KEYWORDS

large language model; multi-agent system; diagnostic errors; cognition; clinical decision-making; cognitive bias; generative artificial intelligence

We read with great interest a recent article in the *Journal of Medical Internet Research* entitled "Mitigating Cognitive Biases in Clinical Decision-Making Through Multi-Agent Conversations Using Large Language Models: Simulation Study" by Ke et al [1]. Large language models (LLMs) have advanced reasoning skills but most studies have focused on assessing their ability to answer questions [2]. Ke et al [1] evaluated the ability of LLMs to avoid reproducing certain biases that physicians experience when making a diagnosis. The authors simulated decision-making using a multi-agent system in which each agent models the reasoning of a physician using an LLM. The experiment shows a significant increase in performance compared to a human, with an odds ratio of 3.91, which is highly remarkable. This is made possible by a particularly low score for humans, which leaves considerable room for improvement by LLMs.

Previously published studies have often shown disappointing results using LLMs, with performance levels that give cause for concern when used in a clinical context. Some studies have observed performance similar to that of physicians and marginally better in a limited number of cases. We are thus surprised to see that the multi-agent approach has led to such superiority compared to the physicians. This superiority may be explained by using a multi-agent framework, but it could also be limited to the context of addressing cognitive biases.

To investigate this hypothesis, it would be interesting to compare the performance of the multi-agent system with that of a single LLM. In particular, a prompt engineering method known as tree of thought allows several reasoning paths to be explored, enabling the initial choice to be modified according to diverse alternatives [3].

Furthermore, a recent study found no added value in associating an LLM with a physician to improve performance when making a diagnosis [4]. Moreover, the quantity of text and the number of interventions produced by multi-agent systems may be overwhelming, and the physician could ignore the suggestions. This was the case for many studies on computerized decision support systems for drug prescriptions, where too many alerts have led physicians to override relevant alerts [5].

The multi-agent system can lead to significantly higher costs and requires the mobilization of a greater number of resources. This depends on the number of agents involved in the multi-agent system and, above all, on the amount of text

XSL•FO
RenderX

generated. The multi-agent system is likely to produce numerous arguments and counterarguments to make a fair diagnosis. It would be interesting to know how many tokens are produced in the application logs compared to a simpler application.

The authors suggest that similar approaches could revolutionize medical practice by making clinical decisions more reliable and more consistent with the levels of evidence available. We subscribe to the idea that LLMs could help physicians, and the authors' approach seems promising. However, there is still a lack of evidence on how these multi-agent systems would perform if they were generalized to other diagnostic challenges.

We read the recently published article titled “Issues in the Adoption of Online Medical Care: Cross-Sectional Questionnaire Survey” by Sugawara Y et al [1] with great interest. The authors conducted two surveys aimed at identifying the current status of telemedicine in Japan and the factors hindering its spread, from the perspectives of both patients and medical professionals providing it. Although the existence of bias cannot be denied because of the voluntary web-based survey, the findings were useful in understanding the current status of telemedicine in Japan.

As corrected in the original paper, the authors cited our study [2] and explained that telepsychiatry was reimbursed at the same or higher rate as in-person consultations in 15 of 17 regions worldwide. In this study, Japan was in the minority, with telepsychiatry reimbursement distinctly lower than face-to-face care. This remains an obstacle to the widespread use of telemedicine in Japan, not only in psychiatry but also across other medical specialties. Even before 2019, and despite deregulation following the COVID-19 pandemic, reimbursement rates for telemedicine have remained lower than those for face-to-face consultations [3].

In addition, telepsychiatry is more strictly regulated than telemedicine in other medical specialties. Even after the most recent deregulation in June 2024, there are still restrictions on prescription drugs and reimbursement rates for initial visits, as well as restrictions on the conditions under which physicians and medical facilities can obtain reimbursement.

The survey by Sugawara et al showed that patients and healthy individuals in psychiatry and psychosomatic medicine are interested in using telemedicine; however, the fact that medical institutions are either unable or unwilling to provide it, due to such strict regulations, is surely the biggest obstacle to its widespread use.

In addition, Sugawara et al emphasize the need to obtain the opinions of psychiatrists and psychosomatic medicine specialists regarding the feasibility of online medical care. In a 6-month randomized controlled trial comprising 199 patients with depression, anxiety, and obsessive-compulsive disorder at 19 medical institutions in Japan, we verified the noninferiority of the combined telepsychiatry group to the face-to-face treatment group [4]. The study also found no significant differences between the two groups on several secondary endpoints, including treatment retention and satisfaction. Furthermore, it confirmed that the telepsychiatry group required less time and incurred lower costs than the face-to-face treatment group. From these studies, we believe that the feasibility of telepsychiatry in the Japanese medical field has already been verified to a certain extent.

In Japan, while the demand for medical care is expected to increase due to further aging of the population, the dispersion

XSL•FO
RenderX

and maldistribution of physicians and hospitals remains unresolved [5]. Since telemedicine is considered an effective measure to improve efficiency and equalize the provision of medical care, the government should ease regulations to make it easier for frontline medical professionals to use.

Introduction

We thank the authors for their knowledgeable comments [1] on our study [2]. Our results suggest that although telemedicine is not widely used in the field of psychiatry and psychosomatic medicine, it is desired by the patient population receiving medical care. Deregulation of the restriction and setting higher reimbursement rates are considered important, but evidence is needed for this to happen. We believe that the results recently presented by Dr Kishimoto and colleagues [3] are very important, and the fact that they show that telemedicine in this field is not inferior to face-to-face care is good information not only for health care providers and the patient population, but also for government agencies as a resource for developing policy. This kind of evidence needs to be accumulated, and more research on telemedicine is needed in the future.

Abstract

We appreciate Reierson’s thoughtful commentary on our 2019 paper, which described our experiences, ethical process, judgment calls, and lessons from a 2016-2017 data-sharing pilot between Crisis Text Line and academic researchers. The commentary raises important questions about the ethical conduct of health research in the digital age, particularly regarding informed consent, potential conflicts of interest, and the protection of vulnerable populations. Our article focused specifically on the noncommercial use of Crisis Text Line data for research purposes, so we restrict our reply to points relevant to such usage. While we acknowledge

XSL•FO
RenderX

the limitations of Crisis Text Line's Terms of Service as a means of informing users about data sharing for research, we maintain that our guidelines were ethically sound and aligned with well-established practices for institutional review board (IRB) review and researcher training. We emphasize the critical role of IRBs in ensuring that research involving vulnerable populations, including minors, is conducted ethically and with appropriate safeguards. Regarding potential conflicts of interest, we argue that unpaid, nonfiduciary advisory board service for a nonprofit organization does not constitute a conflict requiring disclosure. The transparent nature of our collaboration with Crisis Text Line, as evidenced by the authorship and acknowledgments in our paper, further underscores our commitment to ethical research practices. We recognize the complexity and evolving nature of the challenges surrounding data-sharing partnerships in digital health research. As the field progresses, we remain committed to ongoing, transparent engagement and to refining best practices in collaboration with colleagues, stakeholders, and the public. Our response aims to provide clarity and context for the concerns raised in the commentary while reaffirming the integrity and value of our original work. Ultimately, we maintain that our paper contributed meaningfully to the ongoing discourse on ethical data sharing and laid the groundwork for future improvements in this critical area of digital health research.

ethics; data sharing; digital data; text messaging; technology; cooperative behavior

Introduction

Reierson's commentary [1] on our 2019 article [2] highlights important and timely questions about the ethical conduct of health research in the digital age. Interactions with increasingly ubiquitous health-related digital platforms generate enormous amounts of data in which individual users, future users, and society have a vested interest [3]. We share Reierson's concerns about how and under what conditions users ought to be informed about how data generated from their interactions are included in health and prevention research, including research that aims to prevent suicide. We published this paper to share with the field our experiences, ethical process, judgment calls, and lessons from a 2016-2017 data-sharing pilot, understanding that science and ethics advance through publication, critique, and refinement.

Our article explicitly pertains to "noncommercial use of data" for the purposes of research and evaluation. The article neither addresses nor endorses use of Crisis Text Line data for commercial purposes. No members of the Crisis Text Line data advisory board that advised on the data-sharing pilot our article described served in any capacity with Loris.ai. Given that Reierson's commentary on the commercial use of data and Loris.ai is outside the scope of our paper and anachronistic to the data pilot we reported on, we focus our response on his in-scope feedback. The commentary also questions common features and norms in human subject research (such as the definition of a research subject and the role of institutional review boards). The adequacy of well-established ethical frameworks and review processes is always worthy of review, but we will focus here on those questions relevant to our specific conduct.

With respect to including deidentified Crisis Text Line data in research, the commentary raised concern about: (1) the Terms of Service that Crisis Text Line used to inform users of data-sharing policies with respect to research and (2) potential undisclosed conflicts of interest in the author group.

Crisis Text Line Terms of Service and Consent

Regarding the concerns raised about Crisis Text Line's Terms of Service (Terms) with respect to research, we appreciate the limitations pointed out by Mr Reierson. At the time the paper was published, we considered the Terms to be an appropriate means by which to "inform users in an *unobtrusive way* that anonymized data are shared with select research partners." We agree that the Terms could have been simplified with respect to research, and we understand that Crisis Text Line has since improved them.

It is important for the general public to understand that any use of Crisis Text Line data for research must first be reviewed by a researcher's university institutional review board (IRB)—an independent committee that reviews the research protocol, including the adequacy of the consent process and the protection of vulnerable populations, such as minors. This review process is part of the context in which our guidelines were offered. Furthermore, all researchers undergo Human Research Protection Training, which emphasizes the Belmont Report's ethical principles of respect for person, beneficence, and justice, with particular attention to the protection of vulnerable populations. IRBs often consider secondary analyses of data without access to identifying information as not meeting the definition of human subjects research according to the federal definition 45 CFR 46.102(f).

Thus, the authors of the article still conclude that what we wrote at the time adheres to ethical standards of research, even while we welcome retrospective critique of the recommendations we generated at the time. Furthermore, we believed—and continue to believe—that it is not just acceptable, but is imperative, for academic researchers to engage with technology companies to create methods and means for research that both improve the protections of people engaging with that technology and facilitate the use of the generated data for good rather than for harm.

XSL•FO
RenderX

Potential Undisclosed Conflicts of Interest

Regarding questions raised about potential conflicts of interest, it should be noted that Crisis Text Line is a nonprofit organization, and no one on the Crisis Text Line data advisory board had a role in or even knew about Loris.ai, which was founded after the data-sharing pilot took place. We did not and do not consider volunteer nonfiduciary participation in the Crisis Text Line advisory board as a "conflict of interest," and none of the authors had any other relationships or funding from Crisis Text Line at the time this article was written and published. The Crisis Text Line advisory boards convened volunteer experts to provide independent advice, an extremely common practice.

- Members of the Crisis Text Line advisory boards are unpaid and receive no other tangible or intangible benefit from their participation. They volunteer a small amount of time to provide input and expertise, hopefully to the benefit of the nonprofit organization and the people it serves.
- Crisis Text Line has no undue influence on advisory board members' feedback or behavior. Advisory board members are sufficiently independent from Crisis Text Line to be able to provide critical feedback—both positive and negative—on Crisis Text Line's operations.
- Our advisory board had no fiduciary responsibilities to Crisis Text Line.

In studying the Committee on Publication Ethics' (COPE) guidelines, JMIR Publications' policy, and other publicly available ethical statements, we could not find any indication that a relationship of this type would be considered a "vested monetary interest" or a "conflict of interest." *[Editorial Note:While we found no intent to deceive on the part of the authors, we disagree with this interpretation; see corrigendum to Pisani et al's 2019 publication [4]]*. We should note that our author group appreciated the opportunity to consider this question. Most agreed that, while not required nor customary, there would be no harm—and could be some potential benefit—in disclosing unpaid advisory board service, and some of us will choose to do so in the future (eg,[5]).

Further, far from being "undisclosed," the participation and collaboration of members of the author group with Crisis Text Line in documenting the results of their pilot academic data-sharing program was a key feature of the article.

- Crisis Text Line employees were listed as authors along with their affiliation.
- An appendix was provided listing members of the data ethics committee, which included several of the authors.
- The paper is manifestly the result of collaboration with Crisis Text Line—academics and nonprofit leaders transparently described the ups and downs of a pilot program aimed at protecting privacy, conducting research ethically, and contributing to science and society.

Summary

In summary, we share Mr Reierson's concern about ethical use of data and appreciate his thoughtful interaction with our 2019 paper. Our article addressed only noncommercial use of data. We see Mr Reierson's arguments about Terms of Service and consent as welcome and substantive critiques rather than ethical concerns about our 2019 paper. We stand by our work and recommendations as ethically sound, and we highlight that we wrote this publication to advance discourse and future ethical guidelines. Finally, unpaid, nonfiduciary advisory board service to a nonprofit organization by independent academic experts does not constitute a conflict of interest, although we see the benefit of listing such service in certain circumstances in the future.

We remain committed to ongoing, constructive scientific dialog and to refining best practices in collaboration with interested parties and the public. Working together, we can best realize the benefits of research while upholding high standards of ethics, privacy, and trust.

Note: The following authors of the original publication could not be reached or were unavailable to participate in this Authors' Reply: Lisa Soleymani Lehmann, Robert Levine (deceased), and Shirley Yen.

Conflicts of Interest

NK was a salaried full-time employee with Crisis Text Line during 2016-2017. BF was a salaried chief data scientist at Crisis Text Line until 2021 and chaired the Data Ethics Committee. ST previously served as chief medical officer for Crisis Text Line and is chief health officer for Crisis Text Line from 2020 to present and receives a salary. ARP and MSG served as uncompensated advisory members of the Clinical Advisory Board to Crisis Text Line from 2014 to 2022. BP, DR, JEM, and MLR previously served as uncompensated members of the Data Ethics Committee or Data, Ethics, and Research Advisory Board for Crisis Text Line.

KEYWORDS

crisis; research; data privacy; research ethics; digital rights

As current chief executive officer (CEO) of Crisis Text Line, I am writing this commentary on behalf of the organization to clarify the record, provide context, and supply background information regarding Crisis Text Line and its research standards regarding a critique [1] of a viewpoint paper [2] published in the *Journal of Medical Internet Research* in 2019. Below, you will find information about how we protect and do not commercialize personal data; our ethical research standards; our unique data; texter digital rights, privacy, and ethics; and a snapshot of our recent research.

Crisis Text Line: Background

Crisis Text Line is a nonprofit organization that provides free, 24-7, confidential text-based mental health support and crisis intervention in both English and Spanish for anyone in the United States and Puerto Rico. Since our launch in 2013, we have supported nearly 10 million conversations in the United States and have trained over 71,000 volunteers.

All our volunteers are required to accept our policies as a condition of serving as a volunteer with Crisis Text Line, which disclose that we may share anonymized data with researchers. That disclosure and the consent to our all-encompassing privacy policy existed during and prior to the 2016-2017 period of the research that is the subject of the *Journal of Medical Internet Research* study at issue. Volunteers' consent to that broader, generally applicable policy remains effective regardless of our decision to create a shorter and more tailored volunteer-specific policy in 2021 in the interest of greater transparency. Volunteers serve without compensation and are not under any employment agreements.

Crisis Text Line Does Not Commercialize Personal Data

Crisis Text Line does not and has never monetized personally identifiable information directly or indirectly.

Crisis Text Line previously had an open and public relationship with Loris.ai, a for-profit company aimed at helping other for-profit companies employ de-escalation techniques to reduce stress for customers and employees. At the time, we believed that sharing insights from Crisis Text Line's training curriculum

XSL•FO
RenderX

and deidentified data could support stress reduction and improved well-being in spaces beyond the crisis context while potentially contributing to the sustainability of a nonprofit public good. The world of technology and data ethics evolved rapidly, and Crisis Text Line quickly changed course. Loris.ai did not access any Crisis Text Line anonymized data or other information after early 2020.

Public records demonstrate that Loris.ai *did not exist* during the 18-month period of the pilot analyzed in the study; the company was formed months after the pilot ended. Crisis Text Line severed all ties with Loris.ai in 2022 and required the return or deletion of any data previously accessed. We were publicly transparent about the goals of this relationship, which included broader application of our de-escalation strategies and potential revenue to support our important nonprofit work. Ultimately, Crisis Text Line did not receive financial gain as a result of its prior data- and insights-sharing relationship with Loris.ai.

Crisis Text Line is a nonprofit, and those acting as advisory board members did so on a voluntary unpaid basis. To Crisis Text Line's knowledge, there was no conflict of interest, and none of the research authors were advisory board members for the commercial spin-off Loris.ai.

The Critical Need for Ethical Research in Combating the Mental Health Crisis

We can all agree that the need for evidence-based action on the current mental health crisis is indisputable and urgent. The importance of ethical research focused on tackling this crisis cannot be overemphasized. The prevalence of mental health challenges worldwide highlights the critical need for innovative solutions, compassionate care, and evidence-based interventions. Through ethical research efforts, Crisis Text Line contributes to destigmatizing mental health challenges by disseminating accurate information, challenging misconceptions, and promoting empathy and acceptance. Through collaborative efforts [3] between researchers, policy makers, clinicians, and community stakeholders, we help to foster a holistic approach to mental health that addresses systemic barriers and promotes equitable access to care.

In Pursuit of Solutions

Crisis Text Line's anonymized data provide a unique snapshot of mental health across the United States. We are in direct conversation with people in crisis, so what we learn is not simply the result of a survey. Rather, it is real-time insight about how people feel. We ask about the specifics of their crisis, listen, collaboratively problem solve, de-escalate, and then provide them with an optional anonymous postconversation survey. Data shared by texters themselves in the optional postconversation survey suggest that two-thirds of them do not have access to professional mental health support. We believe it is our duty to elevate their voices and support research efforts that might contribute solutions to help with this emergency in an ethical manner. Analyzing that data—carefully secured and anonymized—allows us to observe emerging trends, almost in real time. For example, in March 2020 during the first COVID-19 lockdowns, we observed a spike in conversation volume as people reached out while struggling with isolation, anxiety, and grief, but with lower suicidal ideation. Our dataset of nearly 10 million conversations (nearly 300 million messages) collected in over 10 years of operation offers a broad and deep perspective of mental health trends across the country. Those data position us to have a real impact through ethical research endeavors.

Data Privacy, Digital Rights, and Ethics

At Crisis Text Line, safeguarding our texters' data is paramount. In moments of crisis, our texters can feel assured, trusting the integrity of the support they receive without concerns about their data's privacy, security, or use. To that end, we've published digital rights [4] for texters, outlining rights and principles that we uphold throughout their use of our service. Ensuring texters' safety, privacy, and confidentiality stand as foundational principles of our service. We protect texter privacy rigorously and maintain texter anonymity, except when necessary for safety or legal reasons.

Our privacy policy [5] transparently discloses how we collect and use data, noting our use of encryption and other reasonable measures to protect against unauthorized access. All texters get a link to the policy at the start of every conversation with us, and texters must consent to the policy to use the service. The policy also intentionally contains simple plain-language bullets at the beginning so a user can quickly and easily understand what we do, how we do it, and why—including, among other things, our use of anonymized deidentified data for research. Texters also have the option to ask that we delete their data, including conversation records and contact information, simply by texting or messaging the word DELETE.

We go to great lengths to protect, store, analyze, and share insights from our anonymized crisis conversations to ethically help the world address mental health issues. We further align with the highest international standards for ethical research involving human subjects. In addition to ensuring that external research collaborations are overseen by the institutional review board (IRB) of the lead researcher's institution, since 2023, our in-house research is also overseen by an IRB. These policies and practices disclose and reinforce our commitments to upholding texter privacy and fulfilling our mission.

Our Recent In-House and Collaborative Research

Since our launch in 2013, we have supported nearly 10 million conversations initiated by texters across the United States. Leveraging this anonymized and deidentified dataset, we inform policy makers, journalists, and researchers. Alongside our internal research endeavors, we foster collaborations with partners at research institutions. Recent examples of research contributing unique insights to the field include:

- Crisis Text Line & Common Good Labs: "What Young People in Crisis Need From Their Communities" (2023) [6]

XSL•FO
RenderX

- Crisis Text Line's United in Empathy Report (2023) [7]
- Examining Hurricane Ida's Impact on Mental Health: Results From a Quasi-Experimental Analysis (2023) [8]
- The Use of Crisis Services Following the Mass School Shooting in Uvalde, Texas: Quasi-Experimental Event Study (2023) [9]
- Crisis Response Among Essential Workers and Their Children During the COVID-19 Pandemic (2021) [10]

A Call to Action

As we navigate the complexities of the mental health crisis, we reaffirm our commitment to ethical research as a catalyst for change. We embrace the transformative power of collaborative, ethical, impactful research in illuminating the path toward solutions, healing, and hope.

Conflicts of Interest

In the last 5 years, the author reports the following financial disclosures: employment as salaried CEO at Crisis Text Line; prior employment at Omidyar Network (which invested in Loris.ai); a travel grant and wellness stipend: The Wellbeing Project; and a minority share in Ultimo Studios. The author reports the following nonfinancial disclosures: prior unpaid board of director membership at Crisis Text Line; board membership: High Resolves; prior advisory group: African Leadership University (African Leadership Group). She has never held equity in the commercial entity Loris.ai.

sleep quality; wearable sleep monitoring wristband; intensive care unit; minimally invasive surgery; traditional open surgery

We are writing to provide our comments on the recently published article titled "Quantitative Impact of Traditional Open Surgery and Minimally Invasive Surgery on Patients' First-Night Sleep Status in the Intensive Care Unit: Prospective Cohort Study" by Shang et al [1]. This paper addresses an important clinical question regarding postoperative sleep quality and provides valuable insights into the advantages of minimally invasive surgery (MIS). We commend the authors for their efforts in using both subjective questionnaires and objective wearable technology to explore this topic. However, we would like to share several thoughts that could help further refine the interpretation of results and consider additional avenues for future studies.

First, this study focuses on postoperative sleep but overlooks baseline sleep conditions. Preoperative sleep disorders or psychological issues, such as anxiety or depression, could predispose patients to postoperative disturbances, while good baseline sleep quality may confer greater resilience [2]. Preoperative assessments using tools like the Pittsburgh Sleep Quality Index or short-term monitoring could help clarify the independent impact of surgical methods. Additionally, pain management significantly affects sleep through both direct and indirect mechanisms. While MIS likely reduces sleep interference due to less pain, the absence of quantitative pain scores and analgesic data limits interpretability. Future research should address preoperative sleep and analgesic strategies to provide a more comprehensive understanding.

Second, wearable devices offer convenience but have limitations in postoperative or intensive care unit settings. They rely on accelerometers and heart rate variability without electroencephalogram support, risking overestimation of sleep duration, especially in patients who are sedated [3]. Environmental factors like intensive care unit noise and caregiving activities can further compromise accuracy, while algorithms optimized for healthy populations may not reflect the sleep patterns of patients who are critically ill. Future studies should improve algorithms, validate accuracy in complex environments, and integrate devices with other monitoring methods to enhance clinical utility.

Third, psychological factors such as preoperative anxiety or depression significantly influence postoperative sleep. Patient perceptions of MIS, such as reduced trauma and faster recovery, may also indirectly improve sleep. However, the study did not quantify these factors, potentially underestimating their role. Additionally, the single-center design and small sample size limit generalizability and subgroup analyses. Future research

XSL•FO
RenderX

should adopt multicenter, larger-scale studies and include psychological assessments to enhance applicability and robustness.

In conclusion, Shang et al's [1] study provides meaningful insights into the impact of surgical approaches on postoperative sleep quality, particularly highlighting the potential benefits of MIS. While the findings are valuable, addressing the aforementioned limitations could enhance the robustness and clinical relevance of future research. We appreciate the authors' contribution to this important topic and look forward to further advancements in this field.

KEYWORDS

sleep quality; wearable sleep monitoring wristband; intensive care unit; minimally invasive surgery; traditional open surgery

Thank you for your thoughtful feedback on our article, "Quantitative Impact of Traditional Open Surgery and Minimally Invasive Surgery on Patients' First-Night Sleep Status in the Intensive Care Unit: Prospective Cohort Study" [1]. We appreciate your insights and would like to address the key points you raised [2].

Baseline Sleep Conditions

We fully agree that baseline sleep quality is crucial. In our study design, we excluded participants with chronic sleep disorders based on preoperative medical history and medication use. The suggestion to incorporate sleep scoring tools like the Pittsburgh Sleep Quality Index is valuable, as it could help investigate the impact of surgery on sleep status in different patient populations. Inspired by your comments, continuous monitoring using wearable devices during the preoperative and intensive care unit (ICU) periods could provide valuable insights into how sleep is dynamically affected by different clinical treatment protocols.

Pain Management and Analgesic Strategies

We completely agree that pain is one of the greatest "enemies" of sleep quality. Working in a surgical ICU in a teaching hospital, we use standardized protocols along with the Richmond Agitation-Sedation Scale and Numeric Rating Scale (NRS) to manage pain and sedation. Our sedation and analgesia goals were maintained with Richmond Agitation-Sedation Scale scores of –1 to 0, aiming for an NRS below 3 [3,4]. Our unpublished data showed that both the minimally invasive surgery and traditional open surgery groups demonstrated comparable NRS scores (mean NRS: 1.86, SD 0.76, vs 1.85, SD 0.62; *P*=.96).

XSL•FO
RenderX

This consistency allowed us to isolate the effects of surgical methods on sleep.

Wearable Device Limitations

Rapid screening and diagnosis of sleep disorders in ICU settings remain challenging. Our study aimed to explore the use of wearable devices for patients who were awake in the ICU, helping to reduce bias introduced by sedative medications. We agree that ICU-specific environmental factors affect all electronic monitoring tools. Examining how these environmental factors impact device accuracy would be a meaningful research topic. The development of more sophisticated algorithms—whether embedded in device software or integrated with artificial intelligence–based predictive models using clinical data—represents a promising direction for the field of medical engineering integration.

Psychological Factors and Study Design

Lastly, we appreciate your emphasis on the psychological factors influencing sleep, such as preoperative anxiety and depression. These factors may indirectly affect sleep quality, and the reduced trauma and faster recovery associated with minimally invasive surgery could positively influence psychological well-being. Exploring dynamic and quantitative methods to assess psychological states, alongside studying the effects of clinical treatments and mind-body interventions, presents a valuable opportunity to uncover their relationships with clinical outcomes. Combining these approaches with dynamic sleep state monitoring provides technical support to illuminate both direct and mediating relationships, paving the way for large-scale controlled trials to enhance patient care.

Thank you again for your valuable feedback. We look forward to further discussions and advancing this important field.

KEYWORDS

older adults; artificial intelligence; medication; decision-making; data security; patient trust

We are writing to provide comments on the manuscript titled "Investigating Older Adults' Perceptions of AI Tools for Medication Decisions: Vignette-Based Experimental Survey" by Vordenberg et al [1]. This study addresses a critical area of research, exploring older adults' trust in artificial intelligence (AI) tools for medication recommendations. While the manuscript presents meaningful insights, several aspects could benefit from further clarification or expansion.

First, older adults may encounter practical challenges when using AI tools, such as difficulties with device operation or complex interfaces. Incorporating user testing or enhanced scenario simulations could optimize the usability of AI tools for older adults. As technology evolves, older adults' perceptions of AI may change over time or with increased exposure to its use. A comparison of AI recommendations with those of health care professionals may either strengthen trust in AI or create conflicts with medical advice, which could lead to greater tensions in the doctor-patient relationship [2]. Long-term follow-up studies would be valuable in tracking these dynamics.

Second, the study emphasizes the impact of differences among demographic groups but does not explore the cultural and socioeconomic factors that underlie these disparities. The acceptance of AI recommendations by older adults may be influenced by cultural attitudes, psychological factors, income levels, and past medical experiences. These elements may limit the generalizability of the study's findings across diverse social contexts [3]. Future research should delve deeper into these factors to enhance the applicability of the results.

Third, while the authors have addressed certain issues, we believe that several important considerations remain underexplored. The study assumes controlled scenarios to manage AI-related variables; however, this simplification may be overly idealized and fails to capture the complexity of medication decision-making in real-world contexts [4]. In practice, decisions regarding medication discontinuation are influenced by multiple intersecting factors, including not only the doctor's advice but also communication and trust between the patient and health care provider, the patient's financial situation, the need for coordinated care across multiple chronic conditions, and potential side effects following medication cessation. Additionally, the opinions and interventions of family members, as well as the patient's personal values, may also play significant roles in the decision-making process [5]. Therefore, medication decisions in real-life scenarios are very complex and require a comprehensive consideration of various factors beyond fixed hypothetical scenarios.

XSL•FO
RenderX

Overall, this study makes a significant contribution to understanding older adults' perceptions of AI in health care. Addressing these limitations could enhance the clinical relevance and robustness of future research. We would like to commend the authors for their efforts and thank the editorial team for providing a platform to publish this important work.

KEYWORDS

older adults; artificial intelligence; vignette; pharmacology; medication; decision-making; aging; attitude; perception; perspective; electronic heath record

We appreciate the insights regarding our manuscript, "Investigating Older Adults' Perceptions of AI Tools for Medication Decisions: Vignette-Based Experimental Survey" [1], in the letter to the editor shared by Wang and Chen [2]. The letter emphasizes three key points: (1) older adults may encounter practical challenges with artificial intelligence tools, necessitating user testing and scenario simulations to enhance usability; (2) although our study considered demographic differences, it did not explore underlying cultural and socioeconomic factors, which calls for further research; (3) the complexity of real-world medication decision-making remains significant.

We acknowledge the limitations the correspondents highlight, particularly usability challenges for older adults and the need to examine underlying cultural and socioeconomic factors. Our vignette-based experiment served as an intentionally focused first step in understanding older adults' interest in artificial intelligence–assisted medication decision support.

Wang and Chen [2] note that our previous work showed that medication decision-making is complex [3]. Indeed, various factors influence how patients make these decisions, including their attitudes, beliefs, and preferences regarding medications; the potential benefits and harms of the treatment under consideration; and contextual factors specific to the patient [4-6]. Our study's experimental approach using vignettes, as indicated in the title, was selected to begin exploring this complex area in a controlled manner.

We agree that this initial study lays the foundation for future research that can tackle these important considerations through enhanced scenarios, user testing, and a more in-depth examination of sociocultural factors.

KEYWORDS

adolescent health; digital health literacy; adolescents; online health information; co-design; health education; eHealth literacy; social media

Dear Editor,

The research publication entitled “Developing an Educational Resource Aimed at Improving Adolescent Digital Health Literacy: Using Co-Design as Research Methodology” [1] represents a pivotal intervention in the domain of youth-centric health research. With co-design effectively decentralizing traditional research frameworks by considering authentic adolescent perspectives on digital health literacy through their critiques of accessibility, personal and social factors, and information overload, resulting educational resources were able to incorporate more engaging, culturally and generationally relevant content to improve adolescents’ digital health literacy skills and self-efficacy.

Of all studies involving individuals aged 12-18 years, less than 1% reported using youth advice, and barriers to youth participation included limited researcher understanding, lack of resources, and organizational challenges [2]. This alarming underrepresentation epitomizes a systemic failure to acknowledge adolescents as active contributors to the knowledge that directly impacts their lives, instead perpetuating a research production hierarchy that undermines the unique cognitive capabilities and viewpoints of youth populations. While a variety of innovative digital health interventions, such as social networking sites, apps, and video games, have been developed to support youth, the successful development of these tools requires consistent input from target users [3]. Only in this way can we ensure the alignment of protocols, programs, and interventions to adolescent criteria of trustworthiness, safety, peer-to-peer connection, quality, and engagement, as well as the related usability and accessibility of tools among adolescents.

Research on our youth should ultimately be conducted by our youth, but more importantly, with our youth. Adolescents should not be arbitrarily labeled as mere resources for data but rather included in a detailed and thorough knowledge generation apparatus, including both study design and program implementation [4]. Promisingly, youth participatory action research fosters youth leadership in identifying health values and actions while balancing health promotion with personal growth and development [5]. This approach allies a commitment to empowering youth as cocreators with the recognition that their lived experiences are essential in designing interventions that truly resonate with their generation’s needs, particularly in a digital age where adolescents serve as primary consumers and innovators of social media and technology, respectively.

In traditional frameworks, adolescents are often regarded as passive subjects, with their needs, preferences, and involvement dictated by researchers, funders, or institutional mandates. But when youth are positioned as equals, the collaboration becomes more genuine, and the resulting health tools are more likely to meet their evolving demands. This shift is critical, particularly in digital health, where trends, technologies, and social norms change constantly, and youth are often the most proficient at

XSL•FO
RenderX

staying ahead of these shifts. Thus, interventions, when co-designed with the very individuals they seek to serve, will be inherently more attuned to their preferences, technological fluency, and social contexts, thereby maximizing their potential for adoption, use, and sustainable impact. A radical restructuring of adolescent research involvement is long overdue, and we must redefine the processes by which youth health and knowledge are generated, validated, and disseminated to not just meet but anticipate their needs and realities.

The author of "Adolescent Cocreation in Digital Health: From Passive Subjects to Active Stakeholders" [1] highlights the importance of actively involving adolescents in research about adolescent health. Our co-design with adolescents, outlined in "Developing an Educational Resource Aimed at Improving Adolescent Digital Health Literacy: Using Co-Design as Research Methodology" [2], was characterized as a "pivotal intervention" because we prioritized the youth voice in its design process.

The role played by adolescents in our research was central to our development of a digital educational resource that would help adolescents improve their digital health literacy. We valued the involvement of a diverse group of adolescents as research partners in the co-design, to ensure the resource was engaging and aligned with the educational needs of a broad range of adolescents. Thus, our adolescent research partners' insights and recommended designs were an integral part of the educational resource, which was created for use on handheld devices, based around quizzes and serious games, and featured short videos and still images that are typical of social media platforms that are popular with adolescents.

Our adolescent research partners who rejoined us for beta testing were pleasantly surprised to see that the educational resource was developed based on their design ideas, and they were pleased to have been involved and heard in the project. This highlighted the valuable combination of inputs from these diverse adolescent research partners with the equally diverse research team members, all of whom brought unique

XSL•FO
RenderX

perspectives to the design. In a separate, follow-up evaluation, we found that the educational resource was effective at improving the digital health literacy of another group of adolescents, who felt that the content was engaging and met their age group's educational needs.

Social-cognitive theory's concept of self-efficacy (confidence in one's abilities) was foundational in our co-design approach and the educational resource [3]. To enhance users' self-efficacy and learning through co-design, we ensured the resource was appropriate to adolescents' attitudes and behavior and embedded in their social context.

A participatory research approach is crucial when conducting research in adolescent health with adolescents [4]. There is increasing recognition of adolescence as an important life phase, involving multiple physical and psychosocial changes that influence health behavior and health outcomes into adulthood [5]. Nevertheless, adolescents are not a homogenous group: adolescence ranges in age from 10-25 years and involves broad differences in sociodemographic background, interests, abilities, and gender and sexual identities. When conducting participatory research with adolescents, it is important to collaborate with a group that includes members from all subpopulations of interest who have a stake in the project's outcomes [6].

For participatory research to be maximally effective, adolescents should be involved in the actual research design. This has implications for research planning, with time required for recruiting adolescents to the research team and research training. Acknowledgement and remuneration are required in appreciation of the adolescents' lived experience expertise and time dedicated to research training and design. Adolescents' contributions also need to be in ethics applications to human research ethics committees. When seeking research funding, budgetary provisions need to be available for this preparatory phase of participatory research [7].

The study titled “User Experience and Extended Technology Acceptance Model in Commercial Health Care App Usage Among Patients With Cancer: Mixed Methods Study” by Park et al [1] provides valuable insights into how user experience, interface satisfaction, and external motivation affect the adoption of health care apps among patients with cancer. This work aligns with long-standing theories, such as those detailed by Davis [2], emphasizing that perceived usefulness and ease of use are crucial determinants of technology acceptance. By incorporating an expanded Technology Acceptance Model, Park et al [1] shed light on several key areas where digital health solutions can be optimized for oncological care.

The importance of user-oriented design is unmistakable. Satisfaction with an interface has been repeatedly linked to greater app engagement [2], and Park et al [1] confirm that clinicians’ endorsements bolster consistent usage patterns. Gaps in digital literacy, particularly among older populations, remain a pressing concern and necessitate further policy-level interventions to promote equitable access. Yet several emerging trends suggest that further innovation and collaboration could amplify the benefits of digital health apps in oncology.

Keesara et al [3] argue that the COVID-19 crisis catalyzed a “digital revolution” in health care, unveiling the potential for remote, app-based oncology services. Harnessing these developments may require additional training and infrastructure, especially in resource-limited settings where telehealth adoption remains uneven.

In a systematic review, Kruse et al [4] highlight that both patient and provider acceptance are crucial to sustaining digital solutions. While Park et al [1] primarily focus on patient factors, encouraging provider buy-in through institutional policies and workflow integration could markedly enhance long-term adherence and improve clinical outcomes.

Ammenwerth et al [5] show that electronic patient portals can encourage patient autonomy, enabling individuals to track health metrics, communicate with clinicians, and gain personalized insights. Expanding the features of health care apps beyond simple monitoring to include robust patient portals might address the digital divide, provided adequate educational support is offered.

To conclude, Park et al [1] have laid a solid foundation for understanding how patients with cancer adopt health care apps, emphasizing the centrality of user experience and clinician endorsement. However, broader integration of telemedicine advances, joint patient-provider acceptance, and interactive patient portal functionalities could drive higher engagement rates and better patient outcomes across diverse populations. Although the work provides a basis for assessing app use among Korean cancer survivors, its generalization to other populations needs to be further investigated. Moving forward, policy makers

XSL•FO
RenderX

and health care organizations should focus on closing digital literacy gaps, incorporating patient portals, and reinforcing telehealth infrastructure, thus ensuring that digital oncology solutions effectively serve patients' needs worldwide.

Acknowledgments

Jasper [6], an artificial intelligence–powered language model, has been used to paraphrase selected portions of the manuscript to enhance readability and clarity. The model version integrated into Jasper during the paraphrasing process was GPT-4. Essentially, the use of Jasper was limited to paraphrasing, with no generation of new content, and all scientific claims, data, and interpretations remain entirely our own, derived from rigorous research and analysis.

mHealth; user experience; cancer; technology acceptance model; structural equation modeling; health care app; mixed-method study; medical care; digital health care; cancer survivors; disparities; health status; behavioral intervention; clinician

We appreciate the in-depth review and the critical perspectives provided on our study, "User Experience and Extended Technology Acceptance Model in Commercial Health Care App Usage Among Patients With Cancer: Mixed Methods Study" [1]. This reply aims to address and expand upon the discussion points raised in the letter [2], particularly those concerning the broader implications of telehealth and digital health solutions.

The point raised by Umar Khan and Tariq [2] about enhancing telehealth solutions to address accessibility issues is pivotal. Our study, while primarily focusing on user engagement with health care apps among cancer survivors, indirectly highlighted the urban-rural access disparities and digital literacy gaps. These findings suggest an urgent need for comprehensive telehealth infrastructure that is sensitive to regional disparities. Our data indicated a higher usage rate of health care apps among urban dwellers, likely due to better access to digital resources. This observation underscores the importance of policy interventions aimed at improving digital literacy among older and rural populations, which could significantly bolster the effectiveness of telehealth solutions [3].

Furthermore, the necessity of both patient and provider acceptance for sustained digital health engagement was a key finding in our research. Our study underscored the critical role of clinician endorsements as external motivators that significantly influence both the intention to use and the actual usage of health care apps. However, the real-world application of digital tools in clinical settings often reveals a gap between controlled study environments and everyday clinical practice. In addressing this, we aimed to minimize such discrepancies by using commercial apps without structured reminders, thus fostering more natural user engagement.

The suggestion to integrate robust patient portal features aligns well with our findings on the importance of user-friendly interfaces and perceived utility in promoting app engagement. While our study did not specifically investigate patient portals, incorporating such features could enhance patient autonomy by facilitating access to personalized health information and improving communication with health care providers. To further enhance patient engagement, integrating approaches such as shared decision-making and co-design into digital health tools would be beneficial, fostering a user-centered design that accommodates patient preferences and needs [4,5].

Despite its focus on patients with cancer, our study's application of structural equation modeling to identify key factors influencing digital health acceptance is significant, particularly as patient-physician joint decision-making is crucial for this patient group. We also acknowledge the call for further research

XSL•FO
RenderX

to assess the generalizability of our findings. Our study's cohort, primarily sourced from tertiary referral hospitals in South Korea, may not fully represent the broader population of cancer survivors. This limitation, coupled with South Korea's unique health care context, may affect the external validity of our results. Future studies should aim to include a more diverse participant pool to provide insights that are applicable on a global scale.

In conclusion, we are thankful for the thoughtful critique and the opportunity to engage in this enriching dialogue, which has reinforced the importance of a multidisciplinary approach in advancing digital health care.

Abstract

-

(J Med Internet Res 2025;27:e69204) doi:10.2196/69204

KEYWORDS

mobile apps; digital health; atrial fibrillation; anticoagulants; medication adherence; mobile phone

We appreciate the opportunity to read the recently published article by Yoon et al [1], titled Smartphone App for Improving Self-Awareness of Adherence to Edoxaban Treatment in Patients With Atrial Fibrillation (ADHERE-App Trial): Randomized Controlled Trial. The study addresses an important clinical challenge—improving medication adherence in atrial fibrillation patients using digital health interventions. While the findings are valuable, we would like to highlight some additional limitations and considerations that we believe warrant further discussion.

First, the study population was limited to individuals familiar with Android smartphones and the Korean language, likely excluding older adults with lower digital literacy. This presents a significant limitation, as older adults, who often make up a substantial proportion of patients requiring anticoagulation therapy, frequently struggle to adopt and effectively use smartphone-based interventions. For this demographic, navigating apps, managing settings, and understanding instructions on a smartphone can already be challenging, and unfamiliarity with technology exacerbates these difficulties. Such barriers may significantly restrict the practicality and accessibility of these interventions for those who stand to benefit the most. Expanding the target population to include individuals with varying levels of digital literacy and providing tailored support for older adults would greatly enhance the inclusivity and real-world applicability of future research. Additionally, the exclusive focus on edoxaban limits the generalizability of the findings to patients using other anticoagulants with differing dosing regimens and side effects. Broadening the intervention to encompass a more diverse patient population and various anticoagulants would strengthen the external validity and clinical relevance of the study.

Second, the 6-month follow-up period is another critical consideration, as adherence is a dynamic behavior that often fluctuates over time. While the study demonstrated short-term benefits, long-term follow-up is essential to determine whether these improvements are sustained and lead to meaningful clinical outcomes, such as reduced stroke or bleeding risks [2]. Moreover, relying on pill counts as the primary adherence metric, while practical, does not account for the accuracy of timing or dosage. Using more precise tools, such as electronic medication event monitoring systems, could provide deeper insights into adherence patterns and their clinical implications.

Lastly, although the intervention design is innovative, it could be improved to enhance engagement. Incorporating personalized feedback or adaptive features tailored to individual adherence behaviors might increase user retention and app effectiveness,

XSL•FO
RenderX

especially given the higher dropout rates observed in the intervention group. Additionally, integrating the app with complementary strategies, such as caregiver notifications or telemedicine support, could make the intervention more accessible to patients with varying levels of technological proficiency. Addressing these limitations would allow future research to more comprehensively evaluate the app's practicality and clinical impact.

In conclusion, while Yoon et al [1] provide a well-executed study demonstrating the potential of smartphone apps to improve medication adherence, addressing the above considerations could further enhance the clinical relevance and applicability of their findings. We commend the authors for their contributions to this evolving field and look forward to future research addressing these important aspects.

To the Editor-in-Chief,

Social media platforms have become powerful tools for disseminating health information. The recent study published in this journal by O'Brien et al [1] was of great interest. The authors explored the role of social media influencers in sharing health content, assessing their impact on online followers [1]. While the study found that many social media influencers resisted public health campaigns, especially those regarding COVID-19 vaccine uptake, it also highlighted their capacity to promote vaccine uptake when they are aligned with public health messaging [1]. Drawing from our collective experience in this field, we wish to highlight the significant potential of social media influencers in spreading positive public health messages, provide examples of their influence, and propose strategies to maximize their effectiveness in public health campaigns.

Social media influencers play a critical role in shaping public opinion on a wide range of health topics, including vaccinations, cancer screening, lifestyles, and travel safety [2-4]. Social media influencers can effectively counter vaccine hesitancy caused by misinformation, leading to improvements in community attitudes toward influenza vaccines among ethnic minority populations, for example [3]. Additionally, social media use has been linked to improvements in health and food literacy, particularly among schoolchildren [2]. Furthermore, health professionals who create content themselves recognize the value of social media influencers in disseminating information, especially when these influencers work within the boundaries of accurate and responsible messaging [4].

The so-called accessibility influencers also play a role in raising awareness and advocating for inclusive digital experiences by transforming complex health information into more engaging and understandable content [5]. Their work demonstrates the potential for social media influencers to drive positive societal change. The field of accessibility has evolved from its initial focus on web accessibility to addressing diverse user needs across digital platforms. While influencers focus on raising awareness and advocating for accessibility, they do not have a formal role in the development of standards or policies. Influencers' personal experiences and community engagement underscore the importance of collaboration, demonstrating how social media can be harnessed for the public good [5].

Health expert content creators provide valuable insights into the evolving role of social media influencers in health communication. While they acknowledge the risks of misleading health content, which could confuse audiences or make health information less applicable to a broader population [4], they have also suggested strategies to guide social media influencers more effectively. These include improving public health and social media literacy to help audiences critically evaluate online health content, providing training for content creators to enhance

XSL•FO
RenderX

the accuracy of their messages, and strengthening legal or platform-based regulations to curb the spread of misinformation. They also advocate the verification of health professionals' credentials and encourage them to take a more active role on social media [4].

There is a need for further research to fully understand the impact of social media influencers on health communication. The report from O'Brien et al [1] adds to the ongoing discussion about the potential role of digital influencers and emphasizes the need for a cooperative approach to ensure that their influence is used constructively for the benefit of public health.

Authors' Contributions

GTF led on conceptualization, supervision, and editing of the draft manuscript. RMM led on research, data interpretation, and preparation of the first draft. Both authors read and approved the final version of the manuscript.

KEYWORDS

remote exercise rehabilitation; SCeiP model; coronary heart disease; promotion strategy; home rehabilitation

We read with great interest the study by Xu et al [1] examining the use of the "SCeiP" model to guide exercise rehabilitation in patients with coronary artery disease. The authors assessed the feasibility of a personalized exercise rehabilitation program informed by the "SCeiP" model and suggested that telehealth interventions could enhance both patients' adherence to exercise prescriptions and their overall understanding of rehabilitation. As social workers, we attach paramount importance to the role of cardiac rehabilitation training in improving patients' quality of life. Even with low participation rates, such interventions continue to yield significant benefits. Nonetheless, certain limitations merit further consideration.

First, the intervention group's personalized exercise program, supported by the "SCeiP" model and facilitated through WeChat groups, exercise logs, and activity-tracking bracelets, may have been influenced by individual variations among participants. Such differences could introduce bias. Moreover, the reliance on self-reported data, often in the form of questionnaires and scales, can introduce subjectivity. Overly optimistic or pessimistic self-assessments may compromise data accuracy and obscure the true impact of the intervention.

Second, the study's exercise intervention focused predominantly on a single form of exercise. Future research should consider incorporating a wider array of exercise modalities and exploring their synergistic effects. For instance, aerobic training [2], resistance exercises [3], and aquatic activities [4] have all shown promise in inhibiting the progression of coronary artery disease. Different exercise types may yield distinct benefits for specific patient groups. Franklin et al [5] noted that the cardiac demands of any physical activity depend on the individual's metabolic capacity. Accordingly, future investigations could refine their methods to account for differing responses to various exercise modalities.

Third, while the study demonstrated that 1- and 3-month interventions significantly improved patients' cognitive levels regarding cardiac rehabilitation, their sustainability and long-term clinical implications remain uncertain. Further data collection and longer follow-up periods are essential to determine whether cognitive gains translate into substantive health improvements. Additionally, the absence of subgroup analyses or baseline adjustments for variables such as age, gender, and disease severity may limit the generalizability of the results, despite the study's use of randomized group assignments.

In conclusion, we greatly value the work of Xu et al [1], as their innovative application of the "SCeiP" model presents a new frontier for designing exercise rehabilitation programs for patients with coronary artery disease. Although further

XSL•FO
RenderX

exploration is needed to diversify exercise strategies and evaluate long-term outcomes, these findings support the potential clinical and economic benefits of tele-rehabilitation technologies and offer a vital theoretical foundation for integrating the “SCeiP” model into future cardiac rehabilitation protocols.

exercise rehabilitation; coronary heart disease; promotion strategy; home rehabilitation

Thank you for the comments on our article, "The Effectiveness of Remote Exercise Rehabilitation Based on the 'SCeiP' Model in Homebound Patients With Coronary Heart Disease: Randomized Controlled Trial" [1]. In response to the questions raised by the authors [2], we wish to provide several clarifications. Please refer to the following.

First, considering the individual variations among participants highlighted by the author, we accounted for this factor prior to the study. Consequently, we conducted a specialized statistical analysis of the baseline data of the study participants (T0: week 0) and found no significant differences between the two groups regarding questionnaires and scales, including levels of cardiac rehabilitation cognition, exercise planning, and exercise input. Furthermore, the objective metrics of exercise days and exercise duration were also important outcome indicators.

Second, to evaluate disease severity, 2 primary baseline metrics—New York Heart Association (NYHA) cardiac function classification and the number of diseased vessels—were extracted. Furthermore, other variables such as age and sex were analyzed in the baseline data and found to have no significant differences, thus minimizing their potential influence on the results.

Other unexplored areas will be addressed in future research. We are grateful for the insightful comments provided by Zhang and Chen [2] on our article.

exergame training; Matter of Balance; MOB; pre-frail; tele-exergame; tele-rehabilitation; gaming-based; tele-exercise; physical function; frailty; older adults; aging; physical activity; dementia; CogXergaming; telehealth; dynamic balance

We are pleased to acknowledge the recent publication of the study by Kannan et al [1] in the *Journal of Medical Internet Research*. The study's findings offer valuable insights into the potential for more tailored teletherapy or support interventions for older adults, particularly in the context of rapid technological advancements in health care. Of the 50 older adults initially recruited, 31 successfully completed the full program, yielding a completion rate of approximately 60%. One of the primary reasons for withdrawal was a lack of interest in the content of the intervention. This observation raises the concern that, despite the pervasive presence of advanced technologies in modern life, certain older individuals may be effectively left behind. This phenomenon, known as the digital divide, has garnered increasing attention in recent years [2]. The digital divide refers to the disparity between individuals who have access to and the skills to use information and communication technology (ICT) and those who do not [3]. Although first recognized in the previous century, the digital divide is becoming more pronounced in the context of rapid technological advancements, particularly the frequent updates to ICT. The digital divide has a particularly profound impact on older populations, with many rapidly developing countries experiencing an increase in both the absolute and relative number of individuals affected by the digital divide [4].

In light of the rapid advances in modern medicine, how might we effectively address the digital divide in the older population? It is our contention that the older population should be permitted to transition from a position of passive recipient to that of active initiator and designer of projects. This would enable them to move from being the object of attention to becoming active problem-solvers and contributors to the development process. Before developing a teleprogram application, older adults should be engaged as co-designers, providing feedback from a problem-solving perspective. This ensures that projects are developed from their viewpoint and that they are not treated as passive recipients in the final clinical trial. It is therefore recommended that in future work building on the study by Kannan et al [1], frail older individuals be included as coresearchers in the development and refinement of the CogXergaming program. This inclusion would not only enrich the project but also enhance its generalizability and relevance to the frail older population. Furthermore, Kannan et al [1] did not perform a correlation analysis between the participants' years of education, as reported in the participant demographic characteristics, and their ability to learn effectively—an important factor in addressing the digital divide among older adults. Future studies exploring the correlation between education, learning curves, and application outcomes could provide valuable insights into overcoming the digital divide. In conclusion, CogXergaming presents a novel approach to intervention for frail, older individuals, and it will be of great

XSL•FO
RenderX

interest to explore how this intervention can contribute to bridging the digital divide among older adults.

KEYWORDS

exergame training; Matter of Balance; MOB; pre-frail; tele-exergame; tele-rehabilitation; gaming-based; tele-exercise; physical function; frailty; older adults; aging; physical activity; dementia; CogXergaming; telehealth; dynamic balance

We appreciate the insightful commentary on our study, "Gaming-Based Tele-Exercise Program to Improve Physical Function in Frail Older Adults: Feasibility Randomized Controlled Trial," published in the *Journal of Medical Internet Research* [1], in the letter by Xie [2]. The feedback highlights critical issues regarding the digital divide and the role of older adults in co-designing interventions, which are pivotal for ensuring inclusive and effective digital health solutions.

We agree that addressing the digital divide remains an ongoing challenge, particularly for frail and prefrail older populations. As noted, a lack of interest in the content was a significant contributor to attrition in our study. While we ensured technological accessibility by using familiar platforms (Zoom; Zoom Communications) and step-by-step onboarding, engagement requires more than access—it necessitates meaningful content aligned with participants' preferences and needs.

The suggestion to include older adults as co-designers in the development process is compelling and aligns with the principles of participatory design. Actively involving older adults can ensure interventions are relevant, engaging, and user-friendly. This participatory approach could facilitate a shift from a passive to an active role, empowering older adults to shape technologies that serve them. We acknowledge that future iterations of CogXergaming can benefit from such collaborative input, especially from frail individuals, to improve generalizability and user satisfaction.

Due to the nature of the commercial platforms used in our study, which were chosen for their cost-effectiveness and broad accessibility, tailoring the protocol based on participant feedback was not feasible. However, participants were provided with a choice of games to ensure some degree of personalization within the constraints of the available technology. To enhance the scalability, accessibility, and adoptability of CogXergaming interventions, future efforts should focus on developing cost-effective, customized platforms that allow for greater adaptability and responsiveness to participant preferences and needs. Such platforms could provide more tailored interventions while maintaining affordability, thus bridging gaps in engagement and accessibility.

The commentary further underscores the importance of exploring education levels and their relationship with learning curves. Although we reported participants' education in the section on demographic characteristics, we did not conduct correlation analyses with intervention outcomes. This is an important direction for future research. Investigating the

XSL•FO
RenderX

interplay between education, digital literacy, and intervention effectiveness may yield valuable insights into overcoming barriers imposed by the digital divide.

In conclusion, we appreciate the recognition of CogXergaming's potential to bridge the digital divide among older adults. Future work will focus on integrating participatory design principles, exploring the role of education in digital adoption, and refining interventions to address engagement barriers. This collective effort will contribute to more inclusive and equitable technological solutions for older adults.

(J Med Internet Res 2025;27:e71665) doi:10.2196/71665

In “Weight Loss Patterns and Outcomes Over 12 Months on a Commercial Weight Management Program (CSIRO Total Wellbeing Diet Online): Large-Community Cohort Evaluation Study” ([JMIR 2025;27(1):e65122) the authors noted several errors:

In the Methods section of the Abstract, the sentence:

> *Among members with complete data (6602/24,035, 27.5%), patterns of weight loss and gain were examined, and how this related to total weight loss was explored.*

Has been revised to:

> *Among members with complete data (6602/24,035, 27.5%), patterns of weight loss and gain were examined, and how this related to total weight loss and platform use was explored.*

In the Methods section, the following sentence:

> *This analysis focused on weight loss among longer-term members, defined as individuals who had completed at least 12 weeks of the program, had weight data recorded at baseline and approximately 12 weeks (61,514/152,895, 1.4%), and maintained a paid membership for about a year or longer.*

Has been revised to:

> *This analysis focused on weight loss among longer-term members, defined as individuals who had completed at least 12 weeks of the program, had weight data recorded at baseline and approximately 12 weeks (61,514/152,895, 40.23%), and maintained a paid membership for about a year or longer.*

Finally, in Table 2, n values have been added for the categories under the "Sex, statistic, and time point" heading. The row header "Female" has been revised to: "Female (n=19,972); the row header "Male" has been revised to: "Male (n=4063); and the row header "Total" has been revised to: "Total (n=24,035)".

The correction will appear in the online version of the paper on the JMIR Publications website on February 5, 2025, together with the publication of this correction notice. Because this was made after submission to full-text repositories, the corrected article has also been resubmitted tothose repositories.

Correction of: https://www.jmir.org/2024/1/e54941

(J Med Internet Res 2025;27:e70850) doi:10.2196/70850

In Digital Interventions for Symptoms of Borderline Personality Disorder: Systematic Review and Meta-Analysis J Med Internet Res 2024;26:e54941 there was an omission in published affiliations for one author and the Conflicts of Interest statement. We have also taken the opportunity to update the description of the medical school which has become part of the School of Medicine and Biomedical Sciences.

The affiliations for Saunders KEA were published as:

> *[1]Department of Psychiatry, University of Oxford, Oxford, United Kingdom*
>
> *[2]John Radcliffe Medical School, University of Oxford, Oxford, United Kingdom*

This has been amended to:

> *[1]Department of Psychiatry, University of Oxford, Oxford, United Kingdom*
>
> *[2]School of Medicine and Biomedical Sciences, University of Oxford, Oxford, United Kingdom*
>
> *[4]Oxford Health NHS Foundation Trust, Warneford Hospital, Oxford, United Kingdom*

The affiliation for Henning T was published as:

> *[2]John Radcliffe Medical School, University of Oxford, Oxford, United Kingdom*

This has been amended to:

> *[2]School of Medicine and Biomedical Sciences, University of Oxford, Oxford, United Kingdom*

The conflicts of interest statement were published as:

> *JABL, KEAS, and NMM received nonfinancial support from Big Health Ltd in the form of no-cost access to the digital sleep improvement program, Sleepio, for use in clinical research, outside the submitted work. KEAS is supported by the National Institute for Health Research Oxford Biomedical Research Centre based at Oxford University Hospitals National Health Service Trust and the University of Oxford. NMM is a current employee of and holds shares, restricted share units, and/or share options in Compass Pathways plc; this work is not related to Compass Pathways plc.*

This has been amended to:

> *JABL, KEAS, and NMM received nonfinancial support from Big Health Ltd in the form of no-cost access to the digital sleep improvement program, Sleepio, for use in clinical research, outside the submitted work. KEAS is supported by the National Institute of Health Research (NIHR) Oxford Health Biomedical Research Centre. Correction of: https://www.jmir.org/2024/1/e49089

(J Med Internet Res 2025;27:e72687) doi:10.2196/72687

In Examining the Effectiveness of Electronic Patient-Reported Outcomes in People With Cancer: Systematic Review and Meta-Analysis (J Med Internet Res 2024;26:e49089) the authors (notably the study statistician who conducted the analyses, Calvin Heal) noted an error in formulae used to calculate the SE of the standardized mean difference (SMD).

In the Abstract, Results, the following sections:

> *Results: The search identified 10,965 papers, of which 19 (0.17%) from 15 studies were included. The meta-analysis showed an improvement in HRQOL at 3 months, measured by the Functional Assessment of Cancer Therapy–General (SMD 0.28, 95% CI –1.22 to 1.78), and at 6 months, assessed using various HRQOL measures (SMD 0.07, 95% CI –1.24 to 1.39). The results should be interpreted with caution, given the wide 95% CIs. Of the 15 studies, 9 (60%) reported a positive signal on HRQOL, with two-thirds of the studies (n=6, 67%) including tailored patient advice and two-thirds (n=6, 67%) using clinician alert systems.*
>
> *Conclusions: The meta-analysis showed a potential improvement in HRQOL at 6 months and in Functional Assessment of Cancer Therapy–General scores at 3 months for studies that included tailored advice and clinician alerts, suggesting that these elements may improve ePRO effectiveness. The findings will provide guidance for future use and help health care professionals choose the most suitable ePRO features for their patients.*

Have been revised to:

> *Results: The search identified 10,965 papers, of which 19 (0.17%) from 15 studies were included. The meta-analysis showed an improvement in HRQOL at 3 months, measured by the Functional Assessment of Cancer Therapy–General (SMD 0.29, 95% CI 0.19 to 0.39), and at 6 months, assessed using various HRQOL measures (SMD 0.21, 95% CI 0.11 to*

XSL•FO
RenderX

0.30). Of the 15 studies, 9 (60%) reported a positive signal on HRQOL, with two-thirds of the studies (n=6, 67%) including tailored patient advice and two-thirds (n=6, 67%) using clinician alert systems.

