions longer than an hour. A total of 24% (8/33) of the studies reported participant attendance rates of 71% to 100% of sessions, with 12% (4/33) reporting 100% attendance rates. Reported attrition rates ranged between 0% and 35% (10/33, 30% of the studies; protocol papers excluded).



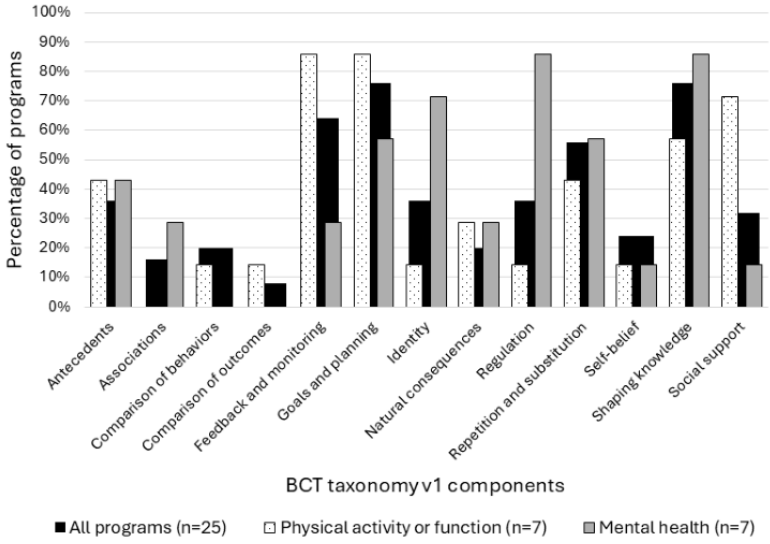
Almost all programs (21/25, 84%) included numerous asynchronous elements in addition to the videoconferencing sessions (Table 3). Active learning elements such as self-monitoring and tracking or between-session practice were commonly reported (10/25, 40% of the programs each), as were more passive learning elements such as printed materials or manuals and access to websites (14/25, 56% of the programs).

On the basis of explicitly stated program goals or objectives, thematic analysis identified 12 distinct program objectives across the 25 intervention programs, with 9 (36%) programs indicating more than one objective (Table 3). Even though programs designed specifically for people with mental health diagnoses and solely exercise-based programs were excluded, the 2 most common objectives were improving physical activity or function and improving mental health, each reported by 28% (7/25) of the programs. The next most frequently reported objective was improving quality of life (5/25, 20%); however, this was rarely the sole program objective. Program-specific health objectives were also found, such as weight loss or improving oral health.

No single theoretical foundation dominated program development. Thematic analysis revealed that the social cognitive theory or cognitive behavioral therapy was the most cited theoretical foundation (6/25, 24%), followed by unspecified behavior change theories (4/25, 16%; Table 3). Studies also cited reviews of the literature or clinical guidelines (5/25, 20%) or previous interventions (5/25, 20%) as program foundations.

No program included content from all TEDSS domains (Multimedia Appendix 5). However, the use of some domains was more common (Figure 2). In total, ≥50% of the programs (18/25, 72%) included content from the *process* domain (eg, finding information, problem-solving, decision-making, and action planning), the *disease control* domain (14/25, 56%; eg, medication and symptom management), the *healthy behaviors* domain (13/25, 52%; eg, diet and exercise), and the *internal* domain (13/25, 52%; eg, staying positive and reducing stress). In contrast, <25% of the programs included content from the other domains (Figure 2).

Figure 2. Intervention program content by program objective. TEDSS: Taxonomy of Every Day Self-Management Strategies.



XSL•FO
RenderX

The diversity of the programs prevented a descriptive analysis based on client group or theoretical foundation; however, descriptive analysis based on 2 program objectives (improving mental health and improving physical activity or function) was possible and demonstrated unique patterns in the included content. Figure 2 illustrates markedly different content in 3 specific TEDSS domains. In total, 100% (7/7) of the interventions with the goal of improving physical activity or function included content on diet, exercise, or sleep hygiene (*healthy behavior* domain) compared to only 14% (1/7) of the interventions intended to improve mental health. The opposite trend was observed for the *internal* and *social interaction* domains—interventions with the goal of improving mental health frequently included content from these domains, whereas those focused on improving physical function did not. In fact, no programs with the goal of improving physical activity or function included content from the *social interaction* domain.

Of the 16 BCT Taxonomy v1 strategy groups, 4 (25%; goals and planning, shaping knowledge, feedback and monitoring, and repetition and substitution) were included in >50% of the intervention programs (goals and planning: 19/25, 76%; shaping knowledge: 19/25, 76%; feedback and monitoring: 16/25, 64%; repetition and substitution: 14/25, 56%), and 3 (19%) were not included at all (Figure 3). None of the programs reported using reward and threat, scheduled consequences, or covert learning techniques. As with program content, analysis based on program objective yielded different patterns of behavior change elements. In programs intent on improving physical activity or function, the feedback and monitoring, goals and planning, and social support strategies dominated. However, in programs with the goal of improving mental health, the shaping knowledge, regulation, and identity behavior change strategies were the most common.

Figure 3. Behavior change components by program objective. BCT taxonomy v1: Behavior Change Technique Taxonomy version 1.

Facilitators of and Barriers to Videoconference Interventions

Text and quantitative results describing facilitators and barriers to using videoconferencing were extracted from 76% (25/33) of the articles (protocol papers were excluded). Health care provider perspectives were reported in only 6% (2/33) of the studies; therefore, only participant perspectives are reported. Five facilitators were categorized and labeled as follows:

1. Feasibility and acceptability to participants (11/25, 44%)
2. Reduced temporal and physical barriers (11/25, 44%)
3. Therapeutic benefit or therapeutic alliance (10/25, 40%)
4. Improved reach to underserviced populations or areas (6/25, 24%)
5. Allowing COVID-19 safety precautions (1/25, 4%)

Although 30% (10/33) of the papers were published in either 2021 or 2022, only 3% (1/33) of the papers [44] identified videoconferencing as a specific benefit during the period of COVID-19 restrictions. Definitions and sample quotes for each facilitator are presented in Table 4. Barriers to delivering interventions using videoconferencing were also identified and are described in Table 4:

1. Reliance on client comfort and technology literacy (8/25, 32%)
2. Limited access to technology and the internet (7/25, 28%)
3. Technical issues or breakdowns (7/25, 28%)
4. Protection of privacy and confidentiality (5/25, 20%)
5. Limited clinical observations and communication (3/25, 12%)

Table 4. Facilitators and barriers of videoconferencing interventions for people with chronic conditions (N=25).

Facilitators or barriers	Interventions, n (%)	Description	Examples
Facilitators			
Feasible and acceptable to participants [37,38,45,46,48,51,53,58,60,63,65]	11 (44)	• Low attrition rate and high completion rate • Positive client feedback—easy to follow, practical, and convenient; easy and quick to reschedule if needed	"The delivery of the TBIconneCT intervention via videoconferencing was feasible and well received by the participants." [58]
Reduced temporal and physical barriers [37,38,40,44,46,51,60,61,63-65]	11 (44)	• Saved time, cost, and energy required traveling to the clinic • Avoidance of barriers in transportation, parking, and accessibility • Particularly beneficial for individuals with greater difficulties traveling or with poorer health conditions	"The ease of completing sessions at home may have reduced treatment access barriers often reported by patients with cancer, such as difficulty with travel and parking." [63]
Therapeutic benefits from receiving the intervention at home or therapeutic alliance building [36,37,40,45,51,58,60,61,65,68]	10 (40)	• Ability to observe and provide environmental recommendations at clients' homes • Direct application and practice of skills in naturalistic settings; no need to generalize skills learned in a clinical or laboratory setting • Meaningful collaborative partnerships	"The first benefit was patient engagement and communication. Video was novel and fun for some patients, more interactive than telephone, and nurses felt they got to know video patients better...Study nurses reported the video was useful for some indications, such as viewing a drawer of medications or observing a patient doing shoulder exercises." [45]
Improved reach to underserviced populations or underserviced areas [38,51,60,62,63,65]	6 (24)	• Improvement of health care service delivery in remote areas for clients with poor health	"Participants connected from diverse locations, including rural and urban areas, spread over large geographic distances. This widespread reach would not have been possible had the intervention taken place in-person." [62]
COVID-19 [44]	1 (4)	• Allowing COVID-19 safety precautions	"In the current COVID-19 pandemic, where social distancing is an essential policy in many countries to decrease the spread of the disease, online interventions have become increasingly common." [44]
Barriers			
Reliance on patients' comfort and technology literacy [38,40,41,45,46,58,63,68].	8 (32)	• Limited confidence, comfort, and skills using technology • Reduced trustworthiness of quality health care services	"In our sample of participants with CI, not unexpectedly, we found that adopting more than one new technology at a time was especially difficult for participants (e.g., learning how to use both the iPad and the video visit software)." [45]
Limited access to compatible technology and the internet [36,40,41,46,55,62,68]	7 (28)	• Home device or software is not compatible with the requirements of videoconferencing • Insufficient internet bandwidth and upload or download speed • High cost of better devices and signal quality	"Participants needed to be familiar with using technology and have access to a computer, limiting the accessibility of this design to all members of the SCI community." [40]
Technical issues [36,45,50,55,58,62,68]	7 (28)	• Delayed or frozen audio or video signal • Technological glitches or system malfunction	"Several expressed frustration with the intermittent loss of connectivity and technical problems related to the videoconferencing during sessions." [68]
Protection of privacy and confidentiality [38,55,58,62,67]	5 (20)	• Unclear privacy protection procedures • Inability to confirm the legitimacy of the health care provider • Inconsistent client health and personal information acts across different jurisdictions	"Ensuring participants are communicating with legitimate personnel, ensuring that the delivery format does not invade privacy." [55]

XSL•FO
RenderX

Facilitators or barriers	Interventions, n (%)	Description	Examples
Limited clinical observations and communication [45,55,62]	3 (12)	• Limited environmental information beyond the scope of the camera	"The therapist could not see the complete context in which the activity was performed...this made it difficult at times for the therapist to analyze performance breakdowns in order to guide the participants most effectively." [55]

Discussion

Principal Findings

Overview

By summarizing what we know about structured, one-to-one videoconference intervention programs for people with chronic conditions, lessons can be gleaned for future development, execution, and feasibility. First, the findings of this review confirm what others have found: videoconference programs are both feasible and acceptable, often providing positive therapeutic benefits. Second, program purpose and objective may provide program developers and interventionists with important insights into program content and behavior change elements. Finally, while technology does overcome some barriers to access, it creates others.

Feasibility and Acceptability

Consistent with previous findings [69,70], this review found videoconference programs to be feasible and acceptable to clients, generating confidence for future program development. As reported by others [71,72], this review also found that spatial and temporal barriers, such as the need to travel to a hospital or clinic, were reduced or removed, and access to care for underserviced populations or areas was increased. Further evidence of participant acceptance was found in the high attendance and low attrition rates. In 67% (4/6) of the studies reporting completion rates, there was 100% completion, suggesting strong client uptake.

Reports on development of therapist-client rapport during videoconference sessions are mixed, with some indicating that providers struggle to build therapeutic alliances [26,73], whereas others indicate that videoconferencing does not hinder the therapist-client rapport or therapeutic alliance [73,74]. The studies in this review found that eye contact, facial expression, voice or tone, and other nonverbal communication were conveyed through the screen with high client satisfaction.

However, feasibility and acceptability were primarily based on qualitative data, client or health care provider impressions, or process evaluations. Future research to quantitatively assess the reduction in spatial and temporal barriers and the fidelity of therapist-client rapport are needed to confirm these findings.

Program Purpose Suggests Content and Behavior Change Elements

Analysis of program content (TEDSS domains) and behavior change strategies (BCT Taxonomy v1 groups) provides direction for health care providers and researchers developing or transferring in-person programs to internet-based format.

A total of 4 TEDSS domains and 4 BCT Taxonomy v1 groups dominated the 25 intervention programs. Over 50% of the programs (18/25, 72%; *disease and control* domain: 14/25, 56%; *healthy behavior* domain: 13/25, 52%; *internal* domain: 13/25, 52%) had content aligned with the same 4 domains (*disease control, healthy behaviors, internal, and process*) of the TEDSS framework, findings that mimic those of others using the TEDSS framework to analyze program content and program outcome measures [11,75]. However, potentially more instructive are the domains that received limited attention. Enhancing clients' role management (ie, *activities* and *social interaction* domains) and strategies to find, access, or manage formal and informal supports and resources (ie, *resources* domain) are also part of managing and living with chronic conditions [76-78]. These content areas are also the very topics that clients identify as most important and least well covered [79]. Qualitative work by Satink et al [80], Audulv et al [81], Audulv [82], and others demonstrates how self-management needs change with time, particularly once clients return home and the focus on medical management diminishes. The paucity of intervention programs addressing clients' role management has been highlighted in other reviews [11,75], as has the limited focus on finding and managing formal and informal resources [34]. On the basis of these findings, future development and adaptation of telehealth care programs could consider broadening the scope of program content and the alignment between client needs, particularly when clients are living in the community. Research to interrogate the relative importance of different content areas based on context, disease trajectory, and time since diagnosis would help identify active ingredients needed to tailor interventions.

BCT Taxonomy v1 techniques used in videoconferencing interventions appear to emulate asynchronous e-interventions for individuals with diabetes and programs for health promotion delivered using the internet or mobile phones [83-85]. Many techniques in the goals and planning and feedback and monitoring clusters, also found in this review, have had significant treatment effects in diabetes management [83-85]. Shaping knowledge and repetition and substitution (eg, practicing and rehearsing learned skills) also appeared to be common elements in the studies in this review, likely due to the inclusion criteria, which stressed active participation. Regardless, the results indicate that a wide array of behavior change techniques can be incorporated into telehealth care programs.

This review specifically excluded intervention programs based solely on repetition or intended for clients with mental health diagnoses. Despite this, the 2 most common program objectives were improving physical activity or function and improving

XSL•FO
RenderX

mental health. Comparison of TEDSS domains and BCT Taxonomy v1 elements provides valuable insights for both in-person and telehealth care program development and delivery. While the analysis was descriptive and limited to these 2 program objectives (7/33, 21% of the studies each), marked differences were found, suggesting that program objectives have, at least up to now, driven content and behavior change strategies, 2 things often considered active ingredients in chronic disease management and intervention programs. These stark differences may reflect theoretical or disciplinary differences or perhaps the siloed delivery of health care. For example, differences in content related to the *healthy behaviors*, *internal, and social interaction* domains may at first seem intuitive. Greater emphasis on the *healthy behaviors* domain in programs focused on improving physical activity or function versus a focus on the *internal* and *social interaction* intuitively understandable. However, significant research links positive mental health outcomes to healthy eating, sleep hygiene, and exercise [86,87]. Similarly, improving physical activity or function in populations living with chronic conditions is often dependent on family and friends for support and motivation [88,89]. Similar contradictions seem to appear in the chosen BCT Taxonomy v1 strategies. Why feedback and monitoring strategies are more successful in building physical activity or function or why identity and regulation strategies are more important in programs that focus on mental health could be questioned. Research to disentangle these inconsistencies and questions is needed.

Regardless of the contradictions and questions, the finding that program content and techniques and, therefore, active ingredients vary by program objective has important implications for program development, training, and effectiveness studies. For example, the development of new intervention programs can be guided by knowledge of existing active ingredients. Moreover, using the TEDSS and BCT Taxonomy v1 in the planning stages may generate innovative programs. It is also important for future systematic reviews to avoid grouping programs with different objectives to avoid findings of average effectiveness across programs with different active ingredients.

Collectively, our findings demonstrate the value of using the well-defined TEDSS and BCT Taxonomy v1 frameworks to unify how interventions are reported and compared. Using common frameworks with defined terminology can potentially address the calls to identify and isolate content or active ingredients within complex interventions and assist providers in tailoring self-management interventions to client needs.

Challenges Delivering Interventions Using Videoconferencing

Despite the feasibility and acceptability of videoconference interventions, barriers related to technology literacy, compatible devices, and quality internet access were found. Evidence of barriers was 2-fold. First, many studies (18/33, 55%) excluded participants without a stable internet connection, compatible hardware, or family or social support at home. While it is unknown how many participants were excluded for these reasons, it is likely that they were marginalized populations or lived in rural areas where Wi-Fi connection is often less stable. This technological gap must be addressed to reduce health inequity using any telehealth care approach. Second, clients' comfort level, confidence, and skills to effectively operate the necessary technology were the most common barriers reported despite efforts to provide initial training and the exclusion of participants without access. Careful planning, communication, and training are imperative to enhance comfort and confidence for service providers and clients [90]. The work by Vassilev et al [71] underscores this, finding "evidence that clients' capability in technology use increased their propensity to benefit from interventions." On the basis of the findings of this review, communicating with clients about confidence and preference of delivery format should be prioritized before the initial session.

Consistent with existing literature, technology breakdowns were a common cause of user frustration [91]. While 39% (13/33) of the studies verified the connectivity before intervention sessions, there were breakdowns or poor audio or video quality. Appointments had to be canceled or rescheduled through email or telephone. Although causes were unreported, limited bandwidth, software malfunction, and old add-on devices (eg, microphone or camera) are potential explanations. These findings recommend intentional preparation and contingency planning, such as a participant manual for troubleshooting common technology issues. Some highly qualified health care providers may also lack the technical skills or confidence to manage videoconference delivery. Adequate provider technology expertise should be assessed before service delivery via telehealth care formats [92]. Adding a technology support team member could meet a portion of this need and potentially enhance the therapeutic experience [93].

Limitations and Future Research

Although this review covered a 20-year span up to January 2023, many interventions were planned or executed before the COVID-19 pandemic and may not capture the rapid development of videoconferencing services and policies after 2020. Technology for telehealth care and videoconferencing (eg, Zoom and Microsoft Teams) has dramatically advanced with the addition of products, video technology, and health care security (HIPAA compliance). Familiarity and comfort with technologies has also increased dramatically. Upcoming articles may reveal additional recommendations. The lack of information reported on security and confidentiality issues during videoconferencing suggests the need for a dedicated and in-depth study across countries and jurisdictions.

The findings of this review are limited to information reported in manuscripts and publicly available to researchers and providers. Authors were not contacted to clarify or confirm the content or active ingredients in the interventions. Therefore, reporting of content and behavior change strategies may be incomplete. More structured and uniform reporting is needed to overcome this gap. While scoping review methodology does not include the assessment of research quality or outcome evaluation, uniformity of reporting would benefit future systematic reviews or meta-analyses, helping identify links between active ingredients and outcomes. Finally, health care providers' perspectives on videoconferencing could not be

XSL•FO
RenderX

reported due to the small number of papers or studies reporting these data. The inherent provider-client collaboration in these interventions [10] warrants the need to also understand the challenges experienced by health care providers.

Conclusions and Clinical Implications

Using videoconferencing to deliver one-to-one synchronous interventions is feasible and acceptable to clients. Health care providers can build positive therapeutic relationships via videoconference and simultaneously reduce temporal and physical barriers associated with access to care and improving reach to underserviced populations and areas. Despite this, barriers and concerns exist. Client confidence and comfort using technology, limited access to compatible and reliable hardware and internet connection, and technology breakdowns are common, highlighting the importance of technical support for providers and clients.

Structured, one-to-one videoconference interventions that actively engage people in the management of their chronic conditions remain primarily focused on medical and, to some extent, emotional management. Focused content to support integration into roles and everyday life, prioritize positive social interactions, and improve access to resources constitutes areas important to clients to strengthen interventions. The value of this content regardless of the program goal should be considered when developing future interventions. Similarly, additional behavior change techniques have potential to increase the effectiveness of interventions. With telehealth care practices expanding, further research is needed to point the way to best practice.