Conclusions: The meta-analysis showed an improvement in HRQOL at 6 months and in Functional Assessment of Cancer Therapy–General scores at 3 months for studies that included tailored advice and clinician alerts, suggesting that these elements may improve ePRO effectiveness. The findings will provide guidance for future use and help health care professionals choose the most suitable ePRO features for their patients.

In the main text, in the Methods section, Data analysis, the following text:

There was no observed heterogeneity (I2=0%), but the 95% CIs were wide (95% CI 0%-64.8% and 95% CI 0%-79.2%), suggesting that the true heterogeneity could plausibly be high; therefore, random effects were chosen.

Has been revised to:

There was no observed heterogeneity (I2=0%), but the 95% CIs were wide (95% CI 0%-68% and 95% CI 0%-79%), suggesting that the true heterogeneity could plausibly be high; therefore, random effects were chosen.

In the Results section, Primary Outcome: Quality of Life, the following text:

Improvements in FACT-G scores were reported by Maguire et al [34] (SMD 4.06, 95% CI 2.65-5.46; P<.001) and Velikova et al [24,39] (SE 2.84, 95% CI 13.64-2.37; P=.006).

Has been revised to:

Improvements in FACT-G scores were reported by Maguire et al [34] (mean difference 4.06, 95% CI 2.65-5.46; P<.001) and Velikova et al [24,39] (SE 2.84, 95% CI 13.64-2.37; P=.006).

In the Results section, Meta-Analysis, the following text:

Overall, treatment at 6 months demonstrated an average small improvement (SMD 0.07, 95% CI –1.24 to 1.39), although with a wide 95% CI, suggesting that an effect in either direction is possible. There was relatively little variability in reported effect sizes, which ranged from –0.22 to 0.56, although the 95% CIs surrounding these values were often wide. Of the 15 studies, 5 (33%) were included in a meta-analysis of FACT-G scores at 3 months (Figure 3 [24,27,31,32,34]). Here too, the effect of treatment on FACT-G scores at 3 months showed a small average improvement with a wide 95% CI (SMD 0.28, 95% CI –1.22 to 1.78), again suggesting that the true effect of treatment could be positive, negative, or null.

Has been revised to:

Overall, treatment at 6 months demonstrated an average small improvement (SMD 0.21, 95% CI 0.11 to 0.30). There was relatively little variability in reported effect sizes, which ranged from 0 to 0.56, although the 95% CIs surrounding these values often crossed 0. Of the 15 studies, 5 (33%) were included in a meta-analysis of FACT-G scores at 3 months (Figure 3 [24,27,31,32,34]). Here too, the effect of treatment on FACT-G scores at 3 months showed a small average improvement (SMD 0.29, 95% CI 0.19 to 0.39).

In the Discussion section, the following text:

The meta-analysis showed an improvement in HRQOL at 6 months, although caution should be taken when interpreting the results due to the wide 95% CI. FACT-G scores at 3 months showed a small average improvement but again with a wide 95% CI. Due to the heterogeneity of the studies, specifically the different outcome measures and the different data collection time points, not all studies were included in the meta-analysis. Only 5 (33%) of the 15 studies were included in the FACT-G 3-month meta-analysis, with the weighting predominantly spread across 3 (60%) studies [27,32,34]. These 3 studies all provided advice for patients and sent reports to clinicians. Of the 15 studies, 8 (53%) were included in the HRQOL 6-month meta-analysis, with the majority of the weighting spread across 4 (50%) studies [27-29,32,35,36].

Has been revised to:

The meta-analysis showed an improvement in HRQOL at 6 months. The FACT-G scores at 3 months also showed a small average improvement. Due to the heterogeneity of the studies, specifically the different outcome measures and the different data collection time points, not all studies were included in the meta-analysis. Only 5 (33%) of the 15 studies were included in the FACT-G 3-month meta-analysis, with the weighting predominantly spread across 2 (40%) studies [27,34]. These 2 studies both provided advice for patients and sent reports to clinicians. Of the 15 studies, 8 (53%) were included in the HRQOL 6-month meta-analysis, with the majority of the weighting spread across 3 (38%) studies [27,28,34].

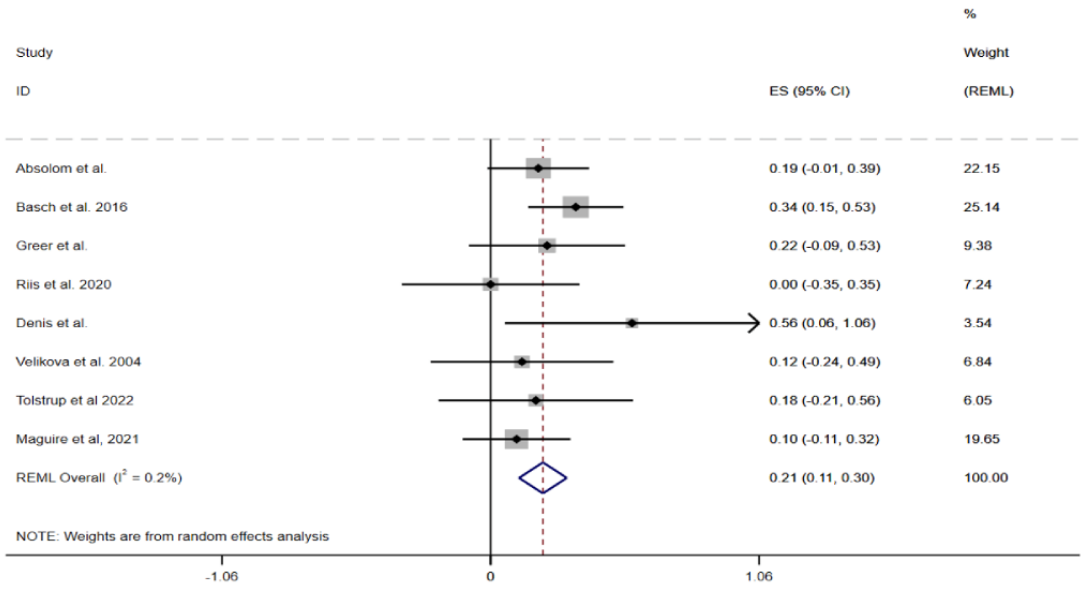
In Conclusions, the following text:

In total, 19 papers of 15 RCTs were identified. Nearly two-thirds (9/15, 67%) of the interventions showed positive effects on HRQOL and symptoms in adults with cancer. However, caution should be taken in interpreting the results of this review due to the heterogeneity in the interventions, outcome measures, and data collection time points, as well as the wide 95% CIs...

Has been revised to:

In total, 19 papers of 15 RCTs were identified. Nearly two-thirds (9/15, 60%) of the interventions showed

XSL•FO
RenderX



positive effects on HRQOL and symptoms in adults with cancer. However, caution should be taken in interpreting the results of this review due to the heterogeneity in the interventions, outcome measures, and data collection time points

Also, Figures 2 and 3 have been revised to the following:

Abstract

Background: Previous studies on public compliance with policies during pandemics have primarily explained it from the perspectives of motivation theory, focusing on normative motivation (trust in policy-making institutions) and calculative motivation (fear of contracting the disease). However, the social amplification of a risk framework highlights that the media plays a key role in this process.

Objective: This study aims to integrate the motivation theory of compliance behavior and the social amplification of risk framework to uncover the "black boxes" of the mechanisms by which normative motivation and calculative motivation influence public policy compliance behavior through the use of media.

Methods: During the COVID-19 pandemic, we conducted a web-based survey of 2309 Chinese citizens from December 4, 2022, to March 21, 2023. We treated the public's policy compliance behavior during the pandemic as the dependent variable. Media use, specifically the use of authoritative media and "we-media," that is, personal social media accounts and media platforms operated by individuals, was set as the independent variable. Trust in government, representing normative motivation, and risk perception, representing calculative motivation, were included as mediating variables. A structural equation model was constructed and analyzed using Stata.

Results: First, the mediation effect of trust in government indicates that the use of authoritative media can enhance trust in government, which significantly increases individuals' policy compliance behavior (β coefficient=0.108, 95% CI 0.080-0.135; *P*<.001). Second, the mediation effect of risk perception shows that the use of we-media heightened individual risk perception, thereby significantly enhancing policy compliance behavior (β coefficient=0.012, 95% CI 0.002-0.021; *P*=.02). Third, the study revealed the "paradox of trust": the chain mediation effect in which authoritative media increased trust in government and reduced risk perception, ultimately decreasing policy compliance behavior (β coefficient=–0.005, 95% CI –0.009 to –0.001; *P*=.008).

Conclusions: By combining the motivation theory of compliance behavior with the social amplification of risk framework in risk communication, we found that trust in government, as a normative motivation, operates through authoritative media, while risk perception, as a calculative motivation, promotes compliance behavior through we-media. In addition, in major crises, the public's use of authoritative media can lead to the paradox of trust: on the one hand, trust in the government increases policy compliance; on the other hand, this trust reduces risk perception, thereby decreasing compliance behavior. Authoritative institutions need to balance providing authoritative information with maintaining the public's risk perception.

Introduction

Background

During the early stages of the COVID-19 pandemic, the Chinese government implemented strict control measures, such as mask-wearing mandates, compulsory nucleic acid testing, and vaccination programs, which effectively curbed the spread of the virus. However, in late December 2022, the government relaxed these stringent policies. Established experience has highlighted the importance of public compliance with health policies in containing the virus [1,2]. It is perhaps more crucial to increase citizens' willingness to comply with proactive prevention policies than to formulate these policies [3]. If citizens do not adequately follow epidemic control measures, governmental efforts may be wasted [4]. Current research on compliance with public health policies mainly adopts 2 perspectives from motivation theory. The normative motivation perspective emphasizes that trust in policy-making institutions helps increase citizens' willingness to adhere to public health interventions [5], whereas the calculative motivation perspective argues that compliance behavior stems from the fear of contracting the disease [1,6].

During a pandemic, the public is in a state of "information hunger" and often actively seeks various sources of information to fill their "information vacuum" [7]. The role of information disseminated through different media in shaping psychological processes and individual behaviors has been widely studied across various fields [8-11]. The social amplification of risk framework (SARF) emphasizes that social media, as well as traditional print and broadcast news media, can serve as "social amplification stations," shaping the public's risk perception [12]. Within this framework, countries have used diverse media to promote the importance and urgency of COVID-19 prevention measures, such as vaccine administration, mask-wearing mandates, and home isolation [13,14]. Therefore, understanding the crucial role of different media in promoting policy compliance should be a key focus for future research [15].

The significance of this study lies in the following. This study was conducted during the COVID-19 pandemic, a unique context that holds substantial research value. Media usage habits and their behavioral outcomes often shift due to the specificity of the situation, making conclusions drawn from general social contexts not necessarily applicable to pandemic scenarios [16]. The COVID-19 pandemic provides a distinctive natural experimental condition for investigating the role of media in public health emergencies, offering deeper insights into the dynamic mechanisms of media in risk communication and behavioral influence compared to studies conducted in general social contexts.

The innovation of this paper lies in several key aspects. In the past, authoritative media often played the primary role of information disseminators and communicators. However, with the rise of the internet and "we-media," that is, personal social media accounts and media platforms operated by individuals, this traditional model is gradually being disrupted. Unlike previous studies on risk communication effects that generally lacked attention to media diversity [6] or those that separately explored the effects of risk perception and trust in government on policy compliance behavior [17,18], we conducted a more in-depth and comprehensive exploration. Specifically, we categorized media into authoritative media and we-media and incorporated them, along with trust in government (representing normative motivation) and risk perception (representing calculative motivation), into a structural equation model (SEM) for analysis. This approach allows us to unveil the "black boxes" of how trust in government and risk perception operate between the use of different media and public policy compliance behavior, thereby providing a more comprehensive investigation of how various media influence public compliance with health policies. This multidimensional analysis not only enriches existing research perspectives but also offers more precise and effective guidance for potential public health crises in the future.

Literature Review

Motivational Perspectives on Compliance Behavior

Overview

Previous research on compliance with public health policies during pandemics primarily explains behavior from the perspectives of normative motivation and calculative motivation within motivation theory [1,3]. Normative motivation focuses on individuals' intrinsic adherence to social responsibility and moral norms [19], while calculative motivation emphasizes individuals' cost-benefit analysis during decision-making [20]. Although these 2 motivations largely explain public behavior, in practice, they often intertwine and collectively influence individuals' compliance decisions.

Normative Motivation: The Role of Trust in Government

Normative motivation involves the internal moral beliefs, values, and social norms that guide individual behavior, primarily stemming from trust in the government [17,21], a sense of social responsibility [1], social interaction [20], and social and peer pressure [19].

The characteristics of trust in government, such as policy legitimacy and institutional trust, are key sources of individuals' normative motivations [22]. China effectively curtailed the pandemic through "rapid and decisive" prevention measures, which enhanced public trust in the government [23]. Strong trust in government facilitates public compliance with government policies and the implementation of these policies [5]. The positive effect of trust in government on policy compliance has been demonstrated not only in China but also in Italy, where research indicates that during the COVID-19 pandemic, regions with high trust in the government saw the public actively responding to government calls and reducing their outdoor activities [24]. In addition, a study in Sweden found that higher public trust in the government correlated with greater self-efficacy, leading individuals to be more inclined to follow government strategies for managing public health risks, thereby also helping to mitigate the pandemic [21]. Increased public trust in government can substantially enhance the effectiveness of governmental management during a pandemic, ensuring smooth policy implementation [25,26]. Some studies have found a negative correlation between government trust and compliance behavior, a phenomenon referred to as the

XSL•FO
RenderX

"paradox of trust." Three theoretical frameworks can be identified within this discourse: the "chain reaction of confidence," the "paradox of support," and the "paradox of confidence" [27]. Furthermore, a "trust, confidence, and cooperation" model has been proposed in the context of risk management [28].

With regard to the COVID-19 pandemic, the basic premise of the trust paradox is that the pandemic is viewed as a source of psychological stress, with trust serving as a psychological defense mechanism that can mitigate the complexities and uncertainties often present during a crisis [27,29,30]. Consequently, public trust in the government's ability to manage the pandemic may lead to a reduction in individual protective behaviors because individuals perceive the government's measures to be sufficient, thereby decreasing their motivation to take additional protective actions [31]. Research has also indicated that in environments where public trust in government is low, individuals may feel a stronger need to engage in personal protective behaviors to alleviate their fear, which can, in turn, enhance support for pandemic containment efforts [32]. These varying manifestations of the paradox of trust profoundly reveal the multidimensional complexity of the relationship between trust and compliance behavior. This finding underscores the necessity for more in-depth exploration in this field. Therefore, this study further analyzes the intrinsic mechanisms underlying the complex relationship between trust and compliance behavior, aiming to provide richer theoretical support and empirical evidence for research in this area.

Calculative Motivation: The Impact of Risk Perception

Unlike normative motivation, which focuses on individuals' intrinsic moral beliefs, calculative motivation emphasizes individuals' weighing and evaluation of the consequences of their actions. Within this theoretical framework, prospect theory, deterrence theory, and protection motivation theory are particularly emphasized. Prospect theory reveals that people are influenced by psychological biases, making them likely to take decisions based on the similarity of events to known samples and the availability of relevant information in memory [33]. Deterrence theory posits that strict policies and enforcement will enhance the public's motivation to comply with policies [34]. Protection motivation theory suggests that high levels of risk perception can influence the public's intention to take protective measures [35]. This study mainly uses risk perception as an entry point to investigate public compliance with policies.

Protective motivation theory offers a valuable framework for understanding public policy compliance behavior during pandemics. Within this theory, risk perception refers to people's subjective judgment of the characteristics and severity of a specific risk, which is the initial reaction individuals have when a crisis occurs [36]. The consequences of risks can directly impact the morbidity and mortality rates of populations considered vulnerable. Although risk perception can have negative effects, such as causing social panic and increasing the costs of government-public cooperation [37], many studies have pointed out that risk perception can also produce positive effects. Risk perception plays a critical role in crisis disasters and in encouraging citizens to cooperate with government preventive and mitigation measures [38]. The positive relationship between government intervention and disaster prevention and control is built on the public's active cooperation with government interventions [37,39]. Specifically, in the context of epidemic spread, studies have found that lower COVID-19 risk perception is associated with lower compliance with social distancing measures [18]. Therefore, public awareness of risk is a key factor in promoting compliance with protective behaviors.

Differences in Media Use During Pandemics

Overview

Traditional communication theories assert that risks and risk events primarily flow through 2 main communication networks: the news media and interpersonal communication networks [12]. During a pandemic, the public relies on various media to stay updated on the latest developments and necessary self-protection measures [40-42]. Among these media, television news, newspapers, and official news websites became the primary sources for the public to obtain information related to the COVID-19 pandemic. Simultaneously, social media platforms such as Facebook and Twitter (subsequently rebranded as X) were widely used by the public for information due to their convenience and interactivity [16,31,43,44]. Research shows that traditional (authoritative) media tend to support government and official viewpoints, paying little attention to the dissemination of differing opinions and often providing a less polarized view of events. By contrast, emerging we-media platforms, characterized by multiple topics and platforms, diverse themes, and varying perspectives, facilitate the easy spread of extremist viewpoints [45]. This study, combining its unique characteristics with existing literature [45-47], categorizes the former as authoritative media (also known as mass media or traditional media) and the latter as we-media (also known as new media or online media). This classification can help us better understand the characteristics and patterns of information dissemination and formulate more precise and effective information communication strategies.

Authoritative Media

The official websites of governments and authoritative institutions are considered the primary sources of authoritative information for the public, acting as the main media that directly affect the public's risk perception [48,49]. Official media often use expert opinions to enhance their authority and persuade the public, using methods such as framing effects or agenda setting. These media primarily operate on a "we-publish-you-read" model [50]. Authoritative media typically provide the latest policy updates, professional guidance, and important announcements, making them crucial channels for the public to obtain reliable information [51]. With their long-established "opinion guidance" capabilities, they gain public recognition and trust [52]. These authoritative media are responsible for providing accurate, unbiased, and reliable information and preventing the spread of misinformation [46,53].

XSL•FO
RenderX

We-Media

The rapid development and widespread adoption of the internet have ushered users into a brand new era of we-media. In this we-media age, all users have a microphone and function as both creators and disseminators of public opinion [54,55]. On the one hand, the we-media formed by family and friends provide references for verifying viewpoints. In a broad sense, this involves sharing passed-on perspectives, which can either amplify or diminish the information [12]. On the other hand, we-media represented by social media platforms such as TikTok offer more personalized content. These platforms use algorithms to recommend relevant content to users and have more interaction-enabled features, allowing users to participate in content creation and discussion. Research has shown that social media played a substantial role in spreading misinformation about COVID-19 [56,57]. Misinformation can lead the public to doubt the severity of a pandemic and the effectiveness of prevention measures, thereby reducing the likelihood of following these measures [18,46].

Theoretical Model and Hypotheses

On the basis of the reviewed literature, we constructed a theoretical model that includes the use of media, normative motivation, and calculative motivation related to compliance with public health policies. Specifically, we propose 3 hypotheses and corresponding supplementary hypotheses to examine the process by which the public's use of authoritative media and we-media influences individual policy compliance behavior through trust in government and risk perception.

Research on COVID-19 has found that authoritative media serve as an important channel for the public to obtain reliable information [51], while we-media are characterized by greater diversification and personalization [16,45]. Moreover, the public's trust in government can have varying effects on policy compliance behavior [17,31]. On the basis of the characteristics of authoritative media and we-media, we propose the following hypotheses:

- H1a: The use of authoritative media enhances individual policy compliance behavior by increasing trust in government.
- H1b: The use of we-media decreases individual policy compliance behavior by lowering trust in government.

Kasperson et al [12] proposed the SARF, which suggests that the media can act as "social amplification stations," amplifying or attenuating the public's risk perception. Protective awareness, stakeholder engagement, and risk awareness can positively influence individuals to take protective measures, with risk perception playing a partial mediating role [58]. Therefore, we propose the following hypotheses:

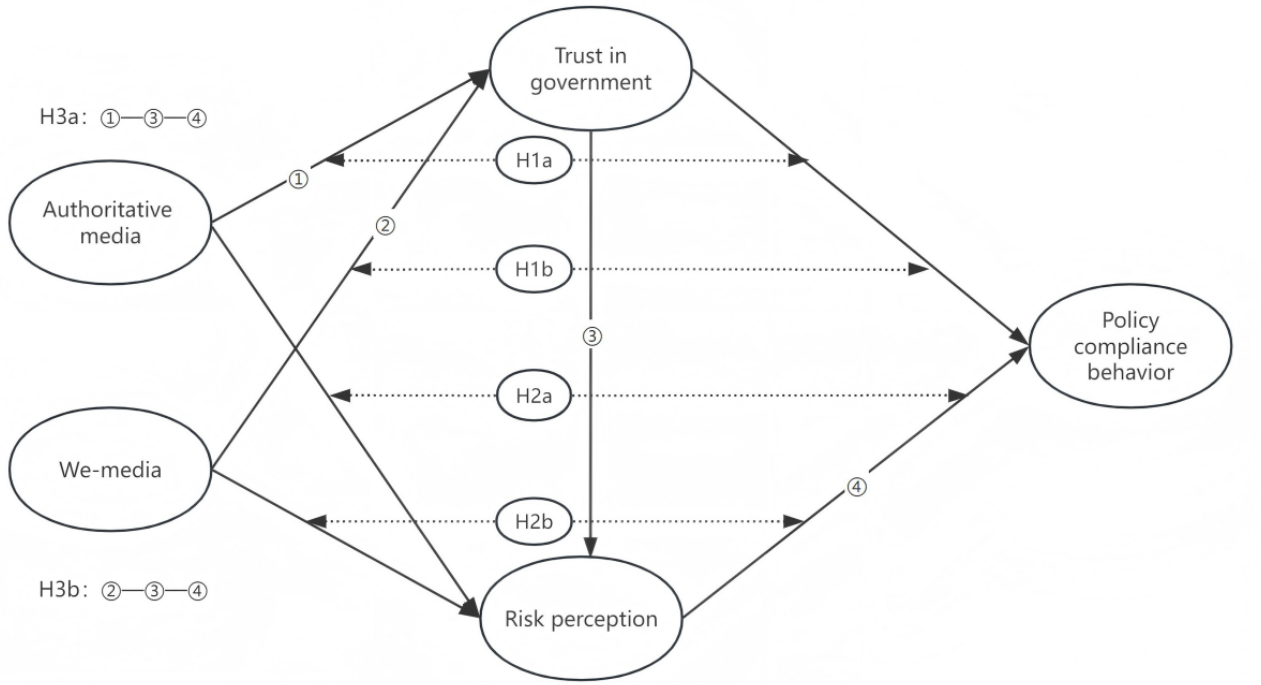
- H2a: The use of authoritative media decreases individual policy compliance behavior by lowering risk perception.
- H2b: The use of we-media increases individual policy compliance behavior by raising risk perception.

Finally, we believe that there is a chain mediation effect of trust in government and risk perception between media use and policy compliance behavior. Members of the public exposed to authoritative media are more likely to trust the government [59]. While some studies found that the use of we-media affects individuals' trust in government [59,60], others found no effect [61]. Moreover, previous studies have found that public trust in government can lower risk perception, leading to reduced compliance with policies [31]. In addition, in environments with low government trust, the public may show greater support for pandemic containment measures [32]. These varying phenomena highlight the "paradox of trust," suggesting the need for further exploration of the complex relationship between government trust and policy compliance.

Consequently, this study constructs a dual mediation model aimed at revealing how different media influence risk perception through trust in government, ultimately shaping attitudes toward policy compliance. Building on prior research, we propose the following hypothesis:

- H3a: The use of authoritative media positively influences trust in government, prompting risk perception to negatively affect policy compliance behavior.

Furthermore, we posit that due to the diversity and personalized content of we-media, the use of we-media may lower public trust in the government, thereby affecting risk perception from a dual perspective, subtly influencing individual policy compliance behavior. Thus, we propose another innovative hypothesis:



- H3b: The use of we-media negatively impacts trust in government, resulting in a positive effect of risk perception on policy compliance behavior.

Interestingly, the "paradox of trust" previously revealed in studies could be triggered if either hypothesis H3a is validated, indicating that the use of authoritative media indeed enhances government trust and leads to a negative influence of risk perception on policy compliance behavior, or hypothesis H3b holds true, suggesting that the use of we-media weakens government trust as anticipated, resulting in a positive influence of risk perception on policy compliance behavior. This phenomenon is not only thought provoking but also ignites our enthusiasm and expectation for exploration and validation.

On the basis of the hypotheses proposed based on the aforementioned theoretical framework, we constructed the theoretical model diagram shown in Figure 1.

XSL•FO
RenderX

Figure 1. Hypothetical model of the theory.

Methods

Data Collection

This study used purposive sampling and snowball sampling methods to collect samples through web-based surveys, with the sample collection period spanning from December 4, 2022, to March 21, 2023. During the questionnaire design phase, we used the professional platform Wenjuanwang to construct the questionnaire framework. To ensure the accuracy and clarity of the questionnaire items, we conducted an extensive literature review and consulted experts from relevant fields. Building on this foundation, we drafted the initial content of the questionnaire.

Subsequently, to further optimize the questionnaire, we conducted a small-scale pilot survey to evaluate the feasibility of the questionnaire items and assess respondents' understanding. On the basis of the pilot survey results, we made necessary adjustments and finalized the questionnaire version. We then promoted the survey through advertisements on social media platforms, specifically WeChat, and recruited participants via web-based snowball sampling. Although the response rate for web-based sample surveys can be low, web-based surveys proved to be a feasible method for conducting research during the pandemic when social distancing and epidemic prevention measures were in place because they are accessible via smart devices and do not have location constraints.

In total, we collected 3690 completed questionnaires. After completing the data cleaning process, we conducted a common method bias (CMB) test to ensure the validity of the data collection. The detection of CMB typically involves exploratory factor analysis (EFA) and the Harman single-factor test. If the first unrotated common factor accounts for >50% of the variance, it may indicate the presence of CMB. The results of our EFA revealed that the variance explained by the first common factor was 23.9%, thereby rejecting the null hypothesis of the Harman single-factor test and indicating that there was no CMB.

Statistical Methods

After completing the data collection, we used Stata (version 16; StataCorp LLC) to perform statistical analysis. First, the basic characteristics of the data were described, followed by the construction of an SEM. The model aimed to explore the relationship between public media use and adherence to public health policies in depth.

Variable Measurement

The questionnaire included items on policy compliance behavior, media use, trust in government, and risk perception, using a 5-point Likert scale for the responses. It also included demographic questions about the respondents' gender, education level, residence type, and annual family income (refer to the Results section for details).

Policy Compliance Behavior

The study used policy compliance behavior as the dependent variable. On the basis of the protection guidelines issued by the National Health Commission of China in August 2021 and existing research [6,62], the questionnaire asked respondents, "How frequently do you follow the following personal protective measures in your daily life?" This question evaluated 4 measures: wearing a mask, washing hands, maintaining a 1-meter distance in public places, and getting vaccinated. Responses ranged from 1=*never* to 5=*always*.

Media Use

The study used "media use" as the independent variable. Information from authoritative media typically has official and

XSL•FO
RenderX

authoritative endorsement from the government, whereas we-media contain more diverse and liberal content. Referring to existing literature [10,46], the questionnaire asked respondents, "How frequently do you use the following media to obtain information in your daily life?" This question assessed the frequency of using various media, including government television news, business websites and news apps (eg, Sina Weibo), health agency websites (eg, expert sources), family and friends, short video apps (eg, TikTok), and social media (eg, QQ and WeChat). Responses ranged from 1=*never* to 5=*always*.

We conducted an EFA on media use (refer to the Results section for details).

Trust in Government

The study used trust in government and risk perception as mediating variables. Trust in government refers to government credibility [63]. When government credibility is high and recognized by the public, the trust in the government or system increases [64]. Therefore, the study referred to the measurement methods of government credibility by Grimmelikhuijsen and Meijer [65] and Ma and Sun [66], combined with the characteristics of Chinese public trust in the government, to measure trust in government by evaluating public satisfaction with specific government actions. The measures included "Your satisfaction with the transparency of government information" and "Your satisfaction with the timeliness of government information disclosure." These indicators capture the public's direct perceptions of the government's ability to disclose information, thereby indirectly reflecting their overall evaluation of government credibility. Scores ranged from 1=*very dissatisfied* to 5=*very satisfied*.

Risk Perception

The measurement indicators for risk perception typically include the severity of the event and its impact scope, with items such as "this event is very severe" and "the impact of this event is very broad" [67,68]. However, during a large-scale crisis, the impact on socioeconomic and personal daily life is especially substantial, making it difficult to accurately measure the heterogeneity of individual risk perception based solely on event severity and impact scope. Therefore, we drew on the research by Zhu et al [69], which uses the direct consequence of risk perception—a sense of security—to measure the cognitive level of risk. The questionnaire asked, "What is the source of your insecurity?" The options included fear of self or family members becoming infected, concern about the lack of material security, worry about employment issues during the public health crisis, and fear of being locked down or quarantined. Respondents rated their concerns from 1=*not worried at all* to 5=*very worried*.

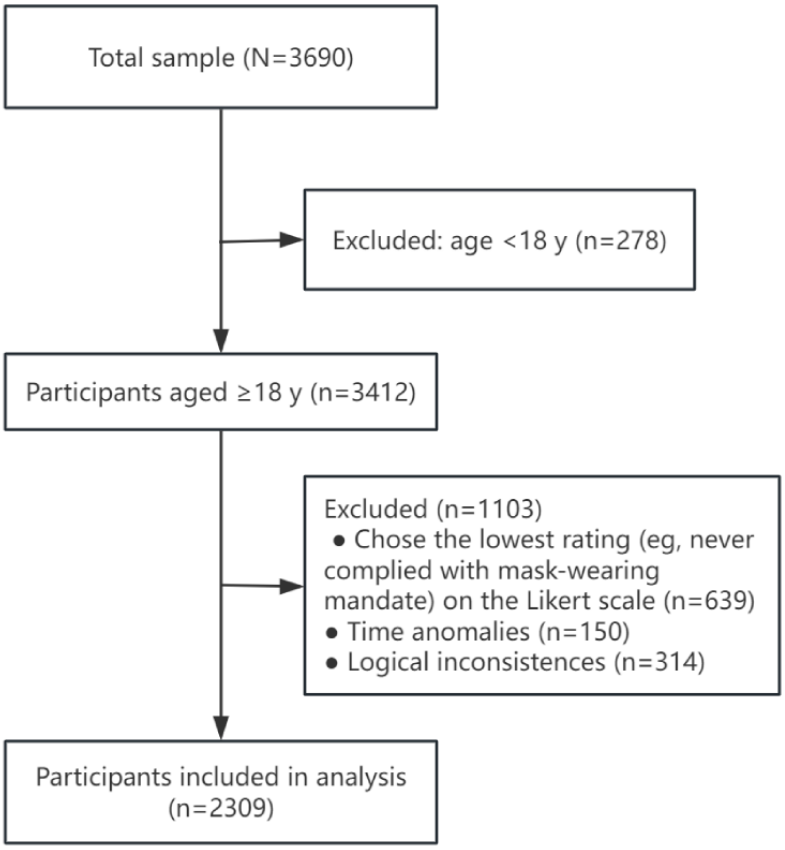
EFA and Reliability and Validity Testing

We conducted EFA using Stata. As policy compliance behavior, risk perception, and trust in government were measured using well-established scales from previous research, only media use underwent EFA. The initial factors were rotated using the Kaiser normalized maximum variance method. On the basis of the EFA results, we labeled factor 1 as "authoritative media use" and factor 2 as "we-media use."

Further confirmatory factor analysis was conducted on each dimension of the scale. The fit indices for the measurement model were as follows: χ^2_{94}=674.1; P<.001; root mean square error of approximation=0.052; comparative fit index=0.961; Tucker-Lewis index=0.950; standardized root mean square residual=0.033; this indicated good overall model fit, supporting the validity and reliability of the measurement results. The Cronbach α values for each dimension of the scale ranged from 0.70 to 0.93, all exceeding the 0.55 threshold commonly used in social science research, and the overall Kaiser-Meyer-Olkin measure of sampling adequacy was 0.77. Factor loadings for each item ranged from 0.48 to 0.95, suggesting moderate to strong associations between the measured items and their respective latent factors. According to Stevens [70], a factor loading of 0.40 is sufficient for explanatory purposes, even with varying sample sizes. Furthermore, Steenkamp and Maydeu-Olivares [71] found that lower factor loadings can still be explanatory, particularly in cases of smaller sample sizes or more complex object of study.

Ethical Considerations

All participants in this study provided informed consent. The study was approved by the Science Ethics and Safety Committee of Guangxi University for Nationalities (Protocol Number: 202410608021). All procedures conducted during the study strictly adhered to the ethical principles outlined in the Declaration of Helsinki (2013).



Results

Data Cleaning Process

We collected 3690 completed questionnaires in total. We used a dual review process to check data quality, focusing on outliers and logical inconsistencies. After cleaning the data, from the 3690 completed questionnaires, we ultimately obtained 2309 (62.57%) valid questionnaires. The flowchart of the data cleaning process is shown in Figure 2.

XSL•FO
RenderX

Figure 2. Flowchart of the data cleaning process.

EFA Results

The EFA results showed that the 6 items of media use were extracted into 2 factors. The items "government television news," "business websites and news apps," and "health agency websites" had higher loadings on factor 1, while "social media," "short video apps," and "family and friends" had higher loadings on factor 2 (Table 1). On the basis of existing literature [45-47] and the EFA results, we labeled factor 1 as "authoritative media use" and factor 2 as "we-media use."

Table 1. Results of exploratory factor analysis.

Variable items	Factor 1	Factor 2
Government television news	*0.6396* [a]	0.2452
Business websites and news apps (eg, Sina Weibo)	*0.6725*	0.2942
Health agency websites (eg, expert sources)	*0.4419*	0.2274
Short video apps (eg, TikTok)	0.2817	*0.5995*
Social media (eg, QQ and WeChat)	0.2828	*0.6426*
Family and friends	0.2732	*0.4293*

[a]Higher loadings are indicated in italics.

Descriptive Statistics

The survey questionnaire included items on policy compliance behavior, media use, trust in government, and risk perception. Participants rated their responses on a Likert scale ranging from 1 to 5 (Table 2). The questionnaire also included demographic questions (Table 3).

XSL•FO
RenderX

Table 2. Descriptive statistics of variables: survey questionnaire responses rated on a 5-point Likert scale (n=2309).

Variables and categories	Scores, mean (SD; SE)
Policy compliance behavior	
Wear a mask	4.38 (0.77; 0.01)
Wash hands	4.41 (0.72; 0.01)
Keep distance	3.98 (0.96; 0.01)
Vaccinate	4.65 (0.67; 0.02)
Authoritative media use[b]

Estimation of Fit Indices

Before conducting hypothesis testing, we used Stata to estimate the fit indices for the SEM. The results demonstrated satisfactory model fit (χ^2_{96}=722.3; *P*<.001; root mean square error of approximation=0.053; comparative fit index=0.958; Tucker-Lewis index=0.947; standardized root mean square residual=0.045). These findings indicate that the model meets acceptable standards and effectively fits the sample data without necessitating adjustments or respecification of the original model. Figure 3 presents the SEM along with its associated path coefficients (error terms for all endogenous variables are assumed but not depicted in Figure 3).

Figure 3. Structural equation model and path coefficient diagram. The solid lines indicate significant paths, while dashed lines indicate nonsignificant paths. ***P*<.01, ****P*<.001.

Intermediate Path Test Results

Trust in government plays a significant positive mediating role in the path "authoritative media use→trust in government→policy compliance behavior" (β coefficient=0.108, 95% CI 0.080-0.135; *P*<.001; Table 4). The use of authoritative media effectively enhances public trust in the government, leading to increased compliance with policies. Therefore, H1a is supported. In the path "we-media use→trust in government→policy compliance behavior," although the path coefficient is positive, the mediating effect does not reach statistical significance (β coefficient=0.021, 95% CI –0.001 to 0.044; *P*=.07). We-media use does not substantially affect public trust in the government, thus having no substantial impact on policy compliance behavior. Therefore, H1b is not supported.

Table 4. Intermediate path test results.

Paths	β coefficient (SE; 95% CI)	Critical ratio	*P* value
Authoritative media use→trust in government→policy compliance behavior	0.108 (0.014; 0.080 to 0.135)	7.70	<.001
We-media use→trust in government→policy compliance behavior	0.021 (0.012; –0.001 to 0.044)	1.84	.07
Authoritative media use→risk perception—policy compliance behavior	–0.001 (0.003; –0.007 to 0.005)	–0.36	.72
We-media use→risk perception—policy compliance behavior	0.012 (0.005; 0.002 to 0.021)	2.35	.02
Authoritative media use→trust in government→risk perception→policy compliance behavior	–0.005 (0.002; –0.009 to –0.001)	–2.64	.008
We-media use→trust in government→risk perception→policy compliance behavior	–0.001 (0.001; –0.002 to 0.000)	–1.52	.13
Authoritative media use→trust in governments→risk perception	–0.071 (0.012; –0.093 to –0.048)	–6.09	<.001
We-media use→trust in governments→risk perception	–0.014 (0.008; –0.030 to 0.001)	–1.78	.08

The path coefficient of risk perception between authoritative media use and policy compliance behavior is negative, but the mediating effect does not reach statistical significance (β coefficient=–0.001, 95% CI –0.007 to 0.005; *P*=.72). Authoritative media use does not significantly affect public trust in the government, resulting in no significant impact on policy compliance behavior. Thus, H2a is not supported. By contrast, the path "we-media use→risk perception→policy compliance behavior" is statistically significant and positive (β coefficient=0.012, 95% CI 0.002-0.021; *P*=.02). It shows that the public's use of we-media enhances risk perception, promoting compliance with policies. Therefore, H2b is supported.

The chain mediation path "authoritative media use→trust in government→risk perception→policy compliance behavior" shows a significant chain mediation effect (β coefficient=–0.005, 95% CI –0.009 to –0.001; *P*=.008). Authoritative media use increases trust in government, which in turn reduces risk perception, ultimately leading to decreased individual policy compliance behavior, reflecting the phenomenon of the "paradox of trust." Thus, H3a is supported. By contrast, the chain mediation effect for the path "we-media use→trust in government→risk perception→policy compliance behavior" has a negative path coefficient, but it does not reach statistical significance (β coefficient=–0.001, 95% CI –0.002 to 0.000; *P*=.13). Therefore, H3b is not supported.

Discussion

Overview

This study integrates motivation theory and the SARF to examine the impact of media use on public policy compliance behavior during a pandemic. The research aims to reveal the roles of different media in influencing public behavior and the changes in their effectiveness. The results indicate that the public's use of authoritative media promotes policy compliance behavior by increasing trust in government. By contrast, the use of we-media can indirectly affect individual policy compliance behavior by influencing individual risk perception. The findings also reveal that trust in government and risk perception serve as chain mediators between the use of authoritative media and policy compliance behavior, validating the phenomenon of the paradox of trust.

Specifically, we identified mediating variables that affect individual policy compliance behavior as a result of media use, leading to differences in individual attitudes toward compliance with epidemic prevention policies. This study uncovers the specific mechanisms, or the "black boxes," through which trust in government and risk perception mediate the relationship between media use and individual policy compliance behavior.

"Black Box 1": Normative Motivation (the Bridging Power of Trust in Government)

The study found that trust in government has a substantial mediating effect between the public's use of authoritative media and policy compliance behavior. However, we-media has no substantial impact on trust in government.

Authoritative media disseminate truthful and objective information, which enhances trust in government [60], thereby increasing the public's willingness to comply with policies [24,72]. Specifically, authoritative media typically communicate key information such as prevention measures and response strategies with high consistency and clarity. This clear and consistent risk information fills the "information vacuum" caused by the public's cognitive limitations [7], effectively alleviating information asymmetry. When the public's need for risk information is satisfied, it fosters a stronger sense of trust in government policies.

In China, policy implementation follows a top-down approach [5], making positive policy perception and trust in the

XSL•FO
RenderX

government crucial for individuals to comply with antiepidemic measures and achieve policy effectiveness [26,37]. Looking at examples from different cultural contexts, Swedish citizens exhibit a high level of trust in their government, which makes them more likely to adhere to strategies for managing public health crises, contributing to relatively effective pandemic control [21]. Similarly, studies from Italy indicate that higher levels of trust in government encourage the public to respond more actively to government appeals, resulting in reduced mobility during the pandemic [24]. Therefore, the enhancement of public trust in government can further strengthen the role of authoritative media in promoting individual policy compliance behavior.

The study found that we-media do not substantially influence trust in government, which aligns with previous research [61]. The diverse, emotional, and personalized nature of information on we-media may not be entirely reliable or consistent [16,45]. Furthermore, the decentralized nature of we-media, the rapid cross-regional dissemination of content, and low interpersonal communication costs, combined with limited fact-checking time, increase the likelihood of the spread of false or unverified content [56,57]. This complexity of information may lead to ambiguous or divergent impacts on public trust in government, resulting in we-media not having a substantial effect on trust in government.

"Black Box 2": Calculative Motivation (the Impact of Risk Perception)

The study found that the use of we-media can increase the public's risk perception of diseases, indirectly promoting public policy compliance behavior, consistent with previous research [46]. The results also reveal that the use of authoritative media does not substantially impact individual risk perception.

The public processes risk information obtained through we-media, forming a sense of the significance of the risk, which in turn influences individual risk perception [73]. However, we-media (eg, TikTok and Twitter) may be subject to looser regulation in certain situations, and their accountability mechanisms may not be as robust as those of authoritative media [11]. This increases the likelihood of the rapid spread of misinformation, which may have elevated the public's risk assessment of the pandemic, thereby further influencing their attitudes toward, and compliance with, antipandemic policies [16]. In addition, the study found that the use of authoritative media does not directly affect individual risk perception, differing from previous research [16]. This may be because, in the Chinese context, authoritative media typically emphasize the accuracy and official nature of information, while during major public health crises, the public may prioritize immediacy and highly perceived risk signals, which are often more easily transmitted through we-media. The information conveyed by authoritative media might be perceived by the public as "official responses" rather than direct threats, thus failing to effectively enhance individual risk perception.

The existence of a mediating effect of risk perception indicates the social amplification of risk by we-media, which can qualitatively and quantitatively amplify signals related to risks, enhance risk perception and risk-related behaviors, and intensify the risks and their consequences [12]. Therefore, the quality and accuracy of information dissemination are crucial for public health, and misleading or inaccurate information can lead to incorrect assessments of risk, subsequently affecting individuals' policy compliance behavior.

The Paradox of Trust

The research results indicate that the use of authoritative media does indeed enhance public trust in government, subsequently lowering risk perception and leading to reduced policy compliance behavior, thereby illustrating the paradox of trust. However, we-media has no substantial impact on trust in government.

If the government can implement effective pandemic management strategies and achieve results, people will trust the government's ability to handle public crises, thereby strengthening its management effectiveness in dealing with pandemics [25,26]. However, there is a complex relationship between public trust in government and individual risk perception. Increased trust in government leading to reduced risk perception may decrease public compliance with preventive policies. If people perceive the risk to be low, they might not feel the need to strictly follow prevention measures such as wearing masks and maintaining social distance [31]. A study on the COVID-19 pandemic in Italy showed that when the public was exposed to authoritative information, their trust in the government increased, but their risk perception decreased, thus reducing their likelihood of complying with preventive policies. This could be because confidence in government institutions can alleviate pandemic-related stress. When people have higher trust in their government, they believe that sufficient measures have been taken to protect them, and they might think it is unnecessary to take personal actions to avoid infection and limit the spread of the virus during a pandemic [27]. The paradox of trust has conflicting effects on policy compliance behavior. The public's willingness to cooperate is influenced by both their trust in the government and their perceived level of risk. In addition, as mentioned previously, the diversity and complexity of we-media content may lead to confusion and misunderstandings among the public when receiving information, making it difficult to form a consistent view of trust in the government. This uncertainty in the information received may further undermine the role of we-media in shaping trust in government.

Limitations

The study primarily relied on cross-sectional data, which, while able to describe public psychology and policy compliance behaviors during the data collection period, were limited. The varying stages of the pandemic, changes in government measures, and shifts in public sentiment make trust in policies a dynamic process. Cross-sectional data often fail to capture the lag effects, cumulative impacts, or long-term trends of public health policy outcomes. Future research should consider the long-term effects of dynamic changes in a pandemic on trust and compliance behavior.

Moreover, the limitations of self-reported data, such as social desirability bias and recall bias, may affect respondents' accurate

XSL•FO
RenderX

description of compliance behaviors. Future studies could use more objective measurement methods, such as actual behavior tracking or observational data, to enhance data accuracy. Furthermore, policy compliance behavior is influenced by various factors, including political ideology, media literacy, policy implementation effectiveness, and social opinion, which also warrant further investigation. Subsequent research could introduce these variables to enrich the theoretical framework and test their applicability in different social contexts.

Conclusions

The study identified the mechanisms through which the use of different media influences policy compliance behavior during a pandemic, as well as the phenomenon of the paradox of trust. Public policy compliance behavior is driven by both normative and calculative motivations. These motivations each tend to rely on different sources of information when guiding public behavior. *Normative motivation* emphasizes individual adherence to social norms, with behavior decisions driven by this motivation being more influenced by authoritative media. Information released by the government, public health agencies, and authoritative media, due to its authority, accuracy, and comprehensiveness, becomes an important benchmark for the public to judge the correctness of their actions. Through the dissemination of authoritative information, public health departments can guide the public to form correct perceptions, enhance trust in the government, and thereby promote policy compliance behavior. However, *calculative motivation* follows a different path. Calculative motivation, based on individual cost-benefit analysis, prompts the public to make behavior decisions after evaluating their own risks and benefits. We-media, such as social media, with their immediacy, interactivity, and personalized features, can quickly spread information that resonates emotionally with the public, potentially promoting policy compliance behavior to a greater extent.

In addition, this study quantitatively analyzes the paradox of trust by constructing a theoretical model. We verified the relationship between trust and compliance behavior through structural equation modeling, confirming that high trust does not necessarily lead to high compliance, thereby clarifying the existence of the paradox of trust. This finding challenges the traditional simplistic assumption of a linear correlation between trust and compliance behavior, providing a new perspective for understanding the relationship between trust and compliance behavior and offering valuable references for future research.

Understanding the paradox of trust can help managers better identify and address trust issues within organizations, as well as optimize organizational structures, incentive mechanisms, and communication methods. By delving into the dynamics of the paradox of trust, public health departments can develop effective and reliable communication strategies to address scenarios where, over time, the public perceives a reduced risk, leading to a decline in willingness to comply with pandemic prevention measures. Such strategies can encourage better adherence to public health policies during pandemics.

The study offers several policy recommendations for public health departments: first, public health officials can enhance public trust by regularly disseminating transparent, evidence-based information. Transparency can reduce uncertainty and prevent the spread of misinformation, thereby helping to improve policy compliance. Second, personalizing and tailoring risk information for different audience groups can help the public better understand the severity of risks and the specific threats they face. Third, the paradox of trust suggests that during a pandemic, governments should focus on enhancing the quality and efficiency of public services to strengthen trust in government. They should also use authoritative media to help the public correctly understand and assess risks, preventing the neglect of risks that could lead to reduced compliance with public policies. Finally, public health departments should establish effective 2-way communication channels to promptly convey risk information, address public concerns, and alleviate panic while avoiding excessive optimism. This balanced guidance of the public's risk perception can help mitigate the impact of the paradox of trust.

Abstract

Background: Effective communication is crucial during health crises, and social media has become a prominent platform for public health experts (PHEs) to share information and engage with the public. At the same time, social media also provides a platform for pseudoexperts who may spread contrarian views. Despite the importance of social media, key elements of communication, such as the use of moral or emotional language and messaging strategy, particularly during the emergency phase of the COVID-19 pandemic, have not been explored.

Objective: This study aimed to analyze how PHEs and pseudoexperts communicated with the public during the emergency phase of the COVID-19 pandemic. We focused on the emotional and moral language used in their messages on various COVID-19 pandemic–related topics. We also analyzed their interactions with political elites and the public's engagement with PHEs to gain a deeper understanding of their influence on public discourse.

Methods: For this observational study, we gathered a dataset of >539,000 original posts or reposts from 489 PHEs and 356 pseudoexperts on Twitter (subsequently rebranded X) from January 2020 to January 2021, along with the replies to the original posts from the PHEs. We identified the key issues that PHEs and pseudoexperts prioritized. We also determined the emotional and moral language in both the original posts and the replies. This allows us to characterize priorities for PHEs and pseudoexperts as well as differences in messaging strategy between these 2 groups. We also evaluated the influence of PHEs' language and strategy on the public response.

Results: Our analyses revealed that PHEs focused more on masking, health care, education, and vaccines, whereas pseudoexperts discussed therapeutics and lockdowns more frequently (P<.001). PHEs typically used positive emotional language across all issues (P<.001), expressing optimism and joy. Pseudoexperts often used negative emotions of pessimism and disgust, while limiting positive emotional language to origins and therapeutics (P<.001). Along the dimensions of moral language, PHEs and pseudoexperts differed on care versus harm and authority versus subversion across different issues. Negative emotional and moral language tends to boost engagement in COVID-19 discussions across all issues. However, the use of positive language by PHEs increases the use of positive language in the public responses. PHEs act as liberal partisans: they express more positive affect in their posts directed at liberals and more negative affect in their posts directed at conservative elites. In contrast, pseudoexperts act as conservative partisans. These results provide nuanced insights into the elements that have polarized the COVID-19 discourse.

Conclusions: Understanding the nature of the public response to PHEs' messages on social media is essential for refining communication strategies during health crises. Our findings underscore the importance of using moral-emotional language strategically to reduce polarization and build trust.

public health; public health messaging; COVID-19; Twitter; emotions; moral foundations; polarization

Introduction

Background

The emergency phase of the COVID-19 pandemic created a worldwide public health crisis, disrupting daily lives and overwhelming health care facilities. During this time, the need for communicating reliable medical information and public health guidance became very important. Social media platforms such as Twitter (subsequently rebranded X; X Corp) provided a space for public health experts (PHEs) from government, academia, and think tanks to communicate timely and reliable information about the COVID-19 pandemic to the public [1,2].

Previous literature [3,4] shows that the public often follows cues from in-group elites and opposes cues from out-group elites. Effective messaging strategies can be crucial in times of public health crises. Individuals with higher COVID-19 knowledge practiced more protective behaviors [5,6]. Messaging that highlights risks to younger adults, in addition to risks to older adults, was found to bring about a higher threat perception about COVID-19 [7]. In contrast, messaging that appeals to the audience's morals or fears to encourage compliance was found to be polarizing, divisive, and detrimental to social cohesion [8]. In one Maryland county, Latinx vaccination rates significantly increased following the introduction of a cartoon grandmother in outreach efforts [9]. Messaging that focused on vaccine safety and efficacy, along with endorsements of vaccination from political leaders, was found to be highly effective [10]. Pink et al [11] found that Republicans who were exposed to endorsements from Republican elites witnessed higher vaccination intentions than those who viewed the Democratic elite endorsement, with out-group elite exposures proving counterproductive.

As the emergency phase of the COVID-19 pandemic progressed, discussions around the pandemic grew highly contentious and ideologically polarized [12,13]. With public's trust in institutions and experts eroding, health-related misinformation proliferated about all aspects of the pandemic, from its origins to alternative treatments and the efficacy of nonpharmaceutical interventions, and eventually the vaccine [14]. At the heart of this proliferation were influential "pseudoexperts," such as the "Disinformation Dozen" [15], who amplified contrarian perspectives and challenged the recommendations of PHEs.

This polarization [5,16-18] of the COVID-19 pandemic laid bare a fractured public health messaging apparatus [19-22]. The emergence of contradictory theories and 2 polarized groups of influential elites and experts [23,24] and conspiracy theories about the origins of the COVID-19 pandemic, its severity, and the efficacy of prophylactic measures started to take hold [25,26]. Initial theories revolved around the severity of the virus with several calling it a "hoax" and "plandemic" [27]. A study by the Pew Research Center [28] found that approximately 25% of the survey responders believed that COVID-19 was probably created intentionally by powerful people. Another study found that approximately 3 in 10 Americans believe that COVID-19 was artificially created in a laboratory [29]. Theories about virus transmission being connected to 5G, bats, pangolins, and wet markets were widely propagated by conspiracy theorists on social media [30,31]. As the COVID-19 pandemic progressed, we also witnessed the propagation of pseudoscientific cures for COVID-19 [32,33]. With increased COVID-19 pandemic–related engagement from the general public, these conspiracy theories soon started to proliferate on social media platforms [34-39]. Findings from the study by Antonakis [40] highlight the role of influential accounts in mitigation efforts. As influential elites, often holding advanced medical degrees, began contradicting other PHEs on various aspects of the COVID-19 pandemic, public consensus was disrupted, occasionally leading to serious consequences [41-43].

Expression of fear and anger were found to indicate support for restrictive COVID-19 mitigation policies such as lockdowns to limit the spread of COVID-19 [44], while anxiety predicted support for economic policies. Anger was found to indicate support for aggressive responses to transgressors [45,46]. Hatemi et al [47] found fear to be a strong underlying factor in anti-immigration and prosegregation stances. Previous studies [48] relied on surveys to show an increase in distress and uncertainty during the emergency phase of the COVID-19 pandemic. Agrawal et al [49] investigated sentiments of posts about the COVID-19 vaccine, post–COVID-19 health factors, and health service providers. Among the 3 topics, health care providers had the largest positive sentiment, resulting in an inference that posters were happy with their care and appreciated the work of health care providers. Lwin et al [50] found that public emotions in Twitter shifted from fear to anger early in the COVID-19 pandemic. Wheaton et al [51] revealed that greater susceptibility to emotion contagion was associated with greater concern about the spread of COVID-19. The moral foundations of care and fairness were found to correlate with compliance of COVID-19 health recommendations, including masking, staying at home, and social distancing [52,53]. Moral attitudes were also able to predict county-level vaccination rate [54] and vaccine hesitancy [55]. Pacheco et al [56] found that care or harm was associated with provaccine sentiment, whereas liberty or oppression was correlated with antivaccine attitudes. While vaccinations are a critical polarizing issue in the discussion of COVID-19, no study yet has explored differences in moral appeals across a broader range of contentious COVID-19 issues.

Social sharing of opinions and emotions is ubiquitous, and social media has greatly expanded its scope [57,58]. Bazarova et al [58] investigated how responses to what a user shared affected their feeling of satisfaction. Analyzing Facebook status updates, Burke and Develin [59] found that posts with positive emotions received more likes. The comments associated with these posts were also more positive [59]. Positive emotion words were also shown to have a positive correlation with the number of reposts [60]. Sousa et al [61] reported that while social connections dominate reply behavior, for authors with large ego networks, there is a separation between who replies based on the topic of

XSL•FO
RenderX

the post. Early thematic analysis of public replies to the COVID-19 pandemic found themes of prevention, symptoms, views on politicians, and humor [62]. Replies by antivaccine users were found to be more toxic than users with other beliefs about vaccines [63]. Gallagher et al [64] found groups to preferentially amplify elites that are demographically similar to them.

In psychology, "affect" is the experience of feeling or emotion, and it significantly shapes individual's attitudes, beliefs, and behaviors. In online interactions, affect influences how a message is crafted and how it resonates with audiences, ultimately affecting the message's spread and impact. Research shows that people respond to the emotions expressed in online messages [65], although due to an asymmetry in human cognition [66], posts expressing negative emotions receive more engagement than positive posts [67,68]. It has also been shown that emotionally charged messages, particularly ones tapping into moral sentiments such as outrage, spread farther on the web [69,70]. Affect provides reliable indicators for gauging public response to major events and policy decisions [44,45,71-73] and interacts with ideology to fuel polarization. Political scientists have identified affective polarization—a phenomenon where individuals like and trust members of their own party while disliking and distrusting members of opposing parties—as a significant threat to effective governance [74,75]. Public's reactions to the COVID-19 pandemic, as measured via attitudes and sentiments expressed in online messages, were multifaceted [76] and grew polarized early in the COVID-19 pandemic [12]. Moreover, there was an ideological asymmetry wherein conservatives shared more low-quality health information than liberals [17] and were also exposed to more misinformation [14]. In addition, conservatives expressed more negative moral sentiments in online posts about the COVID-19 pandemic than liberals [13]. However, to the best of our knowledge, few studies have focused on online influencers and experts who shaped public health policy and disseminated health-related information to the public. As a result, we know little about the messaging strategies they used, the role that affect played in these messages, and how the public responded to the messages.

Objectives

To address these knowledge gaps, we examined messages posted by PHEs and pseudoexperts on Twitter during the emergency phase of the COVID-19 pandemic. We identified a set of 489 PHEs and 356 pseudoexperts and collected >372,000 original posts that they posted between January 21, 2020, and January 20, 2021. Collectively, these accounts had a vast reach; each PHE had on average 94,000 followers (estimated reach approximately 45M), and pseudoexperts had on average 78,000 followers (estimated reach approximately 30M). In addition, we also collected replies to >195,000 original posts posted by PHEs during this period. Our objectives were two-fold: (1) identify *what* public health influencers talk about online and *how* they talk and (2) identify factors that impacted public engagement with the PHEs.

We leverage methods introduced in the study by Rao et al [13] to identify posts about 7 important COVID-19 pandemic–related issues: origins of the virus, lockdowns and stay-at-home orders, masking mandates, online schooling and education, health care, alternative treatments and therapeutics, and vaccines. We use state-of-the-art classifiers [77,78] to analyze the emotional and moral language used in posts. We then use regression to compare how affect shapes the health-related messages on different issues posted by PHEs and pseudoexperts. Finally, we collect all replies for a sample of PHE posts to study how the use of emotional and moral language impacts engagement by the public with these messages.

Our study uncovers the inherent complexities in public health communication during the COVID-19 pandemic by investigating the following hypotheses:

- PHEs and pseudoexperts differ significantly in the issues they emphasize during the COVID-19 pandemic.
- There are asymmetries in the emotional and moral language used by PHEs and pseudoexperts in discussing these issues.
- PHEs and pseudoexperts exhibit affective polarization, with pseudoexperts expressing more positivity toward conservative elites and PHEs favoring liberal elites.
- The emotions and moral language used by PHEs are reflected in the responses from common users.

Methods

Overview

We begin by describing our data collection procedure and present statistics and basic characteristics of the dataset. We believe that this description provides the reader with additional insights to better interpret the results. Finally, we describe our content analysis procedure and models used to produce results.

Study Design and Population

This is an observational study that analyzes the social media communication of 489 PHEs and 356 pseudoexperts on Twitter during the COVID-19 pandemic from January 2020 to January 2021. We focus on the emotional and moral language used in their original posts as well as the public engagement with those posts. The study compares the key issues prioritized by PHEs and pseudoexperts and examines how these groups engaged with political elites and their respective audiences. By analyzing their messaging strategies, the study aims to understand how their language influenced public engagement and discourse. The study population consists solely of users on the social media platform Twitter.

Data Collection

We use a publicly available dataset [79] consisting of 1.4B posts about COVID-19 posted between January 21, 2020, and January 1, 2021. These posts contained ≥1 COVID-19–related keywords, such as coronavirus, pandemic, and Wuhan, among others.

Identifying PHEs and Pseudoexperts

In collaboration with a health policy researcher, we identified accounts belonging to 30 PHEs and 30 pseudoexperts who were active on Twitter during the emergency phase of the COVID-19 pandemic (Textbox 1). PHEs include individuals with advanced degrees in medicine, epidemiology, genomics, infectious

XSL•FO
RenderX

diseases, public policy, and economics. These experts offered informed, evidence-based perspectives grounded in science, shaping public understanding and policy, regardless of whether their views aligned with the scientific consensus.

Textbox 1. Twitter handles of accounts associated with public health experts (PHEs) and pseudoexperts.

PHEs

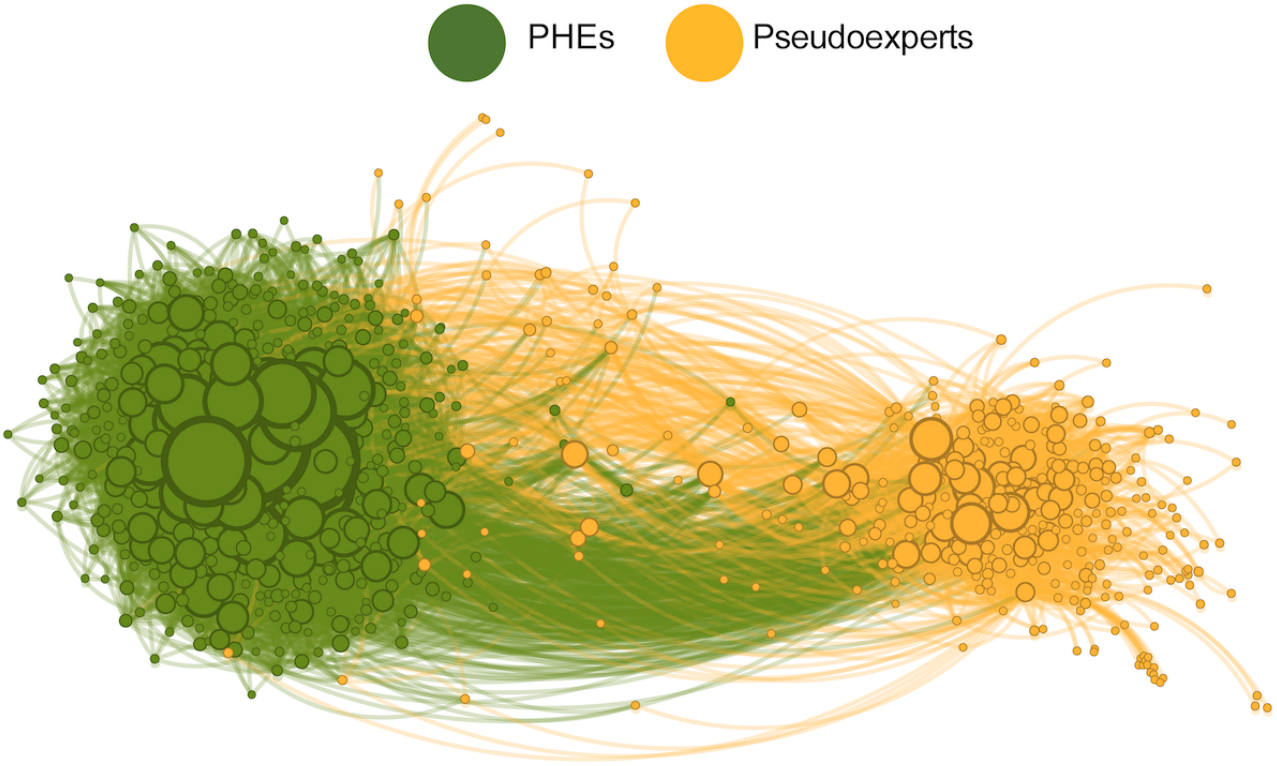
EricTopol, PeterHotez, ashishkjha, trvrb, EpiEllie, JuliaRaifman, devisridhar, meganranney, luckytran, asosin, DrLeanaWen, dremilyportermd, DrJaimeFriedman, davidwdowdy, BhramarBioStat, geochurch, DrEricDing, michaelmina_lab, Bob_Wachter, JenniferNuzzo, mtosterholm, MonicaGandhi9, cmyeaton, nataliexdean, angie_rasmussen, ProfEmilyOster, mlipsitch, drlucymcbride, ScottGottliebMD, CDCDirector, and Surgeon_General

Pseudoexperts

mercola, LEEHIEB_MD, stella_immanuel, DrOz, DrThomasLevy, DrJudyAMikovits, va_shiva, Drericne- pute1, DrButtar, DrArtinMassihi, davidicke, mrmarksteel, drscottjensen, cameronks, RobertKennedyJr, TyCharleneB, BusyDrT, IslamRizza, unhealthytruth, sayerjigmi, kelly- broganmd, DrChrisNorthrup, DrBenTapper1, DrZachBush, SherrillSellman, AFLDSorg, DrSimoneGold, jennybethm, drcole12, JamesTodaroMD, Covid19Critical, and DrJohnWitcher

While most of the individuals identified as PHEs were noncontroversial, we recognize that some may have made questionable statements or provided guidance that diverged from mainstream views. We chose to include these voices as PHEs for several reasons: (1) to reflect the diversity of perspectives among experts and (2) to illustrate that PHEs often participated in nuanced debates shaped by the evolving understanding of COVID-19's risks and impacts. Nonetheless, our primary criterion was that these individuals predominantly based their views on data-driven research and evidence-based analysis, even when their positions significantly deviated from scientific consensus.

The group of pseudoexperts, by contrast, includes individuals with or without medical credentials who consistently promoted pseudoscientific theories, unproven alternative treatments, and unsupported conclusions about COVID-19. Many in this group actively questioned the need to exercise prophylactic measures such as masking and lockdowns, expressed skepticism about the safety of vaccines, referenced retracted studies, and offered unsupported claims, directly contrasting with the PHEs' reliance on evidence-based research. This group also includes the "Disinformation Dozen," a group of individuals and organizations identified by the Center for Countering Digital Hate as being responsible for promoting false claims about COVID-19 [15].



We expanded the initial seed set of PHEs and pseudoexperts (Textbox 1) using the repost network to identify additional influential figures shaping public opinion during the critical period of the COVID-19 pandemic. Our approach relies on repost interactions within a publicly available COVID-19 Twitter dataset, comprising >1 billion COVID-19–related posts collected between January 21, 2020, and January 20, 2021 [79]. Reposts allow users to repost content originally shared by others, and they have been shown to be proxies of endorsement of content [80,81]. Individuals often repost others who share similar beliefs and perspectives [14,82-84]. We used repost interactions involving the initial seed sets of PHEs and pseudoexperts to identify 2 distinct networks: one comprising accounts frequently reposted by PHEs and the other comprising accounts frequently reposted by pseudoexperts. We used Eigenvector centrality [85] to identify the most prominent accounts in each repost network, selecting the top 500 accounts reposted by either PHEs or pseudoexperts. Eigenvector centrality measures a node's influence in a network, where its centrality is based not only on the number of accounts reposting it but also on the influence of the accounts that are reposting those accounts. After filtering out organizational accounts, we were left with 489 individual PHEs and 356 individual pseudoexperts.

With this expanded set of individuals, we proceeded to extract their posts, resulting in a dataset comprising 340,000 posts from PHEs and 175,000 posts from pseudoexperts. This broader dataset allowed us to analyze the discourse and influence patterns across a more comprehensive group of health professionals and pseudoexperts active during the emergency phase of the COVID-19 pandemic.

Figure 1 shows the repost interactions network between PHEs and pseudoexperts (845 nodes and 107K edges). The color of the edge is dependent on the target node. Green edges represent interactions where a PHE was reposted, whereas orange edges represent interactions where a pseudoexpert was reposted. The size of the node is proportional to how many times the account was reposted: highly reposted experts have larger node sizes. The network shows 2 tightly knit communities, 1 for each group, with sparse between-community interactions. This structure is typical of online echo chambers and suggests that each community mainly listens to their own community.

XSL•FO
RenderX

Figure 1. Repost interactions. Nodes represent public health experts (PHEs; green) and pseudoexperts (orange) and repost interactions between them. Green edges represent interactions where a PHE was reposted, and orange edges represent interactions where a pseudoexpert was reposted. The size of the node is proportional to the number of times the expert was reposted.

Textbox 2 shows the 25 most popular hashtags used by PHEs and pseudoexperts. There are notable similarities and differences. While "vaccine" is the most important topic for both groups, PHEs unsurprisingly mention "vaccineswork" and "vaccinate," in contrast to posts from pseudoexperts that mention "vaccineinjury" and "vaccinefreedom" and urge people to "learntherisk" of vaccines.

Textbox 2. Hashtag use. The top 25 hashtags used by public health experts (PHEs) and pseudoexperts on Twitter.

PHEs

sarscov, vaccine, pandemic, wearamask, thisisourshot, publichealth, vaccinessavelive, deltavariant, socialdistance, covidvaccine, mentalhealth, healthcare, vaccinate, scicomm, election, getvaccinate, stopthespread, maskup, vaccineswork, healthworker, medtwitter, stayathome, globalhealth, remdesivir

Pseudoexperts

medtwitter, informedconsent, thedefender, billgatesbioterrorist, wakeupamerica, autism, fauciliedpeopledied, vaccinefreedom, ivermectin, learntherisk, lockdown, hydroxychloroquine, factsnotfear, tipsfornewdocs, censorship, vaccineinjury, vaccinefailure, plandemic, freedom, screenbyvaccine, aluminium, bigpharma, homeopathy, doctorspeakup

Further analyzing the content shared by PHEs and pseudoexperts, we extract the URLs they shared in their posts and identify the pay-level domains (PLDs) these URLs point to. We compute the log-odds ratio to identify which group is more likely to share each PLD. Figure S1A in Multimedia Appendix 1 shows the top 15 PLDs for both groups. We found that PHEs were more likely to share URLs from highly reputable sources, such as *Journal of American Medical Association*, *Boston Review*, and the *New York Times*. In contrast, pseudoexperts share more questionable sources, such as the *Gateway Pundit*, Children's Health Defense, Patriot Project, and *Russia Today*, among others. PLDs often have ideological leanings, ranging from liberal (0) to least-biased (0.5) to conservative (1), where 0 represents the most liberal, 1 represents the most conservative, and 0.5 indicates a neutral or least-biased position. [86]. Figure S1B in Multimedia Appendix 1 compares the distribution of ideological leanings of information sources shared by PHEs and pseudoexperts. While PHEs tended to share more liberal sources, pseudoexperts shared more conservative sources.

Identifying Issue-Relevant Posts

We decompose the multifaceted discussion about the COVID-19 pandemic along various contentious issues: COVID-19 origins, lockdowns and business closures, mask mandates, school closures, therapeutics, health care, and vaccines. To do so, we rely on methods discussed in the studies by Rao et al [13] and Eisenstein et al [87] to extract issue-relevant keywords from Wikipedia articles. Once we identify keywords, we identify posts that explicitly mention any of these keywords as being issue relevant. This approach was validated in the study by Rao et al [13] as being able to accurately identify issue-relevant

XSL•FO
RenderX

content. Table S1 in Multimedia Appendix 1 illustrates sample posts from our dataset discussing each issue.

We define the origins issue to encompass discussions surrounding the possible causes for the origin of the COVID-19 pandemic, including topics such as pangolins, gain of function research, wet markets, and bats. The lockdown issue comprises content pertaining to early state and federal mitigation efforts, such as quarantines, stay-at-home orders, business closures, reopening, and calls for social distancing. Discussions related to masking are defined by considerations of face coverings, mask mandates, shortages, and antimask sentiment. Education-related content involves posts regarding school closures, the reopening of educational institutions, homeschooling, and online learning during the emergency phase of the COVID-19 pandemic. The health care issue deals with conversations on the state of the health care system, availability of personal protective equipment, ventilators, oxygen supplies, and intensive care units. Discourse around therapeutics encompasses varied alternative treatments proposed to fight COVID-19 infections, including hydroxychloroquine, ivermectin, plasma therapy, Chinese medicine, colloidal silver, and herbal remedies. The vaccines issue pertains to discussions about COVID-19 vaccines, vaccine mandates, antivaccine sentiment, and vaccine hesitancy in the United States.

Identifying Emotions and Morality

To identify emotions expressed in posts and replies, we used a state-of-the-art transformer-based multilabel emotion detection model described in another study [77]. This model was fine-tuned using the SemEval 2018 Task 1e-c dataset [88]. It surpasses previous methods in its ability to capture the correlations among various emotions. When presented with the text of a post, the model generates confidence scores for the presence of a wide spectrum of emotions. We later bin these confidence scores using a 0.5 threshold to binarize the output. The emotions it can identify include *anticipation*, *joy*, *love*, *optimism*, *anger*, *disgust*, *fear*, *sadness*, and *pessimism*. The definitions of these emotions are based on the study by Mohammad et al [88] and are as follows:

- anticipation (also includes interest and vigilance)
- joy (also includes serenity and ecstasy)
- love (also includes affection)
- optimism (also includes hopefulness and confidence)
- anger (also includes annoyance and rage)
- disgust (also includes disinterest, dislike, and loathing)
- fear (also includes apprehension, anxiety, and terror)
- sadness (also includes pensiveness and grief)
- pessimism (also includes cynicism and no confidence)

Prior research has shown that emotional and moral language in social media messages impacts how they are received by the audiences and engagement [65,70]. The moral foundations theory [89] provides a framework for understanding how moral values shape people's political attitudes and behaviors. The moral foundations theory proposes that individuals' values and judgments can be described by 5 moral virtue or vice pairs: care or harm, fairness or cheating, loyalty or betrayal, authority or subversion, and sanctity or degradation. More specifically, these include the following:

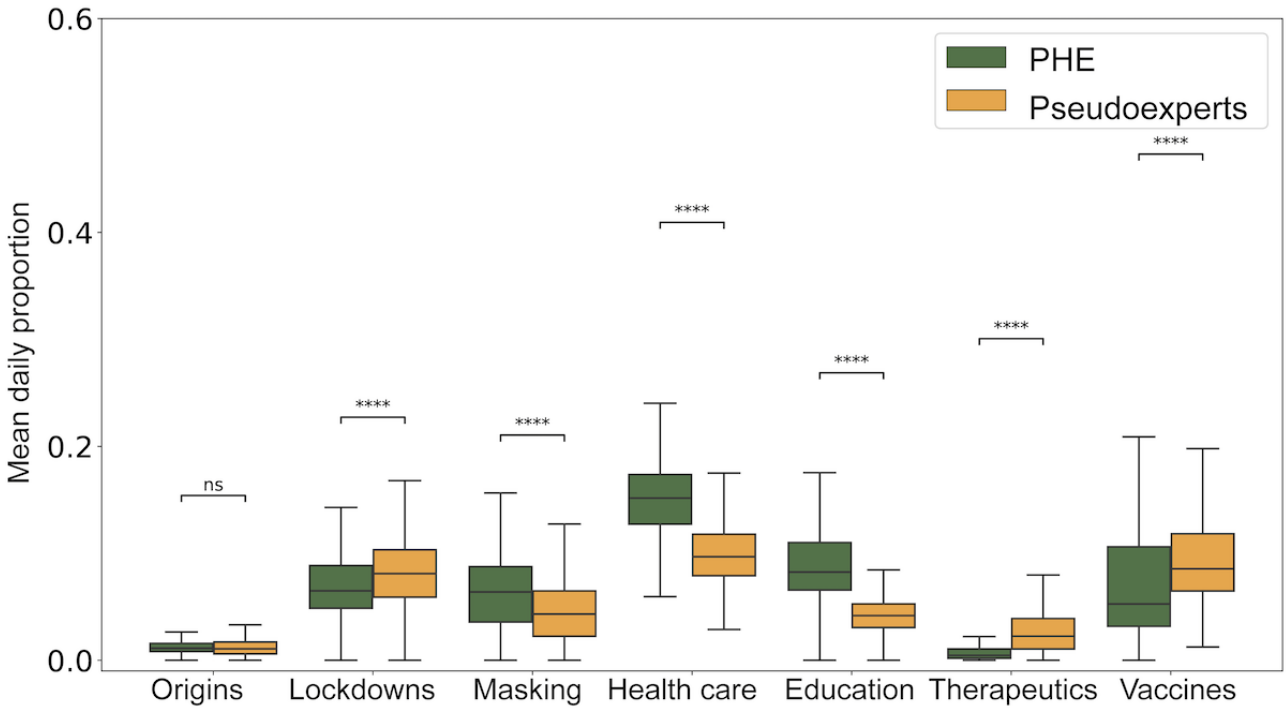
- Care or harm. This foundation revolves around the concept of empathy and compassion. People who prioritize this foundation value caring for others and preventing harm. They are sensitive to the needs of others and strive to promote their well-being.
- Fairness or cheating. This foundation is concerned with issues of justice, reciprocity, and fairness. Individuals who emphasize this foundation are attuned to issues of equality, fairness, and proportionality. They believe in treating others fairly and oppose exploitation and unfair advantage.
- Loyalty or betrayal. Teople who prioritize loyalty value group cohesion, allegiance, and solidarity. They are inclined to support and defend their in-groups, whether it be family, community, or nation, and perceive betrayal or disloyalty as morally reprehensible.
- Authority or subversion. This foundation centers on respect for authority, tradition, and hierarchy. Individuals who emphasize this foundation value social order, respect for authority figures, and obedience to legitimate institutions and norms. They believe that maintaining authority and order is essential for a stable society.
- Sanctity or degradation. This foundation involves the reverence for purity, sanctity, and sacredness. People who prioritize this foundation are concerned with issues related to cleanliness, moral purity, and spiritual transcendence. They may view certain actions, objects, or behaviors as inherently sacred or profane.

Our morality detection model is trained on the transformer-based pretrained language model by Devlin et al [90]. The training process involves 3 Twitter datasets, a manually annotated COVID-19 dataset [91], the Moral Foundation Twitter Corpus dataset covering 6 different topics [92], and a dataset of political posts from US congress members [93]. By incorporating an in-domain training set focused on COVID-19, along with other diverse datasets spanning various topics, we enhance the model's generalizability for application to target data as discussed in the study by Guo et al [78].

Ethical Considerations

This study involved secondary analysis of publicly available Twitter data and was reviewed and deemed exempt by the University of Southern California's Institutional Review Board. The exemption was granted because the data are publicly accessible and do not involve interaction with human participants or the use of identifiable private information. Informed consent was not required as the data were collected from a public platform in accordance with Twitter's terms of service, and there was no reasonable expectation of privacy in the original context. All data were anonymized during analysis, with no identifying features included in the study outputs, ensuring privacy and confidentiality. No compensation was provided as the study exclusively analyzed publicly available data.

Results



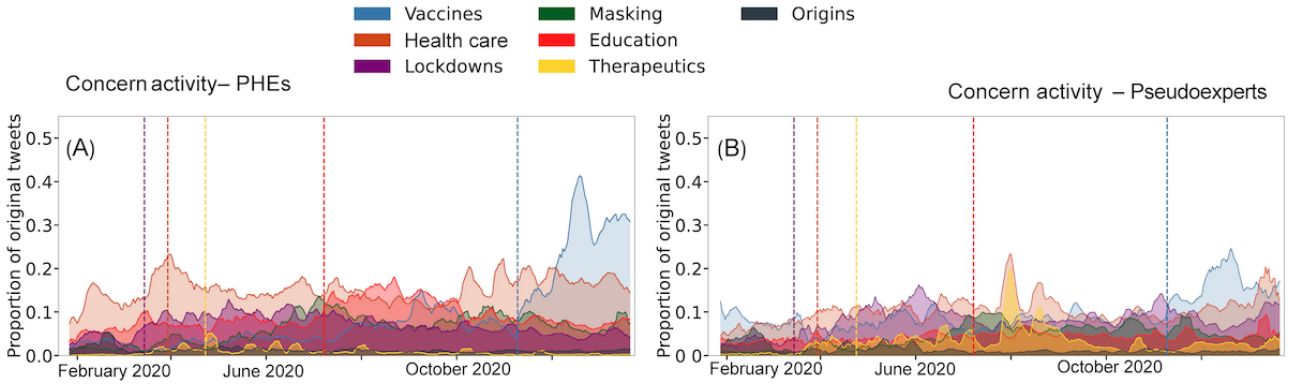
Messaging About COVID-19 Issues

More than half of the posts from PHEs and pseudoexperts mention at least 1 of the 7 COVID-19 issues we identified.

XSL•FO
RenderX

Figure 2 compares the average daily share of posts from both groups on each issue. Overall, we found that pseudoexperts tend to be more vocal on the issues of lockdowns, therapeutics, and vaccines, while PHEs generate more content about masking, health care, and education. We did not witness any significant differences in the discourse about origins of the virus. These trends reflect the attention to issues by each group before President Biden's inauguration, which is the period covered by this study. To better summarize the varied perspectives expressed by PHEs and pseudoexperts on the 7 issues of interest, we randomly sample 25 posts for the 2 groups across these issues and prompt OpenAI's ChatGPT to provide the broad perspective being expressed using the following prompt:

Figure 2. Comparing the activity of public health experts (PHEs) and pseudoexperts. Box plots compare the daily proportion of issue-related posts from PHEs and pseudoexperts. Mann-Whitney U Test with Bonferroni correction was used to assess significance. **P*<.05, ***P*<.01, ****P*<.001, and *****P*<.0001; ns: not significant.



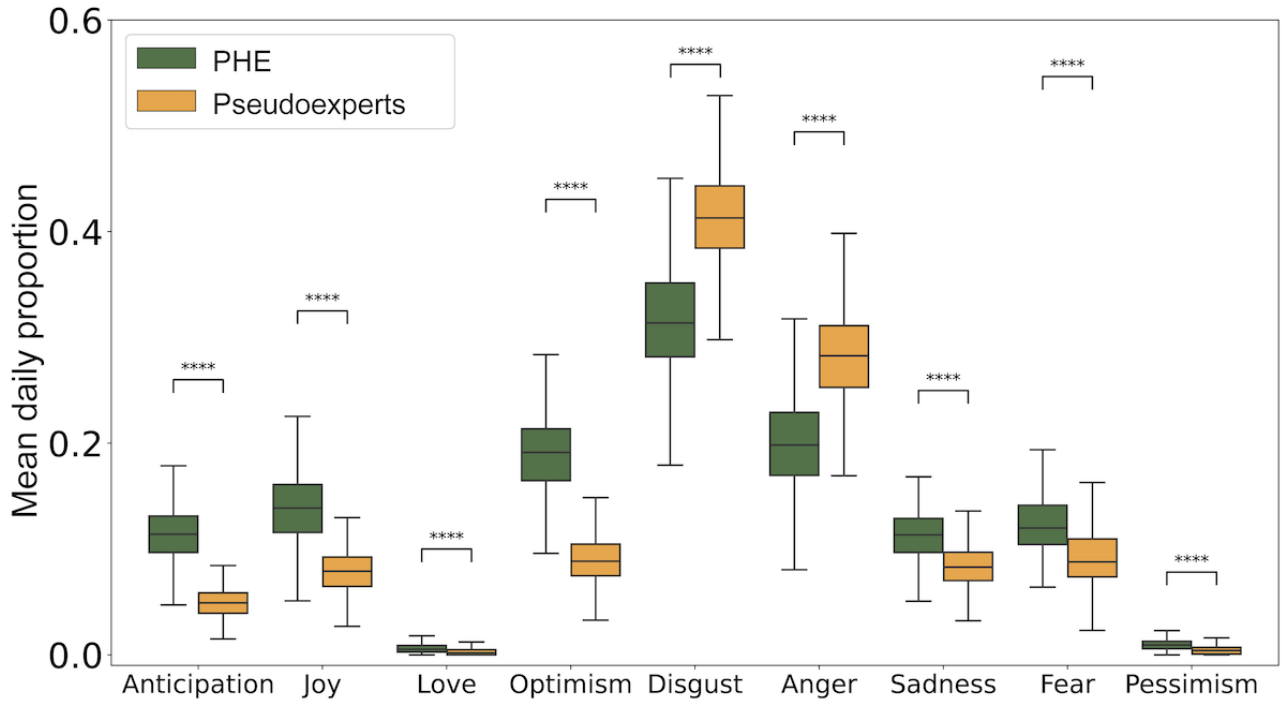
"Summarize perspectives being expressed about <Issue> in these posts: <T>," where <Issue> is one of (Origins, Lockdowns, Masking, Education, Health care, Therapeutics, Vaccines) and <T> represents a concatenation of the 25 posts that were randomly sampled for each issue and group pair.

The results presented in Table S2 in Multimedia Appendix 1 demonstrate the contrasting viewpoints between the 2 groups on various issues. Regarding the origins of the virus, PHEs generally lean toward the belief that it originated in a laboratory, albeit with some skepticism, while pseudoexperts heavily criticize China and its potential involvement in gain of function research. PHEs emphasize the importance of ongoing vigilance, adherence to stay-at-home orders, and widespread use of masks, whereas pseudoexperts question the effectiveness of lockdowns and mask mandates and criticize government intervention in these areas. On the topic of therapeutics, PHEs urge caution against self-prescribing drugs such as hydroxychloroquine, azithromycin, and ivermectin without evidence of their efficacy in treating COVID-19, whereas pseudoexperts advocate for the use of these medications.

Next, we look at the temporal patterns of issue-related discussions. Figures 3A and 3B show the daily share of posts from each group about the issues. Major events are marked with vertical lines—lockdowns: March 15, 2020 (purple dashed line), when stay-at-home orders were issued across the mainland United States; health care: March 30, 2020 (orange dashed line); therapeutics: April 24, 2020 (yellow dashed line), when President Trump proposed using bleach to fight off the virus; education: July 8, 2020 (red dashed line), when Trump called for schools to reopen; and vaccines: November 9, 2020 (blue dashed line), when Pfizer reported 93% efficacy in phase 3 trials. When stay-at-home orders were issued in mid-March 2020, we see a rise in lockdown-related discussions from PHEs. Lockdown-related discourse from pseudoexperts gained momentum in mid-April amid calls to reopen the economy and intensified in early June 2020 during the Black Lives Matter protests, when they criticized the large-scale demonstrations. As COVID-19 cases surged in late March 2020, we see a spike in health care–related discourse from PHEs, with growing calls for emergency preparedness in terms of improving access to personal protective equipment and ventilators. We do not observe a corresponding increase from pseudoexperts.

XSL•FO
RenderX

Figure 3. Daily fraction of original posts by (A) public health experts (PHEs) and (B) pseudoexperts related to each issue. Major events are marked with vertical lines. Major events are marked with vertical dashed lines: Lockdowns (March 15, 2020, purple), health care (March 30, 2020, orange), therapeutics (April 24, 2020, yellow, Trump's bleach proposal), education (July 8, 2020, red, Trump's school reopening call), and vaccines (November 9, 2020, blue, Pfizer's 93% efficacy report).

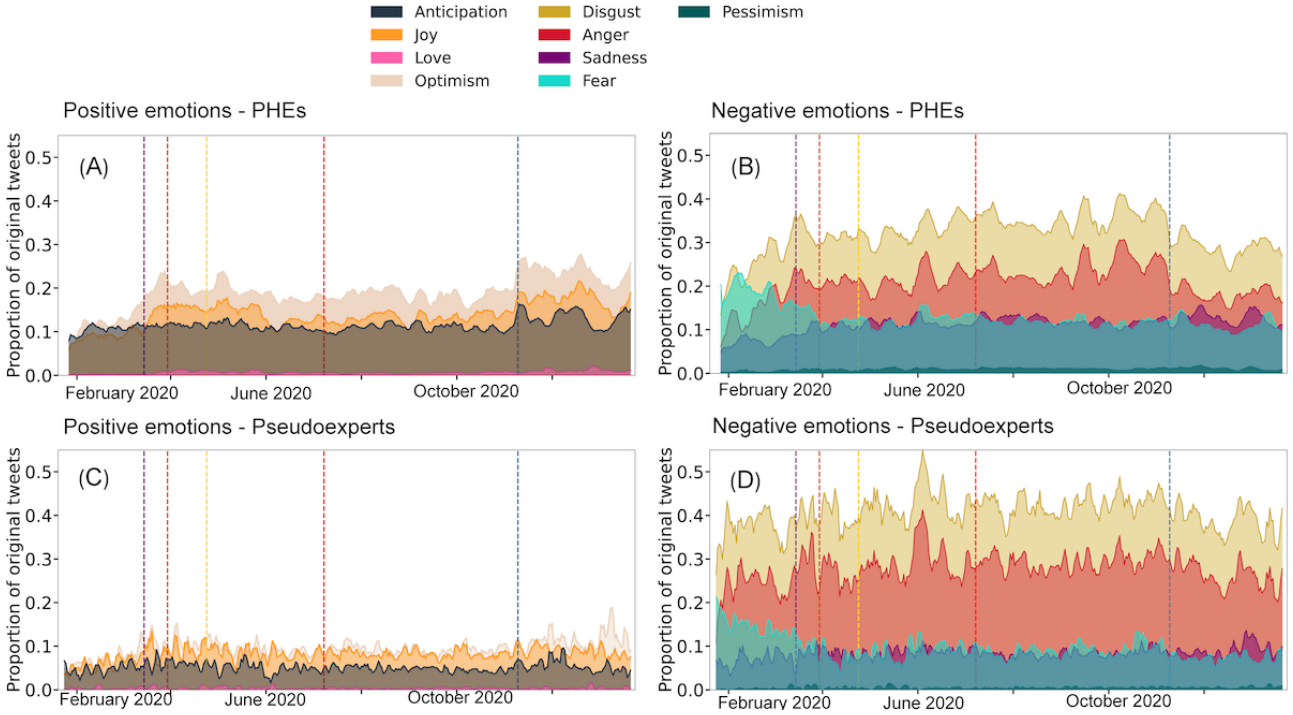


We see a small spike in therapeutics-related discussions among PHEs following President Trump's April 24, 2020, comment on using bleach to ward off the COVID-19 virus. Almost immediately following the Federal Drug Administration's issuance of an emergency use authorization on various therapeutics such as hydroxychloroquine on March 28, 2020, we see an immediate increase in therapeutics-related discussions from pseudoexperts. However, we see highest share of posts from them on July 26, 2020, when then White House chief of staff Mark Meadows announced that alternative therapeutics would be coming soon. We also see spikes in education-related discussions from PHEs and pseudoexperts following President Trump's July 8, 2020, call to reopen educational institutions. However, the spikes were for very different reasons; PHEs expressed increased skepticism toward reopening schools, while pseudoexperts supported the reopening call. The largest spikes for both groups are for vaccine-related discussions following Pfizer's announcement of successful COVID-19 phase 3 vaccine trials (10%-37% for PHEs and 20%-32% for pseudoexperts).

Emotional and Moral Language

Figure 4 compares the distribution of the daily fraction of posts posted by PHEs and pseudoexperts expressing a certain emotion. Overall, PHEs express more positive emotions such as anticipation, joy, and optimism and more low arousal negative emotions such as sadness and fear, whereas pseudoexperts express more high arousal negative emotions such as anger and disgust. Interestingly, we do not see much love or pessimism in our data.

Figure 4. Box plots compare daily proportion of posts from public health experts (PHEs) and pseudoexperts expressing various emotions. Mann-Whitney U Test with Bonferroni correction is used to assess significance. *P<.05, **P<.01, ***P<.001, and ****P<.0001; ns: not significant.



XSL•FO
RenderX

Dynamics of Affect

Emotions fluctuate over time and in response to events. Figure 5 illustrates the temporal dynamics of positive emotions expressed by PHEs and pseudoexperts. We leverage ChatGPT to summarize changes in emotions expressed, which are discussed further in Table S3 in Multimedia Appendix 1. Optimism and joy among PHEs surge following the announcement of stay-at-home orders post March 15, 2020. This can be attributed to factors such as gratitude for guidance by then New York governor Andrew Cuomo and enhanced accessibility to COVID-19 testing. Similarly, we note a corresponding albeit smaller increase among pseudoexperts, particularly in response to President Trump's management of the COVID-19 pandemic and France's endorsement of hydroxychloroquine as a viable COVID-19 treatment.

Figure 5. Dynamics of emotions. Daily fraction of posts from public health experts (PHEs) and pseudoexperts expressing (A and B) positive (optimism, joy, anticipation, and love) and (C and D) negative (disgust, anger, sadness, fear, and pessimism) emotions. Major events are marked with vertical dashed lines: Lockdowns (March 15, 2020, purple), health care (March 30, 2020, orange), therapeutics (April 24, 2020, yellow, Trump's bleach proposal), education (July 8, 2020, red, Trump's school reopening call), and vaccines (November 9, 2020, blue, Pfizer's 93% efficacy report).

Another surge in joy, anticipation, and optimism among PHEs occurs after November 9, 2020, following Pfizer's announcement of successful phase 3 trials for its COVID-19 vaccine. PHEs hailed this development as a remarkable achievement and anticipated emergency use authorization from the Food and Drug Administration. While positive emotions also increased among pseudoexperts, the magnitude was notably lower. Pseudoexperts expressed optimism regarding the success of Operation Warp Speed, the imminent reopening of businesses, and the introduction of Lilly's monoclonal antibody drug.

Negative emotions such as disgust and anger escalated for both groups post March 15, 2020, with a more pronounced increase among pseudoexperts. The upsurge in anger and disgust within each group stemmed from different reasons. PHEs expressed disappointment with the measures taken by the Trump administration to combat the virus, whereas pseudoexperts voiced skepticism concerning the World Health Organization's interactions with China, Governor Cuomo's management of public transportation in New York, and the effectiveness of lockdowns in containing COVID-19. Although both groups experienced parallel declines in anger and disgust after US elections on November 9, 2020, the reductions were more significant among PHEs.

We also examine the use of moral language by the 2 groups. Figure S2 in Multimedia Appendix 1 compares the distribution of the daily share of posts expressing each moral foundation. Overall, PHEs use more positive moral language, emphasizing the dimensions of care, fairness, authority, loyalty, and purity, while pseudoexperts tend to prefer the negative moral dimensions of harm, cheating, subversion, and betrayal. The differences in use of moral language are more subdued compared to those for emotions. Figure S3 in Multimedia Appendix 1 illustrates the temporal dynamics of positive and negative moral language used by PHEs and pseudoexperts. We summarize the positive spikes using ChatGPT in Table S4 in Multimedia Appendix 1.

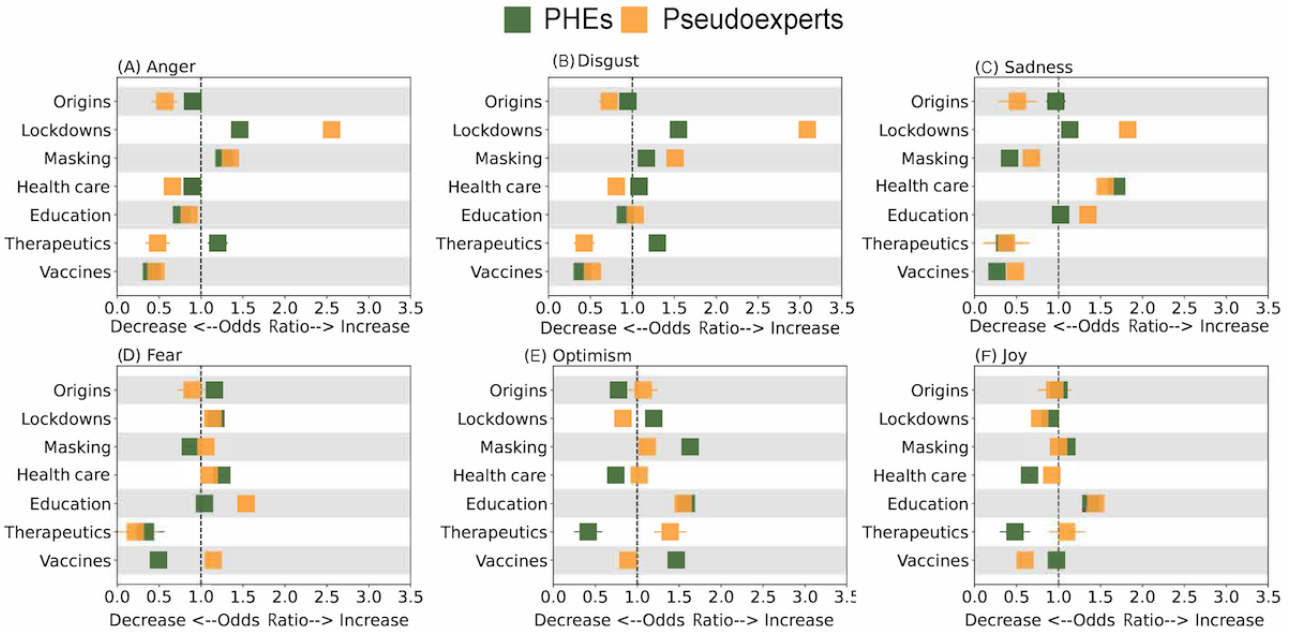
We witness an increase in the expression of care from PHEs after the stay-at-home orders. This increase is marked by calls for widespread lockdown measures, testing, and relief proposals for low-income households. However, there is a marginal decline in care language from pseudoexperts. Use of harm language decreases for both groups, with a more significant reduction for PHEs. In response to Pfizer's successful phase 3 trials, the use of care language increases for both PHEs and pseudoexperts coupled, accompanied by a decline in harm-related language. Both groups express care in discussing

XSL•FO
RenderX

how the introduction of vaccines could bring an end to the COVID-19 pandemic. In addition, pseudoexperts express concerns about the safety of the messenger RNA vaccines and criticize Bill Gates' call for vaccine mandates.

Asymmetries in Emotions and Moral Language

PHEs and pseudoexperts had conflicting priorities. PHEs promoted vaccination and advocated for stringent nonpharmaceutical interventions to curb the spread of the virus. In contrast, pseudoexperts expressed skepticism toward such interventions, emphasizing personal choice. We examine how these differences were manifested in the emotional and moral language used by the 2 groups.



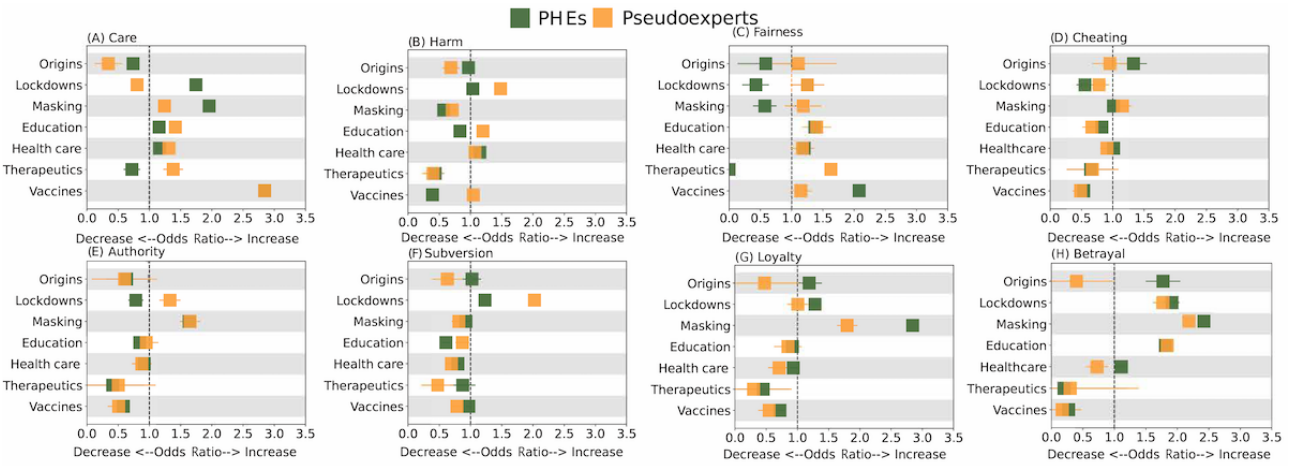
To quantify issue-specific variation in emotions and moral language use by the 2 groups, we conduct a multivariate logistic regression analysis at the post level for each emotion and moral foundation. We examine the relationship between the issue discussed (independent variable) and the emotions or moral foundations expressed (dependent variables). In addition, the model incorporates a categorical variable to delineate between different groups. To account for potential differences in the emotional responses of the 2 groups, we introduce an interaction term between issues discussed and the group variable. We formulate the model separately for each issue as follows:

<Emotion> ~ origins + lockdowns + masking + education + health care + therapeutics + vaccines + (origins + lockdowns + masking + education +health care + therapeutics + vaccines) x group

, where group distinguishes between PHEs and pseudoexperts. We run separate regression models for each emotion. The coefficients for the main effects represent the change in the log-odds of the emotion for the PHEs when discussing an issue, while holding all other issues constant. In contrast, the sum of coefficients of the main effects and interaction effects quantify the change in log-odds for the pseudoexperts. For example, if the coefficient for lockdowns is positive, it suggests that when lockdowns are being discussed, there is an increase in the expression of a particular emotion from when they do not discuss lockdowns. An odds ratio >1 suggests that when a particular issue is discussed, there are increased odds of the post expressing an emotion compared to when the issue is not; an odds ratio=1 indicates equal odds, while an odds ratio <1 signifies lower odds.

Figure 6 compares the log-odds along with the corresponding SEs of estimation to show which group used more emotional language to frame a specific issue. The plot highlights differences between the 2 groups and gives insights into emotionally charged issues. The biggest gap in emotions appears on the issue of lockdowns, where pseudoexperts are far more likely to express anger, disgust, and sadness than PHEs. This position is consistent with the efforts to end the lockdowns (refer to the Great Barrington Declaration by Kulldorff et al [94]). The second largest gap in emotions appears in the discussion of therapeutics, where PHEs are more likely to express anger and disgust, but pseudoexperts are less likely to use these emotions. Pseudoexperts also use more positive language with more joy and optimism when talking about therapeutics, in contrast to PHEs, consistent with the highly contentious debates about this issue. Other notable differences include pseudoexperts expressing more fear and less joy about vaccines, while PHEs express less fear and more optimism.

Figure 6. Comparing emotions used by public health experts (PHEs) and pseudoexperts. It compares (A) anger, (B) disgust, (C) sadness, (D) fear, (E) optimism, and (F) joy across various topics. The figure displays the odds ratio of a post's relevance to a particular issue based on the expression of specific emotions by PHEs.



We conduct a similar analysis of the moral language used by the 2 groups of users. The coefficients for the main effects represent the change in the log-odds of the moral foundation for the PHEs when an issue is being discussed, while holding all other issues constant, and the sum of coefficients of the main effects and interaction effects quantifies the change in log-odds for the pseudoexperts. Figure 7 compares the log-odds, along with the corresponding SEs of estimation, to illustrate which

XSL•FO
RenderX

group relied more heavily on a given moral foundation when framing a specific issue. An odds ratio >1 suggests that when a particular issue is discussed, there are increased odds of the post expressing a moral foundation compared to when the issue is not being discussed; an odds ratio=1 indicates equal odds, while a ratio <1 signifies lower odds. The differences in moral language use are less pronounced compared to emotions. PHEs tend to emphasize care and loyalty in discussions of lockdowns and masking, consistent with their use of prosocial messaging that highlights the collective benefits of these measures. Conversely, pseudoexperts tend to convey more notions of harm, fairness, authority, and subversion when addressing lockdowns. This is in line with this issue being extremely contentious for them. Surprisingly, pseudoexperts are more likely to use fairness to frame their discussions of all issues, except vaccines.

Figure 7. Comparing use of moral foundations. It compares (A) care, (B) harm, (C) fairness, (D) cheating, (E) authority, (F) subversion, (G) loyalty, and (H) betrayal conveyed by public health experts (PHEs) and pseudoexperts across various topics. The figure displays the odds ratio of a post's relevance to a particular issue based on the expression of specific moral foundations by PHEs.

The comparison of emotions and moral foundations between PHEs and pseudoexperts highlights their conflicting positions on key COVID-19 pandemic–related issues, notably through the increased use of negative emotions on issues central to the other group. PHEs tend to focus on discussions related to vaccines, health care, and education, and these are issues on which we see more negative emotional framing by the pseudoexperts. In contrast, pseudoexperts are more focused on therapeutics and alternative treatments. Similarly, their negative framing of lockdowns and vaccines reflects their disapproval of the issues that were heavily promoted by PHEs. This divergence of affect underscores the polarization in the society at large. Understanding these differences is crucial for informing public health communication efforts that promote consensus within different segments of the population.

Affective Polarization in Health Communication

Studies show that public response to the COVID-19 pandemic became polarized fairly quickly, with political partisanship shaping online activity and discussions about the COVID-19 pandemic already in the early stages of the COVID-19 pandemic [12,17]. In addition, online discussions became emotionally polarized: when interacting with members of the opposite party, Twitter users expressed more anger and disgust, more toxicity, and less joy than in their interactions with same-party members [95]. Such interactions are characteristic of affective polarization [74], patterns of in-group love and out-group hate that have contributed to the growing partisan divide, and the erosion of trust between the 2 parties in the United States. As a result, partisanship predicted the adoption of COVID-19 pandemic prevention measures more than other factors [96].

To measure affective polarization, we analyze the emotional language PHEs and pseudoexperts directed at the political elites in their original posts. We use a previously curated list [97] of Twitter handles of >17,000 political elites, which include current and former senators, representatives, and media pundits. Figure 8 shows the proportion of posts from each group with mentions of political elites that express various affect. For instance, PHE-Lib indicates the share of PHEs' posts with a greater frequency of references to liberal elites compared to conservative ones, expressing a specific emotion or moral foundation. Figure 8 shows that PHEs post as liberal partisans: when they mention conservative elites in their posts, they use more negative emotions and moral subversion, but when they mention liberal elites, they express more positive emotions. In contrast, pseudoexperts are conservative partisans: they direct more negativity toward liberal elites, while expressing more positivity toward other conservative elites.

XSL•FO
RenderX

Figure 8. Asymmetries in affect toward elites. (A) Public health experts (PHEs) direct more negative emotions (anger and disgust) toward conservative elites and more positive emotions (joy and optimism) in their mentions of liberal elites, which is a hallmark of affective polarization. In contrast, pseudoexperts direct more negativity toward liberal elites. With respect to moral language, (B) PHEs express more subversion in their mentions of conservative elites, in contrast to pseudoexperts. Lib stands for liberal elites and Con stands for Conservative elites.

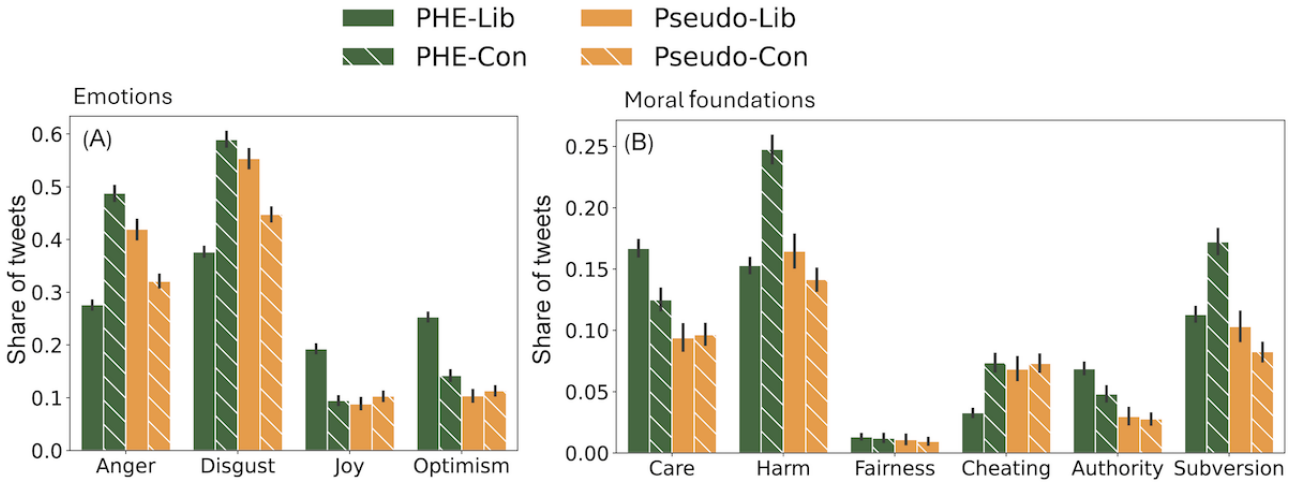


Figure S4 in Multimedia Appendix 1 lists the top 10 accounts that are more likely to be mentioned by PHEs and pseudoexperts positively or negatively. We then assess the repost interactions of PHEs and pseudoexperts with political elites. To this end, we construct a bipartite network comprising directed edges from PHEs or pseudoexperts to political elites, with each edge indicating the political elite reposted by a PHE or pseudoexpert.

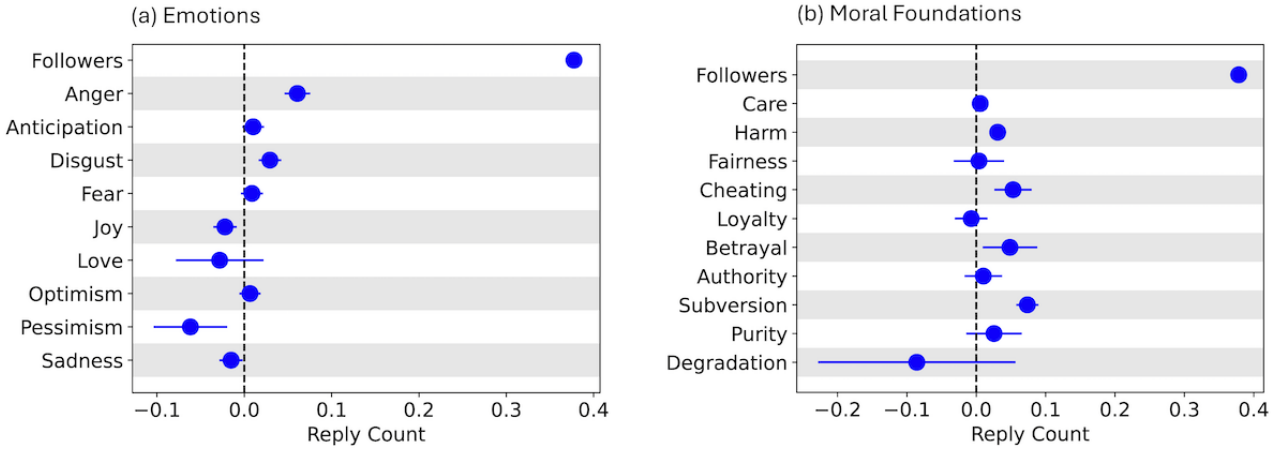
Figure S5A in Multimedia Appendix 1 shows the distribution of ideology estimates for political elites active on Twitter during COVID-19. The ideology estimates were obtained from the study by McCabe [98] and were calculated using methods described in the study by Barberá [99]. The median ideology score of political elites on Twitter is 0.56, which is consistent with the past reports identifying the liberal skew of Twitter [100]. The median liberal and conservative elite have an ideology score of −0.73 and 1.28, respectively. Interestingly, the median ideology score of the elites reposted by PHEs and pseudoexperts is −0.76, indicating that a considerable share of the elites reposted by PHEs and pseudoexperts is more liberal and more conservative, respectively, than the median liberal and conservative elite. In Figure S5B in Multimedia Appendix 1, we visualize this network to find 2 highly clustered interactions. The color of the edge indicates the color of the source node, that is, PHEs (green) or pseudoexperts (orange). We find that PHEs mostly repost liberal elites, whereas pseudoexperts repost conservative ones, highlighting ideological clustering of scientific elites in the United States.

Overall, these findings highlight the existence of a partisan divide within the scientific community, as evidenced by the differential use of emotional and moral language by both PHEs and pseudoexperts toward liberal and conservative elites. Such polarization within the public health elites has implications for the perceived credibility of health messaging and, ultimately, the ability to foster consensus and cooperation in addressing public health challenges.

Public Engagement With PHEs

Effective public health communication relies not only on the dissemination of accurate information but also on how that information is received and interpreted by the public. To investigate this, we extracted original posts (excluding reposts, reply posts, and quoted posts) from PHEs, yielding us a corpus of 144,000 posts. We then collect replies to these posts, aiming to understand the engagement in response to these posts from PHEs. However, our efforts were hindered by challenges encountered when Twitter restricted access to their academic application programming interface, limiting our ability to gather reply interactions to all original posts.

We were able to collect replies for 195,000 original PHE posts, a total of 786,000 replies from 345K unique users. On average, each post received approximately 40.24 replies. The distribution of replies ranged widely, from a minimum of 1 reply to a maximum of 11,700 replies, with a median per post reply count of 5 (IQR 1-7). To quantify the effects of emotions and moral language use on the number of replies a post from PHEs receives, we use linear regression with the number of replies as the dependent variable and emotions or moral foundations expressed in the original post as the independent variables. With different PHEs having varying number of followers, the engagement their posts garner will also be varied. To control for this, we add the number of followers a post's author has as an independent variable. We execute 2 models, one for assessing the impact of emotions and the other for moral attitudes. The emotions model is formulated as follows:



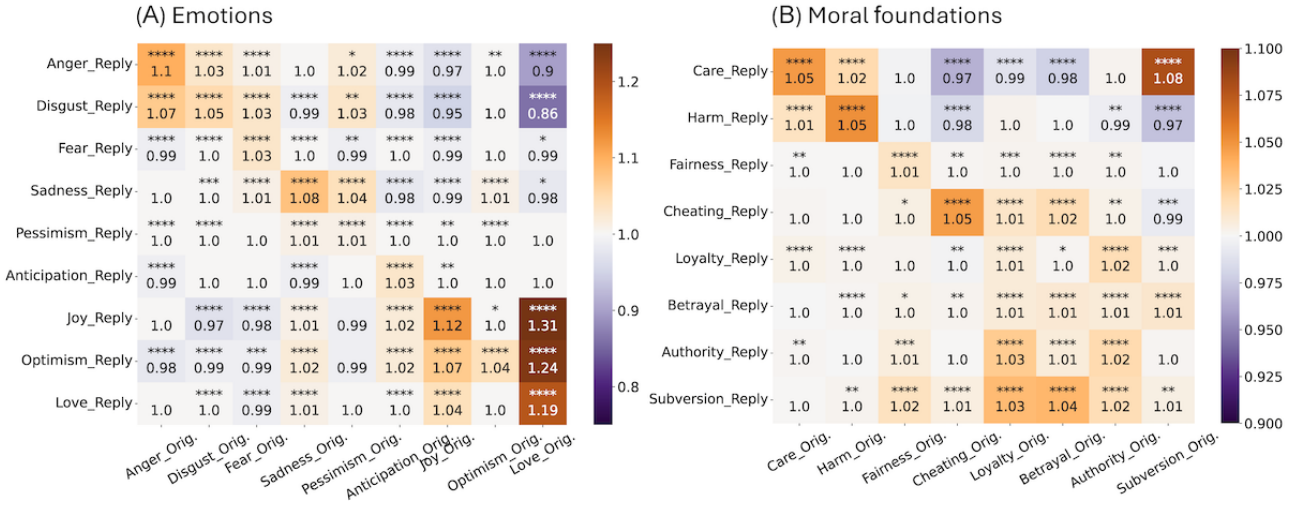
replies ~ followers+ anger+ anticipation + disgust + fear + joy + love + optimism + pessimism + sadness, where replies represent the dependent variable, the number of replies to an original post from a PHE; followers is the number of that PHE's followers; and anger, anticipation, disgust, etc are binary variables indicating whether that emotion is present in the original post. A similar model can be written for moral foundations.

Figures 9A and 9B compare the impact of various emotions and moral foundations on engagement, respectively. We find that, controlling for the number of followers, presence of anger and disgust in the original post generates more replies. This is also true for negative moral language: presence of harm, cheating,

XSL•FO
RenderX

betrayal, and subversion over its corresponding moral virtues is associated with more replies. These findings add important nuance to previous research, which shows that posts expressing negative emotions [101] and moral outrage [69] are more likely to be reposted. Specifically, while negative emotions and moral language also receive more engagement in the form of replies, not all negative language leads to higher engagement: pessimism and sadness in the original posts is associated with fewer replies. Importantly, positive language can even suppress engagement, as is the case for original PHE posts expressing joy and love. Tables S5 and S6 in Multimedia Appendix 1 tabulate the results of this regression analysis.

Figure 9. Engagement with public health experts (PHEs). Dot and whisker plots show the regression coefficients and SEs. The coefficients represent the increase in number of replies when an (A) emotion or (B) moral foundation is used by the PHE in the original post while keeping others constant.



This leads us to question how users react to emotional and moral language of PHEs. We look at whether the use of a particular emotion (or moral foundation) in a PHE post triggers similar language in the replies. We use multivariate logistic regression models to quantify the odds ratio of a user expressing an emotion or moral attitude when presented with a post from the PHE containing certain emotional language (similarly extended to morals). An odds ratio >1 signifies that the user is more inclined to express an emotion or moral foundation, an odds ratio=1 indicates equivalent odds, and a odds ratio <1 suggests a decreased likelihood of expression. The following equation represents the model analyzing the relationship between emotions expressed in replies (<Emotion>_reply) and a set of predictors, including the original emotional content of the post being replied to (anger_orig, disgust_orig, fear_orig, sadness_orig, pessimism_orig, anticipation_orig, joy_orig, optimism_orig, love_orig) and the number of followers of the original poster (followers). Here, <Emotion>_reply denotes the intensity of a specific emotion (e.g., anger, joy) in the reply, while each <Emotion>orig variable represents the emotion in the original post.

$$<\text{Emotion}>_{\text{reply}} \sim \text{anger}_{\text{orig}} + \text{disgust}_{\text{orig}} + \text{fear}_{\text{orig}} + \text{sadness}_{\text{orig}} + \text{pessimism}_{\text{orig}} + \text{anticipation}_{\text{orig}} + \text{joy}_{\text{orig}} + \text{optimism}_{\text{orig}} + \text{love}_{\text{orig}} + \text{followers}$$

Figure 10A shows the odds ratio of users expressing a specific emotion in response to the emotion conveyed in a PHE's original post. We observe that users are more likely to express the same emotions as the original posts. Interestingly, when PHEs express joy and love, users are more likely to express joy, love, and optimism and less likely to express anger and disgust. Conversely, when PHEs convey negative emotions, users are more likely to express anger and disgust. Respondents generally match the emotion tone of the original posts, except when PHEs express sadness, which respondents counter with optimism. Figure 10B illustrates the odds ratio of users expressing a specific moral foundation in response to the moral foundation conveyed in a PHE's original post. Similar to emotions, we observe a mirroring effect in the use of most moral foundations between PHEs and ordinary users. Surprisingly, we notice a higher odds ratio of care being expressed when subversion is used by PHEs. These findings underscore the impact of emotional resonance in shaping user responses to public health messaging. When PHEs rely on positive framing, users tend to echo these positive sentiments. This suggests that the emotional and moral framing used by PHEs influences the emotion expressed by other users. Conversely, when negative framing is used, users tend to reflect these sentiments with increased negative expressions. These insights illuminate the importance of carefully crafting public health messaging to foster cohesive online discourse.

Figure 10. User engagement with public health experts (PHEs) and pseudoexperts. User reactions to (A) emotional and (B) moral appeals from PHEs. The figure demonstrates the odds ratio of users expressing emotions and moral principles in response to those conveyed in the original posts by PHEs. **P*<.05, ***P*<.01, ****P*<.001, and *****P*<.0001; ns: not significant.

Discussion

Overview

The COVID-19 pandemic not only brought about an unprecedented global health crisis but also highlighted the critical role of effective communication in navigating public health challenges. Social media platforms, particularly Twitter, emerged as vital channels for health experts to disseminate timely and reliable information to the public. However, as the COVID-19 pandemic unfolded, discussions surrounding it became increasingly polarized, leading to the proliferation of misinformation and conspiracy theories, often propagated by pseudoexperts. By analyzing a substantial dataset of >515,000 posts generated by approximately 845 elites, this study delves into this infodemic, comparing the emotional and moral appeals used by PHEs and pseudoexperts on Twitter across various COVID-19 pandemic–related issues. In summary, our study offers the following key findings:

- PHEs focus on masking, health care, education, and vaccines, whereas pseudoexperts discuss therapeutics and lockdowns more frequently.
- PHEs typically used positive emotional language across all issues, expressing optimism and joy. Pseudoexperts often used negative emotions such as pessimism and disgust, while limiting positive emotional language to origins and therapeutics. Along the dimensions of moral language, PHEs and pseudoexperts differ on care versus harm, and authority versus subversion, across different issues.
- PHEs act as liberal partisans. They express more positive affect in their posts directed at liberals and more negative affect in their posts directed at conservative elites. In contrast, pseudoexperts act as conservative partisans.
- Negative emotional and moral language tends to boost engagement in COVID-19 discussions across all issues. However, the use of positive language by PHEs increases the use of positive language in the public responses.

Principal Findings

First, we categorized posts from PHEs and pseudoexperts into 7 different issues: origins of the COVID-19 pandemic, stay-at-home lockdown mandates, masking mandates, health care infrastructure, reopening the education system, therapeutics, and vaccinations. Our analysis of Twitter discourse from PHEs and pseudoexperts shows that they focused on different subsets of issues, similar to what was found in other study [24]. While PHEs predominantly focused on promoting public health measures such as social distancing, masking, improving health care infrastructure, and safer reopening of schools, pseudoexperts opposed lockdowns and mask mandates and promoted alternative views on therapeutics and virus origins.