Moving in-person self-management interventions to internet-based formats must be intentional. While technology can reduce barriers, access to care based on device ownership and internet connectivity can be a delivery challenge. Health care teams may need to be expanded to include technical and technology support for providers and clients. Ensuring compliance with local privacy laws and protection of personal health information is required. Prepared contingency plans and a troubleshooting guide are strongly recommended in case of technology breakdowns. Existing program objectives appear to drive content and behavior change strategies, potentially limiting value to clients. Future programs could consider greater emphasis on enabling clients to find and organize formal and informal supports or manage their social interaction and daily activities, which are self-management domains that clients identify as important and poorly covered.

Acknowledgments

The authors would like to thank Kaitlin Sibald, research occupational therapist, for her contributions early in the project, including input into conceptualizing the research question and conducting early database searches. Shelley McKibbon, a medical librarian at Dalhousie University, was instrumental in refining the search strategies. Without this critical step, this review would not have been possible. ML was affiliated with Dalhousie University at the time this review was conducted and is currently affiliated with Think Self-Management Inc. JK was affiliated with the University of Illinois Chicago at the time this review was conducted and is currently affiliated with the Shirley Ryan AbilityLab. This work was partially supported through a Patient-Centered Outcomes Research Institute Project Program Award (MS-1610-37015). Data Availability

The datasets generated during and analyzed during this study are not publicly available due to the complexity of manual coding and the need for related training but are available from the corresponding author on reasonable request.

Authors' Contributions

YTC: methodology, software, formal analysis, investigation, visualization, writing—original draft, writing—review and editing, and project administration.
ML: data curation, formal analysis, investigation, project administration, software, visualization, and writing—review and editing.
TVD: conceptualization, formal analysis, investigation, and writing—review and editing.
JK: conceptualization, formal analysis, investigation, and writing—review and editing.
YW: conceptualization, formal analysis, investigation, and writing—review and editing.
KP: writing—review and editing and funding acquisition.
MP: investigation, writing—review and editing, and funding acquisition.
TLP: conceptualization, methodology, software, formal analysis, visualization, writing—review and editing, supervision, project administration, and funding acquisition.

Conflicts of Interest

ML is cofounder and owner of Think Self-Management Inc, an incorporated company that disseminates evidence-based self-management interventions. TLP was an original cofounder with no financial interest. This review was planned and mostly

XSL•FO
RenderX

completed before the incorporation of this company, and no publications regarding interventions or programs distributed by Think Self-Management met the inclusion criteria for this review. All other authors declare no other conflicts of interest.

Abstract

Background: Virtual reality (VR) has promise as an innovative nonpharmacologic treatment for improving a patient's quality of life. VR can be used as an adjunct or treatment for many acute and chronic conditions, including serious illnesses.

Objective: This systematic review aims to assess the current state of the literature of randomized controlled trials that use VR in patients with serious illnesses. Two secondary aims include assessing intervention components associated with improved quality of life and functional outcomes among older adults, as well as evaluating how well the randomized controlled trials adhere to consensus standards for VR research.

Methods: We searched PubMed, Embase, and CINAHL for randomized controlled studies published at any time. We screened and accepted studies that reported outcomes related to patients' quality of life, provided an immersive VR intervention, and included patients with serious illness. We narratively summarized key attributes of publications that shed light on study efficacy, generalizability, replicability, and clinical utility. All studies were assessed for study quality with the Cochrane Risk of Bias tool and for concordance with 8 recent consensus standards for VR research.

Results: From the 12,621 articles searched in May 2024, a total of 24 (0.19%) studies met the inclusion criteria, and of these, 88% (21/24) reported an improvement in at least 1 patient quality of life outcome and 67% (16/24) had a high risk of bias. In 7 (n=24, 29%) studies, VR was used to provide distraction therapy to reduce pain. In total, 5 (n=24, 21%) studies included training, supervision, and assistance in VR use, which demonstrated improvements in patient quality of life–related outcomes. Of 24 studies, 9 (38%) included patients with stroke, 9 (38%) included patients with cancer, 4 (17%) included patients with cardiovascular disease, 1 (4%) included patients with chronic obstructive pulmonary disease, and 1 (4%) included patients who reported pain in hospital. In all 9 studies that included patients with stroke, the main purpose of VR was to improve mobility and strength; these studies had higher frequency and longer durations of VR use, ranging from 2 to 9 weeks, as compared to a VR use duration of

XSL•FO
RenderX

<2 weeks for studies aiming to reduce pain or anxiety. Regarding consensus standards for VR research, 29% (7/24) of the studies adhered to all 8 criteria, and all studies (24/24, 100%) adhered to ≥5 criteria.

Conclusions: Nascent evidence suggests VR's potential in mitigating pain, anxiety, and depression and improving mobility among persons with serious illnesses. Most studies did not provide detailed information about unassisted or assisted use, suggesting that VR for older adults is currently most appropriate for observed settings with assistance available.

virtual reality; serious illness; pain; anxiety; older adults; patient outcomes; systematic review; palliative care; hospice

Introduction

Background

More than 60% of Americans will face a period of significant disability before death, incurring a diminished quality of life from the impact of serious illness, including multimorbidity [1-3]. Serious illness is defined as a health condition with a high risk of mortality that either negatively impacts daily function or quality of life or strains a person's caregivers [4]. Serious illnesses include those of indeterminate but limited prognosis and those that have a detrimental effect on the quality of life of patients and their caregivers. They encompass malignancy, organ failure, or frailty, a complex state of vulnerability that is often associated with dementia [4,5]. Serious illnesses are associated with burdensome symptoms and functional decline and include many leading causes of death, such as stroke, as well as multimorbidity [6]. Patients also face a significant financial burden because of medical treatment [7]. These conditions interfere with a person's ability to engage in activities they once enjoyed and impose emotional and physical burdens on family members and other caregivers; these conditions are of growing importance with the population aging [4].

Functional outcomes are a useful adjunct to other quality of life–relevant measures to understand the impact of serious illness on a person's life [8]. Activities of daily living (ADLs) include basic functions such as dressing, maintaining personal cleanliness, toileting, transferring, and eating. The impairment of 1 to 2 ADLs occurs in most Americans during the years before death, and ≥3 ADL impairments are associated with institutionalization. Important goals for patients include dying at home and maintaining cleanliness, both of which are abetted by functional status or require dedicated caregiving if adequate support is unavailable [9]. Evaluating functional outcomes in patients with serious illness is especially important because it directly reflects their quality of life and their ability to perform ADLs [10].

Virtual reality (VR) is one among emerging interventions (eg, smart technologies) with the potential to improve a patient's quality of life, patient-reported outcomes, psychological outcomes, and functional outcomes for persons living with serious illness [11-14]. VR offers a computer-generated, stereoscopically rendered, 3D visual environment, often with complementary sound, which responds continuously to a patient's movement. Immersive VR creates a psychological experience of treating the virtual simulation as a real experience. The sensory experience is thus distinct from nonimmersive reality, such as augmented reality that allows the participant to see computer-generated images superimposed on the real-world visual field [15,16]. Immersion and distraction therapies have been shown to be helpful in improving quality of life and functional outcomes. The use of VR in health care for serious illness care has been expanding to address pain, anxiety, and other needs in palliative care and hospice settings [17,18]. There is a need to understand the quality of research and VR's efficacy, especially in randomized controlled trials (RCTs), as it applies to older, seriously ill adults.

Objectives

Several recent reviews have explored content salient to our interest, although not in the specific context of applying VR to palliative care and serious illness [19-21]. We aim to determine the extent to which rigorous studies have focused on the rapidly growing population of older adults, the quality of that research, the extent to which it adheres to recently accepted VR research standards, and the characteristics of that research (eg, common outcomes) [22-24]. Two secondary aims include assessing the components of interventions in RCTs associated with improved quality of life and functional outcomes, as well as assessing the extent to which the current RCTs related to VR adhere to recommended consensus standards for high-quality VR research.

Methods

Protocol and Registration

Our review adhered to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocols statement and Enhancing the Quality and Transparency of Health Research guidelines [25,26]. We registered our protocol to the PROSPERO (CRD42022346178) [27].

Eligibility Criteria

Included in this systematic review are studies published in peer-reviewed journals up through May 2024 that meet the following criteria organized by population, intervention, comparator, outcomes, timing, and setting framework (Textbox 1) [28]. Functional outcomes include patient-reported outcomes relating to the quality of life and patient-demonstrated outcomes (eg, arm curl, chair stand, back scratch, chair sit, reach, walk test, overall cognition, and memory) [29,30]. Biological intermediaries (eg, functional magnetic resonance imaging scans, cortisol levels, blood test values, and balance) that do not directly demonstrate patient function are not included as

XSL•FO
RenderX

patient functional outcomes [31]. Eligibility criteria are described using the population, intervention, comparator, outcomes, timing, and setting framework (Textbox 1).

Textbox 1. Eligibility criteria using the population, intervention, comparator, outcomes, timing, and setting framework.

Population

- Inclusion criteria: studies that include adult patients (aged ≥18 years) with serious illness, such as stroke, defined by a variable but limited prognosis and an important illness impact quality of life
- Exclusion criteria: studies that include pediatric or adolescent patients (aged ≤18 years) or patients without serious illness

Intervention

- Inclusion criteria: study participants must use some form of immersive virtual reality in the intervention arm.
- Exclusion criteria
  - Intervention description insufficient to describe immersiveness
  - Augmented or extended reality (ie, nonimmersive reality)
  - 2D screens (eg, Wii and Wii Fit [Nintendo], Xbox [Microsoft Gaming], and YouGrabber)

Comparator

- Usual care

Outcomes

- Inclusion criteria: patient quality of life–related outcomes, including patient-reported (eg, pain and anxiety) or patient-demonstrated (eg, arm curl, chair stand, back scratch, chair sit, reach, walk test, overall cognition, and memory) outcomes
- Exclusion criteria: only biological intermediaries reported as results (eg, functional magnetic resonance imaging scans, cortisol levels, blood test values, and balance)

Timing: interventions with any follow-up period

Setting: any care setting (including in-patient clinics or outpatient and ambulatory care)

Selection of Sources for Evidence

Concepts included in the literature search were RCTs, VR, and serious illness as shown in Multimedia Appendix 1. We searched PubMed, Embase, and CINAHL for studies published at any time and identified 12,814 articles (n=10,799, 84.28% articles after duplicates were removed). During the title and abstract screening and full-text screening phases, 3 coauthor reviewers screened each study and were blinded to each other's decisions (BM, AK, and SF). During the title and abstract screening, we resolved conflicts predominantly by a "gold standard" reviewer (KL or KG), occasionally by majority consensus. During the full-text screening, reasons for exclusion were identified. Only the gold standard reviewer (KL or KG) resolved conflicts during full-text screening. During full-text screening, if any systematic reviews met inclusion criteria, we added their included articles to the title and abstract screening phase. We used the Covidence (Veritas Health Innovation) software to generate a PRISMA diagram to track studies at each stage of the review (Multimedia Appendix 2 [25]) [32].