Previous studies [13,97] have assessed the use of emotions and moral foundations expressed by users on social media. Harris et al [102] explored the influence of perceived experts in vaccine-related discussions, finding that they held key positions within the network, acting as central figures among antivaccine users and as bridges connecting the antivaccine and provaccine groups. Our study goes beyond previous studies by revealing emotional and moral divides among influential scientific and pseudoscientific elites on several COVID-19 issues. While PHEs expressed more positive emotions and emphasize moral virtues when discussing lockdowns, masking, health care, and vaccines, pseudoexperts expressed more anger and disgust in their posts on these issues and instead were more positive about therapeutics and alternative cures. The disparate use of emotional and moral language toward ideological elites showed that PHEs were aligned with liberal elites and pseudoexperts were aligned with conservative elites, potentially signaling the role of health influencers in increasing polarization.

Slavik et al [103] and van Dijck and Alinejad [104] assessed public engagement with public health messaging in Canada and the Netherlands during the emergency phase of the COVID-19 pandemic. Slavik et al [103] compared engagement levels across different message functions from health experts. Our study, in contrast, identifies a clear trend in emotional and moral language used by people in response to posts from PHEs. When these

XSL•FO
RenderX

experts express anger, disgust, or moral values, they tend to get more replies from users. In addition, we found that it is more likely for replies to echo the same emotional or moral sentiments as in the original posts from PHEs.

Limitations and Future Work

We note several areas of future research. Given that Twitter users are not a representative sample of the US population, our findings may primarily reflect the perspectives of a specific demographic (ie, younger, more liberal, better educated, and more interested in politics) [100]. Future studies can instead focus on multiple platforms and incorporate multimodal data. While our study examines COVID-19–related discourse, there is potential for investigations into scientific divisions in perspectives on polarized topics such as climate change and genetically modified foods. Moreover, exploring the growing debate on the factors contributing to the decline in adolescent mental health presents another avenue for inquiry.

Despite being state-of-the-art models to identify emotions and moral language [77,78], these models are not oracles. The emergence of more powerful, albeit expensive, instruction-tuned language models such as ChatGPT allows future work to leverage them at scale to identify emotions and moral attitudes with greater accuracy. However, given these tasks' inherent ambiguity, this application might not be straightforward. We emphasize that the event-related shifts in use of emotions and moral language allow us to make observational assertions rather than causal ones. Future studies can attempt to conduct natural experiments to quantify the impact of events on different cohorts. Aside from this, the disruption in our access to Twitter's Education Access application programming interface resulted in us only being able to collect replies for a subset of the PHEs posts in our dataset. However, it is important to note that the subset of posts we collected replies for were not intentionally sampled or biased in any way. Finally, while our dataset is extensive, it covers only the period from January 2020 to January 2021, limiting our findings to this time frame and excluding any potential shifts in perspectives that may have occurred afterward.

Conclusions

In summary, our study offers valuable insights into the dynamics of public health communication on social media amidst the unfolding COVID-19 pandemic, exploring viewpoints from both health experts and pseudoexperts. The identification of an ideological and emotional division in the scientific community poses a potential barrier to consensus building and undermines public trust in health messaging. Nevertheless, policy makers can leverage findings from interactions with PHEs to devise tailored strategies aimed at enhancing consensus. Tackling these obstacles demands a multifaceted approach, integrating fact-checking, debunking initiatives, and targeted communication efforts designed to cultivate trust and encourage critical thinking among the public.

Acknowledgments

This study is supported in part by the National Science Foundation under grant CCF 2200256. We use OpenAI's ChatGPT, a generative AI tool, to generate summaries for analyzing changes in the use of emotional and moral language.

Data Availability

The dataset analyzed during this study is available in the COVID-19 repository [105]. Given the restrictions imposed by X (formerly known as Twitter) on publicly sharing post objects, the authors state that there are certain restrictions on its availability. Only the post identifiers used in this study are publicly available. Readers can apply for application programming interface access from X to rehydrate these posts. The ideology classifier used to determine individual ideological leanings in this study is available on GitHub [106]; also available on GitHub are the emotion classifier [107] and the moral foundations classifier [108]. Auxiliary code used to conduct analyses will be released after acceptance [109].

Conflicts of Interest

Abstract

Background: The use of continuous glucose monitoring (CGM) in the hospital setting is growing, with more patients using these devices at home, especially during the COVID-19 pandemic. Frail and critically ill patients with COVID-19 and previously normal glucose tolerance are also associated with variability in their glucose levels during their intensive care unit (ICU) stay. However, very limited evidence supports the use of CGM in ICU settings, especially among frail patients with COVID-19.

Objective: We aimed to investigate the effectiveness of CGM on ICU-related outcomes among frail and critically ill patients with confirmed COVID-19.

Methods: This was an exploratory, prospective, open-label, parallel, single-center, randomized controlled trial. A total of 124 patients was finally analyzed. The primary outcome was 28-day, in-ICU mortality. The secondary outcome included the length of ICU stay as well as the occurrence of hypoglycemia and severe hypoglycemia events.

Results: The mean age was 78.3 (SD 11.5) years. The mean fasting glucose level and hemoglobin A_{1c} level at baseline were 8.12 (SD 1.54) mmol/L and 7.2% (SD 0.8%), respectively. The percentage of participants with diabetes was 30.6% (38/124). The corresponding hazard ratio of the primary outcome in the intermittently scanned CGM (isCGM) group when compared with the point-of-care testing (POCT) group was 0.18 (95% CI 0.04-0.79). The average length of ICU stay was 10.0 (SD 7.57) days in the isCGM group and 14.0 (SD 6.86) days in the POCT group (P=.02). At the end of study period, the mean value of fasting glucose in the isCGM group and the POCT group was 6.07 (SD 0.63) mmol/L and 7.76 (SD 0.62) mmol/L, respectively (P=.01). A total of 207 hypoglycemia events (<3.9 mmol/L) was detected, with 43 in the isCGM group and 164 in the POCT group (P<.001). A total of 81 severe hypoglycemia events (<2.8 mmol/L) was detected, with 16 in the isCGM group and 65 in the POCT group (P<.001). The major adverse event in this study was bleeding in the puncture site, with a total of 6 occurrences in the isCGM group. During the follow-up, none of the participants dropped out because of bleeding in the puncture site.

Conclusions: We found a significant clinical benefit from the use of CGM among frail and critically ill patients with COVID-19. These findings support the use of CGM in the ICU and might help with the extension of application in various in-hospital settings.

Introduction

Continuous glucose monitoring (CGM) is a method of tracking glucose levels throughout the day and night [1]. CGM systems take glucose measurements at regular intervals, 24 hours a day, and translate the readings into dynamic data, generating glucose direction and rate-of-change reports. It is now widely used, medically prescribed, or commercially available for both patients with and without diabetes [2,3]. Several studies have also suggested that CGM has the potential to become the standard of care for some hospitalized patients, overcoming the limitations of current capillary glucose testing [4,5].

The COVID 19 pandemic continues to have a significant impact on the health and wellness of humans despite significant advances in its diagnosis and treatment [6]. CGM has also been used in the management of patients with COVID-19 [7]. In the United States, the Food and Drug Administration (FDA) issued temporary guidance for expanded use of noninvasive remote monitoring devices that reduce contact between clinicians and patients during the COVID-19 pandemic, effectively allowing CGM systems to be used in hospital settings [8].

Several reports indicate that diabetes and hyperglycemia are linked to worse morbidity and mortality in individuals with COVID-19 [9,10]. On the other hand, frail and critically ill patients with COVID-19 and previously normal glucose tolerance are also associated with variability in their glucose levels during their intensive care unit (ICU) stay, which might be caused by the critical illness itself or certain medication therapies such as glucocorticoids and immunosuppressants. Therefore, maintaining optimal glucose levels in hospitalized patients with frailty and critical illness is a key component of care.

However, very limited evidence supports the use of CGM in ICU settings, especially among frail patients with COVID-19. We thus performed an exploratory, prospective, open-label, parallel, single-center, randomized controlled trial (RCT) to investigate the effectiveness of CGM on short-term, in-hospital mortality among frail and critically ill patients with COVID-19.

Methods

Study Design

This is an exploratory, prospective, open-label, parallel, single-center RCT. Eligible participants were recruited from Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine at Lingang Campus and were randomly divided into the intervention group (wearing a CGM device) and the control group (routine fingertip measurements). The allocation ratio was 1:1. This trial was registered at the Chinese Clinical Trial Registry (ChiCTR2200059733) before the first recruitment of the participants.

Ethical Considerations

This trial was approved by the Institutional Review Board of Shanghai Sixth People's Hospital (approval 2022-KY-054). All participants provided written informed consents, and all data collected were only used in this study. All data collected in this study have been anonymized to ensure participant privacy and confidentiality. Personal identifiers have been removed, and unique codes were used to manage data without any direct link to participants' identities. No compensation was provided to participants in this study. The research was conducted voluntarily, and participants were informed of this during the consent process.

Recruitment and Screening

The recruitment process involved identifying potential participants from hospital ICU registries. Hospital databases were systematically reviewed to locate patients meeting the initial eligibility criteria, including age, confirmed COVID-19 diagnosis, and indicators of critical illness. Once potential participants were identified, their medical records were thoroughly examined to verify clinical details, including diagnostic results from real-time, reverse transcription polymerase chain reaction (RT-PCR) assays and assessments of respiratory function, oxygen saturation levels, and pulmonary imaging findings. Following this initial review, clinical evaluations were conducted to confirm the presence of the inclusion criteria. In parallel, exclusion criteria were assessed by reviewing the patients' mental health status and cognitive function to identify any clinically significant psychosis or cognitive impairment that might interfere with their ability to participate in or comply with the study protocol.

Study Participants

Eligible participants were frail older adults aged 65 years or older who were diagnosed with COVID-19 and critical illness. COVID-19 cases were confirmed by real-time RT-PCR assay of nasal and pharyngeal swab specimens. Critical illness was defined as patients with one of the following conditions: shortness of breath, respiratory rate ≥30 times/min; oxygen saturation ≤93% in a resting state; arterial oxygen partial pressure/oxygen inhalation concentration ≤300 mm Hg; pulmonary imaging showing that the lesions have significantly progressed >50% within 24-28 hours; any occurrence of respiratory failure and requiring mechanical ventilation; or shock, combined with other organ failure. Patients were excluded if they had any clinically significant psychosis or cognitive impairment; they were also excluded if they were unlikely to comply with or complete the study.

Interventions

The patients in the intervention group were instructed on the use of an intermittently scanned CGM (isCGM) device (Freestyle libre; Abbott Diabetes Care). The sensor was implanted in a site with sufficient subcutaneous fat on the back

XSL•FO
RenderX

of the upper arm, and this site can remain flat (without bends or wrinkles) during the participants' activities. Scars, moles, obesity lines, or lumps were avoided. One sensor lasted no longer than 14 days. If the sensor was expired or malfunctioned, a new one would be immediately implanted until discharge or death. Data were extracted and processed by using a scanner (by swipes) and auxiliary software. The frequency of the swipes followed the routine care during ICU stays at 4 hours intervals or whenever necessary. Data extracted from the CGM device included the mean glucose levels, coefficient of variance (CV), and times of severe hypoglycemia and hypoglycemia (<2.8 and <3.9 mmol/L, respectively) every day. The patients in the control group received a routine fingertip measurement (point-of-care testing [POCT]) for glucose levels. The frequency was consistent with the CGM swipes, ranging from every 1 hour to 4 hours when necessary. If a patient encountered hypoglycemia, more frequent testing of swipes and POCT were done. The mean glucose levels and CV were calculated based on the fingertip glucose profiles.

Sample Size Calculations

According to a previous case-control study [11], the composite adverse COVID-19 outcome (defined as progression to critical illness or death) occurred in 46% of patients in the isCGM group compared with 66% in the POCT group. Therefore, this study can achieve 80% statistical power at the level of α=.05 by including 50 patients in each group to achieve the superiority end point.

Randomization, Treatment, and Follow-Up During ICU stay

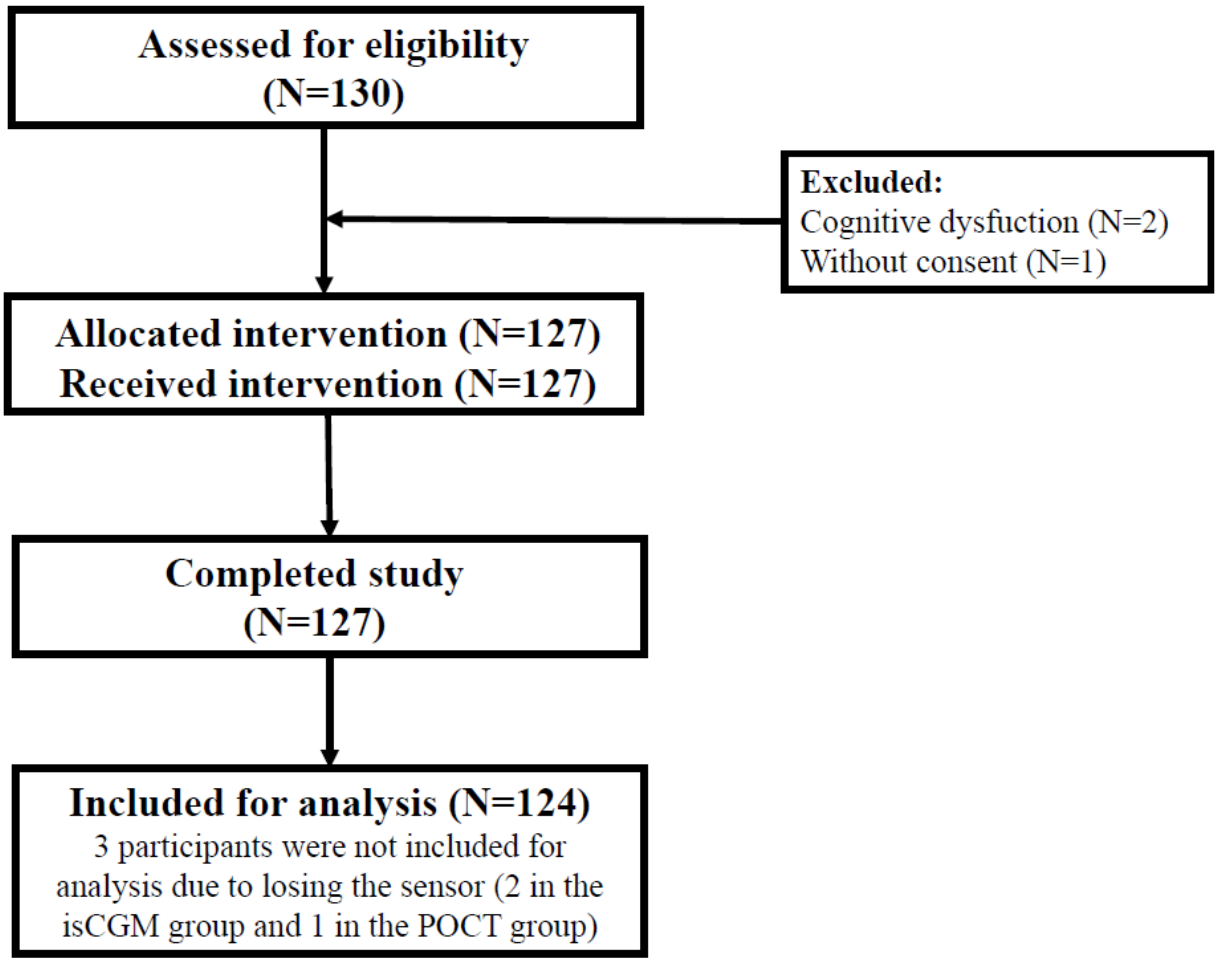
The participants were randomly assigned to the intervention and control groups in a 1:1 ratio at the time of admission to the ICU. The randomization sequence was generated by the staff. No blinding was applied during the study period. Anthropometric and clinical data were collected from the patients' self-reporting or the electronic medical records at baseline and at the end of their ICU stay or death after the intervention. These data included sex, height, weight, laboratory measurements, and history of diseases and medications. BMI was calculated as the weight in kilograms divided by the squared height in meters. The treatments of COVID-19 among critically ill patients were prescribed according to the diagnosis and treatment guideline for COVID-19 (ninth version) in China. For all patients received intravenous glucocorticoids, insulin was initiated when the glucose level was persistently higher than 13.9 mmol/L. The average daily dosages of glucocorticoids (converted to the dosages of prednisone) and insulin were also collected.

Outcomes

The primary outcome was 28-day mortality in the ICU. The secondary outcome included the length of stay in the ICU, as well as the occurrence of hypoglycemia and severe hypoglycemia events (<3.9 and <2.8 mmol/L, respectively).

Statistical Analysis

The analysis was performed according to the intention-to-treat principle. The data are reported as the mean (SD) unless otherwise stated. One‐way ANOVA was used to analyze differences in population characteristics from baseline to the end of study. A multivariate generalized estimating equation model adjusted for sex and age was used to evaluate influential factors on in-hospital mortality. The Kaplan-Meier survival analysis was used to compare the survival rate between patients in the isCGM and POCT groups. All data were analyzed using R (version 4.0.3; R Foundation for Statistical Computing). A 2‐tailed P<.05 was defined as significant.



Results

Baseline Characteristics of the Study Participants

Of the 130 participants who underwent screening in this study, 127 (97.6%) were enrolled and randomly assigned. In all, 64 were in the isCGM group while 63 were in the POCT group. Of these 127 participants, a total of 124 (97.6%) completed the study. A total of 2 participants from the isCGM group and 1 participant from the POCT group discontinued the study because they lost the sensor during the study period (Figure 1).

XSL•FO
RenderX

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow chart of study. A total of 130 participants were screened for eligibility, and 127 were randomly assigned. All 127 participants completed the study. However, 3 partcipants were not included for analysis due to losing the sensor (2 in the isCGM group and 1 in the POCT group). Thus, the final analysis included 124 participants. isCGM: intermittently scanned continuous glucose monitoring; POCT: point-of-care testing.

The baseline characteristics are shown in Table 1. The mean age was 78.3 (SD 11.5) years. The mean fasting glucose level at baseline was 8.12 (SD 1.54) mmol/L. The mean hemoglobin A_{1c} level was 7.2% (SD 0.8%). The percentage of participants with diabetes was 30.6% (38/124). The baseline characteristics were well balanced and comparable at baseline.

[g]AST: aspartate aminotransferase.

[h]LDL: low-density lipoprotein.

[i]HDL: high-density lipoprotein.

[j]eGFR: estimated glomerular filtration rate.

[k]Reported as the dosage of prednisone.

The Changes in Fasting Glucose Levels and Other Glycemic Parameters at the End of the Trial

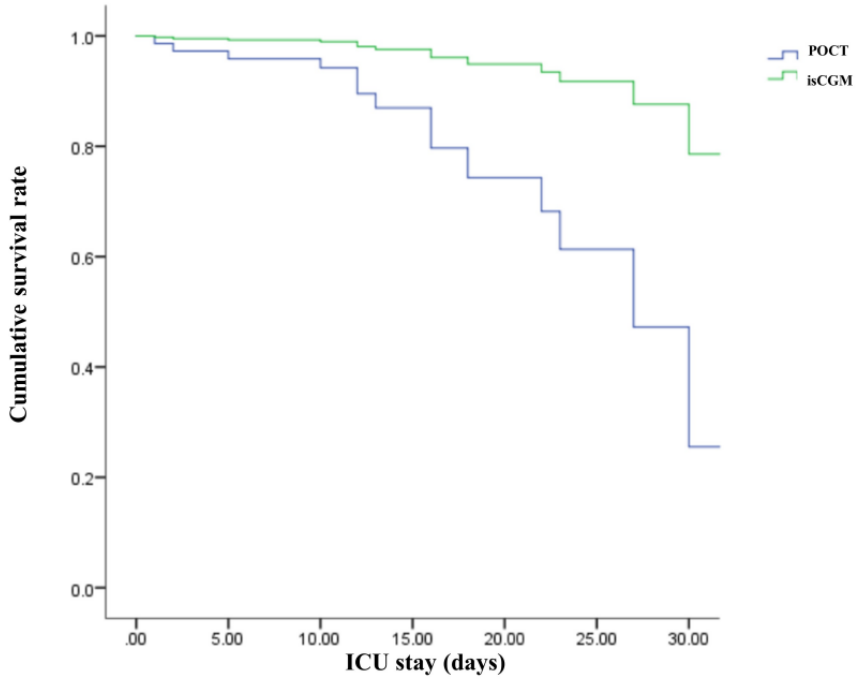
There was no difference in fasting glucose levels observed between the isCGM and the POCT groups at baseline (mean 8.10 SD 1.35 vs 8.13, SD 1.67; *P*=.43). When compared with the baseline value of fasting glucose, both groups showed significant decreases at the end of the study period (isCGM: mean 8.10, SD 1.35 vs 6.07, SD 0.63; *P*=.001; and POCT: mean 8.13, SD 1.67 vs 7.76, SD 0.62; *P*=.04). At the end of study period, the mean value of fasting glucose in the isCGM group and the POCT group was 6.07 (SD 0.63) mmol/L and 7.76 (SD 0.62) mmol/L, respectively, showing a significant intergroup difference (Table 2; *P*=.01). The daily mean glucose levels (6.93, SD 0.72 vs 8.43, SD 0.52 mmol/L; *P*=.02) and the CV (25.2%, SD 1.23% vs 33.7%, SD 1.15%; *P*=.01) were also found to be significantly lower in the isCGM group than those in the POCT group at the end of the trial. Multivariate generalized linear model defined the reduction of fasting glucose levels as a dependent variable and the control group as the reference. After adjustment of age, sex, and BMI, the results showed that at the end of the study period, the intervention (isCGM) was associated with a larger reduction of fasting glucose levels (–1.69, 95% CI –1.65 to –1.73; *P*<.001).

Table 2. Comparisons of glycemic parameters at the end of the trial.

	isCGM[a] group (n=62), mean (SD)	POCT[b] group (n=62), mean (SD)	Relative risk or difference (95% CI)	*P* value
Fasting glucose (mmol/L)	6.07 (0.63)	7.76 (0.62)	–1.69 (–1.65 to –1.73)	.01
Daily mean glucose (mmol/L)	6.93 (0.72)	8.43 (0.52)	–1.50 (–1.47 to –1.53)	.02
CV[c] (%)	25.2 (1.23)	33.7 (1.15)	0.75 (0.71 to 0.79)	.01

[a]isCGM: intermittently scanned continuous glucose monitoring.

[b]POCT: point-of-care testing.



[c]CV: coefficient of variance.

Mortality in the ICU

A total of 15 death events occurred during the study period, with 2 in the isCGM group and 13 in the POCT group. The corresponding hazard ratio of mortality in the ICU in the isCGM group when compared with the POCT group was 0.18 (95% CI 0.04-0.79; Figure 2). The average length of ICU stay was 10.0 (SD 7.57) days in the isCGM group and 14.0 (SD 6.86) days in the POCT group, with a significant *P* value for comparison (*P*=.02).

XSL•FO
RenderX

Figure 2. The cumulative survival rate between the POCT and isCGM groups ($P<.05$). The corresponding hazard ratio of mortality in the ICU in the isCGM group when compared with the POCT group was 0.18 (95% CI 0.04-0.79). ICU: intensive care unit; isCGM: intermittently scanned continuous glucose monitoring; POCT: point-of-care testing.

Hypoglycemia Events

A total of 207 hypoglycemia events (<3.9 mmol/L) was detected, with 43 in the isCGM group (0.0006 times per patient per day) and 164 in the POCT group (0.002 times per patient per day; $P<.001$). A total of 81 severe hypoglycemia events (<2.8 mmol/L) was detected, with 16 in the isCGM group (0.0002 times per patient per day) and 65 in the POCT group (0.0008 times per patient per day; $P<.001$).

Adverse Event

The major adverse event in this study was bleeding in the puncture site, with a total of 6 occurrences in the isCGM group. During the follow-up, none of the participants dropped out because of bleeding in the puncture site.

Discussion

In this exploratory, prospective, open-label, parallel, single-center RCT, we observed a significant improvement on the prognosis of frail and critically ill patients with COVID-19, with fewer in-hospital death events and hypoglycemia events. These findings suggest that the use of isCGM during ICU stay under the COVID-19 pandemic was a protective way to help improve the survival rate among the extremely frail patients.

To date, this might be the first RCT on the use of CGM in the ICU setting among patients with COVID-19, although it was a single-center study with limited sample size. Evidence on the in-hospital use of CGM, especially in the ICU, is still limited. Most studies are observational with a diverse population [12]. While CGM is an efficient tool for patients with diabetes, it has extended its use to other specific populations without diabetes within in-hospital settings such as in the ICU [13], during the perioperative period [14], during pregnancy or labor [15], and among frail populations [16]. The continuous efforts are made by the manufacturers of CGM toward more accuracy, painlessness, and being less burdensome. Early in 2020, the FDA announced the feasibility of using CGM during an in-hospital stay. CGM is essential for the care of glycemic management and can reduce the risk of cross-infections and nosocomial infections among health care professionals.

For the use of CGM in the ICU, several observational studies reported the feasibility and accuracy of different CGM systems. We previously reported the suboptimal overall accuracy of an isCGM system (Freestyle Libre) for critically ill patients. The mean absolute relative difference was reported to be 18% [13]. These data allowed us to further investigate the effectiveness of CGM on ICU-related outcomes among frail patients with COVID-19. We found a significant difference in survival between patients with isCGM and those without isCGM. In another observational study at the Montefiore Medical Center, real-time CGM was used on ICU patients with confirmed COVID-19 infection and glycemic variability [17]. The study demonstrated early feasibility, considerable accuracy, and meaningful reduction in the frequency of POCT. One US study also tested the feasibility among patients receiving operations and those who were admitted to the cardiac ICU, and they provided encouraging results with sustained accuracy of CGM even during exposure to vasopressors [18].

This study aims to fill the gap of evidence on the use of CGM in hospital settings. Less evidence is provided from RCTs of CGM under in-hospital settings. Most of the RCTs focused on the glycemic benefit provided by the use of CGM. Two studies found that the use of the Dexcom senor when compared to either POCT or a blinded CGM device could definitely improve the

XSL•FO
RenderX

glycemic control by increasing time in target range and reducing time below or above target ranges [19,20]. In this exploratory, prospective, open-label, parallel, single-center RCT, we first reported the huge benefit of CGM on ICU mortality as well as the length of ICU stay among frail and critically ill patients with COVID-19. The use of CGM also provided a timely chance for the clinicians to observe the hyperglycemia and hypoglycemia events and treat them [20]. There was also a significant difference in the hypoglycemia events between the CGM group and the POCT group. This study supported the hypothesis that CGM might help with the improvement of glycemic control and the outcomes beyond glucose levels. More trials or longitudinal studies with long-term follow-ups are still needed to demonstrate the effect of CGM on disease outcomes other than glycemic control.

The major limitation of this study is the small sample size within a single center. In addition, selection bias might also be introduced because we used a specific population of patients with frailty and critical illnesses, and those patients tended to be older. Whether the findings can be translated to other populations needs further validation in a multicenter design and with a large sample. The strength of this study is that it is the first to demonstrate the association of CGM use and adverse ICU outcomes in frail and critically ill patients with COVID-19. The RCT design also strengthens the level of evidence.

In conclusion, we found a significant clinical benefit from the use of CGM among frail and critically ill patients with COVID-19. These findings support the use of CGM in the ICU and might help with the extension of application in various in-hospital settings.

Acknowledgments

We really appreciate and respect the efforts by the doctors, nurses, and patients during the COVID-19 pandemic.

Abstract

Background: The emergence of new SARS-CoV-2 variants, the resulting reinfections, and post–COVID-19 condition continue to impact many people's lives. Tracking websites like the one at Johns Hopkins University no longer report the daily confirmed cases, posing challenges to accurately determine the true extent of infections. Many COVID-19 cases with mild symptoms are self-assessed at home and reported on social media, which provides an opportunity to monitor and understand the progression and evolving trends of the disease.

Objective: We aim to build a publicly available database of COVID-19–related tweets and extracted information about symptoms and recovery cycles from self-reported tweets. We have presented the results of our analysis of infection, reinfection, recovery, and long-term effects of COVID-19 on a visualization website that refreshes data on a weekly basis.

Methods: We used Twitter (subsequently rebranded as X) to collect COVID-19–related data, from which 9 native English-speaking annotators annotated a training dataset of COVID-19–positive self-reporters. We then used large language models to identify positive self-reporters from other unannotated tweets. We used the Hibert transform to calculate the lead of the prediction curve ahead of the reported curve. Finally, we presented our findings on symptoms, recovery, reinfections, and long-term effects of COVID-19 on the Covlab website.

Results: We collected 7.3 million tweets related to COVID-19 between January 1, 2020, and April 1, 2024, including 262,278 self-reported cases. The predicted number of infection cases by our model is 7.63 days ahead of the official report. In addition to common symptoms, we identified some symptoms that were not included in the list from the US Centers for Disease Control and Prevention, such as lethargy and hallucinations. Repeat infections were commonly occurring, with rates of second and third infections at 7.49% (19,644/262,278) and 1.37% (3593/262,278), respectively, whereas 0.45% (1180/262,278) also reported that they had been infected >5 times. We identified 723 individuals who shared detailed recovery experiences through tweets, indicating a substantially reduction in recovery time over the years. Specifically, the average recovery period decreased from around 30 days in 2020 to approximately 12 days in 2023. In addition, geographic information collected from confirmed individuals indicates that the temporal patterns of confirmed cases in states such as California and Texas closely mirror the overall trajectory observed across the United States.

XSL•FO
RenderX

Conclusions: Although with some biases and limitations, self-reported tweet data serves as a valuable complement to clinical data, especially in the postpandemic era dominated by mild cases. Our web-based analytic platform can play a significant role in continuously tracking COVID-19, finding new uncommon symptoms, detecting and monitoring the manifestation of long-term effects, and providing necessary insights to the public and decision-makers.

Introduction

Background

COVID-19 is one of the most severe infectious diseases in human history. Although the World Health Organization downgraded the COVID-19 pandemic, declaring it is no longer a global emergency on May 5, 2023 [1], the threat of infection and death remains. As of August 1, 2023, there have been >300,000 confirmed cases weekly worldwide, resulting in >1000 deaths per week; however, major information-publishing platforms, such as that at Johns Hopkins University, stopped collecting and tracking COVID-19 data worldwide on March 10, 2023 [2]. Therefore, it has become more challenging to identify the actual number and trends of COVID-19 infections daily. Traditional public health monitoring methods face several challenges, including delays in clinical data collection, lack of real-time insights, and the underrepresentation of population-level trends, particularly in regions with limited health care reporting infrastructure [3,4]. New tools are required to provide timely awareness and detection of COVID-19 transmission trends, reinfection patterns, and the long-term health impact of the disease.

To supplement the shortage of clinical data and gain further insights into the development trends and variant tendencies of COVID-19, researchers have turned to social media, specifically Twitter (subsequently rebranded as X). Social media data offer unique advantages, such as rapid updates and a broad geographical reach, which traditional clinical data often lack [5,6]. Several studies [7-11] have explored the use of social media for health monitoring, including sentiment analysis of COVID-19–related tweets, the identification of emerging symptoms, and the study of vaccine hesitancy. Early studies [12-16] primarily focused on constructing COVID-19–related tweet databases. However, these works do not provide in-depth analysis of self-reported tweets, and the databases tended to be collected over a short time frame, typically several months, and cannot automatically update. Later, some research endeavors [9,17-19] shifted their focus toward studying COVID-19 symptoms on the basis of tweets and reported the distribution of symptoms in tweets. However, these studies included limited numbers of collected self-reported cases. Some studies [16,20-24] used tweets to study geographic distribution but did not provide a corresponding time-series analysis or predict the spread of COVID-19. Moreover, existing studies have not fully leveraged user-generated content on social media to provide a comprehensive, dynamic view of COVID-19 trends across symptoms, geography, and time. This gap underscores the need for a methodology capable of providing near–real-time insights and broader geographical coverage [25]. As for the visualization tools for COVID-19, some researchers [26-29] have developed platforms or dashboards to study the trends of COVID-19, but most were based on clinical data. A few tweet-based platforms [27,29,30] showed limited information and failed to provide timely updates.

Reinfection often refers to the phenomenon in which an individual who has recovered from COVID-19 is again infected with the virus [31]. Some researchers [32,33] considered that reinfection is identified when an individual tests positive again through polymerase chain reaction (PCR) testing after a minimum of 90 days of a negative result. However, some studies also suggest this duration should be 30 days [34,35]. Other studies [34,36,37] considered reinfection to be a new positive PCR following 2 consecutive negative PCR tests taken after primary infection. Moreover, the periodicity of reinfection, the reinfection rate, and the maximum number of infections are uncertain. Existing studies on reinfection trends and periodicity have primarily relied on clinical data, leaving gaps in understanding population-level reinfection dynamics that may be observable through self-reported data on social media [38]. In addition to reinfection, there is a growing concern about the long-term effects of COVID-19, known as post–COVID19 condition, where patients report symptoms lasting months after recovery [39,40]. Clinical data on long-term effects remain limited [41], but social media offers a platform where individuals can share ongoing symptoms, providing valuable insights for public health research [42,43]. This further highlights the potential of using self-reported data to investigate the periodicity of reinfection, as well as long-term effects and symptoms, complementing traditional clinical datasets.

Health natural language processing (NLP) is gaining increasing attention for its essential role in both methodology development and applications [44]. The technology has been widely applied in areas such as information extraction from electronic health records [45], adverse drug reaction analysis [46], clinical decision support [47], and hospitalization prediction [48]. Using techniques such as topic modeling, sentiment analysis, and deep learning models such as Bidirectional Encoder Representations from Transformers (BERT) [49], NLP can extract valuable medical insights from unstructured text. Combined with real-time analytics frameworks [50] and knowledge graphs [51], these technologies can dynamically monitor COVID-19 trends, identify previously unnoticed symptoms and long-term effects, and provide scientific support for optimizing public health strategies and resource allocation.

RenderX

Objectives

In this study, we address these gaps by leveraging self-reported COVID-19 data from Twitter to provide near–real-time insights into trends across symptoms, reinfection, recovery cycles, and geographical distributions. The proposed approach not only fills the limitations of traditional monitoring systems but also offers a scalable, timely, and comprehensive method to track the pandemic's evolving dynamics. Our visualization tool updates weekly and comprehensively analyzes information related to COVID-19 symptoms, case distribution, reinfections, recoveries, and long-term effects based on large language models (LLMs). Figure 1 depicts our research objectives: (1) we aim to build a publicly available database of >9,836,206 COVID-19–related tweets, and this database is set to automatically update with newly collected data weekly; (2) LLMs will be built to automatically filter the tweets of self-reporters and extract their mentioned symptoms and recovery cycles; and (3) we aim to build a visualization website that refreshes data on a weekly basis, Covlab [52], to track and analyze infection, reinfection, recovery, and long-term effects of COVID-19.

As depicted in Figure 1, the workflow of Covlab comprised the following steps: data collection, models training, tracking, and visualization website. During data collection, COVID-19–related tweets were collected using the Twitter application programming interface (API) and filtered from a broader dataset of social media posts. A subset of these tweets was manually labeled through a specialized annotation tool, creating a high-quality training set essential for developing machine learning models. In addition, historical tweets and user ID databases were incorporated to construct a comprehensive cohort of individuals who self-reported COVID-19 infections, forming the foundational dataset for subsequent tracking and analytical tasks. In models training step, annotated datasets were used to train a variety of machine learning and NLP models, including support vector machine (SVM), logistic regression (LR), BERT, GPT-2, and LLM meta AI 2 (Llama-2), to identify the most effective model for detecting self-reported COVID-19 infection tweets. After selecting the optimal model, it was applied to a larger collection of COVID-19–related tweets to extract tweets reporting personal COVID-19 infections. Throughout this process, performance metrics such as cross-validation and receiver operating characteristic (ROC) curve analysis, were used to ensure the models provided robust and accurate predictions. In the tracking step, the system conducted long-term tracking of individuals who self-reported COVID-19 infections in their tweets, focusing on analyzing symptoms such as breathing difficulties, fever, headache, cough, and fatigue, as well as recovery cycles, long-term effects (ie, sequelae), and geographical trends. In addition, reinfection cases were monitored to provide insights into the temporal dynamics of COVID-19 experiences, helping to uncover patterns in symptom progression, recovery, and recurring infections over time. In the visualization website step, the results of the analyses were presented on an interactive platform, Covlab, which provided a variety of visualization tools, including word clouds, pie charts, box plots, line graphs, geographic maps, and trend tables. This platform enabled users to track epidemic trends, uncover new or previously unreported symptoms, analyze recovery durations, report reinfection statistics, and explore different types of long-term effects (ie, sequelae), offering valuable insights to researchers and public health officials.

Methods

Data Collection and Preprocessing

We collected and processed tweet data from January 2020 to April 2024 based on COVID-19–related keywords and hashtags through the Twitter streaming API. The searching keywords included "I.* tested[ed] positive for [covid | coronavirus | covid19 | covid-19]," "My.* [covid | coronavirus | covid19 | covid-19].* symptoms," "#COVID" "#LongCovid" (all the keywords can be found in Multimedia Appendix 1). The following preprocessing operations were conducted on the tweets collected based on keywords. We first converted all words in the tweets to lowercase, standardized the tweets to American Standard Code for Information Interchange encoding using the Unicode library, and tokenized the tweets. Next, we removed all Unicode symbols and punctuation marks, some uninformative characters about usernames, such as @username, all digits and line breaks in the tweets, all URLs, such as http://, and all words contained in our stop word library (Multimedia Appendix 2). We converted emoji expressions into their corresponding textual expressions. To provide sufficient datasets for subsequent model training, we constructed a self-reported COVID-19 tweets dataset with manual labeling by 9 native English-speaking annotators after obtaining ethics approval. We also established a set of calibration criteria as shown in Table 1 to ensure the consistency and reliability of the tweet annotations. Two additional annotators conducted a secondary annotation on the labeled data. If their new annotations were inconsistent with the originals, all annotators would decide through a voting process whether the tweet should be classified as a self-reported COVID-19 positive tweet. The Fleiss κ index [53] was used to measure the consistency among multiple annotators to ensure the reliability of the annotations (Multimedia Appendix 3). We also developed a web-based annotation tool (Multimedia Appendix 4) to improve the efficiency of manual annotation. We annotated 115,214 tweets, of which 13,701 (11.89%) were positive samples that described self-reported positive COVID-19 cases and 101,513 (88.11%) were negative samples either not describing self-infection with COVID-19 or irrelevant. Multimedia Appendix 5 presents the types of tweets targeted in our study. The tweet depicted on the left serves as a prototypical instance, delineating self-reported information about COVID-19 infections. This includes the date of diagnosis and a detailed account of the symptoms experienced by the individual. Conversely, although the tweet shown on the right also references a diagnosis of COVID-19 and details associated symptoms, it diverges from our criteria for target tweets because it recounts a diagnosis pertaining to a third party, specifically a friend of the tweeter, rather than a self-reported account. Therefore, it falls outside the scope of our target dataset.

Table 1. Labeling criteria for the tweets.

Index	Annotation guideline	Description
1	Self-reported infection	Tweets must be a personal account by the author regarding their experience of contracting COVID-19. If the tweet mentions someone other than the author being infected, such as friends, family, or others, it should be labeled as a negative sample.
2	First-person narrative	Tweets should use first-person pronouns (eg, "I," "me," and "my") to describe the author's experience of contracting COVID-19, not that of others.
3	Concrete information	Tweets should provide concrete details, including infection timeline, test results and medical treatments, among others, rather than general discussions or speculations.
4	Symptom description	Tweets should contain the patient's personal descriptions of COVID-19 symptoms experienced, such as fever, cough, or difficulty breathing.
5	Confirmation information	Tweets should mention how the author was confirmed to have contracted COVID-19, such as the type of test conducted (PCR[a] and rapid antigen test), confirmation by a physician, or official institution validation.
6	Treatment experience	Tweets should describe the author's experience of treatment or recovery after self-contracting COVID-19, including isolation, medication, deterioration, or improvement in their health.
7	Infection timeline	Tweets should contain exact time points or time ranges of the infection rather than general discussions. Providing precise timing helps verify the author's infection period.
8	Test results	Tweets should reference the author's COVID-19 test results, such as testing positive or negative or other relevant test outcomes.
9	Medical Facility	Tweets should mention whether the author received treatment or underwent COVID-19-related tests at a medical facility, such as a hospital or clinic.
10	Social distancing measures	Tweets should discuss the author's adoption of social distancing measures due to their infection, such as self-isolation or notifying close contacts.
11	Substantial evidence	Tweets should contain substantial evidence, such as medical records, official notices, or other documents validating the author's COVID-19 infection.
12	Exclusion of transmission	Tweets emphasizing that the author did not transmit the virus to others may indicate a self-reported infection.
13	Consensus annotation	If 3 or more annotators provide inconsistent annotations for a particular tweet, a discussion among all annotators should be initiated to reach a final consensus.

Ethical Considerations

We have prioritized privacy and ethical considerations in our use of self-reported COVID-19–related tweets from Twitter, which, while publicly available, are processed with strict anonymization measures to ensure that no personally identifiable information can be traced back to individuals. The ethical nuances of using such data are addressed by considering users' implied consent when posting self-reports on a public platform. To safeguard data security throughout collection, annotation, and analysis, we have implemented encryption, controlled access, and other technical measures, ensuring that the data are strictly used for research purposes and never for commercial activities. Furthermore, recognizing the inherent noise and biases in social media data, we explicitly acknowledge the limitations of our dataset and analysis. To mitigate potential risks of misinterpretation or misuse, we emphasize that our findings are intended for population-level trend analysis rather than individual diagnosis, thereby maintaining the integrity and appropriate application of the results. This study is exempt from ethical approval because it only involves the analysis of aggregate data, ensuring that no individual privacy information is disclosed. All data have been fully deidentified, and appropriate anonymization measures have been applied to guarantee that no subject can be traced.

Self-Reported COVID-19–Positive Model

To select text-classification models to determine whether a tweet is a self-reported COVID-19– positive tweet, we trained both traditional machine learning methods and fine-tuned LLMs. We divided the manually labeled dataset in which 80% (92,171/115,214) was used as the training set, 10% (11,521/115,214) as the validation set, and the remaining 10% (11,521/115,214) as the test set. We used word frequency, term frequency–inverse document frequency [54] vectors, and feature hashing vectors as methods for text feature extraction, and we adopted 10-fold cross-validation to ensure the reliability of the results.

For conventional machine learning models, we used both linear and nonlinear models to compare different classification approaches. Because the amount of the manually annotated data were relatively small and the text data features were relatively simple, we experimented with machine learning methods such as naive Bayes [55], SVMs [56], and LR [57]. In the SVM method, we used the radial basis function as the kernel function and set the penalty parameter to 1.2. We used an L2 regularization as the penalty term in LR, with a regularization strength parameter (C) set to 1.0. As for LLMs, we used BERT [49], robustly optimized BERT pretraining approach (RoBERTa) [58], extreme language model [59], GPT-2 [60], Bigscience Large Open-science Open-access Multilingual language model (BLOOM) [61], and Llama-2 [62] for training. These LLMs are pretrained on large datasets using the masked language model objective for BERT and RoBERTa; the permuted language model objective for extreme language model; and the causal language modeling objective for GPT-2, BLOOM, and Llama-2. Because GPT-2, BLOOM, and Llama-2 are generative models, they may generate nonuniform results, rendering result interpretation difficult. These pretrained LLMs were originally designed to process general text of varying lengths. Through fine-tuning these LLMs on tweets, which are inherently short texts, we adapted them to better handle short text-classification tasks. We selected models pretrained on English corpora to ensure appropriate language understanding. We borrowed the idea from previous work [63], leveraging latent representations from LLMs for supervised label prediction. Hence, we designed different LLM-based classifiers integrated with various LLMs and fully connected neural networks. Precisely, each LLM serves as a backbone for encoding the tweets instead of generating text. A fully connected neural network was integrated on top of each LLM for stably accurate detection of self-reported COVID-19 cases. Unlike traditional machine learning methods requiring feature preprocessing, the LLM-based classifiers take only the text of a tweet as input. The specific parameters of the machine learning methods and LLMs can be found in Multimedia Appendices 6 and 7.

To prevent catastrophic forgetting and ensure that LLMs have a broad understanding of self-reported COVID-19 cases during the training stage, we used low-rank adaptation (LoRA) [64] to fine-tune the LLM-based classifiers. LoRA enables the parameters of a model to learn effectively by introducing trainable rank decomposition matrices into the transformer architectures in the LLMs. To achieve this reparameterization, we modified the projection matrices of query, key, value, and feedforward network modules within the self-attention mechanism of the transformer.

The LLM-based classifiers were trained end-to-end with the AdamW [65] optimizer with a cross-entropy objective function. During the training stage, the parameters introduced by LoRA within the pretrained model were updated with gradients, and all remaining parameters were frozen. Early stopping to monitor the accuracy of the validation dataset was implemented during training. All runs were trained on the Nvidia A100 graphical processing unit with a batch size of 5 for Llama-2 and 32 for other models.

We evaluated the performance of each model and chose the one that achieved the best results for predicting the daily number of self-reported confirmed cases. Subsequently, we applied a named entity recognition [66,67] method such as SpaCy [68] and BERT-based models to extract essential symptom-related keywords from the tweets. The model was trained or fine-tuned using a labeled dataset specifically curated for health-related text, which included annotations for COVID-19 symptoms such as fever, cough, fatigue, and loss of smell or taste. For the definition of symptoms, we referred to the descriptions of symptoms within the systematized nomenclature of medicine clinical terms [69] as shown in Table 2. To make our system operational, we deployed the trained model on a server. We used a script program to continuously collect COVID-19–related tweets from Twitter. The collected tweets were then analyzed using the deployed model, and the results were displayed weekly on the Covlab website. This provided users with up-to-date, analyzed information regarding COVID-19 development.

Table 2. Symptoms and their expression found in self-reported tweets.

Symptoms	Descriptions (with their IDs in clinical terms)
Fever	Febrile (386661006), fever (386661006), feverish (103001002), mill fever (85761009), hyperthermia (1197782006), hay fever (21719001), degrees Fahrenheit (258712004), temperature (722490005), high temperature (285717004), high body temperature (50177009), body temperature above reference range (50177009), increased body temperature (50177009), elevated temperature (50177009), raised temperature (50177009), increased skin temperature (17038008), feeling hot (373932008), feeling hot and cold (103002009), and feeling hot and sweaty (373939004)
Chills	Chills (43724002), chills and fever (274640006), chillness (43724002), shivering (43724002), shivering or rigors (248456009), rigor (38880002), brass founders' ague (74800004), algor (425681008), shakes (26079004), shaking (26079004), trembling (267079009), cold (82272006), head cold (82272006), freeze (48103003), freezing (48103003), and frigid (48103003)
Sweating	Sweat (74616000), sweating (415691001), cold sweat (83547004), hot sweat (224962007), hemopoiesis (445961003), hidrosis (415691001), diaphoresis (52613005), perspiration (415691001), perspire (74616000), perspire profusely (74616000), started to perspire (74616000), perspire all over (74616000), perspire during sleep (74616000), excessive sweating (52613005), profuse sweating (52613005), and sweating profusely (52613005)
Runny nose	Sniffle (275280004), nose running (267101005), running nose (267101005), nose dripping (267101005), nasal discharge (267101005), and snotty (267101005)
Nasal congestion	Nasal congestion (68235000), congested nose (68235000), stuffed-up nose (68235000), congestion (85804007), stuffed-up nose (68235000), stuffed nose (68235000), rhinobyon (68235000), nasal obstruction (232209000), nasal airway obstruction (232209000), and stuffiness (232209000)
Nosebleed	Nosebleed (249366005), nose bleeds (249366005), nose bleeding (249366005), bleeding from nose (249366005), nosebleed (249366005), nasal hemorrhage (249366005), epistaxis (249366005), and nasal hemorrhage (249366005)
Cough	Cough (49727002), coughing (49727002), nonproductive cough (11833005), hacking cough (59994004), tussiculation, dry cough (11833005), persistent cough (284523002) acute cough (49727002), bad cough (49727002), coughing all night (161933007), evening cough (161933007), morning cough (161932002), coughing up blood (66857006), coughing and deep breathing (371605008), and begma (49727002)
Headache	Headache (25064002), migraine (37796009), sick headache (193028008), tension-type headache (398057008), and cluster-headache syndrome (193031009)
Sneezing	Sneeze (76067001), sneezing (76067001), sneezing symptom (162367006), sternutation (76067001), niesen (76067001), and achoo (76067001)
Eye pain	Eye pain (41652007), pain in eye (41652007), ocular pain (41652007), ocular headache (86925001), ocular dryness (162290004), dry eye (162290004), cephalalgia (25064002), diplopia (24982008), double vision (24982008), and eyelid edema (89091004)
Loss of taste or smell	Smell (397686008), taste (397627001), lost sense of smell (44169009), absent smell (44169009), sense of smell absent (44169009), anosmia (44169009), can't smell (44169009), smell nothing (44169009), disorder of taste (399993004), loss of taste (36955009), absence of sense of taste (36955009), and ageusia (36955009)
Sputum	Sputum (45710003), expectoration (45710003), productive cough (28743005), productive cough–green sputum (161924005), productive cough–yellow sputum (161925006), and phlegm (52024008)
Shortness of breath	Respiratory disorder (50043002), respiratory disease (50043002), breath (11891009), shortness of breath (267036007), dyspnea (267036007), short breath (267036007), breathless (267036007), difficulty in breathing (230145002), breathing difficult (230145002), labored breathing (248549001), difficulty breath (230145002), and breathing painful (75483001)
Sore throat	Sore throat (267102003), throat sore (162388002), throat pain (162388002), pain in throat (162397003), and pain throat (162397003)
Dizziness	Dizzy (267102003), throat soreness (267102003), dizzy spells (315018008), and dizziness (404640003)
Intolerance to light	Intolerance of light (1285284009), photophobia (409668002), eye sensitive to light (1285284009), light sensitive (1285284009), and light sensitivity (1285284009)
Hearing findings	Pains of ears (301354004), earache (301354004), otalgia (301354004), ears pop (162346006), popping sensation in ear (162346006), tinnitus (60862001), and noise in ears (60862001)
Loss of appetite	Poor appetite (64379006), decrease in appetite (64379006), inappetence (64379006), lost my appetite (64379006), loss of appetite (79890006), no appetite (79890006), anorexia (79890006), and off food (79890006)
Hallucinations	Hallucinations (7,011,001), illusion (5,152,006), illusionary (5,152,006), auditory hallucination (45150006), visual hallucination (64269007), and see things (64269007)

Phase Difference Calculation

Because it took time to provide the official report, the COVID-19 occurrence derived from Twitter (ie, predicted curve) was expected ahead of the official report dates (ie, actual curve). Our research used the Hilbert transform (HT) [70] method to calculate the phase difference between the actual and predicted curves. HT is a method used for analyzing time-varying signals

XSL•FO
RenderX

[71]. It can transform a real-valued signal into a complex-valued signal, rendering it convenient for phase analysis. In signal analysis, HT is often used to calculate the instantaneous phase of a signal, which can be used to compare the phase difference between 2 signals. HT was selected for its ability to compute instantaneous phase and amplitude in the time domain, making it ideal for analyzing temporal alignment and detecting phase shifts between predicted and actual signals. Unlike Fourier transform, which is limited by global frequency components, HT offers a more accurate and intuitive method for capturing time-varying phase relationships. It is particularly useful for nonstationary signals, as it can analyze phase dynamics without assumptions of stationarity or periodicity. The phase spectrum of Fourier transform may have discontinuous jumps in some cases, which can lead to incorrect results when calculating phase differences. HT can accurately calculate the instantaneous phase of a signal and avoid this problem.

The daily predicted cases curve $f(t)$ and the daily actual cases curve $g(t)$ share the same time sequence. To calculate the phase difference between them by performing the HT, we can first transform them into their complex-valued signals:

(1)

(2)

Here, [H] represents the HT operator, and i is the imaginary unit. We can then calculate the instantaneous phase of each signal, usually using the *arctan* function to compute the phase angle:

(3)

(4)

Finally, we subtracted the phase angles of the 2 signals to obtain the phase difference :

(5)

In addition to calculating the phase difference between the 2 curves, we also conducted stationarity tests on both curves. Stationarity verification is an important step in time-series analysis and is used to determine whether a time series is stationary. We used 3 methods, the augmented Dickey-Fuller test [72], the Kwiatkowski-Phillips-Schmidt-Shin test [73], and the Phillips-Perron test [74], to verify the stationarity of the 2 curves. We used the TimesNet [75] approach from prior research to predict the current trends in COVID-19 development based on the time-series relationships between the self-reported case numbers and the actual case numbers.

Evaluation of the Model

Our evaluation of the model used the following methodology. True positive is the number of correct predictions in positive samples, false positive is the number of incorrect predictions in positive samples, true negative is the number of correct predictions in negative samples, and false negative is the number of incorrect predictions in negative samples. Precision is the proportion of positive predictions in all positive samples. Precision is defined as follows:

(6)

Recall is the proportion of correct predictions in the total samples. Recall is defined as follows:

(7)

Accuracy is defined as the percentage of correctly predicted results out of the total sample.

(8)

F_1-score is defined as follows:

(9)

To measure the performance under the unbalanced data distribution, in this work, we used the precision-recall (PR) curve and ROC curve to display the performance. The ROC curve is a curve of sensitivity versus 1–specificity on all possible prediction thresholds. Similarly, the PR curve plots precision versus recall on all possible prediction thresholds. In addition, average precision (AP) and area under the curve (AUC) derived from the PR curve and the ROC curve are also generated for quantitative comparisons in this work.

Results

Model Performance for Self-Reporting COVID-19 Cases

We evaluated the models with AUC, AUC-PR, accuracy, precision, recall, and F_1-score. RoBERTa and BERT achieved the best performance with an AUC of 0.98 and an AP of 0.97, as depicted in Figure 2. Notably, all LLMs outperformed traditional machine learning models in AUC and AP, exhibiting an AUC gain from 0.01 to 0.10 and an AP gain from 0.07 to 0.09. According to the benchmark results in Table 3, BLOOM performed the best compared with other models in accuracy and precision with 0.948 and 0.941, whereas the SVM outperformed others in recall and F_1-score with 0.9362 and 0.9329, respectively. Combining AUC, accuracy, and recall, we believe that the BLOOM model has the best performance.

XSL•FO
RenderX

Subsequently, we used the trained model to assist us in selecting self-reported positive tweets from all COVID-19–related tweets.

Figure 2. Performance of various machine learning methods. (A) Receiver operating characteristics (ROC) curve with area values. The area under the curve (AUC) values, provided in the legend, quantify the overall performance of the models, with higher values indicating superior discriminative ability. (B) Precision-recall curve with average precision. AP: average precision; BERT: Bidirectional Encoder Representations from Transformers; BLOOM: Bigscience Large Open-science Open-access Multilingual language model; Llama-2: large language model meta AI 2; LR: logistic regression; NB: naive Bayes; RoBERTa: robustly optimized BERT pretraining approach; SVM: support vector machine; XLNet: extreme language model.

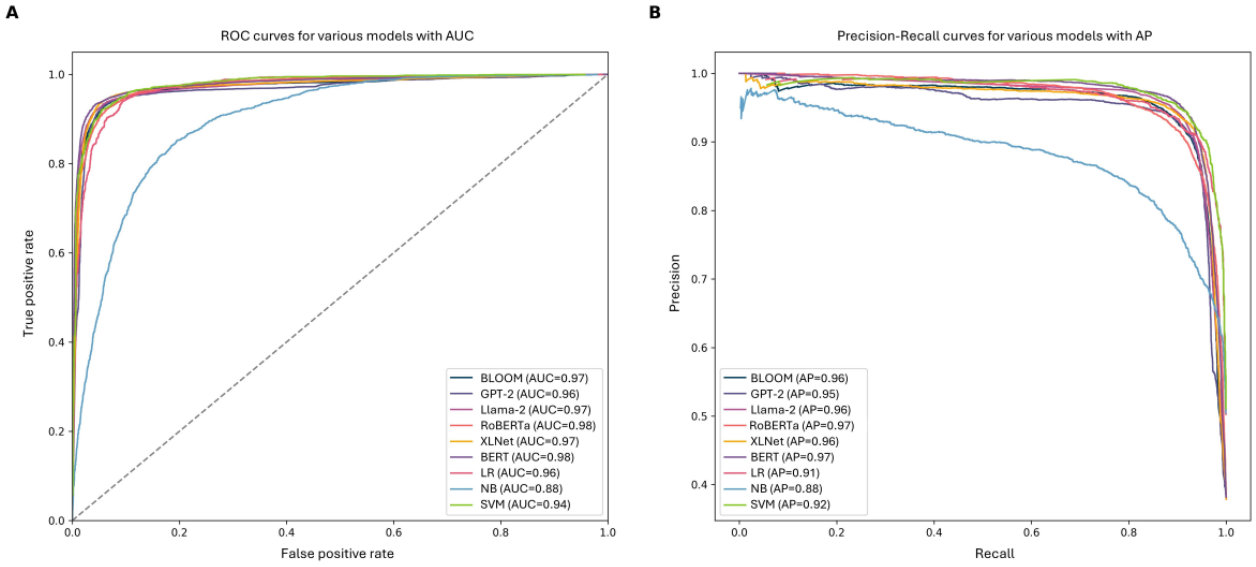

Table 3. Performance comparison of various machine learning models and large language models.

	Accuracy (%)	Precision (%)	Recall (%)	F_1-score (%)
Machine learning				
Naive Bayes [55]	86.86	65.62	52.43	58.29
Logistic regression [57]	92.57	91.73	92.64	92.18
Support vector machine [56]	93.62	92.96	*93.62*	*93.29*
Large language models				
BERT[a] [49]	93.80	92.50	91.00	91.70
RoBERTa[b] [58]	93.60	91.20	91.80	91.50
XLNet[c] [59]	93.00	90.40	91.30	90.80
GPT-2 [60]	94.30	92.00	91.00	92.60
BLOOM[d] [61]	*94.80*	*94.10*	92.00	93.00
Llama-2[e] (7b) [62]	94.20	93.30	91.30	92.30

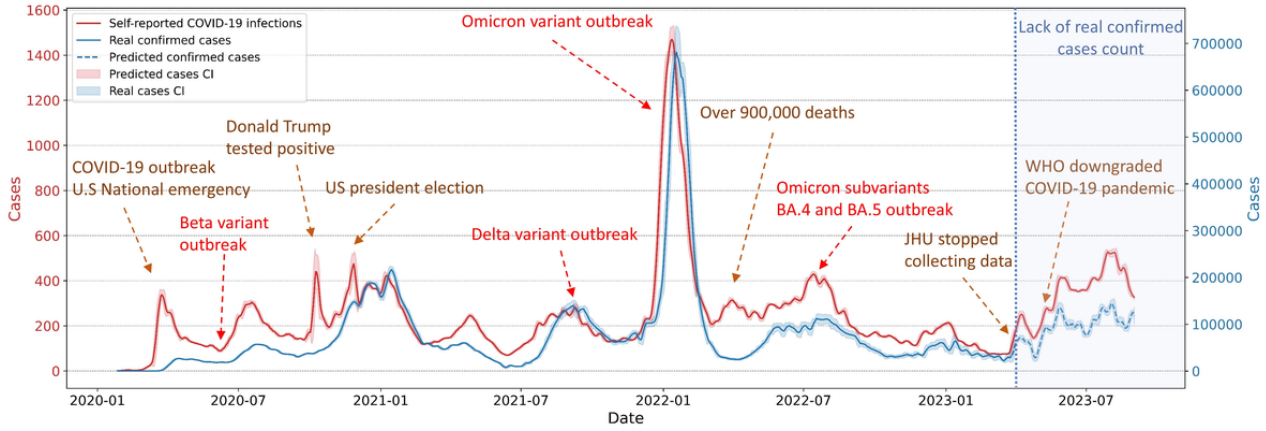
[b]RoBERTa: robustly optimized BERT pretraining approach.

[c]XLNet: extreme language model.

[d]BLOOM: Bigscience Large Open-science Open-access Multilingual language model.

[e]Llama-2: large language model meta AI 2.

Predicted Trend of COVID-19 Cases



From January 1, 2020, to April 1, 2023, we used the trained BLOOM model to evaluate all the collected COVID-19–related tweets and filtered out the tweets that the model predicted as self-reported positive cases of COVID-19. Among 7.3 million COVID-19–related tweets, we identified 317,500 self-reported tweets. Using unique user IDs, we considered multiple tweets reporting a COVID-19 diagnosis by the same user to be a single case, resulting in 262,278 unique self-reported cases. The IDs of these unique confirmed users have been stored separately in an in-house database named the COVID-19 patient database (CPD), and the daily predicted number of confirmed cases by the model has been stored according to Coordinated Universal Time.

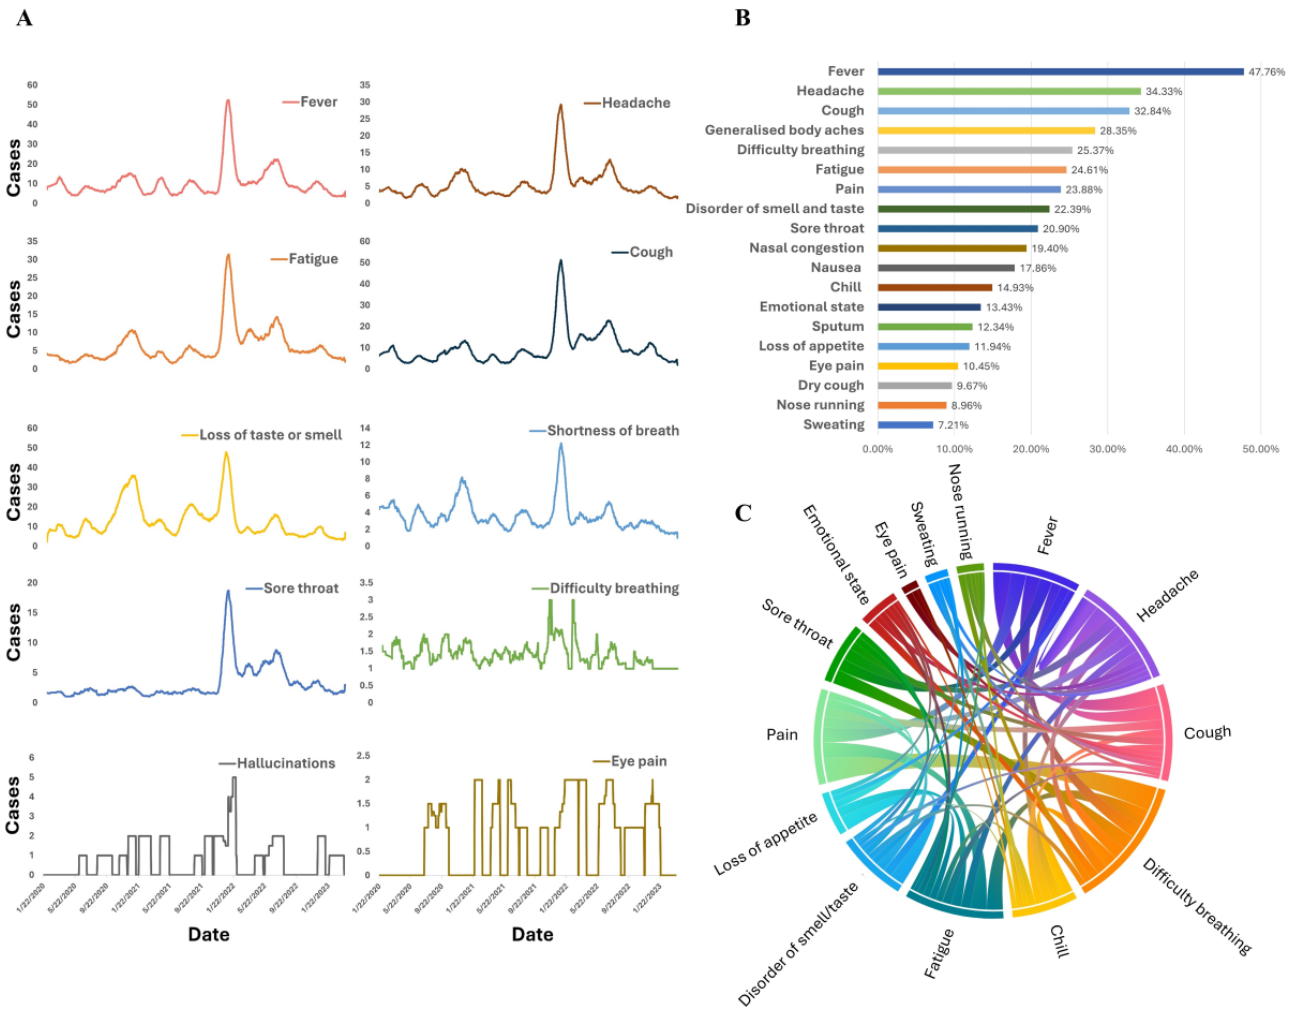
XSL•FO
RenderX

To compare the predicted daily case counts with the actual daily case counts, we obtained the actual daily case counts from public platforms such as Johns Hopkins University and *The New York Times*. Then, we plotted the actual daily case count and predicted case count on a curve, as shown in Figure 3. The blue line represents the daily actual case counts, and the red line represents our predicted case counts. The red text in the figure describes key events during the outbreak, and the brown text represents the time the variant appeared. We used the HT method to calculate the phase difference between the two curves and found that the predicted curve was leading the actual curve by approximately 7.63 days. The Augmented Dickey-Fuller test results indicated values below the critical values of 1%, 5%, and 10%, accompanied by simultaneous *P* values of <.001 and <.001, which rejects the hypothesis of the existence of a unit root. In addition, both the Phillips-Perron and Kwiatkowski-Phillips-Schmidt-Shin tests exhibited *P* values <.05. Collectively, the outcomes from these 3 tests consistently pointed toward the smoothness of the time series under scrutiny as shown in Multimedia Appendix 8.

There are 2 distinct peaks in the red curve. We examined the data for the first peak of the predicted curve on October 2, 2020, and the second peak on November 21, 2020. We found that the first peak on October 2, 2020, was due to then US President Donald Trump's tweet announcing his positive COVID-19 test result, which triggered many Twitter users to also report their self-diagnosed cases on Twitter. On that day, there were 1495 tweets related to self-reported positive cases. As for the second peak in the prediction curve, we examined the relevant tweets on that day and found that most of them were related to the US election results. Many users tweeted about their infection status and discussed the US epidemic-prevention policies. There were 973 tweets on that day regarding self-reported cases of COVID-19 infection out of all tweets.

Figure 3. Real cases and predicted cases curves. The blue curve represents the actual daily confirmed cases, and the red curve represents the daily predicted cases. The shaded areas above and below the red and blue curves represent the CI. The red text represents key events during the outbreak, and the brown text represents the time the variant appeared. The blue shaded area on the right side represents the period during which actual confirmed case data are missing. The solid red line represents the daily self-reported COVID-19 infection numbers, and the blue dotted line represents the predicted actual infection numbers. JHU: Johns Hopkins University; WHO: World Health Organization.

Symptoms



We extracted the historical tweets of users from the CPD using their unique user IDs. The temporal scope of these tweets spanned a period from 1 month preceding the self-reported date of symptom onset to 9 months after the diagnosis date, encompassing a total duration of 10 months. Within a cohort of 24,316 reporting COVID-19 symptoms, an analysis of historical tweets identified the top 10 symptoms. Figure 4A plots the temporal frequency of COVID-19 symptom mentions, providing insight into how symptom prevalence evolved over time. Notably, *fever*, *headache*, *fatigue*, and *cough* emerged as consistently common symptoms. The trends observed in these symptoms closely parallel the overall trend in confirmed COVID-19 cases. We also identified that the onset of symptoms such as *loss of taste or smell* and *shortness of breath* first became prominent in September 2020, possibly correlating with the emergence of the Beta variant. Similarly, the prevalence of *sore throat* spiked in late 2021, potentially aligning with the rise of the Omicron variant. The symptom *difficulty breathing* maintained a steady presence across the timeline. Notably, less commonly reported symptoms, such as *hallucinations* and *eye pain*, not currently recognized by the US Centers for Disease Control and Prevention (CDC), appeared sporadically in user reports, suggesting their rarity in COVID-19 cases. As shown in Figure 4B, these were *fever* (11,613/24,316, 47.76% mentioned), *headache* (8347/24,316, 34.33%), *cough* (7985/24,316, 32.84%), *generalized body* aches (6893/24,316, 28.35%), *difficulty breathing* (6169/24,316, 25.37%), *fatigue* (5984/24,316, 24.61%), *pain* (5806/24,316, 23.88%), *disorder of smell and taste* (5444/24,316, 22.39%), and *sore throat* (5082/24,316, 20.9%), listed in descending order. Notably, all symptoms except for *eye pain* (2541/24,316, 10.45%) aligned with those recognized by the CDC. Additional symptoms, such as *lethargy* (2176/24,316, 8.95%), *dizziness* (1451/24,316, 5.97%), and *hallucinations* (1086/24,316, 4.47%), although mentioned by a minority group, are not currently acknowledged as COVID-19 symptoms by the CDC.

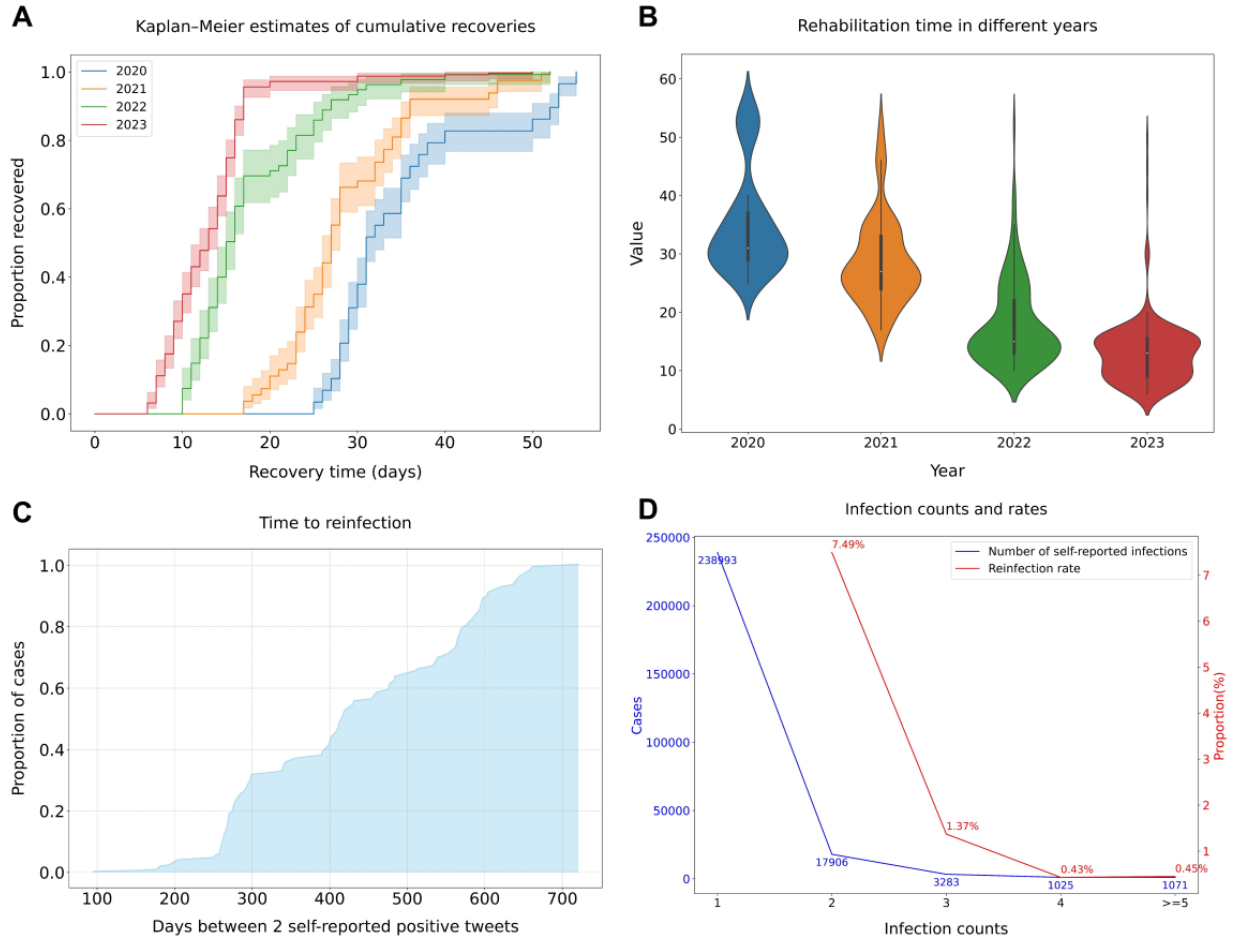
In the dataset of historical tweets from diagnosed individuals, we observed instances in which a patient mentioned multiple symptoms concurrently. To quantify this, we calculated the frequency of cooccurrence of any 2 symptoms and constructed a dependency graph to illustrate these relationships. Figure 4C

XSL•FO
RenderX

elucidates the correlations among various symptoms, highlighting that most individuals with the infection reported experiencing a constellation of related symptoms, such as headache, cough, and fever. Furthermore, Multimedia Appendix 9 presents a heat map that visualizes the Pearson correlation coefficients [76] among these symptoms, offering a quantitative view of their interdependencies. To visually represent the range of self-reported symptoms, we used a word cloud. This graphical representation provides an immediate overview of the symptomatology as expressed by the users in our dataset.

Figure 4. All symptoms mentioned by self-reporting tweets and the correlations among symptoms. (A) represents the number of mentions of COVID-19 symptoms in self-reported tweets over time. (B) represents the percentage of symptoms in all self-reporting COVID tweets, and multiple symptoms can be mentioned in 1 tweet. (C) represents the correlations among symptoms mentioned by the same user. The width of the line between 2 symptoms represents the number of tweets that mention both symptoms.

Reinfection and Rehabilitation



We analyzed historical tweets from users who self-reported COVID-19 infections, identifying 723 individuals who shared their recovery experiences. The annual breakdown of these individuals is as follows: 174 in 2020, 163 in 2021, 135 in 2022, and 251 in 2023. The duration of recovery was primarily inferred from the period mentioned in their tweets. In instances in which the recovery period was not explicitly stated, we computed it by calculating the interval between the date of confirmed diagnosis and the date of reported recovery. The data on self-reported recovery durations have been depicted through the Kaplan-Meier recovery curve [77], as illustrated in Figure 5A. This graphical representation reveals a gradual decrease in recovery time for patients with COVID-19 from 2020 to 2023. Specifically, in 2020, most patients reported a recovery period of around 30 days, with very few recovering in <30 days. In contrast, by 2023, the trend had shifted significantly, with most individuals reporting a recovery within approximately 12 days, despite a minority group still experiencing recovery periods extending beyond 30 days. Figure 5B presents a comprehensive overview of the evolution of recovery periods from 2020 to 2023. In addition, this figure suggests that the prevalent COVID-19 cases in 2023 were predominantly mild, indicating a possible decrease in the virulence of the virus over time.

In this study, we defined a recurrent COVID-19 infection in an individual as a self-reported reinfection occurring >30 days after the initial confirmed positive diagnosis. We meticulously tracked the historical tweets of all confirmed patients in CPD. Figure 5C presents the distribution of the intervals between the first and second infections alongside the corresponding case counts. This analysis reveals a relatively low likelihood of a

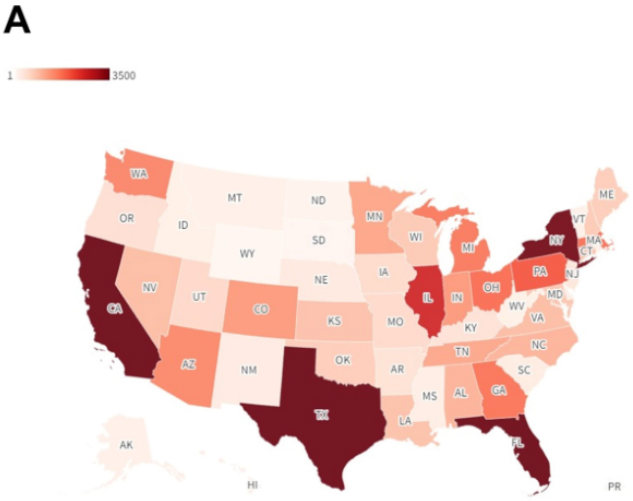
XSL•FO
RenderX

repeat infection within 180 days. Most patients who had recovered from an initial infection reported a second infection approximately 260 days later. Moreover, repeat infections occurring between 300 and 600 days after recovery were also relatively frequent. The longest interval between repeat infections documented in our study extended to 720 days. Of 262,278 patients who self-reported a positive COVID-19 test result, 91.12% (n=238,993) indicated a single infection event, and 6.83% (n=17,906) reported 2 infections. A smaller subset, comprising 1.25% (n=3283) of individuals, reported 3 infections; 0.39% (n=1025) indicated 4 infections; 0.17% (n=445) reported 5 infections; 0.11% (n=301) of individuals reported 6 infections; and 0.12% (n=325) indicated ≥7 infections. Remarkably, the highest number of reported reinfections was 9, with 7 individuals documenting their ninth infection. Figure 5D shows that among the 238,993 patients with a single infection, 7.49% (17,906/238,993) reported a second infection. A further breakdown shows that 1.37% (3283/238,993) reported a third infection, 0.43% (1025/238,993) reported a fourth infection, and 0.45% (1071/238,993) reported experiencing ≥5 infections. We also performed a statistical analysis of the time intervals between infections among users with multiple infections.

Figure 5. Overview of reinfections and recovery. (A) Kaplan-Meier estimates of cumulative recoveries. (B) Rehabilitation days in different years. (C) Time to reinfection for 238,993 individuals. (D) Reinfection cases and rates.

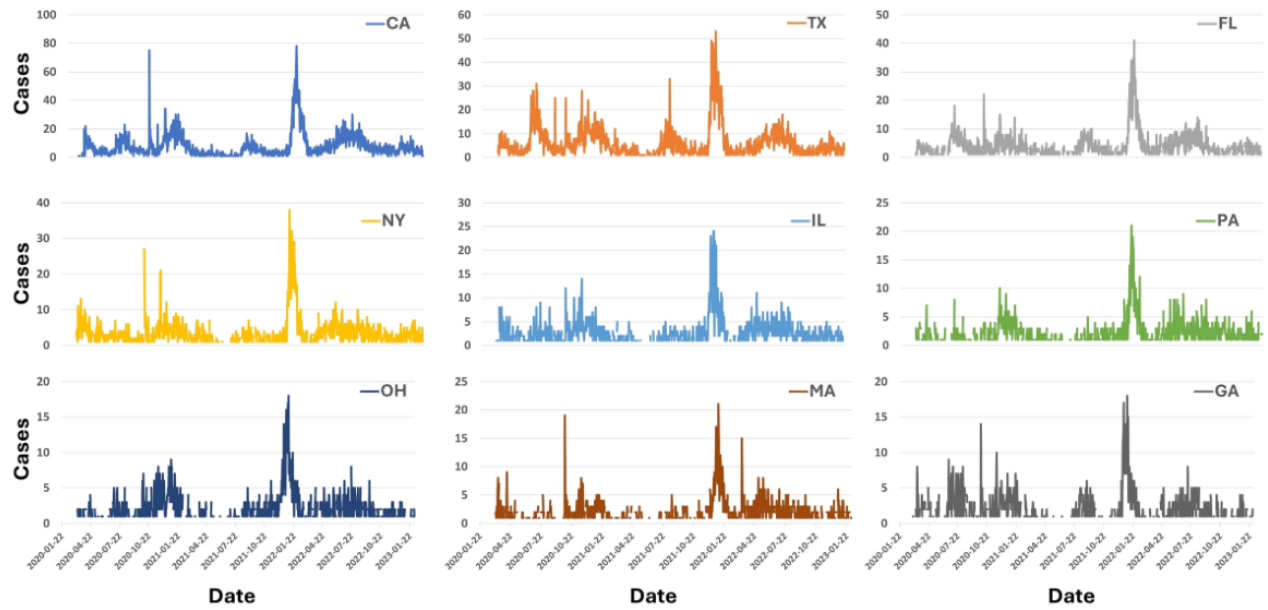
Distribution of Cases

We extracted the geographic locations of the diagnosed users in CPD, and the distribution of all confirmed patients is shown in Figure 6A [52]. California had the highest number of self-reported COVID-19 cases, with 8762 cases, followed by Texas (6619 cases), Florida (4245 cases), New York (3566 cases), Illinois (2649 cases), Pennsylvania (2032 cases), Ohio (1868 cases), Massachusetts (1793 cases), Georgia (1785 cases), and Michigan (1677 cases), in descending order. Alabama and Northern Mariana Islands had the least data, with only 1 self-reported case in each state.



The details of confirmed cases in each state are shown in Figure 6B, in which we provide the average case counts for the entire country and each state as well as the number of self-reported cases per 10 million people per week, the trend over the past 2 weeks, and the positivity rate of each state. For example, we can see that California had the most self-reported COVID-19 cases in the past week, with at least 29 people reporting positive test results. Approximately 7.34 people per 10 million reported self-diagnosed COVID-19–positive status, and the average positivity rate of self-reported cases was 26.69%. However, compared with the previous 2 weeks, the number of self-reported COVID-19 cases decreased by 10.93%. Due to insufficient data, the trend of changes in the past 14 days was unavailable for several states, such as the Virgin Islands and Wyoming.

We also plotted the time-varying curves for the confirmed cases in the top 20 states in terms of confirmed cases, as shown in



XSL•FO
RenderX

Figure 6C and Multimedia Appendix 10. It is evident that the changes in the number of confirmed cases in the top 4 states with the highest number of cases closely resemble the overall trend in the United States. Some states, such as Washington, Arizona, Washington DC, and Indiana, exhibited relatively consistent changes in the number of confirmed cases over time, whereas states such as Nevada, Colorado, Alabama, and Michigan had less-consistent curves, with some dates showing no reported cases. The variation in results could have been influenced by the differing numbers of Twitter users in each state.

Figure 6. Cases across the United States and by state. (A) Self-reported number of infections in each state, with darker colors representing higher numbers. (B) Self-reported weekly number of infections, number of infections per 10 million people, change in trend over the previous 2 weeks, and positivity rate for a subset of states (alphabetical order). (C) Infection curve for the top 20 states with the highest infection numbers.

State	Weekly average	Cases per 10 million people	Biweekly change (%)	Test positivity
US	777	114.800	7.527%	17.832
AL	1	2.039	-55.556%	22.094
AK	2	27.339	33.333%	19.861
AZ	6	8.243	-9.091%	21.897
AR	1	3.314	-33.333%	13.883
CA	27	6.833	-14.063%	22.953
CO	9	15.628	62.5%	24.294
CT	6	16.829	450%	25.012
DE	1	10.269	100%	17.611
FL	8	3.725	-30.556%	20.412

Covlab Visualization Website

To disseminate timely information to the public and policy makers, we have launched a visualization website, Covlab, which features our trained models and a comprehensive data pipeline. This platform consists of an automated script sequence designed to update the data weekly. The home page of Covlab offers users real-time access to the total number of tweets collected to date, including those self-reported as COVID-19–positive. On the Graphs page, users can explore the most recent weekly growth trends in COVID-19 cases alongside predictive models of actual confirmed cases. This section also enables monitoring of infection trends across various states in the United States as well as the prevailing symptom patterns observed to the current date. Furthermore, Covlab displays the proportions of reinfections and recovery

XSL•FO
RenderX

periods, with these metrics also being refreshed weekly. The website's dynamic graphs and tables serve as a valuable resource, providing the public with up-to-date information on the ongoing evolution of COVID-19, including insights into the symptomatic expressions of emerging variants.

Discussion

Principal Findings

The analysis of self-reported COVID-19 tweets offers a valuable perspective, reflecting the actual progression of the pandemic to a considerable degree. The voluminous data generated by self-reporting individuals on Twitter augment clinical datasets, offering a complementary avenue for long-term observation and tracking. This approach is particularly beneficial in bridging the data gap inherent in in-home self-testing scenarios. Our research indicates that reinfections are relatively common, with the likelihood of multiple infections diminishing over time. Moreover, this dataset has proven instrumental in identifying potential new symptoms that were not initially associated with COVID-19, such as lethargy and hallucinations, offering an early warning system for evolving clinical presentations. In addition, the approach has enabled the detection of emerging variants through geospatial clustering of self-reported cases exhibiting distinctive symptom combinations. This tracking capability enhances preparedness and enables timely public health interventions. The breakdown by state of self-reported COVID-19 tweets facilitates more efficient tracking of disease trends. Furthermore, the approach used in this study could potentially serve as a general pipeline for researching and analyzing other infectious diseases.

Symptoms and Sequelae Study

Within the subset of Twitter users who self-reported as COVID-19 positive, numerous accounts contained detailed descriptions of symptoms experienced during the infection. These firsthand accounts are a rich source of information. We extracted and analyzed the symptomatology mentioned in these tweets, compiling a list of the most prevalent symptoms reported by patients. Our intriguing findings closely mirror the commonly acknowledged COVID-19 symptoms listed by the CDC. However, some symptoms mentioned by a subset of patients in their tweets are not yet recognized as typical by the CDC. This discrepancy highlights the significant role of our study in identifying potential new symptoms of COVID-19 that have not been widely recognized. Such findings could provide valuable guidance for further clinical investigation into these symptoms and their association with different COVID-19 variants. In addition, the CPD established through this study offers a robust framework for long-term patient tracking. This database not only complements existing clinical data but also provides an invaluable resource for the study of post–COVID-19 sequelae and post–COVID-19 condition symptoms, thereby enhancing our understanding of the virus's long-term impacts.

Comparison With Traditional Tracking Tools

Traditional clinical data–driven tools, while offering high specificity by relying on confirmed diagnoses, often underrepresent asymptomatic or mild cases. In contrast, our approach leverages self-reported data from social media platforms, such as Twitter, to capture a broader spectrum of cases, including those not reported in clinical settings. Although this may introduce noise, advanced filtering and NLP techniques effectively mitigate inaccuracies, ensuring meaningful insights. Furthermore, clinical data collection and reporting are often delayed due to testing and diagnosis, whereas our tool enables near–real-time monitoring by analyzing self-reported cases as they are posted, facilitating rapid identification of trends and potential hot spots. In terms of coverage, traditional clinical tracking tools may lack granularity, particularly in regions with limited health care infrastructure or reporting capabilities. Using social media, our tool significantly enhances coverage, incorporating underrepresented populations and geographies to provide a more comprehensive view of the pandemic's spread. A key contribution of this approach is the integration of self-reported data, which captures personal narratives, symptom progression, and public sentiment, thereby complementing clinical data to offer a richer and more dynamic understanding of the pandemic. Importantly, while our tool excels in timeliness and coverage, its true potential lies in synergy with clinical data–driven tools. We propose future efforts to integrate these approaches, enabling cross-validation and improving overall accuracy.

Limitations and Future Work

Although our method and website are highly useful, there are some limitations. First, Twitter has a limited quota of public APIs, which renders the platform hugely expensive to run. Second, potential biases in data collection and the varying distribution of Twitter users across different states may impact the predictive accuracy. Furthermore, external factors, particularly notable events in the United States that occurred in 2020, influenced our prediction outcomes. For instance, the 2 notable peaks in self-reported cases observed in 2020 did not necessarily correlate with an actual increase in infections. Instead, these peaks were primarily driven by external events, prompting a surge in infection reporting on Twitter on those specific days. Another significant constraint is the veracity of the information in tweets. However, despite their questionable reliability, these data offer informative trend analyses and hypotheses valuable for future research and validation. Our framework demonstrates significant versatility, with potential applications extending beyond COVID-19 to monitor other self-reported illnesses, such as influenza and respiratory syncytial virus, as well as chronic conditions such as diabetes and mental health issues. Its modular design facilitates easy adaptation by allowing the customization of keywords and analytical strategies tailored to specific diseases. To enhance its functionality, we propose integrating Twitter data with other real-time health data sources, such as wearable devices and electronic health records, enabling a more comprehensive approach to health trend monitoring. In this integration, social media signals would serve as an initial screening mechanism, effectively complementing clinical data. In future work, we plan to integrate self-reported data from other social platforms, such as Reddit, to reduce data limitations and biases, thereby broadening the scope of our analysis. This expansion will support the development of a platform capable of predicting

XSL•FO
RenderX

COVID-19 trends in real time based on self-reported content. Furthermore, we aim to apply this pipeline to other infectious diseases that may emerge in the future, facilitating the understanding and tracking of their development and trends. To maintain robustness and accuracy, we plan periodic retraining of the model using updated data and incorporating LLMs to better capture nuanced expressions in self-reported content. A user feedback mechanism will also be implemented to address false positives and negatives. In addition, we aim to expand the tool's global applicability by automating data pipelines to support content in multiple languages, with a particular focus on underrepresented regions. This global expansion will enable the tool to capture disease trends across diverse geographic and cultural contexts, offering a more holistic view of global health dynamics.

Conclusions

This study demonstrates the significant potential of using self-reported COVID-19 tweets from social media platforms for public health monitoring. By leveraging machine learning and NLP techniques, we developed a tool capable of identifying infection and recovery trends, providing valuable insights into disease spread and public behavior. Our findings contribute to the growing field of digital epidemiology, emphasizing that social media can serve as an effective complementary data source to traditional public health surveillance systems. Beyond COVID-19, this approach holds promise for monitoring other infectious diseases, mental health conditions, and chronic illnesses by adapting the model to new health-related keywords and contexts. Integrating such tools with existing health infrastructure could enhance early detection, improve situational awareness, and enable more proactive public health responses. However, the ethical considerations of using publicly available data and addressing biases inherent to social media platforms must be prioritized to ensure responsible use. Overall, this work highlights the evolving role of digital tools in public health informatics and presents opportunities for future research to further refine these methods. The integration of social media–based monitoring with traditional data systems could transform public health strategies, making them more adaptive, responsive, and inclusive of diverse population segments.

Acknowledgments

This research was supported by the National Institute of General Medical Sciences of the National Institutes of Health (R35-GM126985). The authors would like to thank all the annotators who participated in the calibration of their data, including Kent Studer, James Tipton, Thadeus Meneses, Noah Berry, Sai Akhil Chopparapu, Trinath Adusumilli, Weinan Zhang, Yijie Ren, Li Su, Chunhui Xu, and Congyu Guo.

Data Availability

The aggregated datasets analyzed in this study are available from the corresponding author upon request. Manual labeling data can be viewed through the annotation website. Guest users can use the username *guest* and password *guest* to log into the system for data access. Actual and predicted daily cases are publicly available on the Covlab website [52].

Authors' Contributions

JX and ZZ collected the data and performed the analyses. JH created the data visualizations. SZ ran the large language model and wrote the model performance portion. GA, XT, and XW reviewed and assessed the results. LJ and YY provided technical support. JX drafted the manuscript and designed the website; JX and ZZ wrote the code and conducted all the tests. DX conceived and supervised the study. All authors had full access to all the data in the study as needed and had final responsibility for the decision to submit for publication.

Abstract

Background: As the spread of the SARS-CoV-2 virus coincided with lockdown measures, it is challenging to distinguish public reactions to lockdowns from responses to COVID-19 itself. Beyond the direct impact on health, lockdowns may have worsened public sentiment toward politics and the economy or even heightened dissatisfaction with health care, imposing a significant cost on both the public and policy makers.

Objective: This study aims to analyze the causal effect of COVID-19 lockdown policies on various dimensions of sentiment and uncertainty, using the Italian lockdown of February 2020 as a quasi-experiment. At the time of implementation, communities inside and just outside the lockdown area were equally exposed to COVID-19, enabling a quasi-random distribution of the lockdown. Additionally, both areas had similar socioeconomic and demographic characteristics before the lockdown, suggesting that the delineation of the strict lockdown zone approximates a randomized experiment. This approach allows us to isolate the causal effects of the lockdown on public emotions, distinguishing the impact of the policy itself from changes driven by the virus's spread.

Methods: We used Twitter data (N=24,261), natural language models, and a difference-in-differences approach to compare changes in sentiment and uncertainty inside (n=1567) and outside (n=22,694) the lockdown areas before and after the lockdown began. By fine-tuning the AlBERTo (Italian BERT optimized) pretrained model, we analyzed emotions expressed in tweets from 1124 unique users. Additionally, we applied dictionary-based methods to categorize tweets into 4 dimensions—economy, health, politics, and lockdown policy—to assess the corresponding emotional reactions. This approach enabled us to measure the direct impact of local policies on public sentiment using geo-referenced social media and can be easily adapted for other policy impact analyses.

Results: Our analysis shows that the lockdown had no significant effect on economic uncertainty (b=0.005, SE 0.007, t125=0.70; *P*=.48) or negative economic sentiment (b=–0.011, SE 0.0089, t125=–1.32; *P*=.19). However, it increased uncertainty about health (b=0.036, SE 0.0065, t125=5.55; *P*<.001) and lockdown policy (b=0.026, SE 0.006, t125=4.47; *P*<.001), as well as negative sentiment toward politics (b=0.025, SE 0.011, t125=2.33; *P*=.02), indicating that lockdowns have broad externalities beyond health. Our key findings are confirmed through a series of robustness checks.

Conclusions: Our findings reveal that lockdowns have broad externalities extending beyond health. By heightening health concerns and negative political sentiment, policy makers have struggled to secure explicit public support for government measures,

XSL•FO
RenderX

which may discourage future leaders from implementing timely stay-at-home policies. These results highlight the need for authorities to leverage such insights to enhance future policies and communication strategies, reducing uncertainty and mitigating social panic.

lockdown policy; sentiment analysis; uncertainty; social media; quasi-experiment

Introduction

Background

The spread of the SARS-CoV-2 virus and the associated COVID-19 disease led to an extraordinary rise in uncertainty and negative emotions, resulting in significant economic and social costs [1-4]. Against this backdrop, by April 2020, most governments had implemented lockdown measures to contain the virus's spread within their populations. Lockdown policies, or "stay-at-home" mandates, are temporary restrictions prohibiting residents from leaving their homes except for essential tasks or work in essential businesses. While recent evidence suggests that these measures are effective in slowing the spread of COVID-19 [5-7], their impact on public sentiment remains unclear. Lockdown measures may heighten public uncertainty and negative emotions by amplifying health concerns, shaping expectations of negative economic and social consequences, and triggering political backlash. Conversely, they could also signal a strong commitment to controlling the virus, reducing information asymmetry, and improving public sentiment.

Goal of the Study

This study investigates whether lockdown measures amplify or alleviate uncertainty and negative sentiment. By proposing a nuanced measure of uncertainty and sentiment, we assess the heterogeneous effects of lockdown measures across key public concerns, including economics, health, and politics. Understanding whether the economic and social costs of lockdowns outweigh their health benefits is essential for informed policy decisions.

Prior Work

Determining the causal effect of lockdowns on public sentiment is challenging due to simultaneity and endogeneity issues. In most countries, authorities implemented lockdown measures immediately after detecting the virus, meaning the decline in public sentiment caused by COVID-19 and the enforcement of lockdowns occurred simultaneously. Additionally, endogeneity arises because lockdowns were introduced in response to detecting COVID-19 cases.

These areas are likely the same ones where people perceive a higher risk of pandemic-related costs, resulting in lower sentiment. Given these limitations, most studies on sentiment changes during COVID-19 lockdowns provide correlational evidence [8-12], which may either overestimate or underestimate the impact of lockdowns on public emotions, potentially leading to inaccurate conclusions.

Previous studies reported increasing uncertainty and negativity during COVID-19 but did not determine the extent to which these trends were driven by restrictive measures [13,14].

Moreover, many studies examined overall changes in uncertainty and sentiment during the pandemic [15-17] or focused on specific aspects such as economic uncertainty [8,13], political polarization [18,19], or health-related negative emotions [17,20], without simultaneously analyzing multiple relevant dimensions of public discourse at the time.

Distinguishing the effects of lockdown measures across multiple topics, such as politics, economics, and health, is valuable, as their impact may vary across different dimensions.

Our Study

To address this, we focus on the Italian lockdown of February 2020, the first in a high-income economy. This case allows for a quasi-experimental analysis, as the lockdown was initially imposed on communities where the first COVID-19 cases were detected, effectively creating a form of random assignment.

At the time of implementation, virus transmission rates were similar inside and outside the lockdown areas [21], and health and socioeconomic conditions were comparable, enabling the application of causal inference methods to assess the impact of lockdowns on public opinion. Notably, the timing of these lockdowns—before vaccines were available and with limited knowledge about the SARS-CoV-2—provides a unique opportunity to isolate and measure the direct influence of lockdown measures on public emotions, particularly sentiments and uncertainty.

We use Twitter (X) data to measure uncertainty and sentiment by applying deep learning and natural language processing techniques. To assess uncertainty, we differentiate between tweets that ask questions, express hesitation, irresolution, confusion, or anxiety, and those that seek clarity, as opposed to tweets conveying assurance and confidence. In measuring sentiment, we aim to capture emotions such as anger, disillusionment, and disapproval, which we broadly classify as negative sentiments. Additionally, we distinguish between tweets from users inside the lockdown area (the so-called red zone) and those from users outside, including neighboring cities (referred to as the "orange zone").

This data collection is conducted both before and after the lockdown. To measure uncertainty and negative sentiments in each tweet, we fine-tune the AlBERTo (Italian BERT optimized) model [22], a natural language processing model based on the Bidirectional Encoder Representations from Transformers (BERT) framework [23], specifically designed for Italian text data. BERT efficiently contextualizes words, providing

XSL•FO
RenderX

significant advantages over traditional bag-of-words approaches for measuring emotions [24,25]. It has demonstrated strong performance across various natural language processing tasks, including sentiment analysis, fake news detection, and the analysis of public opinions on Twitter/X during the COVID-19 pandemic [15,26-29]. Given the existing evidence on the accuracy of text analysis using BERT-based models, we believe that our sentiment and uncertainty measures constructed via AlBERTo reliably capture the emotions expressed in the tweets.

To better understand the impact of the lockdown on public emotions, we categorize uncertainty and sentiments into 4 main dimensions: economy, health, politics, and lockdown policy. Identifying health- and economy-related tweets is essential for analyzing how lockdown policies differently influenced perceptions of health and economic risks, as well as for investigating the health-economic trade-off [30]. The political dimension is also considered, as lockdowns could shape sentiments toward politics, affect attitudes toward incumbent politicians [31-35], or heighten political polarization [18,19]. The fourth dimension, which we refer to as policy for simplicity, captures the uncertainty and negative sentiments associated with the behavioral guidelines of the restrictions. This distinction allows us to determine whether uncertainty and negative sentiments arise from concerns about the authorities implementing the policy (political uncertainty) or from confusion regarding the policy's specifics (uncertainty around lockdown policies). Overall, this categorization provides a clearer understanding of how public sentiment evolved in response to the COVID-19 pandemic and government actions.

We use manually curated dictionaries for each dimension to categorize the tweets and construct a document-feature matrix, enabling the identification of words associated with each dimension in the tweets.

Using a difference-in-differences (DiD) specification [36], we estimate the causal impact of the lockdown on economic, health, political, and policy-related uncertainty and negative sentiment. Causal identification is ensured as the treatment assignment—the lockdown policy—was an exogenous shock to public uncertainty and negative sentiment, independent of potential outcomes. Our findings are further validated through a placebo test and a series of robustness checks.

Our findings indicate that, in the Italian context, the lockdown had no significant effect on public concerns about the economy, suggesting that lockdown-induced negative emotions did not heighten economic worries. Economic concerns did not increase among those subjected to the lockdown, which is relevant to the ongoing debate on the economic impact of lockdowns. While stay-at-home mandates have economic consequences [37], these effects likely stem from other, more direct channels, such as business closures and activity restrictions.

By contrast, the stay-at-home mandate significantly influenced health- and politics-related emotions among individuals within the lockdown area. Users in this zone expressed higher uncertainty when discussing health and lockdown policies and displayed more negative sentiments about politics compared with those outside the lockdown area. Rather than reassuring the public about the authorities' commitment to combating the virus, the lockdown heightened concerns about health-related risks. However, this increased uncertainty may have fostered greater awareness and compliance with containment measures, potentially leading to positive public health outcomes [38].

The rise in negative sentiments toward politics represents a significant cost that policy makers must take into account. These political costs may discourage elected officials from implementing lockdowns in future pandemics, regardless of their effectiveness in controlling virus transmission. The increased political discontent could indicate a rise in political polarization, which intensified during COVID-19 [18,19]. However, it may also reflect shifting attitudes toward the incumbent politician, for which existing evidence remains mixed [31-33,39]. The extent to which changes in political attitudes reported in the literature can be directly attributed to lockdown measures remains unclear. Our findings demonstrate that when the effect of the lockdown is causally identified and isolated from other factors influencing emotions, the policy increases negative sentiments toward politics. This shift in sentiment could lead to delays, restrictions to narrower regions, or weaker policy responses when lockdown measures are necessary.

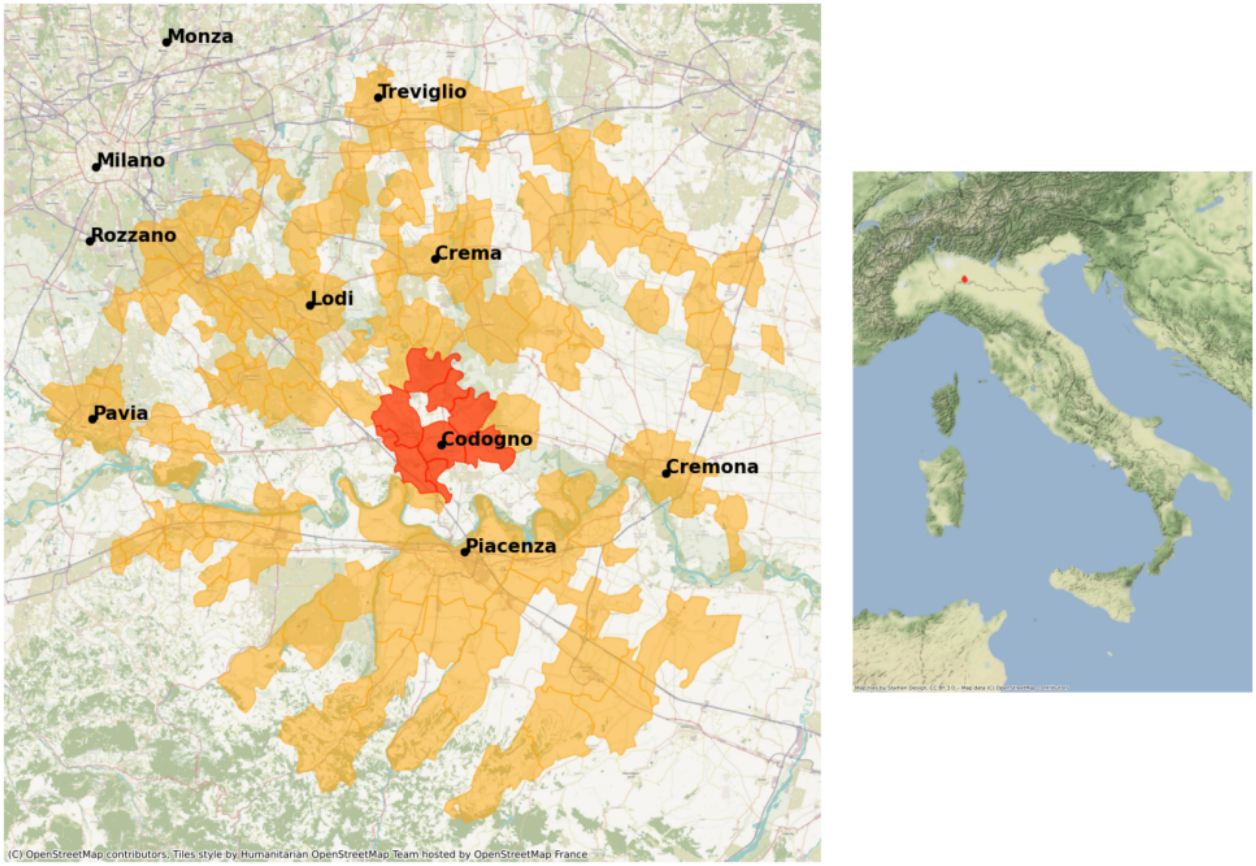
As our study focuses on a specific case, the generalizability of our results is limited. Our findings should be interpreted as reliable causal estimates of the effect of the first Italian lockdown on the red zone units rather than as a universally applicable average across different contexts and periods. By prioritizing internal validity over external validity and providing extensive evidence supporting our empirical strategy, we isolate the direct effect of the lockdown while controlling for comoving factors, particularly exposure to COVID-19.

Our study makes a valuable and unique contribution by quantifying the direct emotional response to the extraordinary and strict public health policies of 2020. It introduces a clear methodology for analyzing geo-referenced social media data to evaluate the causal impact of policy at a local scale. This research significantly advances the current state of the art in social media analysis for studying the profound social and emotional changes brought about by the pandemic (see, eg, [40-43]).

Methods

Identification Strategy

Following the discovery of the first COVID-19 transmission case in the small town of Codogno, the Italian government announced a decree on February 22 imposing strict quarantine measures in Codogno and 9 neighboring municipalities in the province of Lodi (Castiglione d'Adda, Casalpusterlengo, Fombio, Maleo, Somaglia, Bertonico, Terranova dei Passerini, Castelgerundo, and San Fiorano), effective February 23, 2020 [44]. The lockdown was strictly enforced with police presence on the streets, prohibiting entry into or exit from the restricted area.



On March 8, an "orange zone" (*zona arancione*) was established, encompassing municipalities near the red zone. Lombardy and 14 other cities outside the region (Modena, Parma, Piacenza, Reggio nell'Emilia, Rimini, Pesaro e Urbino, Alessandria, Asti,

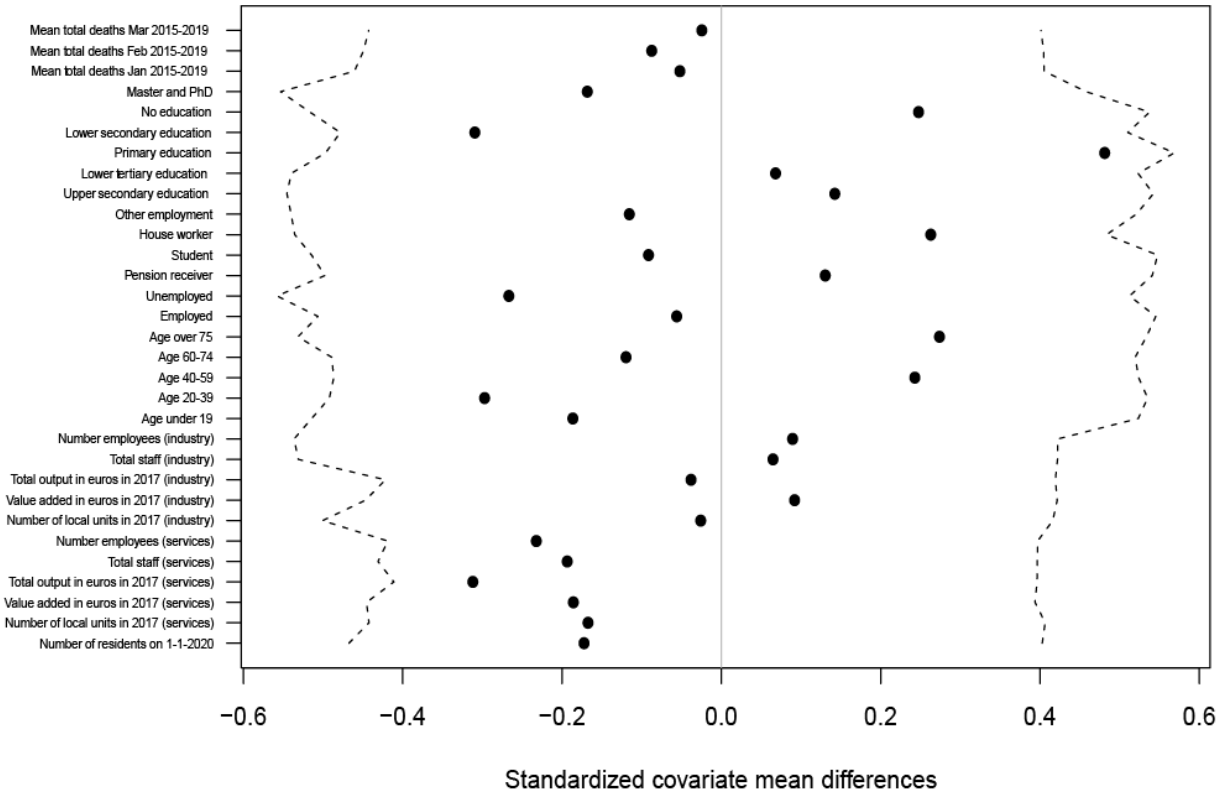
XSL•FO
RenderX

Novara, Verbano-Cusio-Ossola, Vercelli, Padua, Treviso, and Venice), accounting for 16 million people, were placed under *partial* lockdown restrictions [45]. In the orange zone, residents were *invited* to avoid traveling in and out of their municipality of residence, while economic activities were allowed to continue. On March 9, these measures were extended nationwide, effectively ending the strict *red zone* restrictions in the province of Lodi [46]. A full nationwide lockdown was announced on March 22.

We leverage the exogenous shock of the unexpected lockdown measures enacted in Italy on February 23, 2020, to assess the causal impact of lockdown restrictions on public emotions. We argue that the detection of the first European COVID-19 case in the municipality of Codogno, rather than in other nearby municipalities (Figure 1), was purely coincidental. When physicians discovered that the patient, who exhibited symptoms consistent with COVID-19, had been in contact with a friend recently returning from a business trip to China, they decided to override the existing protocol, which restricted testing to Italians and foreigners who had traveled to China [47]. As a result of this first positive case, hospitals in the Codogno area began testing individuals for COVID-19. This decision was driven solely by the identification of the first patient in Codogno.

Figure 1. The red zone (lockdown enforced on February 23, 2020, in Lombardy, Italy) and the surrounding selected control municipalities included in the analysis are shown in orange. We found tweets from 8 out of 10 cities in the red zone. The control area consists of municipalities surrounding Codogno within a 42 km radius. The area we analyzed is homogeneous in terms of demographics, socioeconomics, and virus exposure.

Recent retrospective epidemiological studies on the transmission risk of coronavirus in Lombardy in February 2020 revealed that the virus had a homogeneous transmission potential across different provinces of Lombardy at the time the first case was discovered in Codogno [21]. This indicates that COVID-19 incidence was balanced between the red zone and the neighboring municipalities in the orange zone during the initial lockdown. While the red zone was subjected to strict lockdown measures, nearby locations in the orange zone were not. Consequently, individuals in the orange zone serve as a suitable control group for assessing the impact of lockdown measures on the emotions of those in the red zone.



Causal identification is achieved through the exogenous shock represented by the lockdown policy, allowing us to rule out selection bias among the units under lockdown, which are balanced and comparable to the control group. To establish a quasi-experimental approach, we designate municipalities subjected to the lockdown as the treated group, specifically the "red zone," which was at the epicenter of the COVID-19 outbreak. The control group consists of municipalities surrounding Codogno, designated as the "orange zone." To ensure comparability, only the closest nonurban areas to the red zone were selected.

Figure 2 [48-52] demonstrates that the complete randomization of lockdown assignment holds for municipality-level prelockdown covariates. The quantiles represent the acceptance region of our randomization test with α=.15, using the standardized covariate mean differences as the test statistic. In each iteration, the lockdown is randomly assigned to units, and the standardized mean difference is calculated. The observed

XSL•FO
RenderX

standardized differences fall well within the acceptance bounds [53], confirming that complete randomization holds for all considered covariates. This finding supports the notion that the 2 areas had comparable pretreatment demographic and socioeconomic characteristics, reinforcing the validity of the random allocation.

Figure 2. The standardized covariate mean difference was calculated along with the 7.5% and 92.5% complete randomization quantiles using 2000 permutations. Covariate balance is assessed between the red zone and the control municipalities of the orange zone, matching the user location of tweets featured in the main analysis (8 red zone and 118 orange zone municipalities). We use ISTAT data [48-52] on social, economic, and demographic characteristics, including the number of residents as of January 1, 2020; the average number of deaths in January, February, and March from 2015 to 2019; the share of residents in occupational categories, age cohorts, and education levels. Additionally, we collected data on industry and services from 2017, including total output and value added (in euros), number of employees, total staff, and local units. Missing values for industry and services are imputed using the group mean for 2 treated cities (Castelgerundo, 1473 residents, and Bertonico, 1059 residents). Similarly, missing entries for monthly average deaths are imputed for 2 control municipalities (Calendasco, 2409 residents, and Cerro all'Ambro, 5149 residents) and 1 treated city (Bertonico, 1059 residents). Before testing, we standardize covariates related to mean mortality, industry, services, and total residents.

Moreover, no other major economic or political events occurred in the area during the sample period. The region, while affected by the lockdown, is a relatively less significant hub in the local economy of Lombardia compared with urban centers such as Bergamo, Cremona, or Lodi, as shown in Table S3 in Multimedia Appendix 1. This reduces the likelihood of bias from unaccounted external events influencing public reactions.

Additionally, the influence of news outlets and media coverage on reactions in the red zone was limited, as no local media were operating within the red zone, and national media had no direct access to it. As a result, individuals inside and just outside the red zone were exposed to the same partial and limited media coverage of the lockdown policies, ensuring comparable information exposure between the 2 groups.

Our study design provides strong support for causal identification of the lockdown's treatment effect, as the orange zone serves as a suitable counterfactual for the red zone. As the control observations share similar demographic, geographic, social, and economic characteristics and were exposed to the virus under comparable conditions, trends in overall and topic-specific uncertainty and negative sentiment should exhibit similar patterns between the treated and control groups in the absence of the lockdown intervention.

Data Collection

For our main analysis, we collected Italian tweets before and after the lockdown, both inside and outside the red zone. Data collection took place from December 1, 2019, to March 22, 2020, using the Twitter Stream API (application programming interface). The data set includes information on user activity, user-defined locations, and the content of individual tweets.

Twitter-based indices have proven to be effective tools for understanding people's emotional well-being during the COVID-19 pandemic [8,54]. Social media–based metrics offer a powerful means to accurately identify uncertainty and negative sentiments following major events such as COVID-19 [55]. As public reactions to crises tend to be similar among Twitter users and nonusers, emotions expressed on social media can serve as a representative proxy for the broader population's sentiments [56].

Tweets from the municipality of Codogno and the surrounding areas are collected using the Twitter Stream API with 2 filters:

XSL•FO
RenderX

Italian language and geographical location. The latter allows us to retrieve tweets with GPS coordinates within a maximum radius of 42 km from a target center—Codogno in our case. This enables us to extract tweets from the "red zone" and the "orange zone" near Codogno. We then rely on the locations self-reported by Twitter users to assign tweets to municipalities inside or outside the red zone. These self-reported locations help fine-tune user locations without relying solely on GPS coordinates to distinguish between people inside and outside the red zone, given that movement between the red and orange zones was prohibited. For an overview of Twitter's location-based methods, see [57].

The text of self-reported user locations is cleaned and matched with ISTAT [58] data on the geographical coordinates of Italian municipalities. Additionally, the self-reported locations of tweets were manually checked to verify whether the user's location aligned with the tweet's content (eg, tweets indicating that Codogno users were affected by the lockdown).

We clean the text of tweets by removing URLs, hashtags, and tags and eliminate duplicate tweets—those with the same cleaned text from the same users.

On March 8, all control units (areas not yet subject to lockdown measures) entered a partial lockdown, 1 day before the nationwide expansion of partial lockdown measures on March 9, 2020. Any potential anticipation of the February 23 policy, around the time of the first detected COVID-19 transmission case in Codogno (February 20, 2020), could bias the estimate of the policy's impact. To mitigate this, we deleted observations from February 20 to 22, 2020, and removed all tweets from March 7, 2020—the day the first extension of restrictions was announced. Finally, we removed all users who were information sources or business accounts.

As a result, we obtained a sample of 24,261 unique tweets—1567 from 8 of the 10 lockdown municipalities in the red zone and 22,694 from 118 unique locations within the orange zone. These tweets were posted by 1124 unique users (60 from the red zone and 1064 from the orange zone). Figure 1 highlights the cities with at least one active geo-referenced user account included in our analysis. We observed no tweets from 2 municipalities in the red zone: San Fiorano (1849 inhabitants) and Terranova dei Passerini (731 inhabitants). Additionally, a larger sample of tweets from across Italy (774,407 tweets) was collected during the same period using language filtering and keyword-based queries related to COVID-19. We used these tweets for our placebo analyses, detailed in the "Placebo Test" section in Multimedia Appendix 1. Using the geographical coordinates of municipalities from ISTAT [58], we identified additional unique tweets from the red zone and new municipalities in the orange zone near Codogno. These latest observations were added to the sample of tweets collected around Codogno.

The analysis is based on selected tweets from the red zone and surrounding areas. This stems from an extensive process of data processing and cleaning, which inevitably reduces the number of useful observations. In this paper, we prioritize the internal validity of our estimates over the generalizability of the results to other contexts by focusing on a single case study for credible causal inference. This approach necessitates conservative choices in selecting the subset of tweets included in the analysis to ensure the precision of both sentiment analysis and spatial mapping. Overall, the retrieved sample of users from the red and orange zones is reasonably sized, given that the geographical area covered by the policy is limited, as is its population, as shown in Table S3 in Multimedia Appendix 1.

Ethical Considerations

The data are anonymized by removing tweets and users' original identifiers, as well as users' original names, and replacing them with new, deidentified user identifiers. No ethics review was sought because the study only explored publicly available data on social media and did not conduct any experiments on humans.

Uncertainty and Sentiment Classifier

We fine-tune the pre-trained AlBERTo model [22], a deep learning natural language model trained on a large corpus of Italian tweets (~200 million, TWITA data set), to classify tweets into uncertainty and sentiment categories.

We refine the pretrained AlBERTo model in a 2-step process by manually labeling tweets for training (n=6318). The manual labels indicate degrees of uncertainty (neutral, uncertainty, and certainty) and sentiment (neutral, negative, and positive). The manually assigned labels were independently validated and verified by the authors. In the first step, we distinguish between neutral and nonneutral tweets. In the second step, we further classify nonneutral tweets as either uncertainty or certainty and as having positive or negative sentiment.

After fine-tuning the model and predicting the labels for all tweets, we obtain 2 binary variables: uncertainty and negative sentiment, assigned to each tweet in our data set. The uncertainty variable is set to 1 if the tweet expresses uncertainty—such as concern, questions, or uneasiness—and 0 otherwise, meaning the text conveys a different emotional state, such as certainty or indifference. Similarly, the negative sentiment variable is set to 1 if the tweet expresses negative feelings and 0 if it does not—that is, if it conveys positivity or neutrality. Multimedia Appendix 2 presents word clouds displaying the 100 most frequent terms in tweets classified as expressing uncertainty and negative sentiment.

Topics Classifier

A dictionary-based classifier is used to identify topic-specific words in tweets (see Tables S1 and S2 of the "Topic Dictionaries" section in Multimedia Appendix 1 for the complete list of words used to construct the topic-specific dictionaries). We selected 4 categories likely to be influenced by the policy: health, economy, politics, and policy. For each topic, we created a binary variable indicating whether a tweet contains at least one term from the topic-specific dictionary. Overlap of topic labels within a single tweet is allowed, as tweets can cover multiple topics simultaneously. In the "Top Fifty Tweets" section in Multimedia Appendix 1, we provide a sample of tweets with the highest Shannon entropy by emotion-topic pair and discuss the performance of the machine learning classifier in identifying tweets related to each topic and emotion. Table 1 presents the number of tweets in our sample categorized as

XSL•FO
RenderX

uncertainty or negative sentiment, aggregated and grouped by topic.

Table 1. The number of tweets classified as uncertainty and negative sentiment aggregated and grouped by topic[a] (N=24,261).