Data Extraction

We built an abstraction form through an iterative process (Multimedia Appendix 3). All aspects of the included article interventions were recorded, including what the intervention entailed; the type of VR and media (eg, type of scenery or activity) used; any training, supervision, or assistance provided during VR use; the duration of sessions; frequency of sessions; and duration of intervention. The main outcomes collected were related to patient quality of life–related outcomes. Data abstraction for the included studies was done through Covidence with 2 reviewers per article. Two reviewers (BM, AK, or NI) abstracted each article independently and resolved all abstraction conflicts through a consensus discussion.

Risk of Bias and Quality Assessment

Risk assessment for bias was done using the Cochrane Risk of Bias tool for RCTs [33]. Two reviewers (SF, AK, or BM) independently assessed the risk of bias in the domains of randomization, allocation concealment, blinding, accounting of patients and outcome events, and selective outcome reporting bias. Any disagreements were discussed by each of the 2 reviewers, and a consensus was reached.

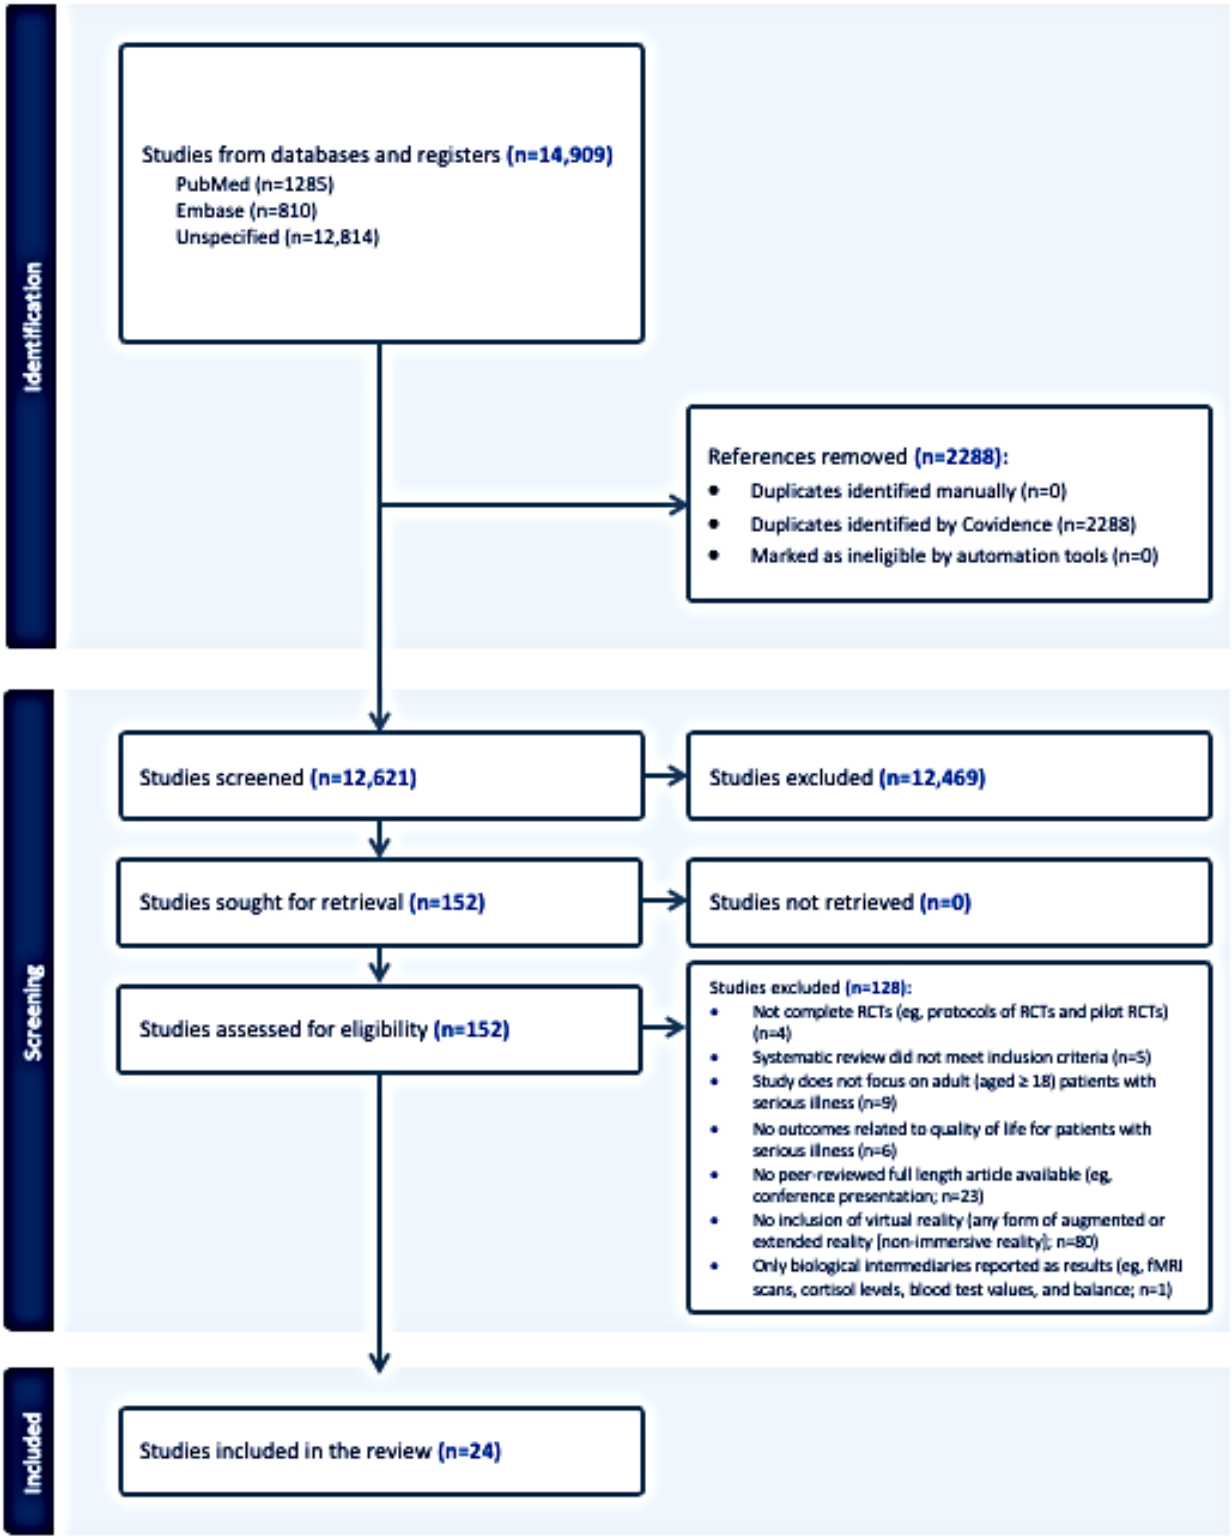
Synthesis of Results

We performed a narrative synthesis of the data abstracted due to the high degree of heterogeneity of the results, as each included article reported different forms of patient functional outcomes. We synthesized each VR-based intervention and extracted the purpose of VR within the intervention and whether there was any training, supervision, or assistance provided in the use of VR. To better understand the individual differences that may affect the efficacy of VR-based interventions, we looked at the average patient age, SD and range, type of serious illness, patient gender, patient ethnicity, and study location for each of the studies. We characterized each study's adherence

XSL•FO
RenderX

to recent consensus standards for high-quality VR research using the definitions below [22].

- Patient population: clear description of the study population (including inclusion and exclusion criteria)
- Clinical setting: appropriate setting for the VR treatment
- Control and randomization: justification for control and appropriate randomization
- Blinding and concealment of allocation: description of the method of allocation concealment
- End points: determination and justification of end points before the initiation of the study
- Study duration: determination and justification of the study duration before the initiation of the study; the study should be an a priori decision or hypothesis
- Presentation and analysis of results: clear presentation of results with appropriate statistical analysis
- Reporting the trial: reporting of the trial with a national or international registry (World Health Organization International Clinical Trials or ClinicalTrials.gov)



Results

Literature Selection

A total of 12,621 unique titles and abstracts were dual screened by coauthors as per the inclusion and exclusion criteria. A total of 152 full-text articles were retrieved and further assessed for eligibility. Of the 152 full-text articles reviewed, 128 (84.2%) studies were excluded for reasons noted in the PRISMA flow diagram (Figure 1 [34]). Finally, we included 24 total studies in our review [35-58], of which 21 (88%) reported an improvement in at least 1 patient functional outcome [35-43,45-48,51-58]. The included articles are summarized in Table 1.

Table 1. Summary of the included studies (n=24).