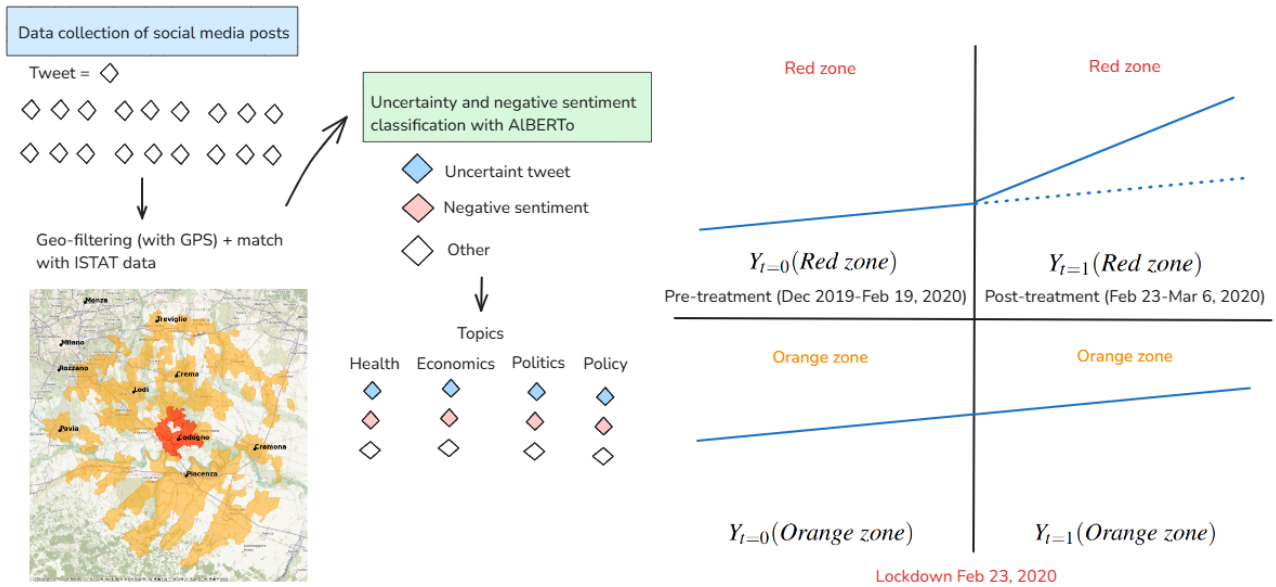
Classification	Value, n (%)	Percentile
Uncertainty[b]		
Aggregated	5270 (21.72)	89
Economics	369 (1.52)	99
Health	1063 (4.38)	97
Politics	301 (1.24)	99
Policy	304 (1.25)	99
Negative sentiment[b]		
Aggregated	8451 (34.83)	82
Economics	497 (2.05)	98
Health	1029 (4.24)	97
Politics	738 (3.04)	98
Policy	253 (1.04)	99

[a]We have omitted the category of Leisure from the table: Uncertainty Leisure, n (%)=3498 (14.4), Negative Sentiment Leisure, n (%)=6248 (25.7).

[b]The other categories, that is, Neutral Uncertainty (Neutral Sentiment) and Certainty (Positive Sentiment), are not reported.

Difference-in-Differences Model

To assess the causal impact of the lockdown on sentiment and uncertainty, we estimated a linear DiD model using repeated cross-sections of tweets from inside and outside the red zone before and after the February lockdown.



In the DiD model, we estimated the difference in the average change in emotion over time between the treated group (red zone) and the control group (orange zone). The estimation followed 3 steps: (1) comparing average outcomes between the treatment and control groups before the lockdown, (2) comparing average responses after the lockdown, and (3) estimating the difference. The first step accounts for preexisting differences, the second captures postlockdown differences, and the third measures the differential effect of the policy in the red zone, effectively isolating and removing time effects, common time trends, and time-invariant group differences.

For this measure to reliably estimate the treatment effect, the empirical framework must satisfy the key assumption of parallel trends, which states that emotions in the treated group would have followed the same trend as in the control group in the absence of treatment. This implies no inherent systematic differences between the treatment and control groups before the intervention. If this assumption is violated, the treatment effect may be biased. This condition is tested in the "Preexisting Trends" section in Multimedia Appendix 1. Another potential source of bias is treatment anticipation, as units might adjust their behavior in expectation of the lockdown. This is unlikely in our case, as this was the first lockdown in Europe. Another potential source of bias is spillover effects, where emotions in the red zone after policy implementation could influence those in the control group. However, because movement between the red and orange zones was prohibited, spillovers should not be relevant. We test this condition in the "SUTVA" section in Multimedia Appendix 1. Under these assumptions, the DiD estimate remains an unbiased measure of the lockdown's causal effect on the treated units. We conducted extensive tests to validate the DiD assumptions in our quasi-experimental setting and to ensure that our statistical method was appropriate for the observational sample. This is essential for credibly interpreting the model's estimates as the causal effect of lockdown on emotions in tweets from the red zone. The tests are summarized later in the text and detailed in the "Testing DiD Assumptions" section of Multimedia Appendix 1. As noted earlier, this case study has limitations regarding the generalizability of results and data expectations. However, by focusing on the red zone established by the February 23, 2020, policy and the selected control sample, we derive unbiased conclusions and obtain a causal estimate as if the policy had been implemented in a randomized experiment.

We define a treatment status indicator, red zone, which equals 1 if a tweet is from the red zone and 0 otherwise. We also define a pre- and postlockdown indicator, post, where post=0 for tweets posted before the lockdown and post=1 for those posted after. As all suitable control units were eventually treated by the partial lockdown on March 9, 2020, we lost our control set. To address this, we use post=2 to identify tweets published from March 9 onward. For each tweet, we define a set of binary outcome variables indicating uncertainty and negative sentiment, either aggregated or by topic. In the DiD regression model, the coefficient of interest is post=1 × red zone=1, which represents the treatment effect—the average impact of the lockdown on the probability of observing negative reactions in tweets from the red zone. Our sample does not allow for longitudinal user analysis, as different users are present across different periods. Figure 3 provides a graphical illustration of our empirical strategy.

XSL•FO
RenderX

Figure 3. Illustrative summary of the methodology. Twitter posts are filtered using global positioning system (GPS) coordinates to select tweets posted within 42 km of Codogno. Each tweet's user location is then matched to geo-referenced ISTAT data to further filter municipalities. Sentiment analysis is performed on the retrieved set of tweets to classify the sentiment and uncertainty expressed in the text. Additionally, tweets are categorized into major topics: Health, Economics, Politics, and Policy. A difference-in-differences (DiD) approach is used to estimate the average effect of the lockdown on the red zone's emotions, measured as the difference between the average change over time (before and after 2020) in the red zone's reactions and the average change over time among the control units in the orange zone. AlBERTo: Italian BERT optimized.

Results

Overview

The DiD model's estimates of the COVID-19 shock's impact on uncertainty and negative sentiment—both aggregated and by topic (economics, health, politics, and lockdown policy)—are presented in Tables 2 and 3, respectively. SEs are clustered at the municipality level (126 clusters) using the Liang-Zeger formula [59]. Model estimates with white SEs are provided in the "Model Estimates With Heteroskedasticity Robust Standard Errors" section in Multimedia Appendix 1 (also see Table S10 in Multimedia Appendix 1).

[b]The parallel trends condition fails to be satisfied for aggregated negative sentiment. See the "Robustness Checks" section and Multimedia Appendix 1 for complete analysis.

We first examine the effect of the lockdown on aggregate uncertainty. In column 1 of Table 2, the treatment effect (red zone=1 × post=1) is positive and statistically significant at .001 (b=0.15, SE 0.03, t_{125}=4.82; *P*<.001). The estimated time trend shows no significant increase in uncertainty following the lockdown (post=1, b=0.02, SE 0.01, t_{125}=1.98; *P*=.05) or after the implementation of partial nationwide measures (post=2, b=0.022, SE 0.017, t_{125}=1.27; *P*=.21). Overall, the results indicate that the lockdown significantly increased aggregate uncertainty among affected individuals (b=0.15, SE 0.03, t_{125}=4.82; *P*<.001). However, these findings may not capture the full picture, as multiple factors could influence the aggregate expression of emotions.

Column 2 of Table 2 presents the effects of the lockdown on economic uncertainty. The lockdown had no significant impact on economic uncertainty among those affected, with a small positive estimated effect (b=0.005, SE 0.007, t_{125}=0.70; *P*=.48). This suggests that the lockdown did not substantially influence economic uncertainty.

Column 3 of Table 2 shows that the lockdown significantly increased concern about health problems among individuals in the lockdown area (b=0.036, SE 0.0065, t_{125}=5.55; *P*<.001). As expected, after the partial nationwide measures on March 9, people in the red zone expressed significantly less uncertainty in health discussions (b=–0.023, SE 0.01, t_{125}=–2.35; *P*=.02) as restrictions eased. However, the overall trend of health-related uncertainty increased significantly following both the local lockdown (b=0.037, SE 0.005, t_{125}=7.50; *P*<.001) and the partial nationwide measures (b=0.042, SE 0.0052, t_{125}=8.00; *P*<.001).

The results for political uncertainty are presented in column 4 of Table 2. The lockdown significantly increased political uncertainty in the treated area (b=0.012, SE 0.0058, t_{125}=2.05; *P*=.04). However, this effect disappears and is no longer statistically different from 0 once all units are subjected to the same nationwide measures (red zone=1 × post=2, b=0.00138, SE 0.007, t_{125}=0.20; *P*=.84).

Column 5 in Table 2 presents the results for uncertainty associated with the lockdown policy itself. The lockdown significantly increased concerns among those affected by the measures (b=0.026, SE 0.006, t_{125}=4.47; *P*<.001). Additionally, the coefficients for post=1 (b=0.01, SE 0.002, t_{125}=5.56; *P*<.001) and post=2 (b=0.01, SE 0.0025, t_{125}=3.98; *P*<.001) indicate that uncertainty regarding the practical effects of the lockdown remained significantly higher than the baseline value.

DiD estimates of the lockdown's effect on aggregate negative sentiment are reported in Table 3 (column 1). The lockdown significantly reduced negative sentiment among those in the red zone (b=–0.072, SE 0.027, t_{125}=–2.67; *P*=.008). Over time, the likelihood of expressing negative sentiment decreases for both the treated and control groups, as indicated by the negative and statistically significant coefficients for post=1 (b=–0.044, SE 0.022, t_{125}=–2.00; *P*=.047) and post=2 (b=–0.056, SE 0.023, t_{125}=–2.45; *P*=.02). Overall, the results suggest that the lockdown significantly reduced aggregate negative sentiment among people in the red zone.

In Table 3 (column 2), we present the effect of the lockdown on negative sentiment about the economy. Although not significantly different from 0, the estimated impact on negative sentiment in economic discussions is negative (b=–0.011, SE 0.0089, t_{125}=–1.32; *P*=.19) and relatively larger in magnitude compared with the estimated effect on economic uncertainty in Table 2 (column 2).

The regression results in Table 3 (column 3) show that the lockdown had no significant effect on negative sentiment regarding health in the lockdown area (b=0.027, SE 0.021, t_{125}=1.27; *P*=.20). However, the overall trend indicates a significant worsening of sentiment about health issues both

XSL•FO
RenderX

inside and outside the lockdown area, as reflected in the coefficients for post=1 (b=0.036, SE 0.0063, t_{125}=5.70; P<.001) and post=2 (b=0.038, SE 0.0057, t_{125}=6.57; P<.001).

Column 4 in Table 3 presents the effect of the lockdown on negative political sentiment. We estimate a positive and significant coefficient for both interactions, indicating that political sentiment became more negative among treated users when the first lockdown was implemented (b=0.025, SE 0.011, t_{125}=2.33; P=.02) and after the nationwide measures (b=0.028, SE 0.011, t_{125}=2.50; P=.01). Notably, the general trend in negative political sentiment decreased significantly following the partial national lockdown (b=–0.02, SE 0.008, t_{125}=–2.30; P=.02).

In Table 3 (column 5), the red zone did not express negative sentiments about the policy significantly more often (b=0.024, SE 0.02, t_{125}=1.22; P=.22). However, negative sentiment toward the policy increased across all areas, both after the first lockdown (b=0.0058, SE 0.0017, t_{125}=3.39; P<.001) and after the nationwide measures (b=0.0066, SE 0.0018, t_{125}=3.60; P<.001).

Overall, our results highlight an important distinction between the impact of the lockdown on economic uncertainty and economic sentiment. While economic uncertainty increased due to the spread of COVID-19 cases (as shown in [24,60]), our case study indicates that the lockdown itself did not exacerbate economic uncertainty or negative sentiment. As shown in Multimedia Appendix 2, tweets during this period were less focused on purely economic discussions: the most frequently used terms in tweets expressing uncertainty or negative sentiment were unrelated to the economy. Although the estimated coefficient for the effect of the lockdown on economic uncertainty is very close to 0 and relatively small, we cannot rule out the possibility that the lack of statistical significance for the relatively larger effect of lockdowns on negative sentiment about the economy (b=–0.011, SE 0.0089, t_{125}=–1.32; P=.19) is due to the small sample size. The sample size of tweets in each topic category is provided in Figure S1 in Multimedia Appendix 1.

Instead, the lockdown affected individuals' emotions on other topics, such as health and politics. Our results show that the lockdown increased health-related uncertainty among people in the treated area. Higher uncertainty about health issues may reflect concerns for personal safety, but it also raises public awareness of the health risks posed by the virus [38]. This suggests that the health concerns arising from the implementation of a lockdown outweigh the reassurance authorities aim to provide through lockdown measures and their commitment to containing the virus. However, our findings indicate that negative sentiment toward health issues was driven by COVID-19 itself rather than the lockdown.

The same logic applies to the impact of the lockdown on emotions expressed in discussions about the lockdown policy. Concern about the guidelines and the consequences of the policy was high among those in the red zone, but this was not accompanied by a significant change in sentiment among the treated population (b=0.024, SE 0.02, t_{125}=1.22; P=.22). Sentiment in discussions about the policy worsened in both the treated and control zones after the measures were implemented, suggesting that this deterioration was likely due to COVID-19 itself rather than the lockdown.

Our results indicate that political sentiment among Twitter users in the treated area deteriorated significantly (b=0.025, SE 0.011, t_{125}=2.33; P=.02). This suggests that the lockdown measures came at the cost of worsening political emotions. The increase in negative sentiment within the red zone may reflect heightened political polarization as a direct consequence of the lockdown measures, aligning with previous findings on political polarization during COVID-19 [18,19]. A rise in negative sentiment toward politics could also signal growing dissatisfaction with politicians in office. Previous research has shown that public attitudes toward politicians improved during the pandemic [35,39,61]. This aligns with the observed significant decline in the overall trend following the nationwide measures implemented on March 9 (b=–0.02, SE 0.008, t_{125}=–2.30; P=.02), which came in response to a sharp increase in COVID-19 cases and deaths across the country.

In addition, the lockdown significantly worsened political uncertainty in the treated area (b=0.012, SE 0.0058, t_{125}=2.05; P=.04). However, as will be explained in the next section, the estimated effect on political uncertainty is not robust to a series of validity checks on the assumptions of the DiD model.

The overall effect of the lockdown on uncertainty was positive, driven by a significant increase in uncertainty related to health (P<.001), policy (P<.001), and politics (P=.04). Conversely, aggregate negative sentiment in the red zone decreased. This decline was primarily due to reduced negative sentiment when discussing topics of lesser interest, mainly those related to entertainment and sports (see Table S8 in Multimedia Appendix 1). However, the estimated effect on overall negative sentiment does not hold up under most of the robustness checks we conducted, as will be explained in the next section. This reinforces the validity of the topic-based analysis in better assessing the impact of lockdowns on uncertainty and sentiment.

In general, our findings highlight the nuanced effects of lockdown policies on various emotional aspects and suggest that their impact on health, economics, and politics differs significantly. The quasi-experimental framework of our analysis allows us to distinguish between the effects of lockdown policies and broader emotional trends related to the pandemic. In the next section, we explain that the effects on aggregate negative sentiment and political uncertainty do not remain robust when subjected to a series of robustness checks.

Robustness Checks

We conducted a battery of tests to assess the robustness of our results and summarize the key findings here.

First, we performed a series of tests to evaluate the validity of the DiD model assumptions—*parallel trends*, *absence of spillover effects*, and *no anticipation* of the treatment. To check whether the parallel trends assumption holds, we examine whether emotional reaction trends differed between the treated

XSL•FO
RenderX

and control groups before the lockdown (see Figures S2 and S3 in the "Preexisting Trends" section in Multimedia Appendix 1). We find no significant differences in pretreatment trends for aggregate uncertainty, health-related uncertainty, policy uncertainty, or negative sentiment toward politics, confirming the parallel trends assumption. However, we do observe differences in pretreatment trends for aggregate negative sentiment and political uncertainty. This suggests that the DiD estimate of the lockdown's impact on these 2 variables may be biased, as the control group does not behave as a true counterfactual, given the significant differences in prepolicy trends.

Furthermore, our findings indicate that estimates of the lockdown's effect on political uncertainty and aggregate negative sentiment are highly sensitive to the inclusion of certain municipalities in the comparison group (see Table S9 in the "Exclusion of Territorial Administrative Units" section in Multimedia Appendix 1).

Finally, we examine the potential local spillover effects of the treatment on control units [62]. Our estimates could be biased if emotions in the control group were influenced by online reactions from the red zone. However, we argue that, in this specific context, it is reasonable to assume that red zone responses primarily affected only nearby control units, while those located beyond a certain distance remained unaffected. These distant units serve as the comparison group for the DiD estimate of the treatment effect. Our findings show that the treatment effect estimates remain consistent with the baseline DiD estimates (see Table S4 in Multimedia Appendix 1).

We also applied Benjamini-Hochberg adjusted *P* values [63] to control for the risk of false positives when testing multiple models with potentially correlated results (see Tables S5 and S6 in the "Multiple Test Adjusted *P* Values" section in Multimedia Appendix 1). The analysis confirms our findings, except for uncertainty related to politics.

As an additional robustness check, we estimate the lockdown's effect on public emotions by comparing tweets before and after the February 23, 2020, policy across different groups: the red zone, the extended orange zone defined by the March 8, 2020, decree, and other Northern Italian locations that were later subjected to nationwide measures starting on March 9, 2020, but were never designated as a targeted priority—referred to as the "white zone" (see Figure S5 in Multimedia Appendix 1). This approach allows us to assess how spatial proximity to the lockdown area and exposure to government policy—under similar media influences—affect our findings. Pretreatment checks reveal significant demographic differences between the red zone and control groups (see Figures S6-S9 in Multimedia Appendix 1). While we rely on manually entered user locations, which are less precise than GPS coordinates, this method still enables us to distinguish tweets originating from within and outside the red zone. We randomly subsampled 20% of tweets from the extended orange zone and 50% from the white zone to ensure computational scalability in estimating the model coefficients while controlling for user-level fixed effects. Compared with the baseline DiD, the treatment effect on aggregated uncertainty, health-related uncertainty, and aggregate negative sentiment is more pronounced in the white zone but smaller in the extended orange zone. The difference increases as the distance of extended orange zone locations from the red zone grows, while it decreases as white zone locations move farther from the red zone. This suggests that differential exposure to (mild) government policies against contagion played a relevant role. Negative sentiment toward politics is higher when treated units are compared with extended orange zone locations after the policy, but the difference is significant only for those in closer proximity to the lockdown area. Additionally, we find a significant difference in economic negative sentiment between the red zone and the white zone (see Tables S11-S14 and the "DiD Estimates Varying for Spatial Proximity" section in Multimedia Appendix 1 for details).

Finally, we conducted a placebo test to examine how *anticipation* of the policy affected behavior and the estimated impact of the lockdown. Following the nationwide lockdown on March 9, we argue that municipalities with COVID-19 risk levels similar to those of the first 10 quarantined towns should not have reacted differently from those with dissimilar risk, as the nationwide measures were widely expected (see Figure S4 in the "Placebo Test" section in Multimedia Appendix 1). Using the percentage increase in monthly deaths from ISTAT as a proxy for contagion rates, we treat the lockdown as a placebo in areas where excess deaths were already high. The results indicate that the national lockdown had no significant effect on public reactions in the placebo treatment group, reinforcing the robustness of our original findings by confirming that potential anticipatory effects did not bias the estimated impact of the policy (see Table S7 in Multimedia Appendix 1).

Overall, the robustness tests support the key findings that the lockdown had significant effects on aggregate uncertainty, health-related uncertainty, policy uncertainty, and negative sentiment toward politics. However, the effects on political uncertainty and aggregate negative sentiment do not hold up across several tests.

Discussion

Principal Findings

Overall, our findings confirm that lockdowns come at a cost, though in an unexpected way. We found no causal impact on economic uncertainty or sentiment, suggesting that economic-related emotions were primarily driven by the rise in COVID-19 cases rather than the lockdown itself. Instead, in the red zone areas under lockdown, users were more likely to express uncertainty about health and lockdown policies, along with increased negative sentiment toward politics.

The evidence suggests that lockdowns increase, rather than reduce, uncertainty about health conditions without significantly altering sentiment in discussions on health or the management of the sanitary emergency. Our findings indicate that the deterioration of sentiment in health- and policy-related discussions is driven by COVID-19 itself rather than stay-at-home measures. Notably, lockdowns carry political costs, as affected areas experience a surge in negative political

XSL•FO
RenderX

sentiment, which may deter future policy makers from implementing stay-at-home mandates to avoid political backlash.

Comparison With Prior Work

Our contribution is 2-fold. First, we develop a new methodological framework to assess the impact of lockdown measures [31-33,39,64]. We focus on the causal effects on public emotions, an area where, to our knowledge, only correlational evidence exists [10,17,39]. Understanding how stay-at-home mandates influence public emotions is crucial for policy makers to weigh the benefits and costs of such measures.

Second, we contribute to the literature on uncertainty and sentiment, which often relies on nontraditional data such as textual analysis. Recent studies have reported particularly high levels of economic uncertainty [65] and health-related negative emotions [17,20] following the enactment of COVID-19 lockdown measures, as well as increased political polarization [18,19]. However, less is known about the specific factors driving these changes. We help bridge this knowledge gap by showing that uncertainty and negative sentiment did not increase uniformly across individuals after the lockdown but followed distinct dynamics. This is the first study to examine the effects of stay-at-home mandates on multiple dimensions of public uncertainty and sentiment.

Limitations

It is important to note that all field experiments may suffer from a lack of external validity. Our study is no exception, as a new lockdown today could be perceived differently from the unexpected lockdown analyzed in this paper. One could argue that the public is now much more informed about the implications of a lockdown than it was in February 2020. People would adjust their strategies based on their experiences, potentially altering the policy's impact on uncertainty and sentiment. Moreover, given the negative political sentiments such measures have generated, policy makers may now be more reluctant to implement them or, at the very least, enforce them with the same level of strictness. Nevertheless, we demonstrate that once the causal effect of the policy is effectively isolated from comoving factors and external influences, lockdowns impose political and social costs by exacerbating uncertainty and sentiment. To ensure robust and reliable causal inference, we prioritize the internal validity of our estimates over the generalizability of our results by analyzing a case study in which the policy change can be viewed as randomly allocated among groups. While it is impossible to predict how the public and policy makers will respond to a future lockdown, our findings offer valuable insights into the costs policy makers must consider before implementing new lockdown measures.

Conclusions

Our findings suggest that communication surrounding lockdown measures may have been unclear, fostering resentment toward the political class among those affected and failing to generate explicit support for the government's plans. Policy makers must enhance communication to reduce uncertainty and negative sentiment [66]. These findings underscore the need for authorities to refine future policies and communication strategies to mitigate uncertainty and social panic.

Abstract

Background: Chronic obstructive pulmonary disease (COPD) ranks among the leading causes of global mortality, and COVID-19 has intensified its challenges. Beyond the evident physical effects, the long-term psychological effects of COVID-19 are not fully understood.

Objective: This study aims to unveil the long-term psychological trends and patterns in populations with COPD throughout the COVID-19 pandemic and beyond via large-scale Twitter mining.

Methods: A 2-stage deep learning framework was designed in this study. The first stage involved a data retrieval procedure to identify COPD and non-COPD users and to collect their daily tweets. In the second stage, a data mining procedure leveraged various deep learning algorithms to extract demographic characteristics, hashtags, topics, and sentiments from the collected tweets. Based on these data, multiple analytical methods, namely, odds ratio (OR), difference-in-difference, and emotion pattern methods, were used to examine the psychological effects.

Results: A cohort of 15,347 COPD users was identified from the data that we collected in the Twitter database, comprising over 2.5 billion tweets, spanning from January 2020 to June 2023. The attentiveness toward COPD was significantly affected by gender, age, and occupation; it was lower in females (OR 0.91, 95% CI 0.87-0.94; P<.001) than in males, higher in adults aged 40 years and older (OR 7.23, 95% CI 6.95-7.52; P<.001) than in those younger than 40 years, and higher in individuals with lower socioeconomic status (OR 1.66, 95% CI 1.60-1.72; P<.001) than in those with higher socioeconomic status. Across the study duration, COPD users showed decreasing concerns for COVID-19 and increasing health-related concerns. After the middle phase of COVID-19 (July 2021), a distinct decrease in sentiments among COPD users contrasted sharply with the upward trend among non-COPD users. Notably, in the post-COVID era (June 2023), COPD users showed reduced levels of joy and trust and increased levels of fear compared to their levels of joy and trust in the middle phase of COVID-19. Moreover, males, older adults, and individuals with lower socioeconomic status showed heightened fear compared to their counterparts.

Conclusions: Our data analysis results suggest that populations with COPD experienced heightened mental stress in the post-COVID era. This underscores the importance of developing tailored interventions and support systems that account for diverse population characteristics.

KEYWORDS

COVID-19; chronic obstructive pulmonary disease (COPD); psychological trends; Twitter; data mining; deep learning

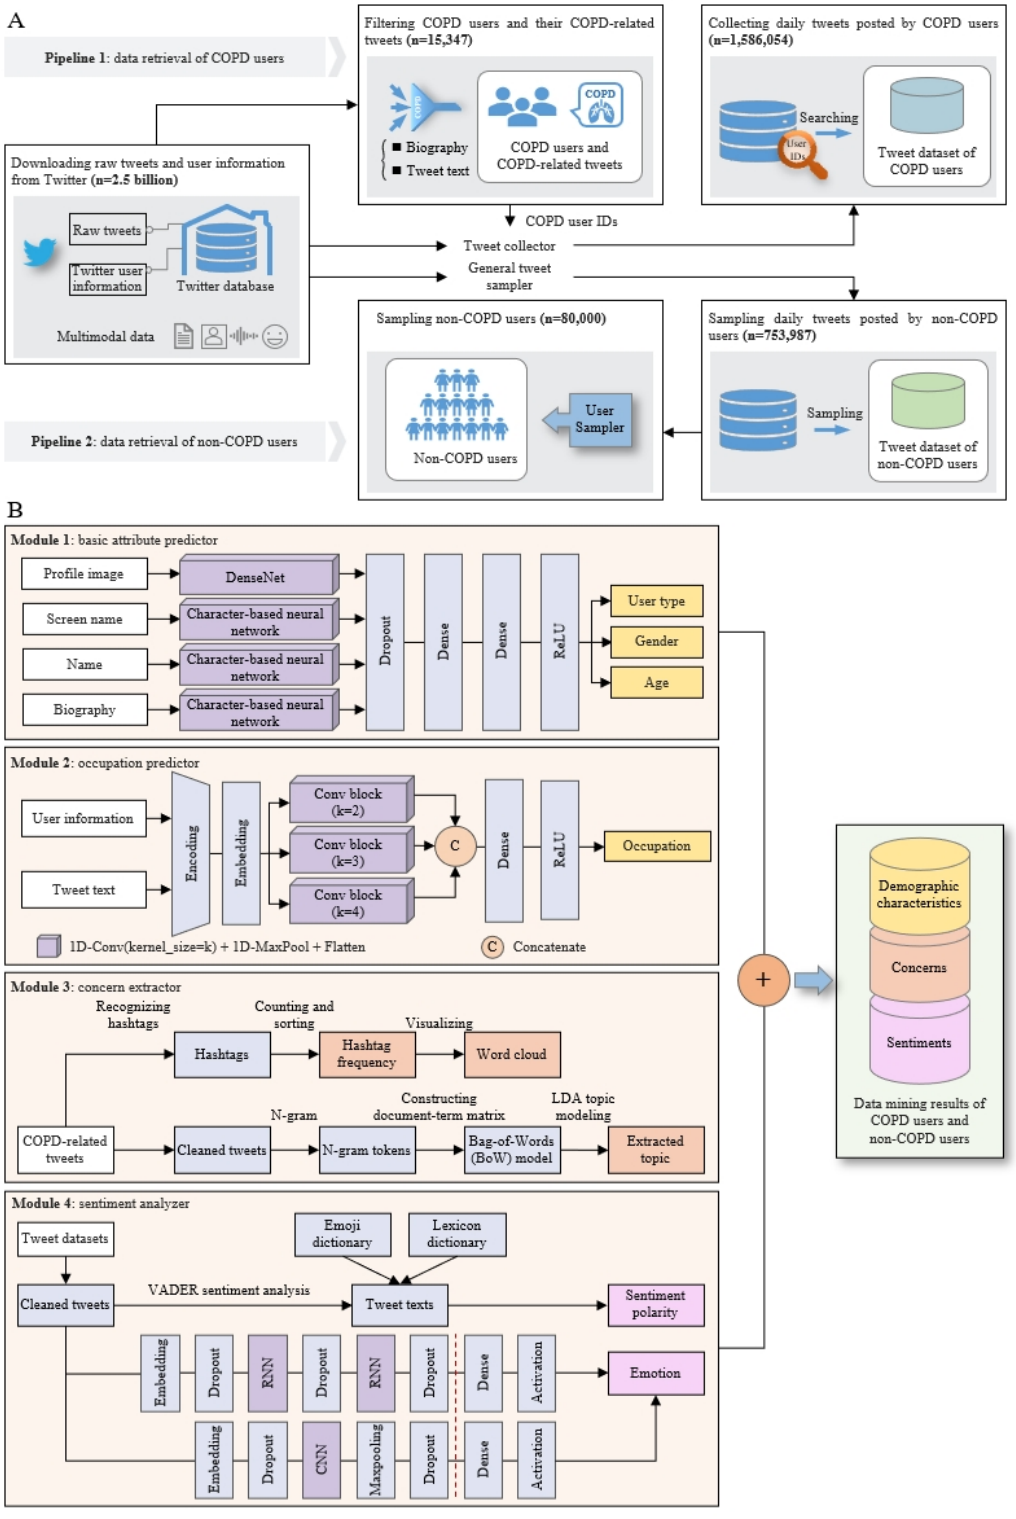
Introduction

On January 30, 2020, the World Health Organization declared the COVID-19 pandemic as a public health emergency of international concern [1]. Three years later, on May 5, 2023, given the encouraging trends observed in the COVID-19 statistics, the World Health Organization determined that COVID-19 no longer constituted a public health emergency of international concern [2]. However, this did not indicate that COVID-19 was no longer a global health threat [3]. The COVID-19 pandemic has had and continues to exert a profound and long-lasting impact on human lives worldwide, affecting public health, food systems, and global job markets [4,5]. In this situation, populations with chronic diseases, particularly chronic obstructive pulmonary disease (COPD), face great hardships [6,7] due to several reasons. First, patients with COPD are more likely to develop severe COVID-19 symptoms due to their respiratory illness [8]. Second, the overwhelming demands of managing COVID-19 may strain valuable health care resources, potentially affecting populations with COPD due to resource allocation [6]. Third, COVID-19 has greatly disrupted the daily lives of patients with COPD, leading to a higher risk of exacerbations and even mortalities. However, in contrast to the tangible physical consequences, the long-term effects of COVID-19 on the psychological conditions of patients with COPD have not drawn sufficient attention.

There are limited studies on the psychological effects of COVID-19 on patients with COPD (Table S1 in Multimedia Appendix 1) [9-14]. These studies have highlighted the high rates of psychological stress, including depression, anxiety, and fear, among patients with COPD under the threat of COVID-19. However, all these studies focused primarily on the early acute phase of COVID-19, thereby providing limited insight into the mental conditions of patients with COPD over the long term. Drawing parallels from the historical context of the SARS pandemic, wherein distinct chronological phases were discerned in the psychological conditions of SARS survivors [15], the psychological aftermath of COVID-19 survivors may exhibit similar enduring and evolving traits over the long term. Furthermore, surveys in the previous studies were conducted through traditional means, including telephone [10-12,14], video calls [14], interviews [13], and questionnaires [10,12], requiring substantial labor resources and physical contacts. This ultimately limited the amount of data that could be collected during the pandemic.

In recent years, social media data mining has been widely used in health-related domains—both physical and mental. In the physical health domain, for example, Pradeepa et al [16] proposed a methodology to identify various symptoms associated with stroke and preventive measures for stroke from social media data. Fu et al [17] conducted a scoping review of methodologies for analyzing social media content in health care research and categorized health care areas into health practice, health services, and health education based on social media. In the mental health domain, for capturing the prevailing psychological conditions of the public during the COVID-19 pandemic, social media data mining has proven to be an effective solution. Compared with conventional survey approaches, social media data mining has significantly higher efficiency while minimizing infection risks by circumventing the need for physical contact. More importantly, the richness of social media data facilitates the discernment of long-term trends in emotional changes within a specific time period. For example, Lwin et al [18] used Twitter data to explore global trends in the 4 emotions—fear, anger, sadness, and joy—alongside their relative salience, spanning from January 28 to April 9, 2020. Similarly, through mining large-scale Twitter data, Zhang et al [19] conducted a cross-sectional study on web-based public sentiments in the early phase of the COVID-19 pandemic. However, these studies tended to either treat the populace as a monolithic entity, thus disregarding possible disparities among various population groups or only focus on general users while ignoring the existence of certain specific populations.

Considering the limitations of existing studies [9-19], this study aims to investigate the long-term psychological trends and patterns of populations with COPD with different characteristics during and after the COVID-19 pandemic. A new deep learning framework has been proposed to intelligently extract and analyze the characteristics of populations with COPD based on large-scale Twitter data.



Methods

Study Design

This study was conducted following the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [20] (Multimedia Appendix 2). In this study, raw Twitter data were collected with our self-designed program via the Twitter application programming interface [21]. These data are composed of multimodal information, including texts, emojis, images, and hashtags and are stored in a chronological order in our Twitter database. To date, over 2.5 billion tweets have been collected, spanning from January 2020 to June 2023. Based on these data, we designed a 2-stage framework, titled Deep-COPD, incorporating a series of deep learning algorithms to track COPD Twitter users (hereafter referred to as COPD users). The flowcharts for the data retrieval (stage 1) and data mining (stage 2) procedures are shown in Figure 1.

Figure 1. Overall design of the Deep-COPD framework. (A) Data retrieval procedure. (B) Data mining procedure. CNN: convolutional neural network; Conv: convolutional; COPD: chronic obstructive pulmonary disease; LDA: latent Dirichlet allocation; RNN: recurrent neural network; ReLU: rectified linear unit; VADER: valence aware dictionary and emotional reasoner.

Data Retrieval

Figure 1A shows the procedure of data retrieval, which involves 2 pipelines: pipeline 1, retrieving the data of COPD users, including user information, COPD-related tweets, and their daily tweets; and pipeline 2, retrieving the data of non-COPD users, including user information and their daily tweets. In pipeline 1, we used a filter pattern implemented as a regular expression composed of a set of COPD keywords to identify COPD users and tweets by searching 2 sources: user biographies and tweet texts (see Multimedia Appendix 1). The specific construction process of this regular expression can be found in the build_match_word_regex() function of the filter_copd.py file (lines 17-35) in the stage 1 folder of our GitHub repository. We collected the daily tweets posted by these COPD users

XSL•FO
RenderX

through their user IDs. To limit the size of the data retrieved in pipeline 2, we sampled the tweets posted by non-COPD users at a rate of 0.05%. Through data retrieval, we obtained raw data that were used for the sentiment and psychological analysis. Moreover, we extracted data representing COPD and non-COPD characteristics from the daily tweets, enabling targeted research on the psychological evolution patterns associated with these 2 distinct groups. Specifically, this approach enables a more focused investigation into how the psychological trends may differ between users with COPD and those without COPD, thereby providing valuable insights into the impact of the condition on mental health over time. By analyzing these 2 groups separately, we aim to uncover specific psychological patterns and trends that could inform tailored interventions and support strategies for each population.

Data Mining

The data mining procedure aims to extract distinct information from multimodal Twitter data by using a variety of deep learning algorithms, including natural language processing, image processing, and symbol processing (Figure 1B). It consists of the following 4 parallel intelligent modules. Module 1 and module 2 are used to extract demographic characteristics, including user type, gender, age, and occupation, from both COPD and non-COPD users. Module 3 extracts concern information from COPD-related tweets, while module 4 extracts sentiment information from the daily tweet datasets of both COPD and non-COPD users.

Module 1: Basic Attribute Predictor

Module 1 is an attribute predictor that predicts the probabilities of 3 demographic attributes, that is, user type, gender, and age, through the analysis of profile images, screen names, display names, and biographies. It was implemented with an open-source package of the M3 (multimodal, multilingual, and multiattribute) model [22], a multimodal deep neural system trained on a massive dataset. It is mainly composed of a dense convolutional network (DenseNet) [23] for image processing, 3 character-based neural networks for text processing, and 2 fully connected dense layers for result classification. The training and validating M3 model uses 5 distinct datasets: a large dataset of Twitter profiles whose gender and age are heuristically identified, a curated dataset of Twitter accounts belonging to organizations, an image dataset of faces from IMDb (internet movie database) and Wikipedia, a massive unlabeled set of users, and a crowdsourced dataset for all 3 attributes. For more detailed information, readers can refer to the original literature [22]. This module was tested with a subset of our tweet dataset, achieving the following benchmark performance: 99.07% accuracy for user type, 95.88% accuracy for gender, and 77.65% accuracy for age attributes.

Module 2: Occupation Predictor

Module 2 is a self-designed deep learning model that derives the 2-class occupations of Twitter users from their profile information and tweet texts. It employs a word-based convolutional neural network that consists of an encoding layer, an embedding layer, 3 parallel convolutional blocks with different kernel sizes, and a dense layer. The training and validation data are obtained from a publicly available dataset [24] with 5191 Twitter users annotated with 9 occupation categories (OCs), which are defined according to the standard occupation classification [25]. In our study, the 9 OCs were merged into 2 OCs, abbreviated as OC1 and OC2 (see Table S4 in Multimedia Appendix 1). Individuals in OC1 are those of relatively higher socioeconomic status (such as managers, directors, and senior officials), and individuals in OC2 are those of relatively lower socioeconomic status (such as process, plant, and machine operatives). Using a 10-fold cross-validation approach, this module achieved an accuracy of 93.15% on the 2-class occupational dataset.

Module 3: Concern Extractor

Module 3 is a concern extractor that captures hashtags and latent Dirichlet allocation (LDA) [26] topics. Hashtags were identified in the tweet texts using a regular expression (#+[a-zA-Z0-9\-_]{1,}), and then the frequencies of these hashtags were calculated. LDA topic modeling was employed to identify the main topics expressed in the tweets. The original tweets underwent preprocessing, n-gram processing, and document-term matrix constructing, yielding a bag-of-words, which was fed into LDA models. The coherence score calculated by Gensim CoherenceMode [27] was used to evaluate the quality of the extracted topics. To pinpoint the optimal number of LDA topics, we performed a grid search within a range of 2-20 with a step of 1 for each year. The selection principle is to choose the number that makes the coherence score of the extracted topics reach the highest value. Through searching, the optimal number of topics and the coherence score for each year were obtained, as shown in Table S5 in Multimedia Appendix 1.

Module 4: Sentiment Analyzer

Module 4 is composed of a sentiment analyzer and an emotion detector to perceive sentiments from 2 different perspectives. The sentiment analyzer utilizes a widely used open-source tool known as the valence aware dictionary and emotional reasoner (VADER) [28]. VADER requires no training data, but it is constructed from a generalizable, valence-based, human-curated gold standard sentiment lexicon. It is highly effective in analyzing social media sentiments, achieving an F_1 classification accuracy of 96%, outperforming human raters of 84% at classifying the sentiment of tweets. The emotion detector was built upon an open-source algorithm for emotion recognition on Twitter, which employs a character-based trained recurrent neural network [29]. The training and validation dataset is a set of tweets containing emotional hashtags and satisfying filtering requirements that searched from 73 billion tweets. Specifically, this study adopted the well-known Plutchik's emotion wheel [30] model, which consists of 8 basic emotions: joy, sadness, fear, anger, trust, disgust, surprise, and anticipation. This emotion detector achieved a macro F_1-score of 0.6950 for Plutchik's emotion model [29].

Specifically, the deep learning algorithms chosen in this study were selected for their strengths in handling various data types. DenseNet was employed for image processing, while character-based and word-based neural networks were used for the text classification of demographic attributes and occupations. LDA's topic modeling capability made it suitable for extracting

XSL•FO
RenderX

concerns from large text datasets. VADER's high accuracy ensured robust social media sentiment detection. Additionally, a character-based recurrent neural network enabled the emotion detector to effectively capture and classify complex emotional states.

The data mining procedure extracts valuable information from multimodal Twitter data by using advanced deep learning algorithms. This process involves 4 parallel intelligent modules, of which the outputs are as follows: module 1 (basic attribute predictor) predicts demographic attributes such as user type, gender, and age by analyzing user profile images, names, and biographies; module 2 (occupation predictor) classifies Twitter users' occupations into 2 groups based on their profiles and tweet content; module 3 (concern extractor) identifies user concerns by extracting hashtags and topics by using LDA; and module 4 (sentiment analyzer) analyzes sentiments from tweets by using VADER for general sentiments and a character-based recurrent neural network for emotion detection. Together, these modules provide a comprehensive analysis of the demographic, psychological, and emotional factors affecting both COPD and non-COPD Twitter users.

The outputs from data retrieval and data mining are crucial for assessing the psychological trends in populations with COPD, particularly the changes in sentiments, prevalent emotions, and evolving concerns (eg, health-related topics) during and after COVID-19. Through data retrieval, raw Twitter data are collected, allowing for data extraction of COPD and non-COPD groups, which enables focused analysis of psychological patterns within the target population. The data mining process further analyzes these data, extracting key demographic attributes, concerns, and sentiments by using deep learning algorithms. The concern extraction identifies health-related topics, while the sentiment and emotion analyzer tracks shifts in emotional states and sentiments, providing critical insights into the psychological evolution of populations with COPD in response to the pandemic. This comprehensive data processing directly supports the study's goal of understanding the psychological trends of COVID-19 in populations with COPD.

Data Analysis Tools

Based on the data mining results from our Deep-COPD framework, we conducted attentiveness analysis, concern analysis, and sentiment analysis. In these analyses, multiple statistical tools were used, namely, odds ratio (OR), difference-in-difference (DiD), and emotion pattern method.

Statistical Measure OR

OR is a statistical measure widely used in medical literature to evaluate the relevance between an event (such as lung cancer) and a particular exposure (such as smoking) [31]. In this study, the event refers to COPD, and the exposure factors include gender, age, and occupation. The ORs are used to quantitatively assess the levels of attentiveness toward COPD under these different exposure factors (Table 1).

Table 1. A 2x2 table for the chronic obstructive pulmonary disease event and the gender exposure factor (a, b, c, and d represent the number of users).

	Chronic obstructive pulmonary disease event	No event of chronic obstructive pulmonary disease
Female exposure	a	b
Male exposure	c	d

Taking gender as the exposure factor as an example, the 2×2 table shown in Table 1 is used to calculate the attentiveness OR toward a COPD event in females compared to males. The formula is as follows: OR = (a/b)/(c/d) = ad/bc

An OR of 1 indicates that the gender factor does not affect the level of attentiveness toward COPD. When OR>1, it suggests that the attentiveness toward COPD is higher in females than in males. Conversely, when OR<1, it indicates that the attentiveness toward COPD is lower in females than in males. The confidence interval in OR provides a range of values within which the true OR is likely to fall, offering an indication of the precision and reliability of the estimate. As a typical value, 95% CI is commonly used, indicating that there is a 95% probability that the true OR lies within the specified range [31]. The following formula is used for 95% CI:

In addition, the *P* values were obtained using the chi-square test to evaluate the significance levels of the differences between groups under different exposure factors. A lower *P* value indicates a more statistically significant difference between the groups [32].

DiD Model

The DiD model is typically used to estimate the effect of a specific intervention or treatment by comparing the changes in outcomes over time between a population that is enrolled in a program (the treated group) and a population that is not (the control group) [33,34]. In this study, we took COPD users as the treated group and non-COPD users as the control group and adopted the DiD model to estimate the relative sentiment trends of COPD users. The formula of the DiD model is as follows:

where Y_{it} is the dependent variable representing the sentiment status for group G_i and time t; G_i is a dummy variable for the treated group (G_0) or control group (G_1); D_t is a dummy variable for time t; α, β_k, γ, δ_k are the regression parameters; K is the total time period ($k \in [1, K]$); and ε_{it} is an error item.

The coefficients of interest are those of the interaction term, β_k, which can reflect the relative sentiment trends of COPD users compared to those of non-COPD users. A value of $\beta_k = 0$ signifies that both groups have parallel sentiment trends, whereas a negative value indicates the extent to which the sentiment

XSL•FO
RenderX

trend of the COPD group declines compared to that of the non-COPD group and vice versa.

Emotion Pattern

We proposed an emotion pattern method to calculate the values of the sentiment components of Plutchik's 8 emotions. The emotion pattern of population p is composed of the sentiment component scores of Plutchik's 8 emotions, which is expressed as follows:

where $e \in$ [joy, trust, surprise, anticipation, sadness, disgust, anger, fear], $S(p)|_e$ is the sentiment component of population p on emotion e,

is the calculated sentiment scores of tweets

expressing emotion e via the VADER method f, m_e is the number of tweets expressing emotion e, and N is the total number of tweets from population p.

Ethical Considerations

This analysis did not receive approval from an institutional research board. Analysis of large bodies of text written in social media such as the Twitter social network is generally not considered human subjects research [35], and therefore, ethics approval was not sought. We confirm that all data used in this study have been deidentified, and no individual user is identifiable in any of the images included in the manuscript or supplementary data.

Results

Demographic Characteristics of the Participants

In total, 15,347 COPD users were identified as participants in this study. From this cohort, 1,586,054 daily tweets were retrieved, spanning from January 2020 to June 2023. For comparison, 80,000 non-COPD users and 753,987 general tweets were also selected in the same period. Table 2 presents the statistical data on the demographic characteristics of these two groups. To obtain a comprehensive understanding of the psychological conditions of populations with COPD during COVID-19 and beyond, we analyzed the data mined by the Deep-COPD framework along 3 dimensions: attentiveness analysis, concern analysis, and sentiment analysis.

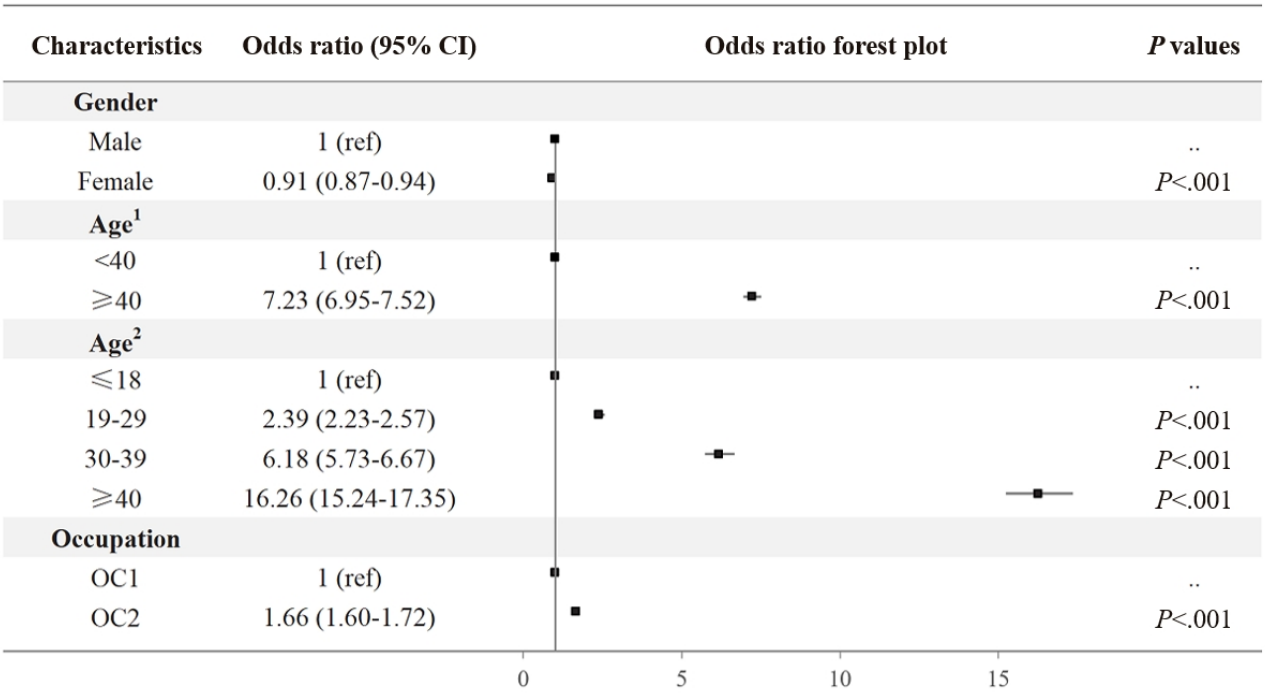
Table 2. Statistical data of chronic obstructive pulmonary disease and non–chronic obstructive pulmonary disease users.

Characteristics	COPD[a] users (n=15,347), n (%)	Non-COPD users (n=80,000), n (%)
User type		
Individual	13,375 (87.15)	75,468 (94.34)
Organization	1972 (12.85)	4532 (5.67)
Gender		
Male	7854 (58.72)	42,509 (56.33)
Female	5521 (41.28)	32,959 (43.67)
Age (years)		
≤18	1179 (8.81)	29,810 (39.50)
19-29	2373 (17.74)	25,086 (33.24)
30-39	2091 (15.63)	8551 (11.33)
≥40	7732 (57.81)	12,021 (15.93)
Occupation category		
OC1[b]	7356 (55)	50,566 (67)
OC2[c]	6019 (45)	24,902 (33)

[a]COPD: chronic obstructive pulmonary disease.

[b]OC1: occupation category 1 (relatively higher socioeconomic status such as managers, directors, and senior officials).

[c]OC2: occupation category 2 (relatively lower socioeconomic status such as process, plant, and machine operatives).



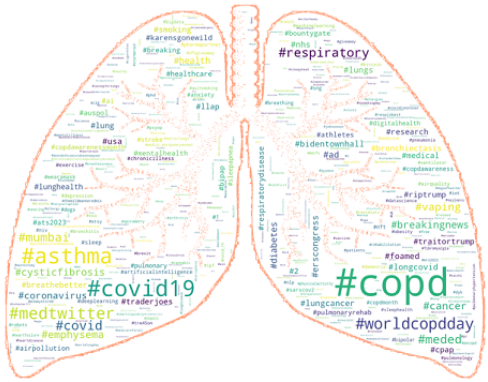
Attentiveness Analysis

Based on the statistics in different demographic groups (Table 2), a comparative study was performed between COPD and non-COPD users. As mentioned in the data analysis tools, we employed ORs to quantitatively assess the levels of attentiveness toward COPD in different groups (Figure 2). The ORs were calculated between COPD and non-COPD users under different exposure factors, including gender, age, and occupation. Results showed that the attentiveness toward COPD in females (OR 0.91, 95% CI 0.87-0.94; P<.001) was lower than that of males. The cohort aged 40 years and older exhibited a high OR of 7.23 (95% CI 6.95-7.52; P<.001), which was significantly higher than those younger than 40 years, and it showed a significant increase with age across 4 age groups. As for occupation, users

XSL•FO
RenderX

in OC2 occupations exhibited a notably higher OR of 1.66 (95% CI 1.60-1.72; *P*<.001) compared to those in OC1 occupations. These results suggested that gender, age, and occupation are 3 important factors influencing attentiveness. Specifically, older male users with lower socioeconomic status (OC2) were the most concerning group.

Figure 2. Attentiveness odds ratios toward chronic obstructive pulmonary disease in different demographic groups. Age 1: 2 age groups; age 2: 4 age groups; OC: occupation category; ref: reference.



Concern Analysis

The word cloud of the top 500 hashtags in the tweets shows that #COPD and #COVID-19 were the most frequently used hashtags throughout the 4 years (Figure 3A). Among the top 10 hashtags in each year, #COPD consistently remained the primary concern throughout the 4-year period (Figure 3B). In 2020 and 2021, #COVID-19 ranked second but later gave way to health-related hashtags such as #medtwitter and #meded. To study the trends in the evolving concerns of COPD users, we categorized the 100 most frequently used hashtags from each year into 6 categories: COPD, COVID-19, health, politics, economics, and others. It is evident that the COPD category maintained the highest prevalence among COPD users, peaking at over 50% in 2021 (Figure 3C). The COVID-19 category held the second position in 2020, accounting for nearly 20%, but substantially decreased in 2021. On the other hand, the health category experienced continuous growth over the 4-year period, surpassing 30% in 2023 (Figure 3C). Figure 3D shows that the concerns from the perspective of LDA topics (see detailed topics in Table S6 in Multimedia Appendix 1) over the years follow the same trends as the hashtags. These statistical results highlight that, among COPD users, personal health became an even more significant concern as the pandemic receded.

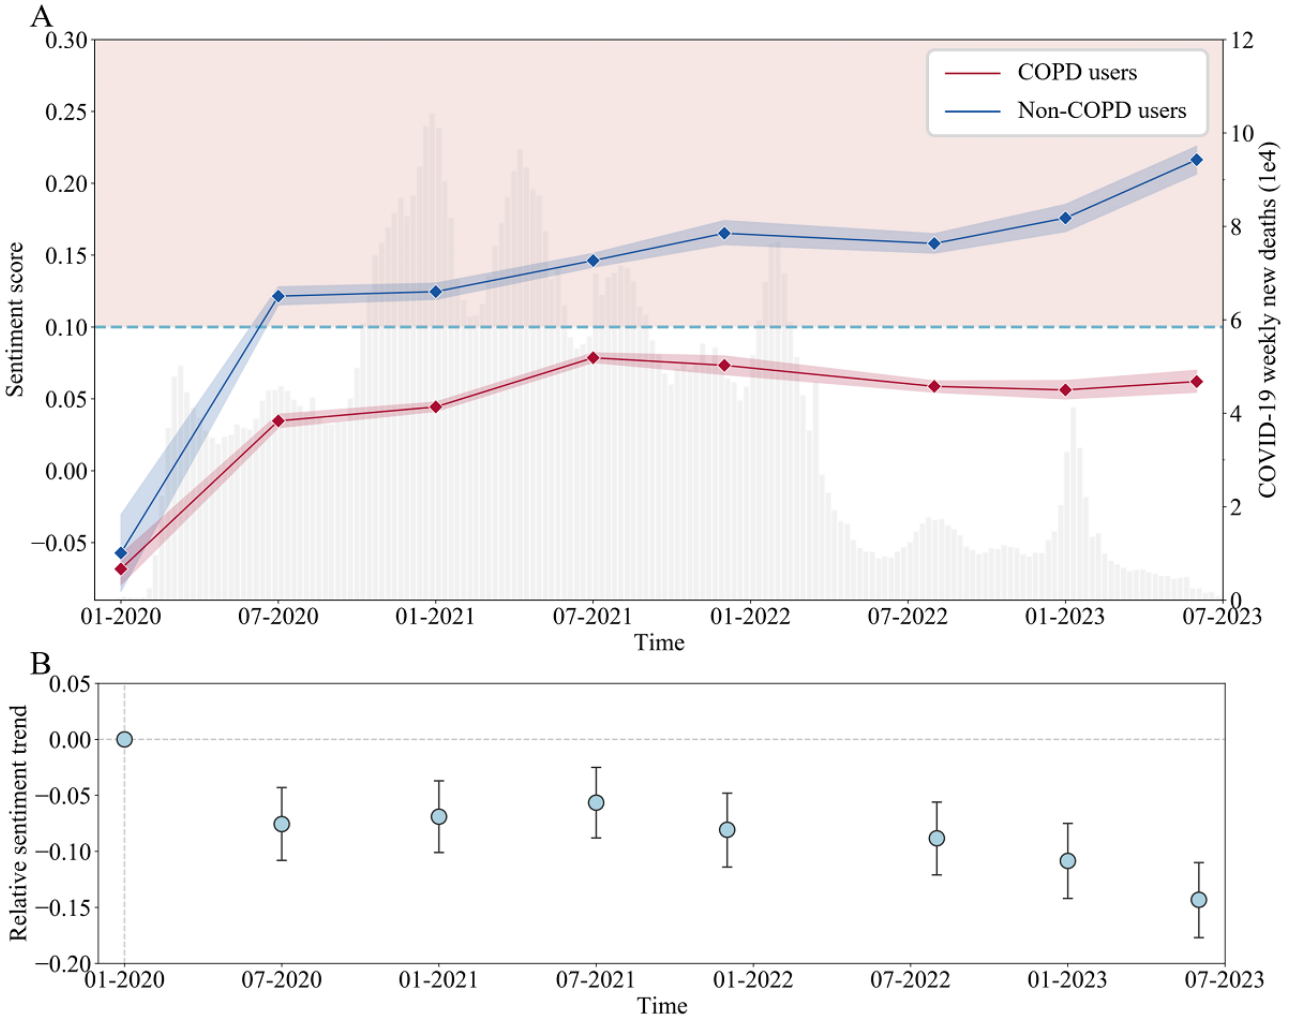
Sentiment Analysis



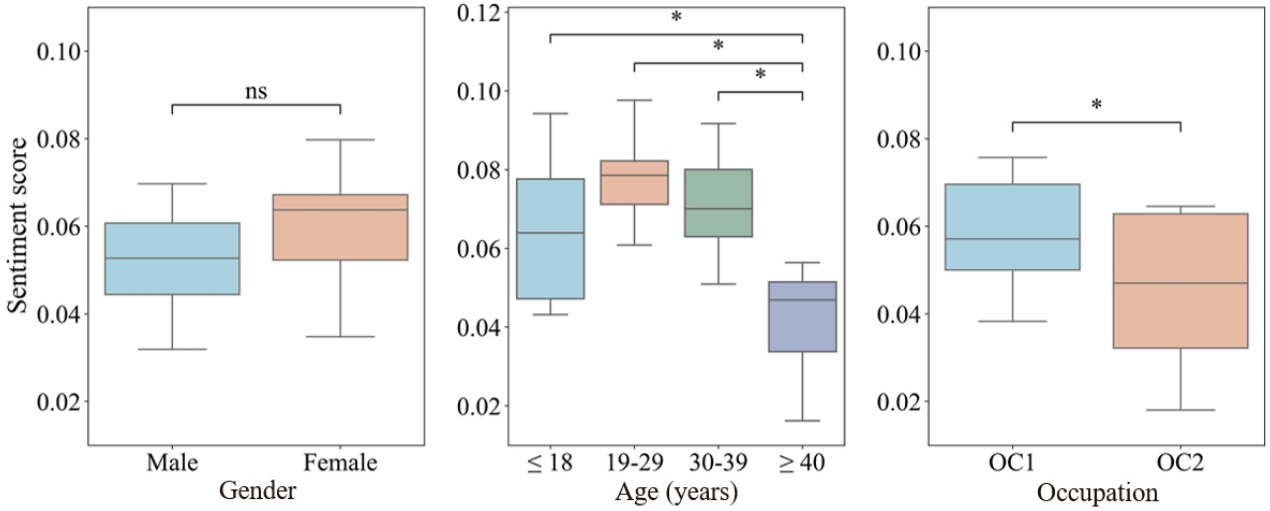
To gain an insight into the long-term trends and disparities of sentiments among different groups, we conducted a sentiment analysis spanning from January 2020 to June 2023. The sentiment score, calculated by VADER, was used to quantify the sentiment intensity of a tweet. This score ranges from –1 (most negative) to 1 (most positive), with [–1, –0.1) indicating negative, [–0.1, 0.1] indicating neutral, and (0.1, 1] indicating positive [36].