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
Bani Mohammad and Ahmad [35], 2018	The patients wore a head-mounted display with headphones and chose either deep sea diving or sitting on the beach. The VR exposure session ended at the peak time of morphine efficacy.	• The patients were given morphine (same dose and timing as given to those in the intervention arm) with no additional intervention.	Distraction therapy to improve pain and anxiety in patients	The primary investigator remained near the participants during the VR session.	• Statistically significant improvement in pain scores (VASb; P<.001) and anxiety levels (SAIc; P<.001)
Burrai et al [36], 2023	Participants used the Oculus Quest 2 HMD[d] to observe specific virtual environments in a contemplative mode. The scenarios included 310 videos classified into 9 categories (eg, Africa, hills, rivers, lakes, and waterfalls). The audio content of scenarios had a background of nature sounds and soothing musical stimuli in high definition with panning stereo, and was listened to via earphones to ensure an immersive audiovisual experience with high-intensity multisensory immersion.	• One group of patients received narrative medicine, where patients shared their experience with cancer. • Another group of patients received standard care and served as the control arm.	Distraction from the stress of antiblastic therapy to reduce anxiety, fatigue, and pain	A nurse helped each participant position the VR headset and the joysticks. After immersion, the nurse removed the VR headset visor from the participant.	• Statistically significant decrease in anxiety (P=.001) and fatigue levels (P=.001) but no statistically significant change in average pain levels (P=.31)
Chatterjee et al [37], 2022	The main requirement was to allow the patients to practice ADL[e] completely or in part when placed within a suitable environment. The materials needed such as food items, kitchen gadgets, and coins were within reach of the patient when they were immersed in the environment. All the tasks were designed to be completed from a sitting position using a single handheld controller. The intervention was delivered 5 days a week for up to 2 weeks before the patient's hospital discharge. The dose of the virtue treatment varied depending on the benefit and tolerability.	• The patients received sham VR, where they were offered the same first VR session as the intervention arm and were subsequently offered the same VR session through the rest of the study.	Improve recovery and reduce the time that a patient spends in the hospital	Supervised by a therapy assistant while taking part in the VR session. Assisted in wearing the headset and ensured a comfortable and correct seating position. The virtue program was started by the therapy assistant, and the difficulty of each scenario was graded depending on their needs.	• Statistically significant improvement in attention and orientation • No statistically significant difference in the primary outcome measures at 3 months • Secondary outcomes: statistically significant reduction in anxiety scores in the mild to moderate cognitive impairment (MoCAf 15-24) treatment group
Chirico et al [38], 2020	Each chemotherapy treatment lasted for 45 to 90 minutes. Patients used the VR system for 5 to 10 minutes to become accustomed to it, and then the nurse administered the chemotherapy. In particular, participants explored an island by walking through a forest, observing different animals, climbing a mountain, and swimming in the sea.	• One group of patients received music therapy, where they were provided an MPEG audio layer 3 reader and headphones 5 minutes after starting the chemotherapy infusion. Patients listened to relaxing music pretaped by an expert music therapist for 20 minutes. • Another group of patients was allowed to choose common activities during treatment, such as conversation or reading.	Reduce the anxiety, depression, and fatigue related to chemotherapy through distraction	A research nurse, together with a trained psychologist, explained how to use the VR equipment and helped patients with putting on the headset.	• Statistically significant reduction in anxiety levels between pretest and posttest and a significant interaction effect between the time factor and the intervention factor (time×intervention) on the patient's level of anxiety. Furthermore, the analysis showed a significant main effect for the time factor. There was a significant reduction between the preintervention and the postintervention phases in the following negative mood states: tension, depression, anger, and fatigue (P<.001)

XSL•FO
RenderX

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
Groninger et al [39], 2021	The study used the Forest of Serenity (Holosphere VR), which features a 10-minute guide through a forest and waterfall with voice narration. Each assigned experience (VR or guided imagery) was administered at the bedside by the study coordinator. When the participant was ready, the coordinator left the bedside to stand immediately outside the room, started to time the experience per the protocol, and waited either for the end of the assigned experience time or for a verbal signal from the participant requesting assistance with the equipment.	• The patients received a guided imagery session on a portable tablet, which had options of guided meditation, instrumental background music, and 2D imagery of a peaceful lakeside view.	VR aimed to provide distraction therapy	The study coordinator explained the equipment and positioned it, then left the room until the end or if assistance was asked for.	• Statistically significant decrease in pain scores (Likert scale); the VR group had significantly lower scores than the guided imagery group (P<.001). • Secondary outcomes: there was a statistically significant improvement in the total FACIT-Palg 14 score and an insignificant change in the distress score
Hsu et al [40], 2022	In addition to 20 minutes of therapist-facilitated task-specific training as a usual care session, patients each received 30 minutes of VR time. The sequences of the hand exercises of VR consisted of the movements of the forearm, supination or pronation, wrist extension or flexion, finger extension or flexion, thumb opposition with the little finger, thumb extension or flexion, and tendon-gliding exercises, which involve a series of hand movements (straight hand, hook fist, straight fist, and full fist). Each movement was repeated 50 times. The participant sat in a comfortable chair in front of a desk with the VR system.	• One group of patients performed hand exercises and looked at their hand motions through a mirror. • Another group of patients received OTh in addition to physical therapy and speech therapy.	Improve upper extremity movement, quality of motor movement in the affected arm, and manual dexterity	Participants received 20 minutes of therapist-facilitated task-specific training. They were supervised and assisted by the physical therapist.	• Statistically significant improvement in only the FMA-UEi motor coordination (P=.002) and the MAL-AOUj (P=.002)
Huang et al [41], 2022	A total of 20 VR scenes from commercial games were selected for the participants. Selected scenes were chosen based on the original upper limb activities. Participants could accomplish the first-contact task with the help of their unaffected hand, and then, they were encouraged to use the affected hand or both hands at the same time. Upper limb movements in most scenes involved aiming, shooting, hitting, waving arms, punching, and throwing objects. Participants' activity performance and information were recorded, including training intensity, duration, game scores, level completed, and invalid activities. This information allowed the therapist to assign the tasks, adjust the difficulty in the VR game settings, and even design a new way to play the game for each participant according to their needs and capacities.	• The patients received OT.	VR aimed to improve upper extremity movement and range of motion	After the participant confirmed that the sight and sound were clear and comfortable, the controllers were handed to the participant, and the therapist could even design a new way to play the game for each participant according to their needs and capacities.	• Statistically significant time effect for all items of upper limb assessment (P<.05), except FMA-UE motor coordination and speed
Huang et al [42], 2024		• Patients received a 60-minute conventional rehabilitation program per day.	Improve motor impairment and ADL		• Statistically significant improvements in upper extremity motor impairment and ADL for up to at least 12 weeks postintervention, and the magnitude of these improvements was much greater than that of other intervention programs (P=.02)

XSL•FO
RenderX

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
	Participants in the imVR[k] system received the first 30 minutes of conventional rehabilitation, and in the second 30 minutes, the rehabilitation was performed in imVR systems. Participants in the imVR group were required to complete 6 programs: frying dumplings and noodles by controlling a wok handle in a virtual kitchen; popping balloons by controlling a sword in a virtual fencing hall; punching dolls by controlling a big fist in a virtual boxing arena; playing basketball in a virtual court, in which the ball is shot by a controller and the height and distance is varied over time; collecting eggs into a virtual basket by a controller; and tidying up a desk and moving objects to a designated position in a virtual office. All participants received rehabilitation training for 5 days per week for 3 weeks.			No training, supervision, or assistance was provided; however, in the early stages of rehabilitation, due to poor functioning of the hemiplegic side upper limb, participants used the help of their unaffected side limb.	
Jo et al [43], 2024	Each participant of the 360° MTG[l] performed treatment tasks using their unaffected extremities, which were recorded with a 360° camera (Insta 360° X3; Insta 360). The patients received treatment in the same place where the videos were recorded. The therapist instructed and guided patients to use the affected side following the immersive video during all tasks. The MT[m] tasks were the same as those of TMTG[n] (finger flexion and extension, wrist flexion and extension, pronation and supination, and elbow flexion and extension for 10 repetitions; the tasks instructed participants to use the affected limb while following the mirror images of the unaffected limb to induce movement re-education; and playable tasks using ring toys were also provided for 5 repetitions). The 360° MT was provided for 30 minutes per session, 3 sessions a week for 4 weeks. The 360° MTG also received additional conventional physical therapy.	• One group received traditional MT through an acrylic mirror that mirrored the unaffected side upper limb, where the affected side limb was hidden behind the mirror. • Another group received a conventional physical therapy program consisting of warm-up, circuit, and cool-down exercises.	Upper extremity rehabilitation in patients with stroke	A therapist adjusted the device to fit the eye level of each patient. The therapist instructed and guided patients to use the affected side following the immersive video during all tasks.	• FMA-UE, MFTo, and BBTp scores were significantly improved in 360° MTG and TMTG, while improvements in CGq were not significant. In group comparisons, changes in 360° MTG were significantly higher compared to changes in TMTG and CG (P<.001)
Laghlam et al [44], 2021	The VR session started during the preparative phase, at least 5 minutes before the removal of the drains, and was continued for 10 minutes after. We used a VRx helmet with a 90° field of view with head tracking. Patients had a choice between 5 different immersive environments (360° videos): a snowy mountain, a landscape in India or Camargue (France), a balloon ride, or a canoe descent.	• The patients received Kalinox (Air Liquide) 1 minute before the removal of the drains. This was delivered continuously and stopped 1 minute after removal to avoid side effects.	Reduce pain during cardiac surgery, specifically during the removal of drains	The nurse supervised and assisted patients while using VR.	• No statistically significant improvements in patient functional outcomes (Analgesia Nociception Index; P=.69)
Lee and Kang [45], 2020		• The patients received a daily routine sleep intervention.	Induce meditation and improve sleep quality		