Sentiment Trends of the Populations With COPD

The sentiment scores from both COPD and non-COPD users are shown in Figure 4A, revealing a consistent pattern of lower sentiments in the long term among tweets posted by COPD users compared to those posted by non-COPD users. At the outbreak of COVID-19 in January 2020, the sentiment scores of both the population groups were below –0.05. Between July 2020 and June 2023, the sentiment scores of COPD users remained below 0.1, whereas those of non-COPD users exceeded 0.1. Notably, as the pandemic gradually subsided in 2023, the sentiment scores of non-COPD users increased progressively. In contrast, the sentiment scores of the COPD group still stagnated at a low level.

XSL•FO
RenderX

Figure 4. Results of the sentiment trend analysis. (A) Mean sentiment scores with 95% CIs of daily tweets from COPD and non-COPD users over time. The horizontal dashed line (sentiment score = 0.1) is the dividing line between positive (pink area) and neutral (white area). The background bar chart shows the number of COVID-19 weekly deaths. (B) Relative sentiment trends of COPD users, as reflected by the estimated coefficients with 95% CIs calculated by the difference-in-difference model. COPD: chronic obstructive pulmonary disease.



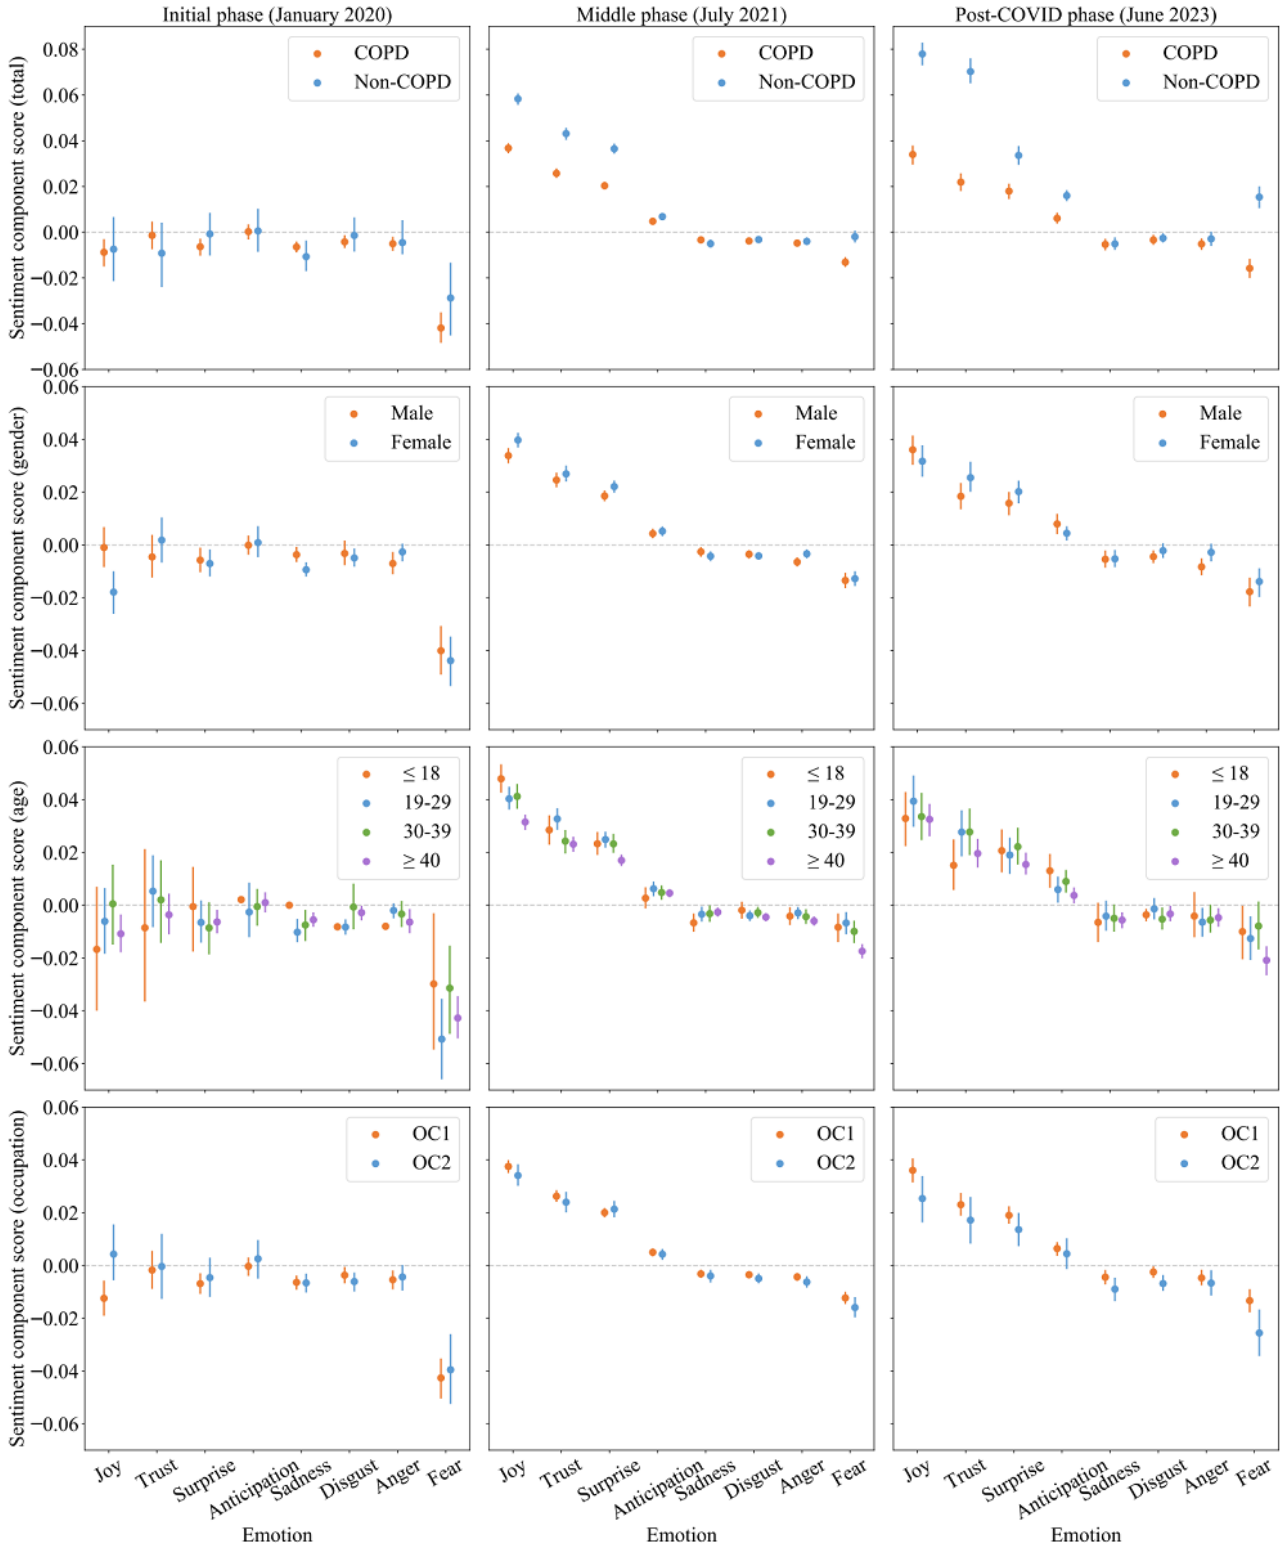
To accurately understand the relative sentiment trends in the COPD group in contrast with those in the non-COPD group, we employed a DiD model [34] to calculate the estimated coefficients between them. The results calculated by the DiD model can be found in Table S7 in Multimedia Appendix 1. Figure 4B shows that these estimated coefficients remained constantly negative, except for the initial time point, which was set to 0. These coefficients gradually approached 0 until July 2021 but significantly decreased afterward, reaching the lowest point in June 2023. This indicated a continuing relatively downward sentiment trend in the COPD group compared to that in the non-COPD group, and this trend was more pronounced after July 2021.

Sentiment Disparities Among Different Population Groups

As shown in Figure 5, sentiment scores differ among demographic groups. The average sentiment score of females was higher than that of males; yet, the difference was statistically insignificant (P=.08). Among age groups, those aged 40 years and older exhibited much lower sentiments than all the other 3 younger groups. As for the occupation, COPD users with OC2 occupations received lower sentiment scores than those with OC1 occupations (P=.03). In short, male COPD users aged 40 years and older with lower socioeconomic status (OC2) had the lowest sentiment in their daily tweets.

XSL•FO
RenderX

Figure 5. Sentiment comparisons of COPD users among population groups. COPD: chronic obstructive pulmonary disease. OC: occupation category; ns: not significant. *P<.05.



To identify emotion patterns in the sentiments of various population groups, we proposed a new method to calculate the values of the sentiment components of Plutchik's 8 emotions, denoted as sentiment component scores. Detailed descriptions of the emotion pattern method can be found in the Data Analysis Tools. We selected 3 representative timepoints corresponding to the different phases of COVID-19: the initial phase in January 2020, when the pandemic was declared public health emergency of international concern by the World Health Organization; the middle phase in July 2021, when the sentiments of COPD users reached the highest point; and the post-COVID phase in June 2023, after the pandemic was declared over. In the initial phase, fear was the predominant negative emotion among both COPD and non-COPD users. In the middle phase, the sentiment component scores of positive emotions such as joy, trust, and surprise of non-COPD users were significantly higher than those of COPD users. In the post-COVID era, the sentiment component scores of joy and trust of non-COPD users exceeded those of COPD users by far, while the sentiment component score of fear of COPD users became even more negative.

As shown in Figure 6, we studied the sentiment component scores of different demographic groups across the 3 COVID-19 phases. The results indicated that females exhibited significantly lower scores of joy than males in the initial phase (January 2020), whereas no obvious difference was observed in the middle phase (July 2021) and post-COVID phase (June 2023). Regarding age, those aged 40 years and older displayed lower sentiment component scores in most emotions, especially fear, compared to those younger than 40 years. As for occupations, those with lower socioeconomic status (OC2) demonstrated lower sentiment component scores than those with higher socioeconomic status (OC1).

Discussion

Principal Findings

In this study, we designed a deep learning framework, Deep-COPD, incorporating a series of data retrieval and deep learning methods to investigate the psychological conditions of populations with COPD by using large-scale Twitter data collected during COVID-19 and beyond. First, we computed the attentiveness toward COPD among populations with different demographic features. Subsequently, we identified the popular concerns by hashtags and LDA topics in tweets posted by COPD users in 4 years. Finally, we examined the sentiment trends and prevalent emotions of populations with COPD in contrast to those of populations without COPD.

To the best of our knowledge, this study is the first research effort dedicated to exploring the psychological trends of

XSL•FO
RenderX

populations with COPD during and after COVID-19. Unlike in the existing investigations into the psychological impacts of COVID-19 on patients with COPD via conventional survey approaches, where the participant cohorts comprised only a few hundred individuals [10-14], our study intelligently recognized a cohort of 15,347 COPD users as participants. Moreover, by leveraging large-scale Twitter data spanning from January 2020 to June 2023, our study offers invaluable insights into the long-term psychological trends among populations with COPD in the pandemic.

By executing a comparative study between COPD and non-COPD users, this study shows that gender, age, and occupation affected the attentiveness toward COPD. The attentiveness toward COPD was lower in females than in males, significantly higher in adults aged 40 years and older than those younger than 40 years, and significantly higher in individuals of lower socioeconomic status than those of higher socioeconomic status. These interesting findings are aligned with the scientific statistics on the prevalence of COPD. In terms of gender, the prevalence of COPD is reported to be about 5% higher in males than in females [37]. As for age, the prevalence of COPD is appreciably higher in those aged 40 years and older compared to that of COPD in those younger than 40 years, with the incidence progressively increasing with age [38]. For occupation, individuals with lower socioeconomic status (OC2) were more likely to have poorer COPD outcomes than those with higher socioeconomic status (OC1) [8].

Through concern analysis, a notable decline in the popularity of COVID-related concerns among COPD users was observed after 2021. This phenomenon can be attributed to the fact that the SARS-CoV-2 virus undergoes constant mutations. With the emergence of the Omicron variant in November 2021, there has been a decline in the death rate [39]. As more knowledge of the virus has been gained, the associated attention has subsided. Concurrently, a steady rise in health-related concerns among COPD users was noted throughout the course of the pandemic. This trend can be attributed to the higher risk of patients with COPD to more severe diseases under COVID-19 (63%) compared to 33.4% among patients without COPD [8].

By tracking the sentiment trends from January 2020 to June 2023, we found that the sentiments of COPD users were much lower than those of non-COPD users across our study period. Remarkably, through DiD analysis, we noticed an increasingly significant downward trend in sentiments among COPD users compared to non-COPD users after the middle phase of COVID-19 (July 2021). This is an important warning that deserves our close attention. By analyzing the emotion patterns of 3 representative timepoints, this study further demonstrates that negative emotions, including fear, sadness, disgust, and anger, all contributed to the low sentiments of COPD users. Notably, in the post-COVID era (June 2023), COPD users exhibited decreased levels of joy and trust and increased fear compared to their levels of joy and trust during the middle phase of COVID-19. In particular, males, older adults, and individuals with lower socioeconomic status showed heightened fear compared to their counterparts. These results indicated that the populations with COPD experience a much longer impact from COVID-19 than the healthy population.

Last but not the least, similar psychological challenges have also been reported in studies on other chronic conditions under COVID [40-42]. Among all the chronic disease groups studied, including COPD, diabetes, and cardiovascular disease, the patients experienced long-term emotional distress during COVID-19, reinforcing the importance of psychological interventions tailored to different demographic and health characteristics.

Implications

Considering the implications for practical scenarios, it is clear that patients with COPD need targeted mental intervention and support. The findings of this work reveal a notable surge of fear among COPD users in the post-COVID era, stemming from their health-related concerns. In view of this, we suggest improving the situation in 2 ways to address the emotional challenges faced by patients with COPD. First, offline health care organizations are encouraged to actively offer easy-to-use mental health screenings, interventions, and self-management measures tailored to different population groups in addition to COPD treatments. For example, tools such as the Hospital Anxiety Depression Scale [43] or the Depression Anxiety Stress Scale [44] can be employed to identify patients with COPD who may have mental health concerns, thereby providing suitable guidance and periodic monitoring. Second, by utilizing the potential of social media platforms, web-based health care organizations and influential users can disseminate accessible psychological content, including videos, games, and helpful resources, to raise awareness of mental health and promote positive lifestyles. This approach involves targeted delivery to COPD users according to the distinct demographic and psychological patterns of different groups. By synergizing these offline and web-based approaches, health care organizations and professionals may effectively tailor their intervention measures to alleviate the psychological toll on populations with COPD.

Limitations

This study has several limitations. First, the identification of COPD users was solely based on self-reported data from Twitter, which may not fully capture all individuals with COPD. Second, this study relies on the VADER tool for sentiment analysis, which, despite its high accuracy, has limitations due to its static lexicon. This restricts its ability to adapt to evolving language trends or capture domain-specific terminology, potentially impacting the accuracy of sentiment classification. Finally, this study is limited to English-language tweets, potentially excluding non–English-speaking populations with COPD and missing cultural variations in psychological responses. These factors should be considered when interpreting the generalizability of our findings. Future research could address these limitations by incorporating data from multiple social media platforms, using more comprehensive methods to verify user health conditions, analyzing multilingual content to capture a broader and more diverse population with COPD, and exploring adaptive or domain-specific sentiment analysis tools to enhance sentiment detection accuracy.

XSL•FO
RenderX

Conclusions

This study proposes a novel approach to tracking the psychological trends of COPD users via large-scale Twitter mining. This study reveals that although COVID-19 has been declared to be ended, COPD users remain emotionally distressed, with much higher levels of fear than the healthy population. Therefore, strategies for the prevention and treatment of psychological problems in patients with COPD should be tailored to the characteristics of different population groups. The findings in this study offer valuable guidance to health care providers, policymakers, and researchers on the necessary measures to address the psychological needs of patients with COPD in the post-COVID era. The method implemented through our deep learning approach can be easily repurposed to study the psychological effects of other social events from a long-term perspective.

Data Availability

The source code for the deep learning framework is available at [45]. In compliance with Twitter's agreements and policy, we can only share data about Twitter user IDs and tweet IDs for academic purposes. These data are available through data access agreements from the corresponding authors.

Abstract

Background: Investigating the safe range of orthodontic tooth movement is essential for maintaining oral and maxillofacial stability posttreatment. Although clear aligners rely on pretreatment digital models, their effect on periodontal hard tissues remains uncertain. By integrating cone beam computed tomography–derived cervical and root data with crown data from digital intraoral scans, a 3D fusion model may enhance precision and safety.

Objective: This study aims to construct a 3D fusion model based on artificial intelligence software that matches cone beam computed tomography and intraoral scanning data using the Andrews' Six Element standard. The model will be used to assess the 3D effects of clear aligners on tooth movement, to provide a reference for the design of pretreatment target positions.

Methods: Between May 2022 and May 2024, a total of 320 patients who completed clear aligner therapy at our institution were screened; 136 patients (aged 13-35 years, fully erupted permanent dentition and periodontal pocket depth <3 mm) met the criteria. Baseline ("simulation") and posttreatment ("fusion") models were compared. Outcomes included upper core discrepancy (UCD), upper incisors anteroposterior discrepancy (UAP), lower Spee curve deep discrepancy (LSD), upper anterior teeth width discrepancy (UAW), upper canine width discrepancy (UCW), upper molar width discrepancy (UMW), and total scores. Subanalyses examined sex, age stage (adolescent vs adult), and treatment method (extraction vs nonextraction).

Results: The study was funded in May 2022, with data collection beginning the same month and continuing until May 2024. Of 320 initial participants, 136 met the inclusion criteria. Data analysis is ongoing, and final results are expected by late 2024. Among the 136 participants, 90 (66%) were female, 46 (34%) were male, 64 (47%) were adolescents, 72 (53%) were adults, 38 (28%) underwent extraction, and 98 (72%) did not. Total scores did not differ significantly by sex (mean difference 0.01, 95% CI –0.13 to 0.15; *P*=.85), age stage (mean difference 0.03, 95% CI –0.10 to 0.17; *P*=.60), or treatment method (mean difference 0.07, 95% CI –0.22 to 0.07; *P*=.32). No significant differences were found in UCD (mean difference 0.001, 95% CI –0.02 to 0.01; *P*=.90) or UAP (mean difference 0.01, 95% CI –0.03 to 0.00; *P*=.06) by treatment method. However, adolescents exhibited smaller differences in UCD, UAW, UCW, and UMW yet larger differences in UAP and LSD (df=134; *P*<.001). Extraction cases showed smaller LSD, UAW, and UCW but larger UMW differences compared with nonextraction (df=134; *P*<.001).

XSL•FO
RenderX

Conclusions: The 3D fusion model provides a reliable clinical reference for target position design and treatment outcome evaluation in clear aligner systems. The construction and application of a 3D fusion model in clear aligner orthodontics represent a significant leap forward, offering substantial clinical benefits while establishing a new standard for precision, personalization, and evidence-based treatment planning in the field.

KEYWORDS

clear aligners; CBCT; intraoral scanning; fusion model; artificial intelligence; efficacy evaluation; orthodontic treatment

Introduction

Background

Alveolar bone remodeling is closely linked to orthodontic treatment. Investigating the safe range of orthodontic tooth movement is crucial for the stability of the oral and maxillofacial system following such treatment. Previous studies aimed at evaluating tooth alignment have primarily focused on clinical crown alignment, often neglecting root alignment, except when using panoramic x-rays to assess root parallelism. However, panoramic x-rays exhibit limited accuracy in evaluating the relationship between roots and the surrounding alveolar bone [1,2].

Cone Beam Computed Tomography and 3D Digital Models

Cone beam computed tomography (CBCT) has emerged as the most widely used imaging technique capable of effectively distinguishing between soft and hard tissues, and it has been extensively applied in orthodontic treatment. Tsukiboshi et al [3] used CBCT images from 28 patients, generating skull and mandible images through surface rendering, and established standard ranges for these surfaces, thereby allowing clinicians to reliably quantify and visualize patients' 3D hard tissues of the face. While complete tooth models can be reconstructed from CBCT images, the accuracy of this data ranges from 0.1 to 0.5 mm, and the precision, particularly for the crown portion, does not meet clinical requirements [4-6]. In recent years, digitally reconstructed 3D dental models have demonstrated high accuracy when compared with traditional plaster models, along with the added benefit of reproducible measurements [7-9]. However, these models cannot capture data on the cervical and root portions of the teeth. Therefore, we speculate that fusing the CBCT-obtained data of the necks and roots of the teeth with intraoral scanning (IOS) data of the crowns may address this limitation.

Clear Aligner and Andrews Six Elements

Clear aligner orthodontic technology uses a goal-oriented pretreatment target position model; however, the effects of this technology on periodontal hard tissues during orthodontic treatment remain uncertain. Existing research has proposed several methods for evaluating orthodontic treatment outcomes, including the American Board of Orthodontics Objective Grading System and the Peer Assessment Rating Index [10,11]. Based on Angle's standard of ideal normal occlusion, Andrews conducted a study in the 1960s that examined the natural dentition of 120 permanent teeth that had not undergone orthodontic treatment. The six standards of normal occlusion represent the optimal natural state of occlusion and serve as the objectives of orthodontic treatment. Meanwhile, Andrews defined 6 standards of normal occlusion based on Angle's principles, encompassing 6 aspects (Textbox 1), which set treatment targets for teeth, dental arches, jaw relationships, and facial esthetics [12]. Previous studies and some scholars have indicated that Andrews' Six Elements possess advantages in assessing the effectiveness of orthodontic treatment, while the 3D positioning of treatment target positions has also proven effective [13,14].

Textbox 1. Elements.

- Element I: ideal dental arch (shape, length, crown torque, root position, Spee curve depth, surface contact)
- Element II: ideal front-to-back jaw relationship
- Element III: ideal horizontal jaw positioning
- Element IV: ideal vertical jaw positioning
- Element V: ideal chin protrusion
- Element VI: ideal occlusal relationship

Objectives

This study aims to develop a 3D fusion model that integrates CBCT data of the cervical and root portions with IOS data of the crown portions, using AI software per Andrews' Six Elements. We hypothesize that this fusion model will accurately assess the 3D effects of clear aligners on tooth movement, providing a reliable reference for designing pretreatment target positions and ultimately enhancing the precision and safety of orthodontic treatments.

RenderX

Methods

Participant Recruitment

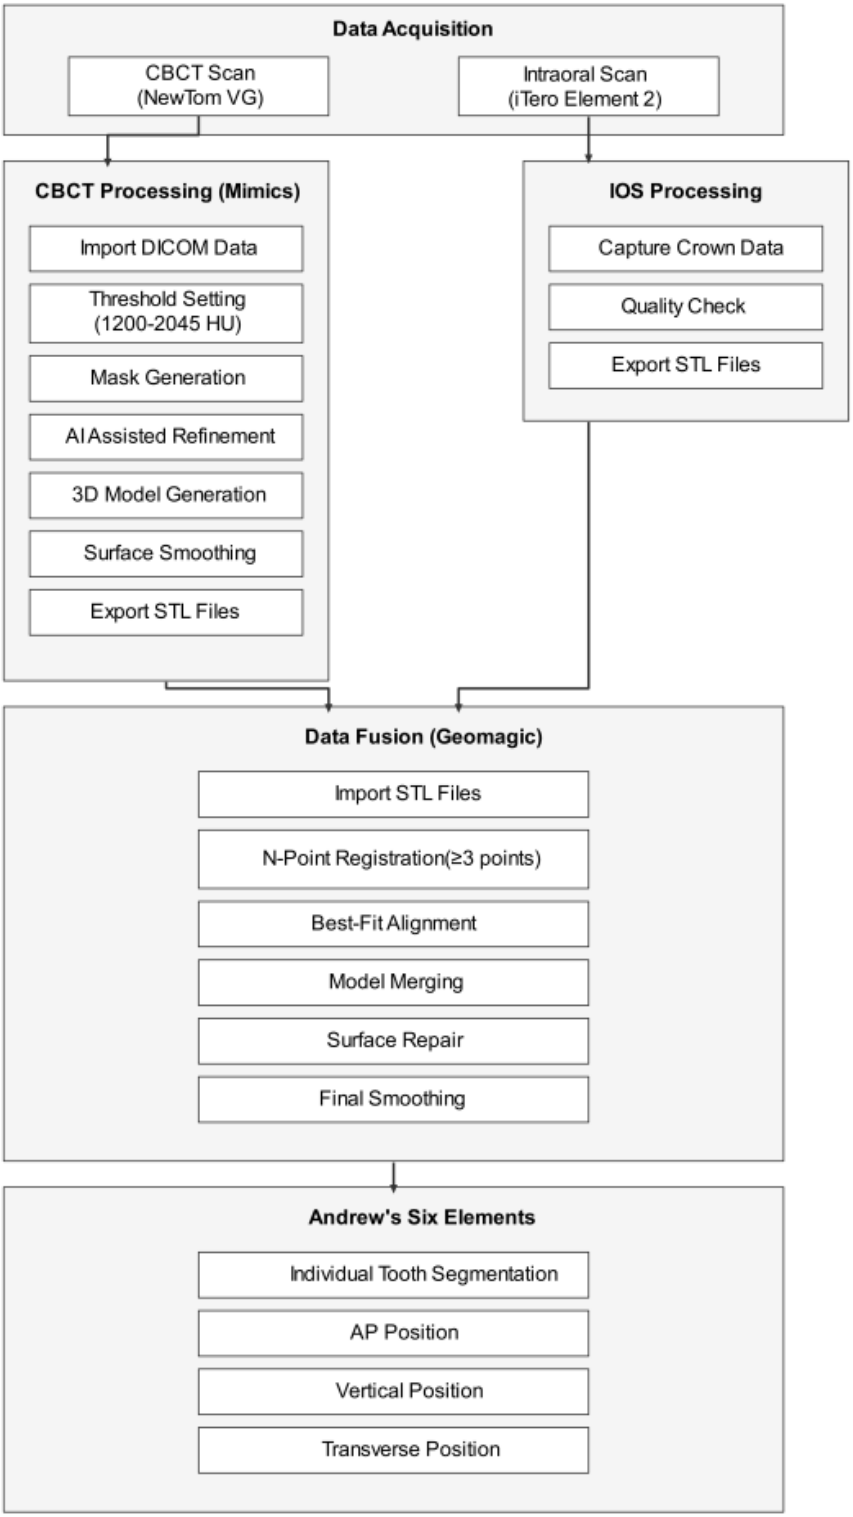
This study was funded in May 2022. We are randomly recruiting patients who have completed orthodontic treatment using clear aligners at the Department of Orthodontics of Kunming Medical University Affiliated Stomatological Hospital. As of the submission of this paper, 320 patients have been recruited. To ensure diversity, patients were purposefully stratified according to sex, age, ethnicity, treatment methods, and types of appliances. Members of the research team invited patients to participate in person. All patients had signed informed consent forms for orthodontic treatment, allowing the use of their anonymized data for research purposes. The collected data included digital intraoral scan models, x-ray images, and clinical photographs. The digital 3D dental models were exported from the iTero Element system and saved in standard template library (STL [3D SYSTEMS]) format. All patient data were encrypted and securely stored in the cloud to ensure confidentiality. Data collection and processing took place from May 2022 to May 2024.

Sample Selection

Inclusion criteria encompassed individuals aged 13 to 35 years with fully erupted teeth, a good periodontal condition, and a periodontal pocket depth lower than 3 mm. Exclusion criteria included individuals with lip and palate clefts, craniofacial deformities, or skeletal discrepancies that required orthognathic surgery. Based on these criteria, a total of 136 individuals were selected.

Model Construction

Materials and Software



This study used a CBCT scanner (NewTom VG, Aperio Services) to obtain detailed images of the maxillofacial region, along with IOS (iTero Element 2, Align Technology) to capture high-resolution 3D models of the dentition. The software used included the Mimics Innovation Suite (Version 23.0; Materialise) for processing the CBCT data, Geomagic Wrap (Version 2023.0; 3D Systems) for data fusion and model refinement, and specialized orthodontic planning software for computer-based tooth arrangement according to Andrews' Six Elements diagnostic system.

Protocol Steps

The data from the CBCT and IOS were collected and exported as digital imaging and communications in medicine (DICOM) and STL files, respectively. Within the Mimics software, the CBCT data underwent a series of processes including thresholding (1200-3045 HU), segmentation, and 3D model generation. This was followed by surface smoothing and jaw separation to create individual STL models for the upper and lower jaws. AI Edit Masks tool is used to manually correct the segmentation results, removing nondental tissues in order to reconstruct a 3D model of dental arches that contains only teeth [15]. AI Smooth tool is applied to enhance the model's surface, while the Split tool is used to separate the jaws, allowing for individual editing and optimization of each part. The output is in STL file format. The software Geomagic Wrap is then used to fuse the data [16]. Initial alignment was achieved through N-point registration by selecting at least 3 corresponding anatomical landmarks, treating the IOS models as moving objects and the CBCT models as fixed references. Refined alignment was subsequently performed using the Best-Fit Alignment feature, with specified parameters to ensure high accuracy. The aligned models were merged using a Boolean Union operation, prioritizing the IOS data for crown detail and the CBCT data for root structures. Mesh repairs and Laplacian smoothing were applied to enhance the surface quality of the fused models, which were ultimately exported as STL files. In the final step, the orthodontic planning software was used to segment individual teeth and arrange them virtually in accordance with Andrews' Six Elements, adjusting tooth positions and orientations to achieve optimal occlusion and aesthetics. The 3D model construction process is shown in Figure 1.

Figure 1. Digital dental imaging and data fusion workflow. This flowchart outlines the comprehensive workflow for digital dental imaging, integrating data from CBCT scans (NewTom VG) and intraoral scans (iTero Element 2). CBCT: cone beam computer tomography; DICOM: digital imaging and communications in medicine; STL: standard template library.

Patient Data Management

We ensured that all patient data were anonymized in compliance with data protection regulations and kept detailed records of all parameters and adjustments for each patient.

Calibration and Quality Control

We confirmed that all software versions used are compatible with each other. We were also aware that updates or changes in software versions may affect functionality. Scanners were calibrated regularly to maintain data accuracy. A quality control process to verify the accuracy of models at each step was also implemented.

XSL•FO
RenderX

Data Acquisition

CBCT and intraoral scans are performed to gather detailed dental data.

CBCT Processing

CBCT processing involves importing DICOM data, threshold setting, mask generation, AI-assisted refinement, 3D model generation, surface smoothing, and exporting STL files. IOS processing involves capturing crown data, conducting quality checks, and exporting STL files.

Data Fusion

Data fusion was done through Geomagic software to import STL files, perform N-point registration, best-fit alignment, model merging, surface repair, and final smoothing.

Analysis

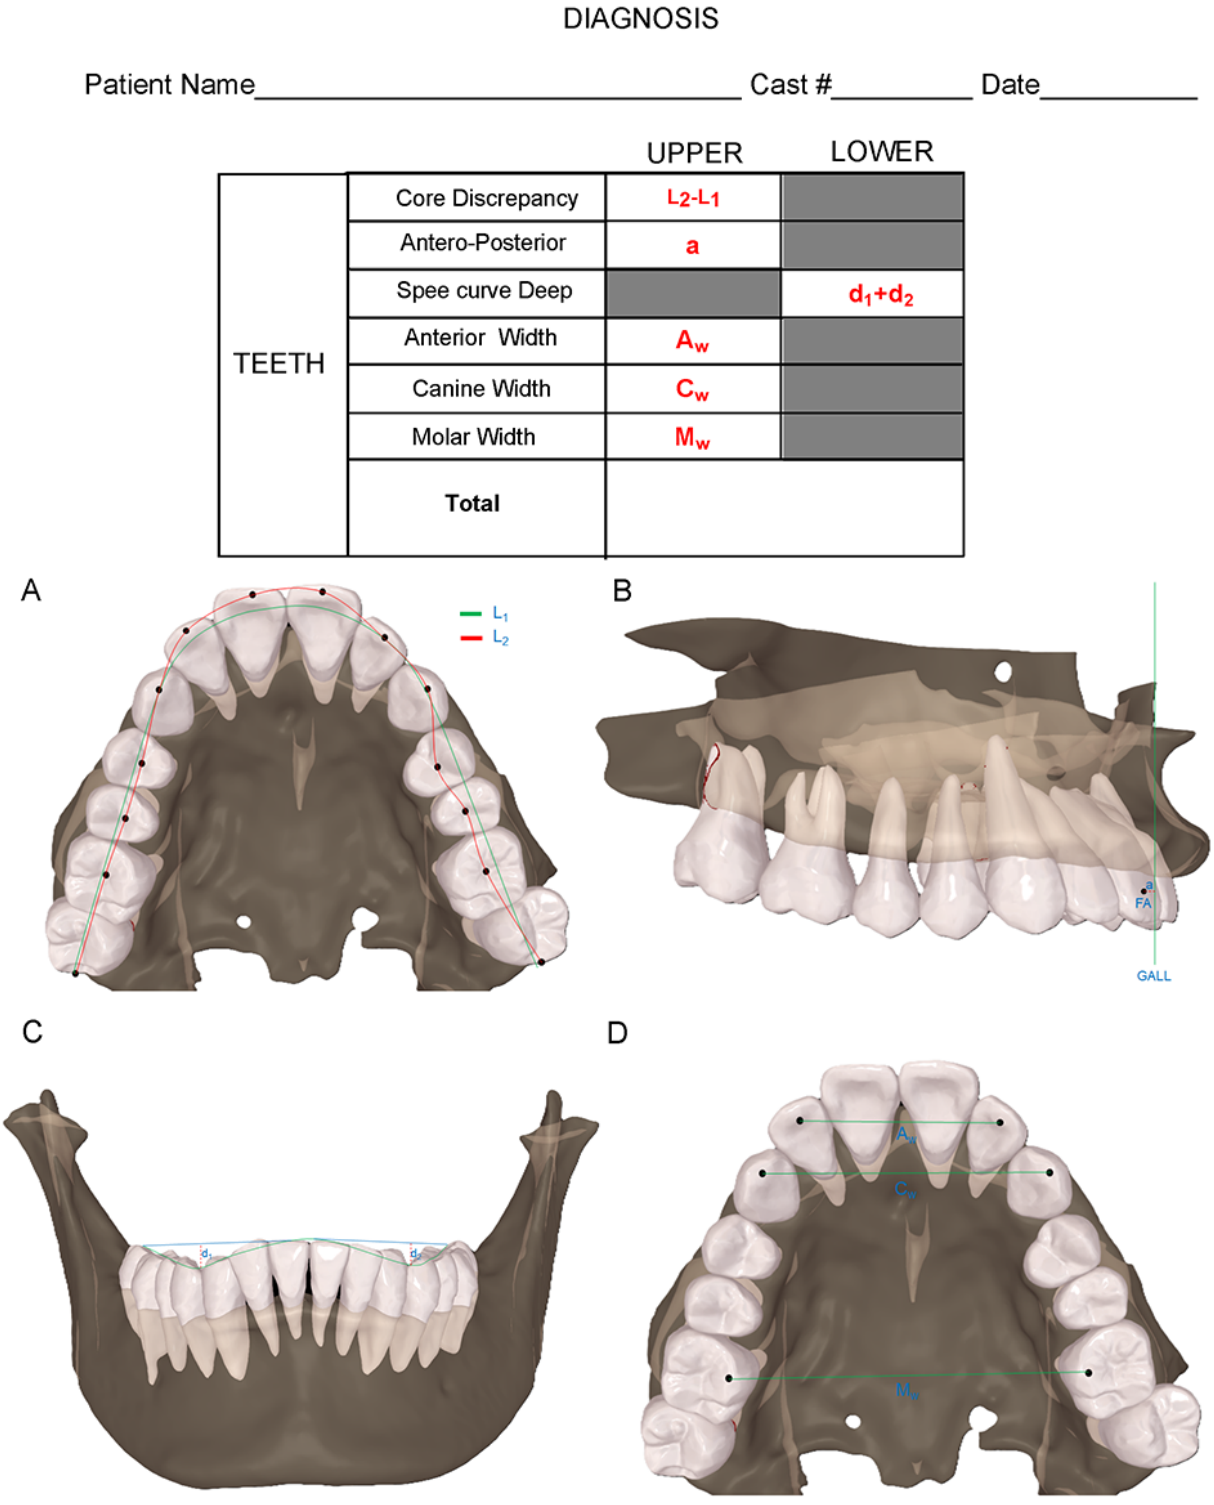
For analysis, we applied Andrew's Six Elements for individual tooth segmentation and positional analysis, including anterior-posterior, vertical, and transverse positions.

Interexaminer Reliability

A total of 2 independent examiners, both practicing orthodontic specialists, each with at least 5 years of clinical and research experience, assessed the samples. Their identities remain confidential in accordance with ethical guidelines. Each examiner is a certified orthodontist with a solid foundation in 3D measurement techniques and orthodontic treatment evaluation. Before data collection, both examiners underwent the same standardized training protocol to ensure uniform measurement methods, including identifying standard landmark points and using specified software tools. A consistent set of guidelines and reference standards (including validated criteria from the literature) was used, guaranteeing that the same benchmarks were applied. Each examiner scored the samples independently and under blinded conditions, with the sequence of sample numbering randomized to mitigate potential observer bias. To evaluate interexaminer scoring consistency, the intraclass correlation coefficient (ICC) was used. Bland-Altman plots were used to illustrate any differences in scores between the examiners and to evaluate the presence of systematic bias. Discrepancies in measurements were revisited and, if necessary, remeasured or discussed to improve scoring consistency.

Participant Grouping

Between May 2022 and May 2024, a total of 320 patients, who successfully completed clear aligner treatment at the Department of Orthodontics, Kunming Medical University Affiliated Stomatological Hospital, were invited to participate in the study. Ultimately, 136 participants met the inclusion criteria. Of these participants, 90 (66%) were female and 46 (34%) were male, 64 (47%) were adolescents, and 72 (53%) were adults. Regarding extraction status, participants were assigned to either the extraction or nonextraction group based on the clinical treatment plan established at their initial assessment. Specifically, those requiring the removal of premolars, often to address moderate to severe crowding, resolve substantial discrepancies in arch length, or correct significant malocclusion, were categorized in the extraction group (n=38, 28%), whereas those whose treatment plans did not involve premolar removal were placed in the nonextraction group (n=98, 72%).



Measurement and Scoring

Based on Andrews' Six Elements criteria [12], measurements encompass the following 6 indicators. Each indicator is scored individually, and the total score is the sum of these individual scores (Figure 2).

In Figure 2, the dental arch core line is given(A), where L_1 is the desired length of the arch and L_2 is the existing length of the arch. The anteroposterior position of incisors is given in B, where FA is the center point of the clinical crowns of the upper mesial incisors, GALL is an imaginary line passing through the interbrow point and perpendicular to the ground plane when in the natural cephalic position, and "a" is the perpendicular distance from the FA point to GALL. Mandibular Spee curve deep is given in C, where d_1 and d_2 are the depths of the Spee curves on the left and right sides, respectively. The width of the dental arch is given in D, where A_w is the width of the anterior teeth, C_w is the width of the canine, and M_w is the width of the molar. Upper core discrepancy (UCD) is measured from the distal of the last molar, along the central fossa of the molars and premolars, the canine cusp, and the incisor incisal edge, connecting to the opposite side. Upper incisors anteroposterior discrepancy (UAP) refers to the anteroposterior distance between the target position and the posttreatment position of the clinical crown center point (FA point) of the maxillary central incisor. Lower Spee curve deep discrepancy (LSD) is a curve formed by connecting the incisor incisal edge, canine cusp, the buccal cusps of the molars and premolars, and the distobuccal cusp of the last molar. The depth of the lowest point of the curve is measured on both the left and right sides and the 2 values are summed to obtain the Spee curve depth. Upper anterior teeth width discrepancy (UAW) is defined as the distance between the midpoints of the incisal edges of the bilateral lateral incisors. Upper canine width discrepancy (UCW) measures the distance between the midpoints of the cusps of the bilateral canines. Upper molar width discrepancy (UMW) is the distance between the midpoints of the palatal cusps of the bilateral first molars.

Figure 2. Measurement and scoring diagnostic sheet.

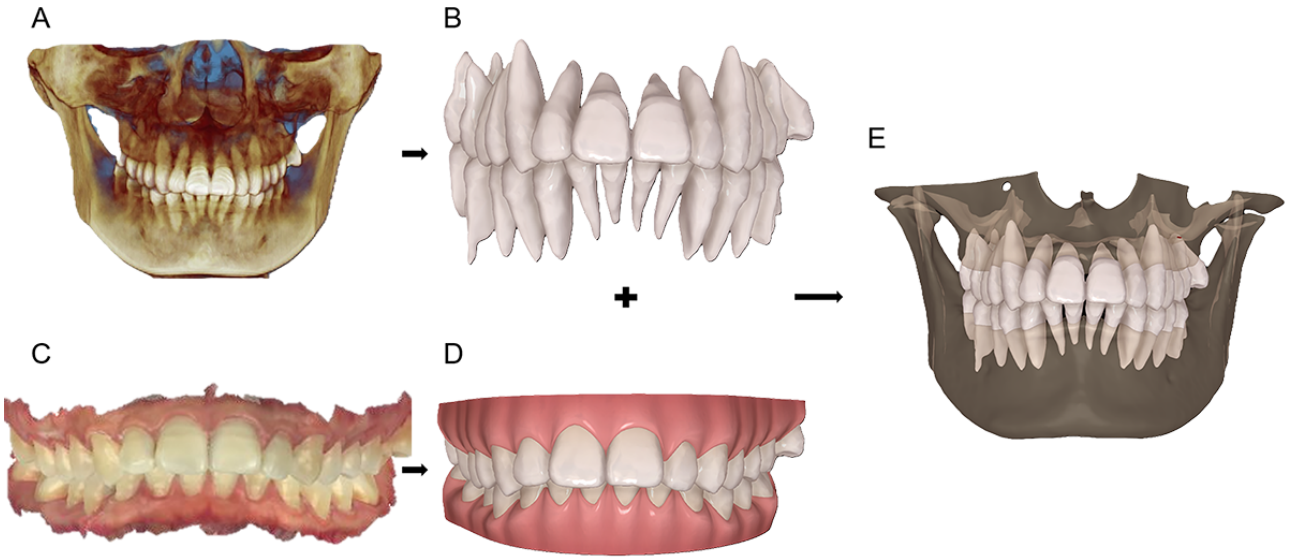
Ethical Considerations

The study was registered on the Chinese Clinical Trial Registry (registration ID ChiCTR2400094304) and was granted ethics approval from the Medical Ethics Committee (approval KYKQ2022MEC0046). All participants provided written informed consent before participating in the study. No compensation of any kind was provided to the participants.

Results

Overview

The study received funding in May 2022, with data collection commencing in the same month, and is projected to conclude in May 2024. At the time of approval, 320 participants had been recruited, of which 136 met the inclusion criteria based on subgroup selection. The research team is now in the final phase



XSL•FO
RenderX

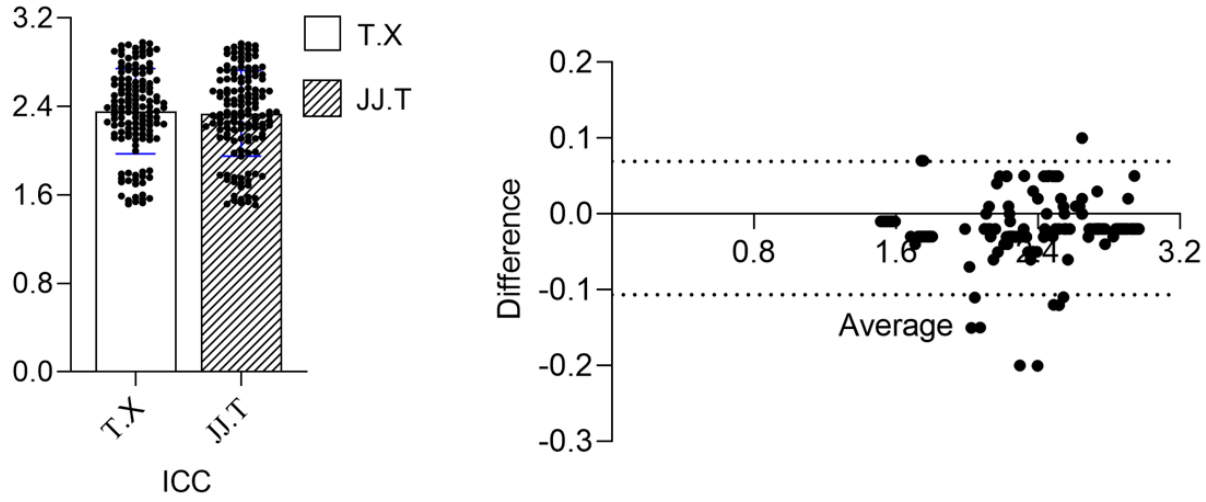
of data analysis, having completed the advanced statistical modeling. Validation and quality checks are currently underway to ensure the accuracy and reliability of results before the study's conclusion. Final results are to be announced by the end of 2024.

Model Construction

A total of 136 patient data sets were processed to create accurate 3D dental models. CBCT and intraoral scan data were exported as DICOM and STL files, respectively. Using Mimics software, the CBCT data underwent thresholding, segmentation, and 3D model generation, followed by surface smoothing and jaw separation. The AI Edit Masks tool refined the segmentation, isolating dental tissues. Geomagic Wrap was then used for data fusion, achieving initial alignment through N-point registration and refining it with Best-Fit Alignment. The models were merged, enhancing surface quality through mesh repairs and Laplacian smoothing. Finally, orthodontic planning software segmented individual teeth and arranged them according to Andrews' 6 Elements, resulting in a successful 3D model construction, as shown in Figure 3.

Figure 3. Construction of 3D fusion model.

In Figure 3, the CBCT data (A) were imported into Mimics software using artificial intelligence (AI) tools to reconstruct a 3D model containing crowns and roots (B); the intraoral scan data (C) were imported into Invisalign simulator software using AI deep learning tools to reconstruct a 3D model containing crowns and gingiva (D). Then the AI tool was used in Geomagic Wrap software to combine the two to form a 3D fusion model (E).



Interexaminer Reliability

A total of 2 independent examiners assessed the same set of measurements following the standardized protocol described in the Methods section. A total of 136 samples (from 136 participants) were evaluated, resulting in 272 total measurement sets. The overall ICC for the interexaminer agreement was 0.98 (95% CI 0.96-0.99), indicating an excellent level of consistency between the 2 examiners' scores. A Bland-Altman plot was generated to compare the scores of Examiner A and Examiner B, visually illustrating the difference plotted against the average of the 2 measurements (Figure 4). The mean difference (bias) between the examiners' measurements was 0.02 (SD 0.11) mm. The 95% CI of agreement extended from –0.20 mm to 0.24 mm, suggesting minimal systematic discrepancy. No trend was observed in the differences as a function of the measurement magnitude, implying that the 2 examiners were consistent across the entire range of measurements. Collectively, these results demonstrate a high level of agreement (ICC=0.98) and minimal systematic bias between the examiners across all measured parameters. The rigorous application of a uniform measurement protocol, coupled with examiner blinding and random sample order, contributed to the strong reliability indices. Consequently, the scoring system and methodology can be deemed robust for evaluating tooth movement outcomes in this study.

The data measured by 2 independent examiners are visually represented, with each dot signifying an individual measurement and the horizontal line indicating the mean. The near overlap in the distribution and mean values for both examiners suggests that their measurements are nearly identical. Furthermore, an ICC of 0.98, indicating extremely high consistency, confirms that the 2 examiners evaluated the samples in a closely aligned manner, reflecting excellent interrater reliability.

Group and Statistical Analysis

Subjects were categorized by sex, age stage, and treatment method, with "Adolescent" defined as individuals aged 13-17 years and "Adult" as individuals aged 18-35 years (Table 1). Based on the scores, we calculated the mean and SD for individual and total scores across various groupings, using independent samples *t* tests for comparison. The confidence interval for all analyses was set at 95%. Statistical analyses were performed using GraphPad Prism (version 9; GraphPad Software, Inc).

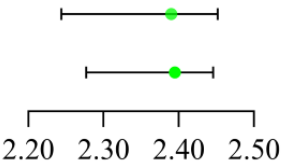
Table 1 lists the distribution for total samples. A total of 136 samples were selected, and individuals were categorized by sex (female and male), age stage (adolescent and adult), and treatment method (extraction and nonextraction).

Table 1. The groups of objects (N=136).

Groups	Values, n (%)
Sex	
Female	90 (66)
Male	46 (34)
Age	
Adolescent	64 (47)
Adult	72 (53)
Treatment method	
Extraction	38 (28)
Nonextraction	98 (72)

Measurement and Scoring

Sex Group



Among the different sex groups (Figure 5), the male group comprised 46 cases aged 13-35 years (mean age 21.30 years), with a total mean score of 2.35 (SD 0.35), a minimum score of 1.53, and a maximum score of 2.97. The female group included 90 cases aged 13-35 years (mean age 21.00 years), with a total mean score of 2.36 (SD 0.40), a minimum score of 1.52, and a maximum score of 2.98. A comparison of total mean scores between the 2 groups revealed a *t* value of 0.19 and a *P* value of .85, indicating no statistically significant difference.

In Figure 5, the total score distribution for sex groups is given. The male group had a total mean score of 2.35 (SD 0.35) and the female group had a total mean score of 2.36 (SD 0.40). Comparing the total mean scores between the two groups, a *P* value of .85 >.05 indicated no statistically significant difference.

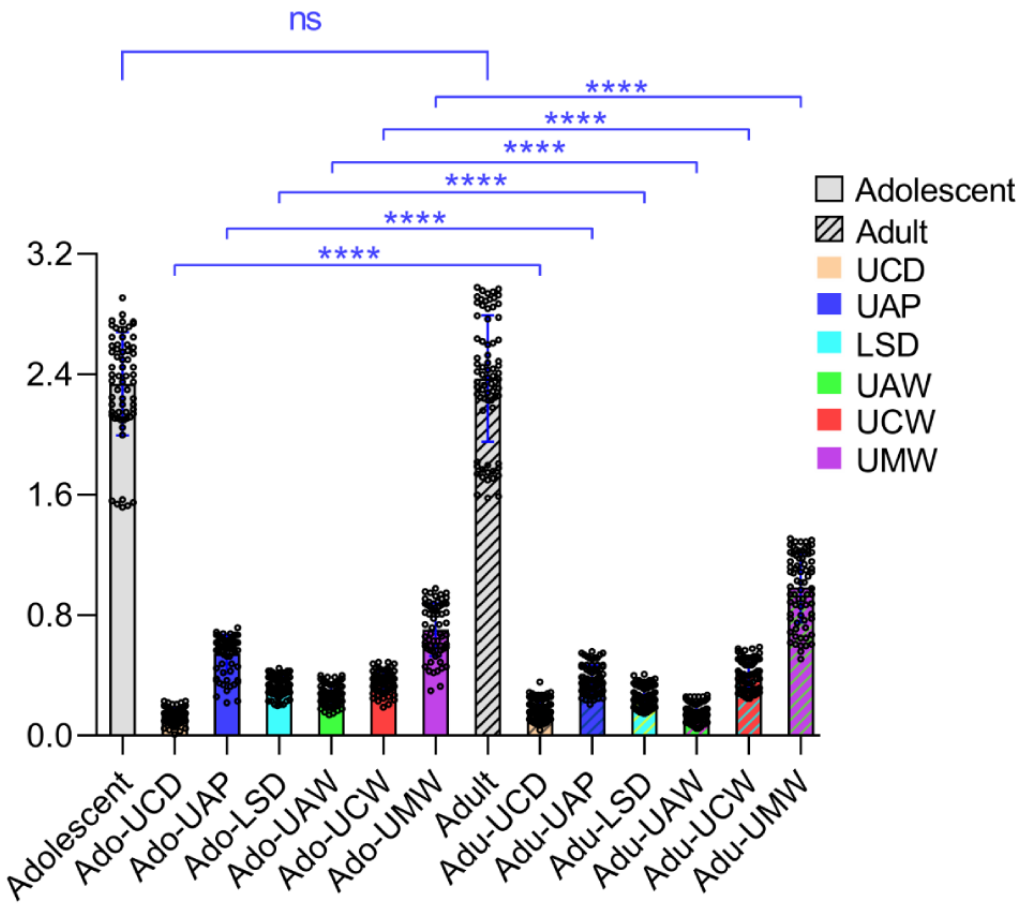
Figure 5. Comparison of total scores in different sex groups.



Groups	Number, n (%)	Mean	SD	t value	*P* value	OR, 95% CI
Male	46 (34)	2.35	0.35	0.19	.85	2.39 [2.24~2.45]
Female	90 (66)	2.36	0.40			2.40 [2.28~2.45]

Age Stage Group

Among the different age stage groups (Figures 6 and 7), the adolescent group comprised 64 cases aged 13-17 (mean 13.58) years, with a total mean score of 2.34 (SD 0.34), a minimum score of 1.52, and a maximum score of 2.91. The adult group included 72 cases aged 18-35 (mean 26.53) years, with a total mean score of 2.37 (SD 0.42), a minimum score of 1.58, and a maximum score of 2.98. A comparison of total mean scores between the two groups showed a *t* value of 0.52 and a *P* value of .60, indicating no statistically significant difference. However, in the individual score items, significant statistical differences (*P*<.001) were observed in the following indicators: UCD, UAP, LSD, UAW, UCW, and UMW.

Figure 6. The score distribution for adolescent and adult samples. LSD: lower Spee curve deep discrepancy; UAP: upper incisors antero-posterior discrepancy; UAW: upper anterior teeth width discrepancy; UCD: upper core discrepancy; UCW: upper canine width discrepancy; UMW: upper molar width discrepancy.

In Figure 7, the score distribution for age stage groups is given. The adolescent group had a total mean score of 2.34 (SD 0.34), and the adult group had a total mean score of 2.37 (SD 0.42). Comparing the total mean scores between the two groups (*P*>.05) indicated no statistically significant difference. In the individual score items, significant statistical differences (*P*<.001) were observed in the following indicators: UCD, UAP, LSD, UAW, UCW, and UMW.

Total Score	2.34	0.34	2.37	0.42	0.52	.60	0.002 [-0.096~0.166]

Treatment Methods Group

Among the different treatment method groups (Figures 8 and 9), the extraction group consisted of 38 cases, aged 13 to 35 (mean 19.74) years, with a total mean score of 2.30 (SD 0.36), a minimum score of 1.53, and a maximum score of 2.90. The nonextraction group included 98 cases, aged 13 to 35 (mean 21.63) years, with a total mean score of 2.38 (SD 0.40), a minimum score of 1.52, and a maximum score of 2.98. A comparison of the total mean scores between the 2 groups yielded a t value of 0.99 and a *P* value of .32 (*P*>.05), indicating no statistically significant difference. In the individual scoring items, there were no statistically significant differences (*P*>.05) in the comparisons of UCD and UAP. However, significant statistical differences were observed (*P*<.001) in the comparisons of LSD, UAW, UCW, and UMW.

Figure 8. The score distribution for extraction and nonextraction samples. LSD: lower Spee curve deep discrepancy; UAP: upper incisors antero-posterior discrepancy; UAW: upper anterior teeth width discrepancy; UCD: upper core discrepancy; UCW: upper canine width discrepancy; UMW: upper molar width discrepancy.

Discussion

Principal Findings

Based on the findings, a 3D fusion model was successfully constructed by integrating CBCT data of the cervical and root portions with IOS data of the crown portions, using AI software in accordance with Andrews' Six Elements Criteria. This model effectively assessed the 3D effects of clear aligners on tooth movement and provided a reliable reference for designing pretreatment target positions. The results indicated that neither sex nor age had a significant effect on total scores; however, adolescents exhibited significant differences in specific parameters, including UCD, UAP, LSD, UAW, UCW, and UMW. Similarly, while the treatment method did not significantly affect total scores, it did have a significant impact on individual items such as LSD and the buccolingual widths of certain teeth. Overall, the study validates the effectiveness of the 3D fusion model in enhancing the precision and personalization of orthodontic treatments using clear aligners, thereby establishing a new standard for evidence-based treatment planning in the field.

Model Construction

Based on pretreatment CBCT and intraoral scans, a digital full-arch dental model integrating IOS and CBCT was constructed. 3D tooth arrangement was performed in accordance with Andrews' Six Keys diagnostic system, successfully establishing a pretreatment 3D integrated prediction model. This model encompasses 3D images that include root and alveolar bone information. By comparing the differences between pre- and posttreatment 3D integrated models, the actual 3D tooth movement following clear aligner treatment can be examined. Baan et al [8] conducted structured light scanning, CBCT scanning, and IOS on 10 dry human skulls, achieving notable clinical accuracy in the integration of CBCT and IOS. Deferm et al [5] registered intraoral scans with CBCT for 8 dentate patients and 14 edentulous patients, finding that the average error for dentate jaws was 0.49 (SD 0.26) mm, for edentulous jaws was 0.16 (0.08) mm, and for alveolar ridges was 0.16 (0.05) mm, indicating high precision in the registration of intraoral scans with CBCT. These studies provide a theoretical foundation for the modeling used in this research, The results of this study are consistent with the above studies.

Potential limitations in model construction, particularly regarding the accuracy of the CBCT-IOS fusion technique, may significantly impact treatment planning. First, image registration errors present a major challenge. When fusing IOS data with CBCT data, discrepancies can arise, resulting in a 3D model that does not accurately reflect the patient's actual anatomical structures [8,17-19]. Such errors may stem from slight patient movements during scanning, limitations in equipment precision, or deficiencies in the registration algorithms used. Second, differences in resolution between the 2 scanning methods can affect the accuracy of the fused model. CBCT typically provides lower-resolution images, while IOS offers high-resolution surface detail. This mismatch in resolution can lead to deviations in the detailed representation within the fused model, thereby impacting the assessment of fine anatomical structures [6,20-22]. These accuracy limitations can influence treatment planning in several ways.

Inaccurate Localization of Anatomical Structures

Misalignments in the model may lead to incorrect judgments regarding the positions of teeth, bones, and other critical anatomical features, adversely affecting the precision of surgical or orthodontic interventions.

Impact on the Formulation of Treatment Plans

Developing treatment strategies based on inaccurate models may result in suboptimal outcomes or even complications. To mitigate these impacts, it is essential in clinical practice to enhance scanning and fusion techniques. This can be achieved by using higher precision equipment, refining registration

XSL•FO
RenderX

algorithms, and performing manual corrections when necessary to ensure the accuracy and reliability of the models used in treatment planning.

Sex

Research indicates that the sex demographic variable does not influence treatment outcomes. Xie et al [23] assessed the clinical effectiveness of SmartTrack aligners and found that sex did not affect anterior tooth rotation movement. Scott et al [24] discovered that Damon3 self-ligating brackets resulted in less discomfort during initial tooth alignment, regardless of sex. Tepedino et al [25] evaluated the predictability of the Nuvola aligner system and concluded that sex did not influence the results. Mario et al [26] investigated the accuracy of the F22 Aligner system and found that sex did not play a significant role. Taner et al [27] evaluated pretreatment dental models, lateral cephalometric measurements, and wrist x-rays, discovering that sex did not affect the outcomes of skeletal and dental cephalometric measurements. Finally, Mandall et al [6] found that sex did not influence orthodontic patients' compliance and treatment motivation. The above research is consistent with our findings.

Age Stage

In this research, adolescents scored lower than adults, suggesting that adolescents may have a higher bone remodeling capacity to meet tooth movement driven by orthodontic forces. Large amounts of clinical studies suggested that adolescents experience faster tooth movement and improved treatment outcomes compared with adults, as their bone tissue responds more readily to mechanical stress, allowing for quicker bone resorption and formation. Kanou et al [28] discovered that younger individuals display accelerated rates of bone remodeling. Zheng et al [29] analyzed differences in alveolar bone support between adolescents and adults, noting that adults exhibited reduced alveolar bone support posttreatment. Kalina et al [30] assessed changes in the lower incisor alveolar bone in both adolescent and adult patients, finding that while alveolar bone thickness decreased in both groups when lower anterior teeth were proclined or retracted, the reduction was less pronounced in adolescents. Furthermore, Kuc et al [31] evaluated maxillary morphological changes resulting from incisor movement and revealed that adolescents demonstrated significantly greater maxillary remodeling capacity than adults following such movement. These results may suggest that adolescents are more effective than adults in moving teeth, a phenomenon attributed to the biological adaptability of their dental arches, which enhances the efficacy of orthodontic treatment, particularly in adjusting the transverse width of the dental arch [32]. During this phase of growth and development, adolescents exhibit higher skeletal plasticity, facilitating more efficient bone remodeling throughout orthodontic treatment.