XSL•FO
RenderX

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
	The "Relaxing Music for Meditation" program was designed to induce meditation and consists of 8 meditation videos of 30 minutes. Scenes of mountains, seas, or lakes appear on the VR screen, and background sounds and calm music allow participants to immerse themselves in the experience. The study began on the day of admission to the ICU[r].			No training, supervision, or assistance was mentioned; however, it took about 20 minutes for the experimental group to learn how to use the HMD.	• Statistically significant increase in sleep scores (Pittsburg Sleep Quality Index), sleep time, and mean sleep efficacy in the experimental group compared to CG (P=.002)
Mekbib et al [46], 2021	The VR rehabilitation training included reaching, grasping, and releasing tasks. Following the training schema, all patients in the VR group received 1-hour VR and 1-hour OT per day, 4 days per week for 2 weeks. In each VR session, the therapy modes were set by a therapist based on the patient's interest and actual motor capability. After choosing the therapy mode, the therapist randomly set 20 colored balls from the aerial view map. Then, the patient was instructed to reach, grasp, and release each ball into the basket. After completing the first VR session (20 balls), the therapist could set the next VR session and adjust the task complexity to be slightly higher or lower or keep it as it was in the previous session based on the patient's activity performance.	• The patients received OT.	Upper extremities to aid in the recovery of motor function after stroke and improve upper extremity function and the ability to perform ADL	The therapist helped train the patient. If the patient was not able to move their upper extremity toward the target ball, the therapist could help move the affected extremity to assist in the intended task.	• Statistically significant improvement in the FMA-UE scores (P<.001) and BIs scores (P=.003)
Menekli et al [47], 2022	Patients in the intervention group were educated on the use of VR glasses by the researcher. A smartphone and the various number of parks, nature, and seaside walks; submarine; and museum tours with the Matic Music were provided to patients in the intervention group. Each of these videos took approximately 3 to 10 minutes, and patients could choose the video that they wanted to watch. Patients started to use the VR after the baseline assessment (about 1 minute before the implantation) and continued to use it until the end of the implantation. Patients were instructed to use VR after implantation when they felt pain from the implantation.	• The patients received conventional care.	Pain management after implantation	Supervision and assistance were provided by a nurse, who was giving directions to patients on how to use the videos.	• Statistically significant improvement in the SAI scores (P<.001) and VAS scores (P<.001)
Ögün et al [48], 2019		• The patients received conventional upper extremity active exercises comprising the same tasks as used in the VR group.	Improve upper extremity functionality and make daily activities more accessible	None mentioned	• Statistically significant improvement in FMA-UE, ARATt, FIMu, and PASSv scores (P<.001)

XSL•FO
RenderX

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
	Patients used the VR device to play task-oriented games that focused on gripping and handling objects with arm and forearm motion and stability. A different game was used for each function, with 4 games: a cube handling game used for grip function integrated with the leap motion device to make the patients feel like they were handling a real object using their own fingers without the use of any external device to track hand motion; another leap motion–integrated game involving decorating a tree with leaves and fruits or picking up vegetables from a bowl and putting them back, which was chosen to facilitate all hand motions combined with complex motions in a task-oriented job; a kitchen experience game used for stimulating forearm supination and pronation and for combining complex arm movements; and a drumming game, selected to randomly assign each separate movement of upper extremity flexion and abduction.				
Park et al [49], 2013	The VR-based postural control program consisted of a program for the improvement of gait ability by visual feedback compared to reference motion scenes and reality motion. The program consisted of 3 stages: trunk stability and pelvic tilting in a supine position (stage 1); trunk upright control and pelvic tilting exercise in a sitting position, and a selective movement between trunk and pelvis (stage 2); and lower extremity muscle strengthening exercise and weight bearing under maintenance of trunk stability in a standing position (stage 3). The participants were provided with specific scenes on HMD showing the simultaneous output.	• The patients received targeted lower extremity muscle strengthening exercises, static and dynamic balance training, and gait training.	Improve postural control, spatiotemporal gait ability, and functional gait ability and to increase walking ability	The participant saw the prerecorded reference motion and practiced it again 3 times. No other provision of training, supervision, or assistance was mentioned.	• No statistically significant improvements in patient functional outcomes
Rousseaux et al [50], 2022	A 20-minute VR session was conducted, where participants watched a 3D graphical landscape consisting of a mountain cabin near a lake at sunrise, followed by a relaxing moment in the clouds. The display was visual and audio, with sounds of ambient nature but no voice.	• The patients received conventional care.	Lower anxiety and decrease pain	None mentioned	• No statistically significant differences in the effectiveness, either between the techniques themselves or between the techniques and no treatment
Rutkowski et al [51], 2021		• The patients received the traditional pulmonary rehabilitation program.	Reduce depression, anxiety, and stress levels and improve functional capacity	None mentioned	• Statistically significant improvement in the HADS-Ax (P<.001), HADS-Dy (P<.001) and general HADSz (P<.001)

XSL•FO
RenderX

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
	The primary aim of the software was to calm the patient down and improve his or her mood. The software features a virtual therapeutic garden and is based on the Ericksonian psychotherapy approach. The garden is a metaphor for the patient's health: at the beginning, it appears untidy and gray; however, with each session, it becomes more colorful and alive, thus symbolizing the process of recovery of energy and vigor. The 2 groups participated in the traditional pulmonary rehabilitation program. Components were performed once a day each, for 15 to 30 minutes (depending on the task), 5 times a week for 2 weeks. Exercises were performed as follows: fitness exercises while standing on the knees and lying on the side, abdomen, and back; strengthening exercises of the diaphragm with resistance; prolonged exhalation exercise; chest percussion; inhalation with a 3% sodium chloride isotonic solution administered via an ultrasonic device; and stationary cycle ergometer exercise to obtain a training heart rate according to GOLD[w] spirometric stages. The difference between the groups is in the type of relaxation training: the VR group performed 10 VR therapy sessions of 20 minutes, and the CG performed 10 Schultz autogenic training sessions of 20 minutes.				
Shin et al [52], 2023	In the virtual world, patients were greeted by their respective attending physicians and guided through the visual and audio unfolding of the RT[aa] process. Patients were guided virtually with 360° viewing of the different treatment environments and RT machines that they would encounter when undergoing RT. Throughout the physician's explanation, patients were able to witness a real example of a patient with breast cancer undergoing the RT, offering patients a concrete example of what to expect on treatment days.	• The patients received conventional care.	Alleviate anxiety related to undergoing RT	Patients were assisted with the proper positioning of the VR headset and noise-cancelation earphones provided by the hospital.	• Significant reduction in patient anxiety immediately, not only on the primary end point, APAISab, but also on the STAIac and LASAad anxiety scales. Among the 3 anxiety scales, long-term anxiety reduction was observed only when anxiety was measured by LASA
Song and Lee [53], 2021		• The patients performed exercises, such as turning on lights, arranging a chest of drawers, and arranging a kitchen as part of bilateral upper extremity training in a real environment.	Improve the range of motion, bilateral upper extremity movement, and upper limb function	There was some training, supervision, or assistance provided; however, this was not written, although figures in the study show someone guiding the participant.	• Statistically significant improvement in the proprioception test (P<.05)

XSL•FO
RenderX

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
	The VRBAT[ae] group underwent immersive VRBAT. The VR content consisted of rehabilitation tasks to improve upper limb function, the ability to perform ADL, and visual perception. The VR tasks performed included everyday activities, such as turning on lights, organizing a chest of drawers, organizing a kitchen, watering plants, and purchasing items at a convenience store. The virtual living room, kitchen, veranda, and convenience store were designed to simulate real environments. Interventions were performed for 30 minutes a day, 5 times a week, for 4 weeks, for a total of 20 sessions. All participants in the VRBAT group also underwent an hour of conventional rehabilitation per day.				
Spiegel et al [54], 2019	Participants selected one of the 21 VR experiences from an app. Patients were asked to use the headset for 10 minutes in the presence of study staff to practice with the equipment and then advised to use the headsets thrice daily, for 10 minutes per session, and later, as needed for breakthrough pain, for the subsequent 48 hours. Following these initial instructions, patients decided for themselves and in partnership with their care team whether, how frequently, and how long to use the VR equipment without direct input from study staff.	• The patients watched the "Health and Wellness Channel," which includes guided relaxation content (eg, yoga and meditation programming), discussions about health and wellness topics, and poetry readings.	Reduce pain in hospitalized patients	Participants were instructed on procedures for wearing the headset, how to select among the 21 VR experiences, and how to adjust volume and brightness. Regarding supervision, patients were initially asked to use the headset for 10 minutes with the presence and assistance of the study staff and care team.	• Significant improvement in pain scores 48 hours and 72 hours postintervention using a numeric rating scale (P=.03 and P=.04, respectively)
Torres García et al [55], 2023	The sessions recreated a chemotherapy procedure. Using VR, patients managed their anxiety and fear through relaxation, attentional focus, and mindfulness strategies. The complete intervention included 3 modules, which each patient repeated during 4 individual sessions, aiming to improve their preparation and adaptation to the cancer treatment they had to start.	• The patients received a regular psychoeducational intervention.	Improve patients' anticipatory anxiety and adherence to chemotherapy and facilitate better and faster adaptation to treatment coping mechanisms	The therapist was present throughout the procedure.	• Statistically significant differences in the decrease of anxiety and depression with the Anxiety and Depression Scale. At 3 months, a more notable decrease in the Emotional Discomfort Detection Scale was observed in the experimental group, and the fighting spirit and cognitive avoidance increased, which was assessed with the MINI-MACaf coping scale
Turrado et al [56], 2021		• The patients received conventional care.	Reduce presurgical anxiety and depression	None mentioned	• Statistically significant changes for both the HADS subscales and for those measuring status and trait in the STAI scale for patients who were exposed to the VR simulation experience (P<.001)

Study	Description of the intervention and media content	Control arm	Purpose of VR[a] in the intervention	Training, supervision, or assistance provided in the use of VR	Patient-reported outcomes or patient-demonstrated outcomes
	A realistic environment was generated in which the patient could experience the various steps of their admission to surgery, from the first interview with the surgeon to admission into the surgical ward, the operating room, and the postoperative recovery room. Patients completed both questionnaires to assess their basal anxiety levels. The patients in the intervention group had unlimited access to VR glasses and to the VR app. This group completed both questionnaires again on the day before the surgical procedure.				
Uslu and Arslan [57], 2023	The patients watched and listened to beach and nature content with VR glasses for 30 minutes. The VR glasses used were Zore G04BS VR Shinecon VR glasses, compatible with smartphones (eg, Android and IOS). The contents were determined in the YouTube library and included 360° relaxing beach and nature images.	• The patients received conventional care.	Reduce anxiety and fatigue levels	Patients were informed about using VR and viewing the content. From the content opened by the researcher, it was ensured that the patient watched and listened to the content of their choice.	• The mean postintervention anxiety scores decreased in the intervention group. In this group, the mean posttest fatigue and subscales scores decreased in all cycles compared with the mean pretest scores
Zhang et al [58], 2023	The patients watched and listened to beach and nature content with VR glasses for 30 minutes. The VR glasses used were Zore G04BS VR Shinecon VR glasses, compatible with smartphones (eg, Android and IOS). Participant Characteristics

In total, the studies included 1225 participants. Of the 24 included studies, 3 (12%) included patients with an average age of <50 years [43,49,58]; 8 (33%) included patients with an average age of 51 to 60 years [35,36,38-41,46,52,55,57]; 5 (21%) included patients with an average age of 61 to 65 years [42,45,48,51,52]; 3 (12%) included patients with an average age of 66 to 70 years [44,50,56]; and 1 (4%) included patients with an average age of >75 years [37]. Two studies did not report the average age of the patients, as listed in Table 2 [47,54]. No studies reported how many patients in the sample were aged >65 years. A total of 16 (67%) of the 24 included studies had a high risk of bias (Multimedia Appendix 4 [35-58]).

[b]MI: myocardial infarction.

[c]COPD: chronic obstructive pulmonary disease.

[d]LAR: low anterior resection.

[e]TaTME: transanal total mesorectal resection.

Serious Illness

Stroke, cancer, and cardiovascular disease were the most common types of serious illnesses for which VR interventions were used to impact the outcomes related to patients' quality of life. Out of 24 included studies, 9 (38%) focused on patients who experienced stroke, which included both ischemic stroke and hemorrhagic stroke [37,40-43,46,48,49,53], and 9 (38%) included patients who were diagnosed with some type of cancer, varying in the stages of cancer in each patient [35,36,38,42,43,47,52,55-58]. In 5 (21%) of the 24 studies, only patients who were diagnosed with breast cancer were included; 1 study (4%) included patients with colorectal cancer, and 1 (4%) included patients with heterogeneous types of cancer. Four

XSL•FO
RenderX

(17%) out of 24 studies included patients who had some form of cardiovascular disease, including heart failure and other conditions that required cardiac surgery [39,44,45,50]. One study included patients with chronic obstructive pulmonary disease (COPD), and another included patients who reported pain during their hospitalization [51,54].

Purpose and Content of VR

In 9 (38%) out of 24 included studies, the main purpose of VR was to improve mobility and strength in the patient, ranging from upper extremity, lower extremity, and pelvic or abdominal region to a combination of these regions [37,40-43,46,48,49,53]. All of these mobility studies also included patients who experienced strokes. The VR media used in these studies encouraged active participation from the patients in various tasks and games. Some examples of VR media used to help improve mobility and strength in patients' poststroke treatment were daily exercises that encouraged increased range of motion, strength for specific movements, and reach and grasp through the use of balls. A total of 8 (89%) of the 9 studies that used VR for the purpose of improving mobility and strength improved patient quality of life–related outcomes [37,40-43,46,48,53].

There was some overlap in the protocols and diseases of the additional studies. Out of 24 studies, 12 (50%) used VR distraction therapy to reduce pain in patients with cancer or, cardiovascular disease or hospitalized patients [35,36,38,39,42-44,47,50,52,54-58]. A total of 9 (38%) out of 24 studies used VR to reduce anxiety in patients with cancer, cardiovascular disease, or COPD [36,38,42,43,50-52,55-58]. In studies aiming to reduce pain and anxiety, patients experienced immersive natural scenery and comforting music while comfortably sitting or lying down. In another study, to reduce anxiety, patients experienced the hospital environment and could visualize and review all the steps of an upcoming procedure [56]. In another study, patients with cardiovascular disease went through a visual guided meditation track with the VR media for patients with cardiovascular disease [45].

Training, Supervision, and Assistance

In 18 (75%) out of 24 studies, staff or physical therapists either trained patients on VR use before the intervention or supervised or assisted them through the experiment. Supervision was defined as the research team watching over the participants, ensuring their use and adherence to study guidelines. However, assistance was defined as the research team supporting patients during the intervention without constant watching throughout the experiment. A total of 5 (20.8%) out of 24 studies included VR training, supervision, and assistance, all of which reported improvements in patient quality of life–related outcomes [38,40,43,46,54]. Of 24 studies, 7 (29.2%) included VR supervision and assistance only [36,37,41,44,47,53,57], and 2 (8.3%) included VR training and assistance only [39,49]. Two (8.3%) out of 24 studies included only VR supervision while patients were using VR [35,55]. In studies that included a variation of personnel working with the patient, only 1 staff member physically accompanied the patient in the room, where they freely communicated with the patient to fulfill their role. During a typical training, the staff member would walk the patient through the VR activity and teach them how to adjust the headset. Out of 24 studies, 6 (25%) did not describe training, supervision, or assistance with the use of VR [42,45,48,50,51,56].

Frequency and Duration of Intervention on Quality of Life Outcomes

The frequency and duration of VR experience varied based on the intervention purpose; interventions aiming to improve pain or anxiety were shorter. while those aiming to improve mobility and strength were longer. Out of the 24 included studies, 9 (38%) studies with pain or anxiety reduction as a goal, involved only 1 VR session, ranging from 8 minutes to 4 hours (ie, patients could use VR at any time within a 4-hour window) [35,38,39,44,47,50,52,56]. A total of 7 (78%) of these 9 studies had improvements in pain and anxiety metrics, such as the Hospital Anxiety and Depression Scale (HADS), State Anxiety Index, or the Numeric Pain Scale (NPS). One study, which conducted a single 30-minute meditation session, showed improvement in sleep scores of patients with cardiovascular disease [45]. In 1 case where VR was used for 10 minutes per session, for 3 sessions per day for 2 days, patients experienced statistically significant improvement in the NPS (P<.04) [54]. Patients in another study who used VR for 20 minutes per session for 5 sessions per week for 2 weeks had statistically significant improvement in the HADS (P<.001) [51].

In the 9 studies aimed at improving mobility and strength in patients who had a stroke, VR was used for a longer duration than in pain and anxiety studies. Out of 9 studies, 6 (67%) lasted between 2 and 4 weeks [37,42,43,46,49,53], while 3 (33%) lasted between 5 and 9 weeks [40,41,48]. A total of 8 (89%) of these 9 studies showed an improvement in the patient's functional capacity measured via the Fugl-Meyer upper extremity assessment, proprioception, or orientation metrics.

Gold Standard Adherence

As shown in Table 3, 7 studies adhered to all the 8 gold standard VR consensus standards criteria (100%) [41,43,44,48,51,52,54], 10 adhered to 7 criteria (88%) [36,37,39,40,42,46,55-58], 6 adhered to 6 criteria (75%) [35,38,47,49,50,53], and 1 adhered to 5 criteria (62%). The reasons for not adhering to the criteria were inadequate blinding, concealment of allocation, reporting of the trial, and a priori failure to justify study duration. The studies that did not report the trial via World Health Organization International Clinical Trials or Clinicaltrials.gov originated from countries where it may not be standard practice to report the clinical trial before the study initiation. All 24 assessed studies received the institutional review board or ethics committee approval. A total of 4 (17%) of the 24 included articles were published before the 2019 study by Birckhead et al [22] that defined the gold standard VR consensus standards criteria.

Met criteria	Completely met	Completely met	Completely met	Not completely met	Completely met	Completely met	Completely met	Not completely met
Description	• A total of 80 patients (average age of 52 years) with breast cancer	Medical and surgical wards of a specialized cancer center in Jordan	Random assignment was done based on flipping a coin; if heads appeared, then the first participant was placed in the intervention group. The rest of the participants were placed in the study groups by the order of meeting the eligibility criteria.	N/A[a]	The VAS[b] was used to measure pain, and the SAI[c] was used to measure anxiety.	One session occurred for 20 to 30 minutes; VR[d] was timed with peak morphine efficacy and the goal was acute pain relief.	• There was a statistically significant improvement in pain scores and anxiety levels, and no MCIDe was mentioned.	None mentioned outside of ethics or IRB[f] approvals from individual hospitals
Burrai et al [36], 2023								
Met criteria	Completely met	Completely met	Completely met	Not completely met	Completely met	Completely met	Completely met	Completely met
Description	• A total of 74 patients (average age of 59 years) with cancer	Regional hospital in Italy	An independent researcher used a random number generation software with simple randomization. A total of 3 numerical codes for the 3 allocation groups were used: 1 for the VR group, 2 for the narrative medicine group, and 3 for the standard care group. To implement the random allocation sequence, sequentially numbered, opaque, sealed envelopes were used.	Owing to the nature of VR and narrative medicine interventions, it was impossible to obtain a blinding between the participants and knowledge of the group, so this study is open-label type.	Anxiety was measured with the STAI-Y1[g]; fatigue was measured with the revised Piper Fatigue Scale; and pain was measured with the VAS scored from 0 to 10, where 0 indicates no pain and 10 indicates the worst possible pain.	VR was administered just after AT[h] began and the immersion duration was 30 minutes.	• Mean anxiety significantly decreased over time for the VR group and narrative medicine group. • There was no significant difference in levels of fatigue, but overall levels of fatigue decreased for participants in the VR intervention. • There was no significant difference in pain levels.	The study was registered in the US National Institutes of Health (NCT05629507).

Study	Patient population	Clinical setting	Control and randomization	Blinding and concealment of allocation	End points	Study duration	Presentation and analysis of results	Reporting the trial
Description	• A total of 40 patients (average age: not provided, median 77.5 years) with unilateral stroke	Stroke unit at the Countess of Chester Hospital NHS[i] Foundation Trust.	Participants were randomized on a 3:1 allocation basis.	This study was not effective to implement as a double-blind trial, as most patients were able to deduce whether they were a part of the treatment group.	The MoCA[j] was the primary measure used and the NEADL[k], HADS[l], and quality of life (EuroQoL[m]) were the secondary measures used.	A total of 5 days a week for up to 2 weeks before their hospital discharge time that each patient spent in a VR session was very specific to the individual. Time spent in a session would depend on their level of wellness on the day and how tired they were feeling.	• There was a statistically significant improvement in attention and orientation. • There were no statistically significant differences in the primary outcome measures at 3 months. • Secondary outcomes: there was a statistically significant reduction in anxiety scores in the mild to moderate cognitive impairment (MoCA 15-24) treatment group.	The trial was registered in the ISRCTN[n] registry (ISRCTN16608742).
Chirico et al [38], 2020								
Met criteria	Completely met	Completely met	Completely met	Not completely met	Completely met	Completely met	Completely met	Not completely met
Description	• A total of 58 patients (average age of 55 years) with breast cancer • Tumor stages, n (%): 1: 8 (26.6); 2: 13 (43.3); 3: 9 (30)	National Cancer Institute, IRCCS "Fonda-zione G. Pascale," Naples, Italy	Patients were randomly assigned to the VR or music therapy group and were compared with a nonconcurrently recruited CG[o].	Participants and personnel knew which groups were control and intervention groups.	SAI for adults and SV - POMS[p]	Each chemotherapy treatment lasted for 45 to 90 minutes, but the patient used VR for 20 minutes.	• There was a statistically significant reduction in anxiety levels between the pretest and posttest and a significant interaction effect between the time factor and the intervention factor (time ×intervention) on the patient's level of anxiety. Furthermore, the analysis showed a significant main effect for the time factor and significant reduction between the preintervention and the postintervention phases in the following negative mood states: tension, depression, anger, and fatigue.	None mentioned outside of ethics or IRB approvals from individual hospitals.

Study	Patient population	Clinical setting	Control and randomization	Blinding and concealment of allocation	End points	Study duration	Presentation and analysis of results	Reporting the trial
Description	• A total of 88 patients (average age of 56 years) with ACC or AHAq stage C or D heart failure	A 912-bed academic hospital located within MWHC[r] in Washington, DC.	Participants were randomized by the study coordinator on a 1:1 basis using a computerized randomized scheme.	The nature of the study prevented participants and the study coordinator from being blinded to assigned interventions.	Self-reported pain scores and the FACIT-Pal 14[s] item scale were used.	There was 1 session for 10 minutes. In distraction therapy research, there is currently no predetermined time threshold for the effect on pain experience; 10 minutes falls within the range of time frames (2 to 15 minutes) that have demonstrated the benefit of using VR for pain management.	• There was a statistically significant improvement in pain score.	The trial was registered on ClinicalTrials.gov (identifier: NCT04572425).
Hsu et al [40], 2022

Description	• A total of 52 patients (average age of 55 years) with stroke	Department of physical medicine and rehabilitation at a medical center in South Taiwan	Following eligibility screening, patients meeting the inclusion criteria were randomly allocated to conditions using opaque envelopes with computer-generated random numbers that the investigator opened upon receiving a consenting participant.	Eligible patients were randomly allocated until all the available envelopes had been exhausted, resulting in a 1:1:1 ratio in the MT[t], COT[u], or VR-MT group.	The FMA-UE[v] motor coordination score and the MAL[w] were used.	The study duration was 30 minutes twice a week for 9 weeks. VR timing was time-matched to the control group.	• There was a statistically significant improvement in only the FMA-UE motor coordination and the MAL amount of use; no MCID was mentioned.	None mentioned outside of ethics or IRB approvals from individual hospitals

Description	• A total of 120 patients (average age: not provided) with pain	Cedars-Sinai Medical Center, a large, urban, tertiary care hospital	Patients were randomized on a 1:1 basis between groups using the Microsoft Excel random number generator.	A script that used neutral language regarding both interventions was used. Investigator interactions with the study participant were minimized, relying on nonstudy nursing staff to collect pain scores.	An NRS of patient-reported pain was used.	The study duration was 10 minutes per session, 3 times a day, for 48 hours; 10 minutes was selected to reduce the risk of developing cybersickness. Longer exposure times are associated with a higher risk of cybersickness.	• There was a statistically significant improvement in pain scores 48 hours and 72 hours postintervention.	The trial was registered on ClincialTrials.gov (NCT02887989).

Description	• A total of 133 patients (average age of 49 years) with breast cancer	OCCU[av] of the CIMA[aw] Campus, Milenium Iradier Medical Center, Barcelona, Spain	Randomization was carried out using a random number list obtained with the Random.org app. The order in which it was generated was unknown to the oncologist.	The oncologist was unaware of the information provided other than the order in which randomization was generated.	HADS, DDE[ax] scale, and the Mini-MAC[ay] coping scale were used.	The study comprised 4 sessions lasting approximately 30 to 45 minutes. The first 3 sessions coincided with the chemotherapy treatment prescribed by the oncologist. The fourth session was conducted 3 months after the third session to check whether the benefits of the previous interventions were maintained.	• There was a statistically significant reduction in anxiety and depression and significant improvements in emotional distress and coping mechanisms, including fighting spirit, cognitive avoidance, and anxious worry.	The study was approved by the Clinical Research Ethics Committee (CEIC) of Hospital CIMA (Barcelona, Spain), a center authorized by the Department of Health (H08621946).

Description	• A total of 126 patients (average age of 66 years) with the following condition, n (%): colorectal cancer: 58 (46); right colectomy: 21 (16.7); sigmoidectomy: 20 (15.9); LARaz+TaTMEba: 25 (19.8); transverse colon resection: 2 (1.6)	Third-level Academic Center in the Gastrointestinal Surgery Department in Barcelona, Spain	Patients were randomized using en bloc randomization with random block sizes.	Patients and health care professionals could not be blinded regarding group assignment.	HAD-D, HAD-A, STAI_A/S, and STAI_A/T scores were used.	The patients in the intervention group had unlimited access to VR glasses and to the VR app.	• There was a statistically significant improvement for both the HADS-A and HADS-D subscales and those measuring status and trait in STAI scales in patients who were exposed to the VR simulation experience.	The trial was registered on ClinicalTrials.gov (NCT04058600).

Met criteria	Completely met	Completely met	Completely met	Not completely met	Completely met	Completely met	Completely met	Completely met
Description	• A total of 66 patients (average age of 52 years) with breast cancer	Oncology outpatient department of a university hospital in Turkey	This study was conducted using the randomization block method (6:5). Combinations with randomization were enumerated using a web-based random queue generator with permuted random block allocation (block size: 33). The intervention group and CG were determined by lots.	Blinding was not possible due to the nature of the study. With VR, the patients could not be blinded during the intervention because they knew that they were in the intervention group. Randomization was prepared by a statistician, but this was hidden from the researcher performing the study.	The STAI scale and the CFS[bb] were used.	The study was conducted once every 21 days for 4 sessions (1 session per chemotherapy cycle for 4 cycles) for 30 minutes.	• There was a statistically significant decrease in mean postintervention anxiety scores and mean posttest fatigue.	The trial was registered with the US National Institutes of Health Clinical Trials Registry on September 12, 2021 (NCT05168696)

Study	Patient population	Clinical setting	Control and randomization	Blinding and concealment of allocation	End points	Study duration	Presentation and analysis of results	Reporting the trial
Description	• A total of 60 patients (average age of 34 years) with leukemia	A public hospital in Guangzhou, China	Participants were randomly assigned to the intervention group and CG in a 1:1 ratio by generating 70 codes written on identically sized pieces of paper, which were placed in opaque, sealed, and sequentially numbered envelopes.	Owing to the nature of VR intervention, blinding the participants and the interventionist was impossible.	The SAI scale, CES-D[bc] scale, and FACT-leu[bd] questionnaire were used.	From days 1 to 14, participants experienced 14 different immersive videos. To avoid interruption from common treatment activities, every intervention occurred from 3 PM to 6 PM.	Those in the intervention group demonstrated a significantly greater reduction in anxiety (P<.05) and improvement in quality of life (P=.04). There was no significant difference in depression levels between groups (P=.09), although a decreasing trend was observed in the intervention group.	The protocol was registered retrospectively in the ISRCTN registry (ISRCTN 84842464; June 6, 2022).

Discussion

Principal Findings

We found 24 RCTs of VR for older adults with serious illness that encompassed diverse conditions, such as stroke, cancer, cardiovascular disease, and COPD. Among these studies, VR has been applied to improve anxiety and pain, as measured by the HADS, State Anxiety Inventory, or NPS, or mobility and strength, as measured by the Fugl-Meyer upper extremity assessment, proprioception, or orientation metrics. In this review, short VR experiences were typically used to improve outcomes related to anxiety and pain, while longer ones were used to improve mobility and strength after stroke. Training, supervision, and assistance provided were described in 5 studies [38,40,43,46,54]. Of the included RCTs, all 24 studies addressed older adults; however, only a few focused entirely on the older adult population: 3 studies (12%) included adults with an average age of 66 to 70 years [44,50,56], and only 1 study (4%) included older adults with an average age of >75 years [37]. From the 24 RCTs included in this systematic review, 7 (29%) studies adhered to all 8 gold standard VR consensus standards criteria, and all studies (100%) adhered to at least 5 criteria.

Although there are emerging bodies of evidence on VR use for acute pain, physical therapy, and mental health, we found relatively few studies that met our criteria, focused on symptomatic and functional aspects of serious illness or their use for older adults [59-61]. Acute pain and pain associated with serious illness are distinct, as suggested by the total pain model for serious illness by Saunders; are multifactorial; and explicitly consider physical, emotional, social, and existential factors in worsening symptoms [62,63]. Function is also impaired to a greater degree in older adults, and the average American lives with 1 to 2 ADL disabilities during the last 2 years of life [64]. Comorbidity is common among older adults, and underlying conditions and treatments can interact to exacerbate symptoms [65]. Owing to this, the same interventions used to manage acute pain may not be efficacious for managing pain associated with serious illness, especially among older adults with serious illnesses.