In this research, we found that adolescents exhibit better alignment of teeth, as well as sagittal and transverse width adjustments of the incisors and molars compared with adults. This phenomenon may be attributed to the intrusion of anterior teeth along the long axis during clinical treatment, which causes the entire periodontal tissue to move coronally, resulting in a higher rate of tooth movement. Adolescents possess a stronger capacity for bone remodeling. Some researchers have longitudinally assessed changes in intercanine and intermolar widths from childhood to adulthood, discovering that both maxillary and mandibular arch intercanine and intermolar widths increase significantly between the ages of 3 and 13 years [12,33-37]. Following the complete eruption of permanent dentition, arch widths experience a slight decrease, with intercanine width decreasing more than intermolar width. The mandibular intercanine width is generally established by 8 years of age after the eruption of the 4 incisors. After the eruption of permanent dentition, clinicians should anticipate either no change or slight decreases in arch width. Although arch width changes from birth to adulthood, the magnitude and direction of these changes do not provide sufficient scientific evidence to support the expansion of dental arches beyond their established dimensions for typical patients. This is consistent with the results of this research. Nevertheless, a recent study was conducted to evaluate the effectiveness of Invisalign in reducing deep overbite in adolescent patients [38]. The findings indicated that the reduction in overlap achieved during the correction process was less than half of what the orthodontist had anticipated or planned. Furthermore, the age of the patients did not significantly influence the accuracy of overlap reduction. Notably, a trend was observed indicating a more pronounced overlap reduction in patients who did not use the bite ramp; however, this trend did not reach statistical significance.

Treatment Methods

In this research, the extraction group scored lower than the nonextraction group, suggesting that extraction may not significantly affect effective tooth movement. Kirschneck et al [39] studied adolescents with borderline cases treated with tooth extraction and found no significant difference in the improvement of vertical relationships between extraction and nonextraction treatments in orthodontic patients. Xu et al [40] compared Chinese borderline cases with and without extraction treatment and discovered that extraction treatment may lead to differences in facial profile at the end of treatment, but no differences were observed in tooth alignment, overbite, overjet, midline, or posterior occlusion. Extraction treatment may have advantages over nonextraction treatment regarding the sagittal, vertical, and anteroposterior alignment of the anterior teeth; however, it is slightly inferior concerning the horizontal width adjustment of the posterior teeth. This may be due to extraction treatment resulting in the medial movement of molars and the distal movement of anterior teeth, which causes changes in the buccolingual width among molars, incisors, and canines. Extraction may provide additional space for adjusting the Spee curve. Elias et al [41] compared the effects of extracting premolars versus nonextraction treatment on dental arch width, contour, treatment duration, occlusal outcomes, smile aesthetics, and stability. They found that extraction led to decreased intermolar width in both arches and upper or lower lip retraction, while nonextraction treatment resulted in increased intercanine width in the lower jaw and a shorter treatment time [41]. Shafique et al [42] recruited borderline cases and found that orthodontic treatment involving tooth extraction had a significant effect on the vertical dimension. The above research results enrich this study.

Limitations and Prospects

The limitations of this study must be acknowledged. As a retrospective study, strict inclusion and exclusion criteria were established to minimize the selection bias inherent in all retrospective investigations, but they cannot completely eliminate bias in personalized prediction models. Future research could further integrate AI technologies and use big data analysis to enhance the predictive capabilities of personalized models. While the growing demand for esthetic and modern orthodontic solutions are facilitated by technological advancements, such as 3D imaging, planning, and printing, it does not specifically address potential limitations in model construction. In particular, the accuracy limitations of the CBCT-IOS fusion technique are not discussed. These limitations can impact treatment planning by affecting the precision of digital models used for diagnosis and aligner fabrication. Inaccuracies in the fusion process may lead to suboptimal fit of aligners or misalignment in tooth movement predictions, potentially compromising treatment outcomes.

Conclusions

The fusion model that integrates cervical and root sections from CBCT with crown data from IOS ensures highly accurate measurements and assessments of tooth positioning. This precision is crucial in orthodontics, where even minor deviations can significantly impact clinical outcomes. The use of a 3D model, facilitated by AI, enables practitioners to tailor treatments more effectively to individual patients. By validating the safe range of orthodontic movement, these models help mitigate the risk of adverse effects on periodontal hard tissues. Such stability is essential for long-term success, reducing the likelihood of relapse or complications post treatment. The study's findings, including the adaptive differences between adolescents and adults and the effects of extraction versus nonextraction methods, provide invaluable insights. Practitioners can rely on these data-driven insights to make informed decisions that optimize individual patient care. The integration of AI and 3D modeling technology introduces new methodologies that have the potential to transform traditional orthodontic practices. This technological advancement not only enhances diagnostic capabilities but also streamlines the treatment process, making it more efficient and patient-friendly. In conclusion, the construction and application of 3D fusion models in clear aligner orthodontics represent a significant leap forward, offering substantial clinical benefits while establishing a new standard for precision, personalization, and evidence-based treatment planning in the field.

Acknowledgments

The authors would like to thank the Department of Second Clinic for providing imaging and IOS data. Support with obtaining funding was provided by authors XYH and LCF. This research was funded by the Reserve Program of Yunnan Province Young and Middle-aged Academic and Technical Leaders (grant 202205AC160067), the Youth Project of Yunnan Province Oral Diseases Clinical Medical Research Center (grant 2022QN003), the Kunming Health Science and Technology Talent Cultivation Project (grant 2022-08-03-002), and the Kunming Medical University Teaching Research and Reform Project (grant 2022-YJ-Y-143).

Authors' Contributions

LCF initiated the study and played a significant role in the design, data generation, analysis, and interpretation of the results. LCF is also a major contributor to the manuscript writing. XT, TJJ, DPP, LCY, SY, and DHY participated in data generation, analysis, and interpretation. In addition, XYH contributed to the study design, data interpretation, and manuscript writing.

Abstract

This study examines disparities in research retractions due to misconduct, identifying countries with the highest retraction counts and those disproportionately represented relative to population and publication output. The findings emphasize the need for improved research integrity measures.

(J Med Internet Res 2025;27:e65775) doi:10.2196/65775

KEYWORDS

affiliation; country; fraud; integrity; misconduct; plagiarism; publication; research; retraction; ethical standards; ethics; research misconduct; literature

Introduction

Retractions are essential for maintaining scientific integrity, especially in cases of research misconduct [1-4]. Data from 2013 to 2015 show that retraction rates vary by country due to differences in research culture, regulations, and publication pressures [3]. Understanding these variations is vital to identifying systemic issues in research integrity.

We examined the countries with the highest numbers of retractions due to misconduct, analyzing both absolute counts and proportions relative to population size and publication output. Our goal is to show the geographical distribution of research misconduct and identify countries disproportionately represented in retraction statistics.

Methods

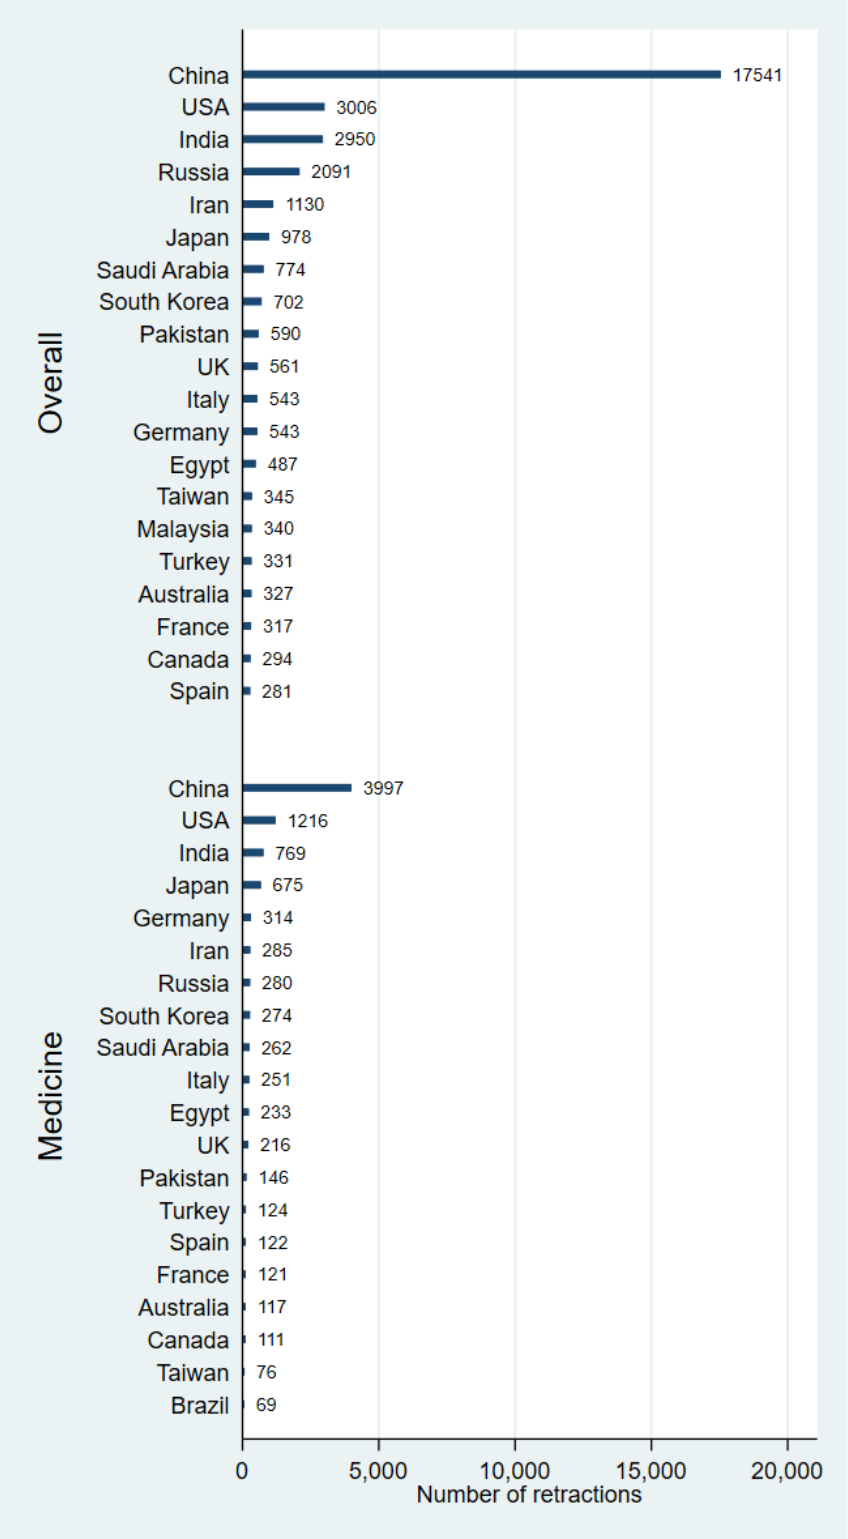
Data Source and Analysis

We used data from the SCImago Journal & Country Rank (SJR), based on Scopus data, to identify the top 100 countries by publication volume from 1996 to 2023—both overall and within the field of medicine. This approach was previously used to identify the most productive countries [5]. Retraction counts (1996-2023) were obtained from the Retraction Watch (RW) database, isolating retractions due to misconduct. Misconduct was defined according to criteria previously established [6] and detailed in Multimedia Appendix 1.

Both SJR and RW consider all authors listed on an article, regardless of position, when attributing publications and retractions, respectively, to a country. They use full counts, equally attributing publications and retractions to all listed countries. For each country, we analyzed absolute retraction counts and proportions weighted by population size (United Nations 2023 data) [7] and by publication output, calculated by dividing retraction count by total publication count. Data were collected independently by two researchers (PS and MS), with any discrepancies resolved through discussion.

Ethical Considerations

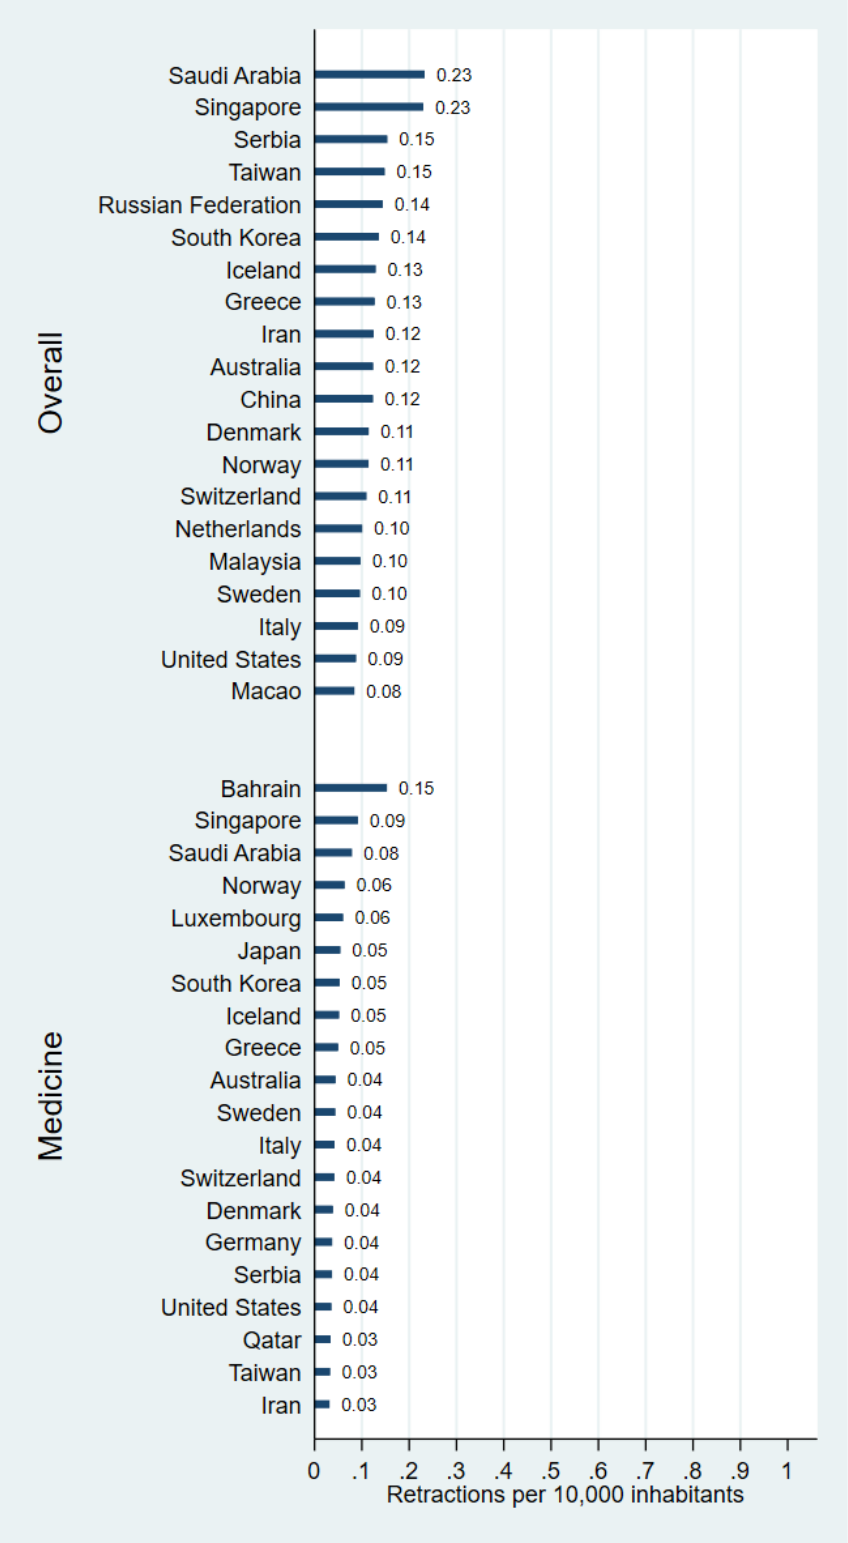
As this study did not involve the collection of personal health-related data, it did not require ethical review in accordance with Swiss legislation.



Results

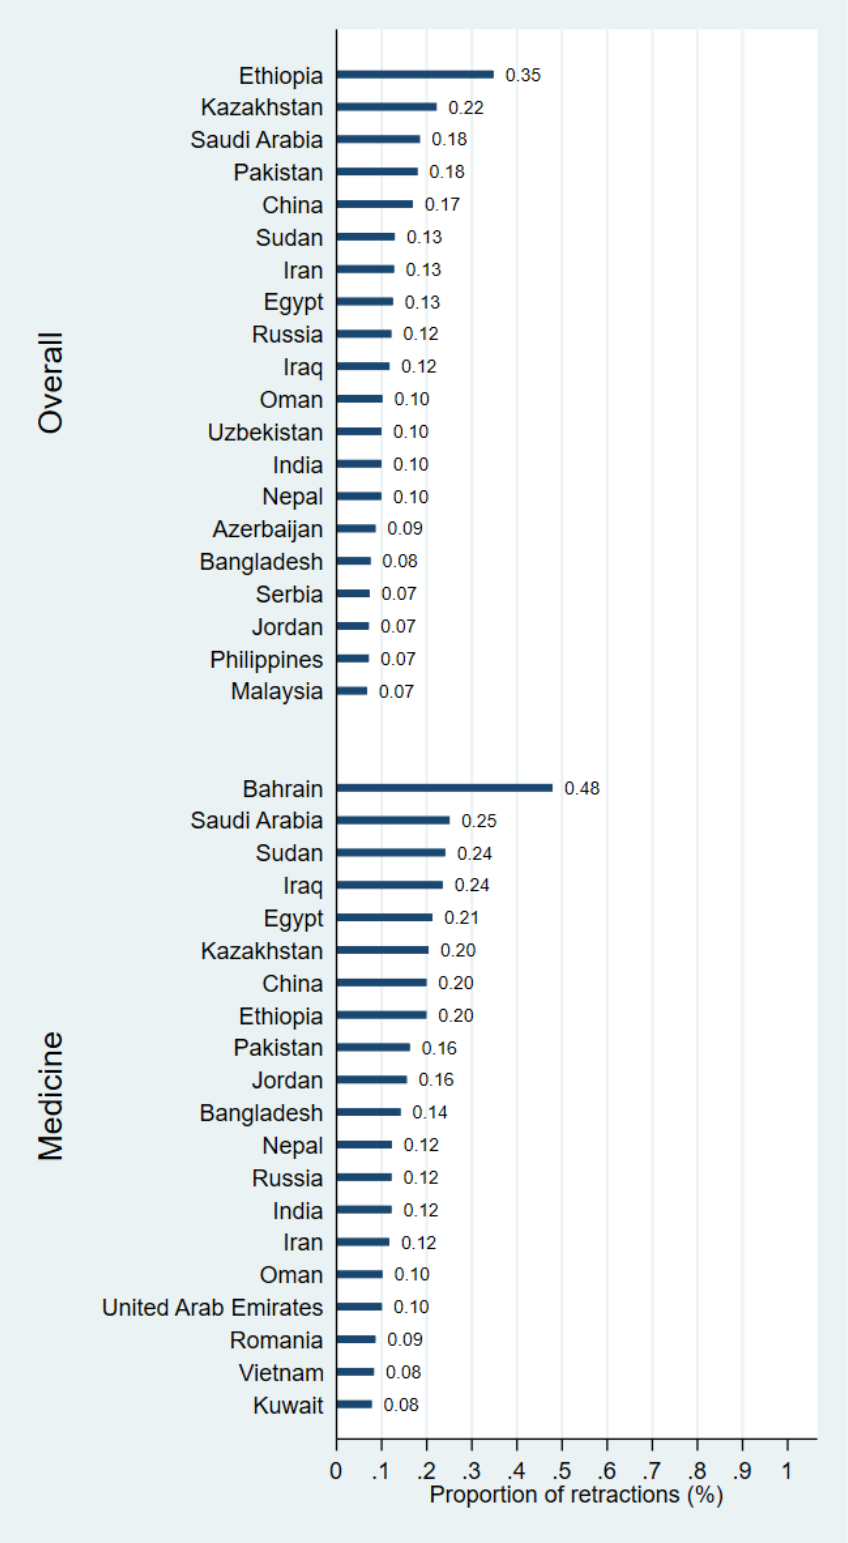
Detailed results are available in Multimedia Appendix 1 and Figures 1-3. The US, China, the UK, Germany, and Japan are

XSL•FO
RenderX



the top 5 productive countries in terms of both overall publications and publications in medicine. Across the 100 countries analyzed, there were 37,858 retractions out of 79,645,579 publications overall (0.048%), and 10,890 retractions out of 23,175,369 publications in medicine (0.047%).

Figure 1. Number of retractions by country (1996-2023) based on overall publications and those in the field of medicine.



XSL•FO
RenderX

Figure 2. Number of retractions per 10,000 inhabitants by country (1996–2023), based on overall publications and those in the field of medicine.

XSL•FO
RenderX

Figure 3. Proportion of retractions relative to publication output, by country (1996-2023), based on overall publications and those in the field of medicine.

Our data suggests that China leads in retractions, far surpassing the US with more than five times as many retractions overall (17,541 vs 3006) and three times as many in medicine (3997 vs 1216). India ranks third with 2950 retractions overall and 769 in medicine. When adjusting for population size, Saudi Arabia, Singapore, Serbia, Taiwan, and Russia have the highest retraction rates overall, while Bahrain, Singapore, Saudi Arabia, Norway, and Luxembourg lead in medicine. Asian, Middle Eastern, and European countries are notably overrepresented in population-adjusted retractions. The highest retraction proportions relative to overall publication output were found in Ethiopia (0.35%), Kazakhstan (0.22%), Saudi Arabia (0.19%), Pakistan (0.18%), and China (0.17%), and in Bahrain (0.48%), Saudi Arabia (0.25%), Sudan (0.24%), Iraq (0.24%), and Egypt (0.21%) when evaluating the medicine subset, with

XSL•FO
RenderX

overrepresentation among Asian, Middle Eastern, and African countries.

Discussion

Our findings reveal that China, the US, and India have the highest numbers of retractions due to misconduct, with China particularly overrepresented. Retractions are disproportionately high in several Asian, Middle Eastern, and European countries when adjusted for population, as well as in several Asian, Middle Eastern, and African countries when adjusted for publication output. These results highlight regional disparities in research integrity.

These findings align with previous research identifying China, the US, and India as leaders in retraction numbers [2,3], with China's prominence especially noticeable in recent years [8-10]. The overrepresentation of retractions among countries with emerging research sectors, as observed in this study, reflects challenges such as weaker oversight and high publication pressure [1-3]. Measures like stricter peer review, automated plagiarism detection, open data sharing, and pre-registration of studies can help mitigate misconduct and improve oversight.

Limitations of this study include reliance on the RW database, which may miss some misconduct cases, and a primary focus on medicine, potentially overlooking trends in other disciplines. Nonetheless, RW remains a trusted source for aggregated retraction data [8], with findings consistent across both overall and medicine-specific data. Additionally, differences between SJR (Scopus-based) publication data and RW's broader retraction sources may slightly impact proportion calculations but are unlikely to affect key findings

In conclusion, this study underscores substantial geographical disparities in research misconduct, emphasizing the need for improved oversight and ethical standards, especially in regions with growing research sectors. Our findings contribute to ongoing discussions on the reliability of scientific research and the importance of global efforts to address misconduct.

Abstract

Artificial intelligence–enabled ambient digital scribes may have many potential benefits, yet results from our study indicate that there are errors that must be evaluated to mitigate safety risks.

(J Med Internet Res 2025;27:e64993) doi:10.2196/64993

KEYWORDS

artificial intelligence; AI; patient safety; ambient digital scribe; AI-enabled scribe technology; AI scribe technology; scribe technology; accuracy; safety; ambient scribe; digital scribe; patient-clinician; patient-clinician communication; doctor-patient relationship; doctor-patient communication; patient engagement; patient safety; dialogue script; scribe

Introduction

Generative artificial intelligence (AI)–enabled ambient digital scribe (ADS) technology uses the patient-clinician conversation to generate clinical documentation; it has the potential to improve patient engagement and reduce clinician burden [1,2]. These technologies are becoming more prevalent, especially in ambulatory care settings, yet there is little known about documentation accuracy and the types of errors that may stem from ADS use [3]. Error-prone ADS technology may have serious patient safety consequences [4]. We evaluated 2 popular commercially available ADS products in a simulated setting to systematically identify the frequency and pattern of documentation errors.

Methods

Ethical Considerations

This study was approved by the MedStar Health Institutional Review Board (00007789) to cover secondary analysis of existing patient data without additional consent. All data were deidentified. Participants did not receive any form of compensation.

Recording and Simulation

Recordings of 11 real outpatient encounters from a range of service lines (otolaryngology, cardiology, rheumatology, family medicine, pediatrics, endocrinology, internal medicine, gastroenterology, oncology, and urgent care) were transcribed by automated software and then deidentified and edited by a senior physician (NKC) for clarity to create 11 unique dialogue scripts. The dialogue scripts were used to evaluate 2 commercial ADS products. For each script, a researcher (JB or VK) simulating the patient and a medical resident simulating the physician read from the script while the ADS products were in use. Each script was read by 2 different residents per ADS product, yielding 22 draft notes per product and 44 draft notes in total across products. The residents reviewed the draft notes to identify errors. Each error was independently categorized by 2 reviewers (JB or JLH) as either an omission, addition, wrong output, or irrelevant or misplaced text, as defined in Table 1. Disagreements were discussed to reach consensus.

XSL•FO
RenderX

Results

There were 127 errors (mean 2.9, SD 2.7 errors per draft note) in 31 of 44 (70%) draft notes. ADS product A resulted in 66 errors (mean 3, SD 2.7 per draft note) and product B resulted in 61 errors (mean 2.8, SD 2.7 per draft note). Error frequency by error type and product is detailed in Table 1, with omission errors being the most frequent across products. Error types significantly differed between the 2 ADS products (Fisher exact test: P=.002).

Table 1. Frequency counts, percentages, definitions, and examples of ambient digital scribe (ADS) error types.

Error type	Errors by ADS product, n (%)		Definition	Example
	Product A (n=66)	Product B (n=61)		
Omission	55 (83)	33 (54)	Model leaves out key information from its response	"[N]o laterality mentioned in ears in physical exam section"
Addition	3 (4)	7 (11)	Model adds inappropriate or irrelevant information	"Patient doesn't refer to any flare ups in awhile, but the note shared that patient was using X medication to help with flare ups in HPI"
Wrong output	4 (6)	6 (10)	Model provides an incorrect response	"[A]ssociated the wrong test with the contrast"
Irrelevant or misplaced text	4 (6)	15 (25)	Model output is technically correct but not appropriate in clinical context	"[C]aptured all the supplemental information (asthma, mammogram, etc.) and harped on the steroid injections which doesn't matter"

Discussion

While ADS technologies may have potential benefits, there are frequent errors in the generated note. Across both products, errors of omission were the most common; this error type may be the most difficult for clinicians to identify since the identification process requires memory recall of details from the patient encounter. If clinicians review their documentation after several patient encounters, recalling omitted details may be challenging. It may be easier to identify errors such as additions and wrong outputs since this relies on recognition of an issue in the text being presented to the clinician. Notably, there was a different pattern of errors between the two products.

There are limitations to this study. The ADS technologies were evaluated against a limited number of patient cases in a controlled environment that did not fully represent clinical workflows. In addition, the cases were read by 2 researchers acting as patients, and it is likely that both clinicians and patients would have more variability in language, tone, volume, and many other characteristics that could impact ADS accuracy.

It is imperative that ADS technologies be evaluated in a realistic clinical setting (either in situ or in a representative simulation) to determine the frequency and types of errors so that appropriate risk mitigation and safety plans can be developed. Developing methods to capture AI-related safety issues was a component of President Joe Biden's "Executive Order on the Safe, Secure, and Trustworthy Development and Use of Artificial Intelligence" [5], and robust processes for AI safety are needed. In the absence of a standardized evaluation framework, health care facilities currently bear the burden of testing and reporting these results in the United States. It is to be noted that, effective August 2024, the European Union Artificial Intelligence Act legally requires developers of AI-based systems to evaluate the safety of their products [6]. While a step in the right direction, the underlying vendor algorithms are often proprietary, opaque, and the subject of continuous innovation; thus, there is still a need for independent ongoing testing to confirm vendor claims of safety. Future work should develop a robust, standardized, and repeatable ADS evaluation framework to facilitate efficient knowledge sharing in this fast-paced, decentralized system.

Abstract

This study provides preliminary evidence for real-time functional magnetic resonance imaging neurofeedback (rt-fMRI NF) as a potential intervention approach for internet gaming disorder (IGD). In a preregistered, randomized, single-blind trial, young individuals with elevated IGD risk were trained to downregulate gaming addiction–related brain activity. We show that, after 2 sessions of neurofeedback training, participants successfully downregulated their brain responses to gaming cues, suggesting the therapeutic potential of rt-fMRI NF for IGD (Trial Registration: ClinicalTrials.gov NCT06063642; https://clinicaltrials.gov/study/NCT06063642).

(J Med Internet Res 2025;27:e64687) doi:10.2196/64687

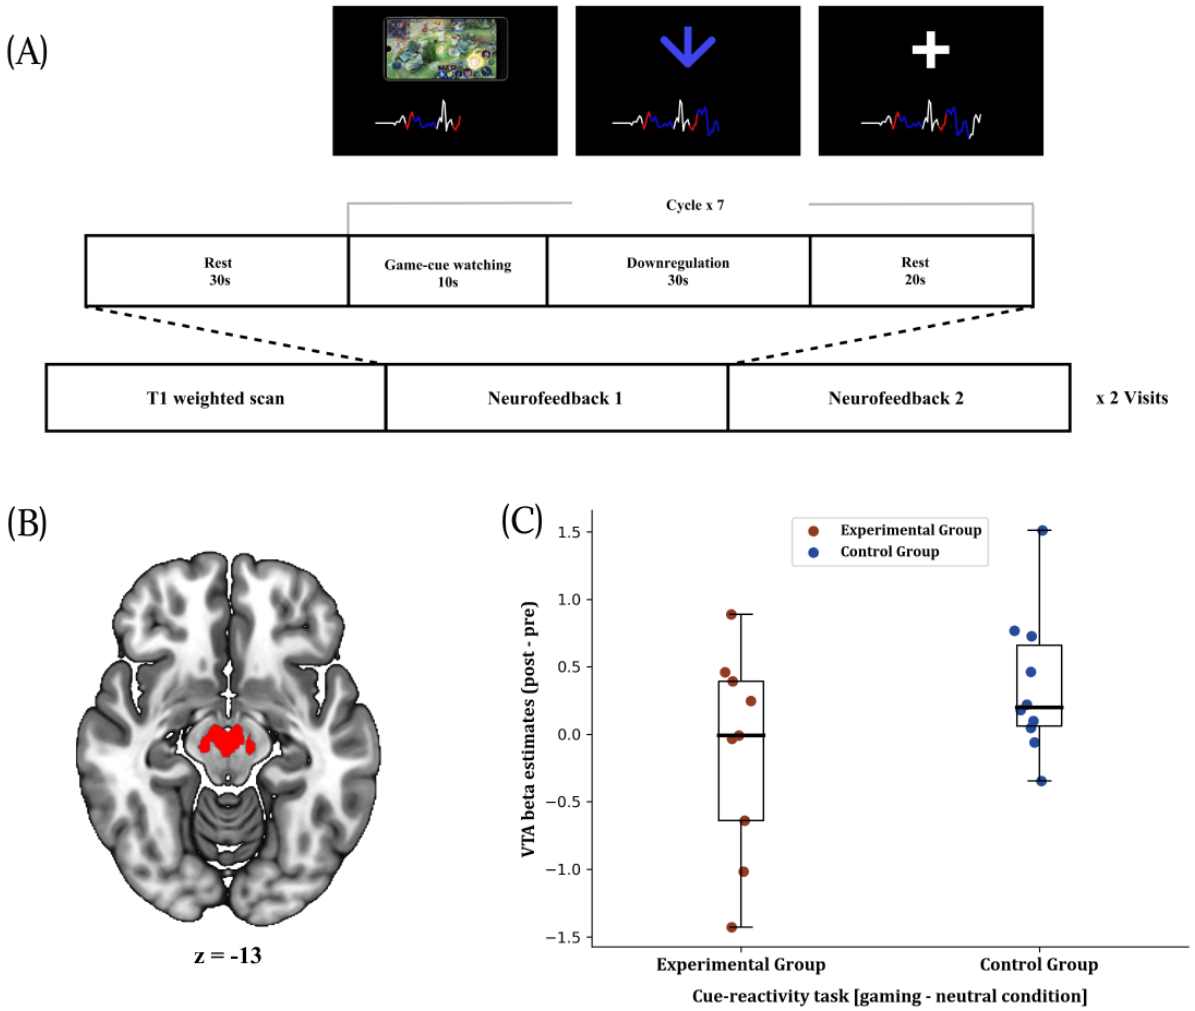
KEYWORDS

real-time functional magnetic resonance imaging neurofeedback; internet gaming disorder; craving; reward processing; ventral tegmental area

Introduction

Internet gaming disorder (IGD) had a global prevalence of 10.4% by 2022; it disproportionately affects younger individuals [1]. The effectiveness of traditional psychosocial and pharmacological treatments, however, remains inconclusive [2]. Real-time functional magnetic resonance imaging neurofeedback (rt-fMRI NF) training allows for self-regulation of brain activity patterns and shows promise for several psychiatric conditions [3]. This preregistered, randomized, single-blind study examined rt-fMRI NF as a potential intervention for IGD. Given the key role and potential modifiability of the ventral tegmental area (VTA), a dopaminergic midbrain region involved in reward processing functions [4,5], we validated the association between VTA response and gaming addiction severity in a small sample (N=9). In a larger study (N=20), we evaluated whether 2 neurofeedback training sessions for VTA downregulation reduced craving for internet gaming.

XSL•FO
RenderX



Methods

Overview

We recruited young participants with IGD risk through social media–based advertisements. In study 1, 9 participants performed a gaming video–based cue-reactivity task (Multimedia Appendix 1, Figure S1) to establish the association between VTA cue-reactivity and IGD symptom level [5]. In study 2, 20 different participants were screened and randomly assigned to 1 of 2 groups. The inclusion criteria and screening instruments are described in Multimedia Appendix 1, Figures S2 and S3. The experimental group received feedback from the VTA (Montreal Neurological Imaging [MNI] coordinates [1, –17, –13]; 246 voxels; Figure 1B), while the control group received sham feedback from the right middle temporal gyrus, specifically an 8-mm–radius sphere centered at MNI coordinates [53, 6, –18]. This region was chosen because it is unrelated to reward processing and is not functionally connected with the VTA. Multimedia Appendix 1 describes the training details. Briefly, during neurofeedback training, blood-oxygen-level–dependent signals in the feedback regions were presented to participants as line graphs in real time (Figure 1A). Both groups were instructed to downregulate the signals using mental strategies that are helpful against craving; they reported their effort and perceived success after each run (Multimedia Appendix 1, Table S1).

Participants completed a 1-item visual analog scale (VAS) for current craving levels at baseline, after the second imaging session, and a month after the last scan; VAS scores were the primary outcome measure. The neural-level VTA cue-reactivity and inhibitory control performance in an affective go/no-go task [6] (Multimedia Appendix 1, Figure S4) measured at baseline and after the second training session were the secondary outcome measures. Analysis of the outcome measures used JASP (version 0.18.3; JASP Team) and the *nparLD* toolbox [7].

Figure 1. (A) The structure of the neurofeedback setting. Blood-oxygen-level–dependent activities of the trained regions for both groups are visualized as line graphs. Participants were not informed about the feedback region or its function. The blue arrow and white cross denote downregulation and rest, respectively. (B) The location of the ventral tegmental area (VTA) region of interest in the Montreal Neurological Imaging brain image is marked in red. (C) VTA cue-reactivity change (post – pre) in the cue-reactivity task based on a gaming – neutral comparison (*P*=.06).

XSL•FO
RenderX

Ethical Considerations

Both studies were approved by the Panel on Research Ethics of the University of Macau (BSERE23-APP004-ICI-M1). The neurofeedback study was preregistered at ClinicalTrials.gov (NCT06063642). Participants provided written informed consent prior to participation and were compensated with MOP 200 (US $24.96) supermarket vouchers. All data were deidentified.

Results

In study 1, the cue-reactivity task successfully activated the VTA (P=.004 after correction for false-discovery rate at a whole-brain level; Multimedia Appendix 1, Figure S5A). Moreover, the VTA response was significantly correlated with addiction severity (Pearson r=.733; P=.02; Figure S5B).

Group comparison results for study 2 are shown in Table 1, and the baseline characteristics of the neurofeedback completers can be found in Multimedia Appendix 1, Table S2. Both groups showed significantly decreased subjective craving levels (P=.002; Multimedia Appendix 1, Figure S6) with no significant group differences (P=.10). Over the course of the neurofeedback sessions, the experimental group downregulated their VTA activity to a greater extent than the control group (P=.02). In contrast to sham feedback, VTA neurofeedback led to more pronounced decreases in VTA cue-reactivity (Figure 1C; P=.06), a trend that might suggest successful transfer of learned VTA regulation. No significant interaction or group effects were found for inhibitory control (accuracy and reaction time in the go/no-go task: P>.12 for all groups).

Table 1. Overall outcomes for study 2.

Outcome measures, variables, and effects	Test statistics	*P* values
Primary (Multimedia Appendix 1, Figure S6)		
Change in visual analog scale score[a]		
Main effect of time	$F_{1.75,\infty}$=10.54	*P*<.001
Post hoc time effect	Pre vs post: *z*=2.41; Pre vs follow-up: *z*=3.24	Pre vs post: 2-tailed P_{holm}=.01; Pre vs follow-up: 2-tailed P_{holm}<.001
Secondary		
Ventral tegmental area cue-reactivity change[b] **(Figure 1C)**		
Group effect	Cohen *d*=–.85	1-tailed *P*=.06
Go/no-go performance[c]		
Main effect of time (accuracy)	$F_{1,15}$=8.90	*P*=.01
No interaction effect or group difference (reaction time and whole-brain functional magnetic resonance imaging data)	Reaction time: $F_{1,15}$≤2.79; whole brain: not applicable	*P*>.12 (all groups)
Exploratory (Multimedia Appendix 1, Figure S7)		
Ventral tegmental area control during neurofeedback[d]		
Time × group interaction	$F_{1,16}$=6.98	*P*=.02
Post hoc main time effect	Experimental group: t_8=–2.17; control group: t_8=–1.63	Experimental group: 1-tailed *P*=.03; control group: 1-tailed *P*=.93
Ventral tegmental area cue-reactivity change and neurofeedback control[e]		
Pearson correlation	*r*=.64	*P*=.004

[a]Nonparametric time (pre vs post vs follow-up) × group (experimental vs control) ANOVA. One participant was lost to follow-up, leaving a total of 18 participants in this analysis. The changes in visual analog scale score showed a significant time effect (*P*<.001) with no group or time × group effects (*P* >.10). The post hoc paired-sample Wilcoxon signed-rank test for the time effect showed a significant pre vs post difference (pre-neurofeedback visual analog scale median: 61; post-neurofeedback visual analog scale median: 40; *z*=2.41; 2-tailed P_{holm}=.01) and pre vs follow-up (follow-up visual analog scale median: 43; *z*=3.24; 2-tailed P_{holm}<.001). P_{holm} indicates that the Bonferroni-Holm method was used to control for false positives.

[b]Time (pre vs post) × group (experimental vs control) analysis of covariance controlling for age and sex. The experimental group showed greater reduction in cue-reactivity compared to the control group (experimental group median change: –0.37; control group median change: –0.15; 1-tailed *P*=.06).

[c]Time (pre vs post) × group (experimental vs control) ANOVA (accuracy, reaction time and whole-brain functional magnetic resonance imaging data). Go/no-go task data were lost for 2 participants due to technical issues, leaving a total of 17 participants. Accuracy on the go/no-go task improved for both groups after intervention (pre-neurofeedback median: 0.67; post-neurofeedback median: 0.83; *P*=.01); no other main or interaction effects were found for behavioral performance (*P*>.12 for all groups). No brain activation results remained significant after correction for false-discovery rate at a whole-brain level.

[d]Time (day 1 vs day 2) × group (experimental vs control) ANOVA. Data were lost for 1 participant from the third run of training, resulting in 18 participants being included in this analysis. During neurofeedback training, there was a significant interaction effect of time (day 1 vs day 2) and group (real vs sham feedback) for downregulated activation (*P*=.02). A post hoc *t* test indicated that ventral tegmental area activity decreased significantly for the experimental group (median change: –0.07; *P*=.03) but not for the control group (median change: 0.11; *P*=.93).

[e]Ventral tegmental area activity change in the cue-reactivity task was positively correlated with neurofeedback training (day 2 – day 1; *r*=.64; *P*=.004).

Discussion

We previously proposed rt-fMRI NF as a promising therapeutic strategy for individuals with internet addiction [3]. The efficacy of rt-fMRI NF, however, has not been empirically examined for any behavioral addictions. In this trial, we found that individuals with problematic internet gaming behaviors could learn to downregulate their VTA activity through genuine feedback, and that this effect translated into changes in VTA reactivity to gaming stimuli. Although we found no improvements at the behavioral level after NF, the neural activity findings underscore the potential of VTA NF training in restoring reward processing functions in individuals with IGD risk.

The study has several limitations. First, our participants were not diagnosed with IGD, meaning that their symptoms might not have been severe enough to benefit from the intervention. Furthermore, due to the small sample size, this study was potentially underpowered to detect group differences in behavioral changes. Larger-scale trials are needed to further examine the clinical efficacy of this intervention protocol.

Abstract

This study focuses on the prevalence and dangers of selective androgen receptor modulator use through a social media (Reddit) analysis. Physicians should be aware that patients are increasingly seeking medical advice through social media, and adverse events are likely underreported in the literature.

(J Med Internet Res 2025;27:e65031) doi:10.2196/65031

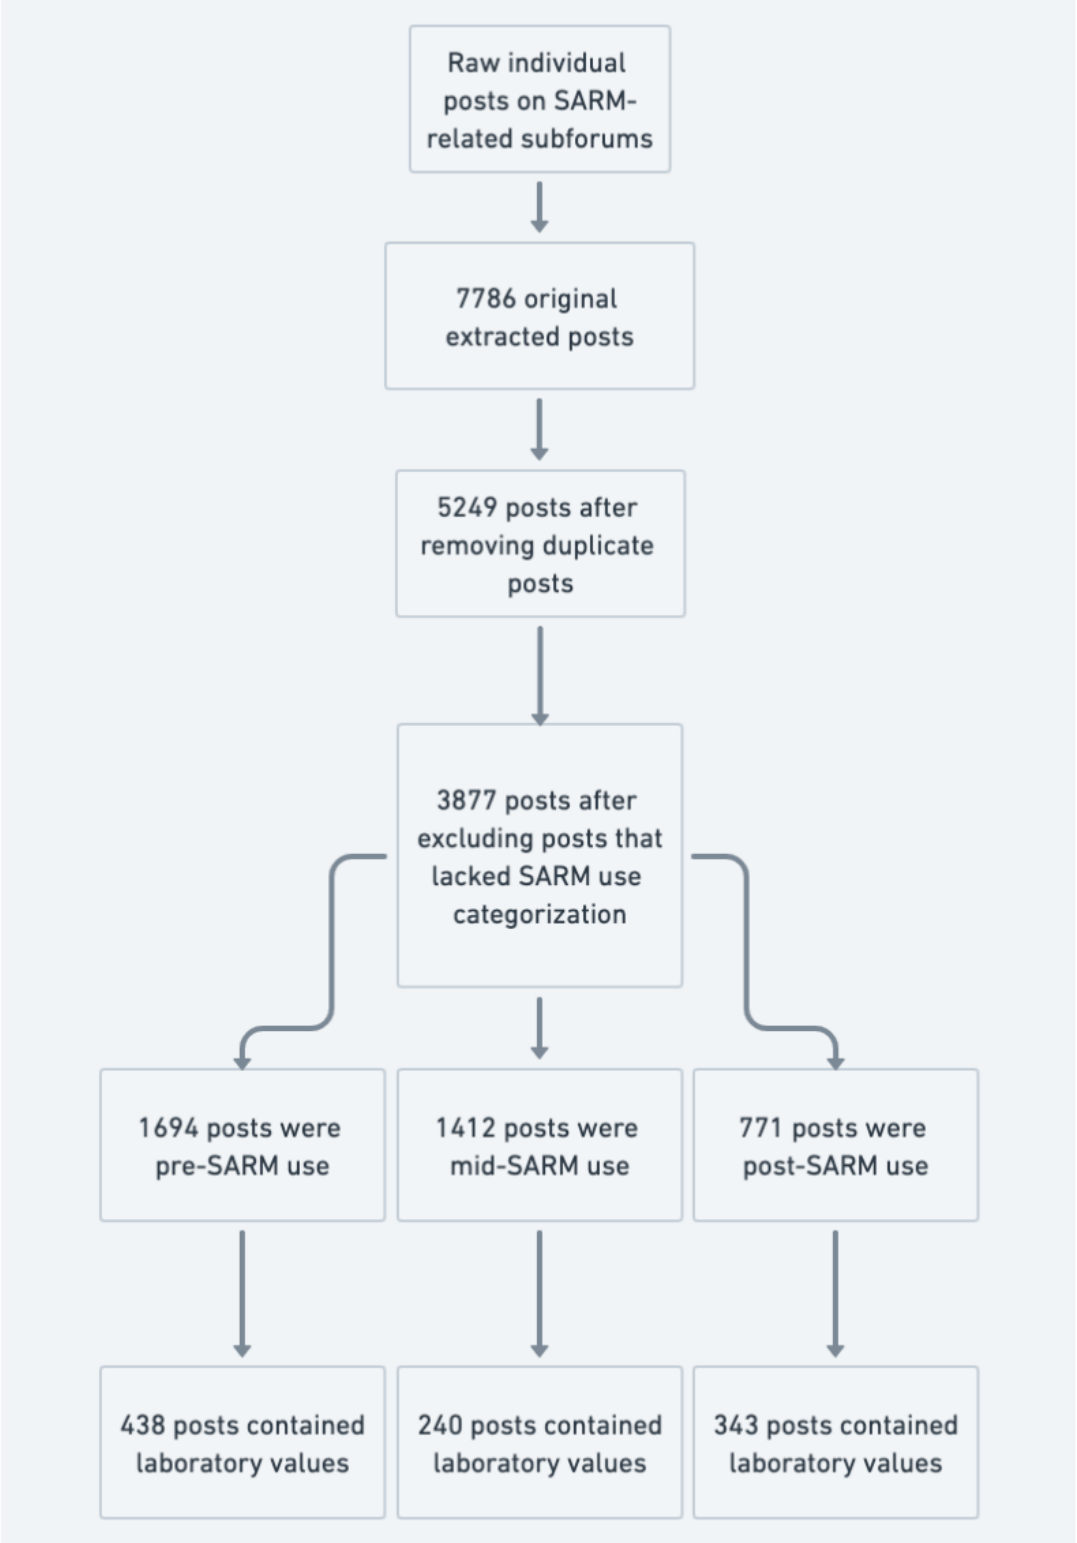
KEYWORDS

selective androgen receptor modulator; SARM; liver toxicity; social media; data analysis; anabolic; muscle; bone; toxicities; self-report; side effect; retrospective analysis; public post; Reddit; androgen receptor ligands; drug

Introduction

Selective androgen receptor modulators (SARMs) are synthetic androgen receptor ligands designed to have anabolic effects in muscle and bone while minimizing unwanted androgenic effects in areas like the prostate and cardiovascular system [1]. This tissue selectivity makes SARMs an attractive option for treating conditions such as osteoporosis and muscle wasting while avoiding the systemic side effects associated with traditional androgen therapies. However, no SARM has received US Food and Drug Administration approval to date. Studies show SARMs are associated with acute hepatotoxicity [2], and recent case reports indicate long-term testosterone suppression along with nephrotoxicity and cardiotoxicity [3,4]. Abuse of SARMs has become increasingly prevalent due to targeting of both athletes and youth through social media platforms. While reports of SARM abuse and toxicity have been rising, no study has examined adverse events (AEs) and laboratory data using self-reported social media posts.

Methods



Overview

This study involved a retrospective analysis of public posts from March 2015 to November 2023 on Reddit. Data collection used a Python-based script to extract and filter posts from SARM-related subreddits. Posts were identified through a keyword-matching process, using “liver,” “AST,” “ALT,” “lab-work,” “bloodwork,” and “symptoms.” Initial keywords were selected and refined to capture posts reporting laboratory results and hepatic outcomes associated with SARM use. Posts were manually reviewed and systematically excluded if unrelated to SARM use. Posts were categorized based on users’ self-reported stages of SARM use: “precycle,” “midcycle,” and “postcycle” (Figure 1). Demographic data, specific SARMs taken, mentions of concurrent medications, self-reported symptoms, and self-reported laboratory values were extracted. Means of self-reported laboratory values were calculated and compared across stages of SARM use. Female posters were excluded from the calculations of luteinizing hormone,

XSL•FO
RenderX

follicle-stimulating hormone, total testosterone, free testosterone, estrogen, and sex hormone–binding globulin.

Figure 1. Flowchart of data extraction methodology. Data extraction of posts from selective androgen receptor modulator (SARM)–related subreddits yielded 7786 initial posts. Manual data cleaning removed 2537 duplicates and 1372 uncategorizable posts. The remaining 3877 posts were classified into pre-SARM use (n=1694), mid-SARM use (n=1412), and post-SARM use (n=771). Clinical laboratory values were voluntarily reported in 438 pre-use, 240 mid-use, and 343 post-use posts, enabling analysis of physiological changes associated with recreational SARM use. This retrospective analysis captured real-world SARM use patterns and their associated clinical outcomes in a young male population.

Ethical Considerations

To protect user privacy, identifying information was anonymized during data extraction. Data were aggregated to prevent linkage to individual users. No identifiable information was retained or reported. This study was exempt from institutional review board approval and strictly adhered to ethical guidelines for digital data use.

XSL•FO
RenderX

Results

Initially, 5249 unique posts were extracted, of which 1372 were excluded due to irrelevance or the inability to categorize the stage of SARM use. Of the remaining 3877 posts, 1694 were pre-SARM use, 1412 were mid-SARM use, and 771 were post-SARM use. RAD140 was the most mentioned SARM, with 1389 posts. The mean reported age was 27 (range 13-63, SD 7.9) years. In 418 posts reporting gender, 20 (4.8%) posters identified as female. Significant changes in aspartate aminotransferase, alanine aminotransferase, creatinine kinase, high-density lipoprotein, low-density lipoprotein, total testosterone, and sex hormone–binding globulin were observed before, during, and after SARM use (Table 1 and Multimedia Appendix 1). Of 2183 SARM users, 382 (17.5%) reported using tamoxifen or enclomiphene, and 170 (7.8%) reported using N-acetylcysteine or other hepatoprotective supplements (milk thistle or tauroursodeoxycholic acid) during or after SARM use.

Table 1. A comparison of the mean self-reported clinical markers before, during, and after selective androgen receptor modulator (SARM) use. This retrospective analysis examined changes in liver function, kidney function, hormones, and lipid profiles in recreational SARM users who voluntarily reported laboratory results. Of note, the study population consisted primarily of young men. Statistical significance was assessed using paired t tests comparing baseline values to both during-use and post-use periods. $P<.05$ indicates statistical significance. The large SDs in many measurements indicate high variability in individual physiological responses. Normal values refer specifically to men. Women were removed from the analysis of luteinizing hormone, follicle-stimulating hormone, total testosterone, free testosterone, estrogen, and sex hormone–binding globulin.

Clinical markers	Normal values	Before SARM use		During SARM use		*P* value	After SARM use		*P* value

Discussion

Recent years have seen an alarming increase in targeted marketing of SARMs on social media, where they are portrayed as safe and effective [5]. Despite being illegal to sell for human consumption, SARMs are available for purchase through numerous online platforms, including commercial websites and chemical suppliers [6]. This analysis revealed that prior, current, and prospective SARM users frequently discuss their experiences, sources, dosing regimens, perceived benefits,

XSL•FO
RenderX

laboratory results, and AEs on social media. Distributors also frequent these platforms to offer advice while marketing their products.

Our analysis revealed serious AEs of SARMs, with hepatotoxicity as a prominent concern. Comparing mean aspartate aminotransferase and alanine aminotransferase values across different stages of SARM use showed significant increases, indicative of drug-induced liver injury. Users attempted to self-manage hepatic complications through N-acetylcysteine, milk thistle, and tauroursodeoxycholic acid supplementation and hormonal imbalances with tamoxifen and enclomiphene. Our findings corroborate previous literature that has reported consistent patterns of hepatic changes attributable to SARM use [7].

This analysis has important limitations. The demographics of the sample predominantly comprised young men, limiting generalizability across gender and age. While self-reported laboratory values offer valuable preliminary insights, interindividual variability and small sample sizes in the reported data present an inherent challenge. To increase the robustness of the findings, future work should integrate traditional clinical data and include sensitivity analysis or weighted modeling. Moreover, since efforts were made to capture a wide net of hepatotoxic-specific data, the extraction methodology may underrepresent other AEs. Nonetheless, our findings highlight the need for increased awareness and regulation to address a growing public health crisis posed by SARM abuse. Until then, physicians should recognize that patients are increasingly seeking medical advice through social media and that AEs are likely underreported in the literature.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

Multimedia Appendix 1

Changes in liver function tests with selective androgen receptor modulator (SARM) use. Changes in mean aspartate aminotransferase (AST), alanine aminotransferase (ALT), and alkaline phosphatase levels across 3 time periods: before (black bars), during (light gray bars), and after (dark gray bars) SARM use. Data were collected from self-reported laboratory values posted by young men on online forums. Sample sizes varied for each marker: AST (before: n=121; during: n=89; after: n=125), ALT (before: n=143; during: n=99; after: n=139), and alkaline phosphatase (before: n=84; during: n=43; after: n=78). Statistical significance is indicated by asterisks (*P<.05, **P<.01, ***P<.001). Values are presented as means with error bars representing SDs. Notable elevations were observed in both AST and ALT during and after SARM use, while alkaline phosphatase remained relatively stable.

Abstract

Despite excitement around artificial intelligence (AI)–based tools in health care, there is work to be done before they can be equitably deployed. The absence of diverse patient voices in discussions on AI is a pressing matter, and current studies have been limited in diversity. Our study inquired about the perspectives of racial and ethnic minority patients on the use of their health data in AI, by conducting a cross-sectional survey among 230 participants who were at least 18 years of age and identified as Black, Latinx, Indigenous, or Asian. While familiarity with AI was high, a smaller proportion of participants understood how AI can be used in health care (152/199, 76.4%), and an even smaller proportion understood how AI can be applied to dermatology (133/199, 66.8%). Overall, 69.8% (139/199) of participants agreed that they trusted the health care system to treat their medical information with respect; however, this varied significantly by income (P=.045). Only 64.3% (128/199) of participants felt comfortable with their medical data being used to build AI tools, and 83.4% (166/199) believed they should be compensated if their data are used to develop AI. To our knowledge, this is the first study focused on understanding opinions about health data use for AI among racial and ethnic minority individuals, as similar studies have had limited diversity. It is important to capture the opinions of diverse groups because the inclusion of their data is essential for building equitable AI tools; however, historical harms have made inclusion challenging.

Introduction

Despite excitement around artificial intelligence (AI)–based tools in health care, there is work to be done before they can be safely deployed. Addressing dataset diversity and racism perpetuated by large language models is paramount [1-3]. The absence of diverse patient voices in AI discussions is a pressing matter, and current studies have been limited in diversity [4,5]. Our study examined the perspectives of racial and ethnic minority patients on the use of health data in AI.

Methods

Overview

A cross-sectional survey was administered via Qualtrics to participants aged 18+ years who identified as Black, Latinx, Indigenous, or Asian. Categorical variables were summarized by frequency and percentage. The chi-square test was used to assess the relationship between responses and demographic variables. Statistical significance was based on $P<.05$. No multiple testing adjustment was performed. All analysis was

XSL•FO
RenderX

done by R (version 4.0.5; R Foundation for Statistical Computing).

Ethical Considerations

This study was exempt from approval by the University of California, San Francisco Institutional Review Board (IRB #22-36156). Informed consent was collected. All data collected were anonymized. Participants were not compensated.

Results

Overall, 230 participants enrolled, and 199 surveys were completed (Table 1). While familiarity with AI was high, a smaller proportion of participants understood how AI can be used in health care (152/199, 76.4%), and an even smaller proportion understood how AI can be applied to dermatology (133/199, 66.8%). These outcomes did not vary significantly when stratifying by demographics such as race, age, gender, income, insurance type, or schooling (all $P>.05$).

Most participants (139/199, 69.8%) agreed that they trusted the health care system to treat their medical information with respect, which varied significantly by income ($P=.045$). Patients with lower incomes often experience more structural barriers to health care, and this could be one factor contributing to our finding that they are not as likely to trust the health care system. Only 64.3% (128/199) participants felt comfortable with their medical information being used to build AI tools. Most (181/199, 91%) want to be notified if their medical information is used in such a way. This varied by race ($P=.002$) and age ($P=.03$). Most (166/199, 83.4%) agreed they should be compensated if their medical information is used to develop AI, which varied by age ($P=.045$; Figure 1).

Discussion

To our knowledge, this is the first study focused on understanding opinions about health data use for AI among people who identify as Black, Latinx, Indigenous, or Asian. Similar studies have had limited diversity [4,5]. It is important to capture the opinions of diverse groups because the inclusion of their data is essential for building equitable AI tools; however, historical harms have made robust inclusion challenging. For racial and ethnic minority communities, historical experiences of racism, discrimination, and exploitation (eg, medical experimentation on populations without informed consent) may contribute to distrust in the health care system and, hence, decrease their comfort level with their data being used to develop AI systems. This suggests that AI development may not be inclusive, ethical, or aligned with the concerns of racial and ethnic minority communities enough to be safely deployed in health care settings. Ignoring these concerns could deepen distrust in AI, leading to lower rates of research participation in these already underrepresented communities, deepening biases and inequities in industries where AI is being deployed.

The educational gaps in AI uncovered by this inquiry should be addressed, as a fundamental understanding of AI is essential for patients to offer fully informed consent for health data use in AI development. There are existing initiatives addressing these educational gaps [6].

Most participants agreed that they should be notified if their data are used to build AI tools, which is not the current convention. For example, in dermatology, photos taken for clinical monitoring can be repurposed as data in AI tools without patient permission as long as they are “deidentified.”

Over 80% of participants agreed that they should be compensated when their data are used to build AI tools. Community-based participatory research shares findings and benefits with study participants. Sharing revenue with patients who contribute their data to build these valuable tools is thematically similar to sharing benefits of a work product and is something that should be explored.

Limitations include the study population. Participants were recruited from an academic medical center and research database, meaning that they may not represent the broader population. Future research should include a more diverse and

XSL•FO
RenderX

representative sample from various backgrounds and regions to enhance generalizability.

Abstract

This cross-sectional study evaluated gender parity in the oncology workforce on social media, demonstrating that women oncologists are enriched on X, with higher self-engagement, suggestive of a heightened motivation for professional X use.

(J Med Internet Res 2025;27:e66054) doi:10.2196/66054

KEYWORDS

social media; gender disparities; gender differences; cross-sectional study; twitter; oncology

Introduction

In 2023-2024, women comprised 55% of matriculating US medical students but continue to be underrepresented in academic medicine [1,2]. This is particularly true in the workforce and leadership of oncology disciplines [2]. Social media platforms have gained popularity for professional development [3], though data characterizing gender parity in the social media oncology workforce are lacking and studied herein.

Methods

Overview

Twenty regionally distinct National Cancer Institute (NCI)–designated cancer center websites were accessed from December 2023 to July 2024 (Table 1) and physician demographic information was collected. Apparent gender (binary) was assigned by a single researcher (VT) using names, pronouns, and/or public profile images. Among physicians on X, publicly available data were manually collected. Physicians with missing numbers of “likes” (public reporting discontinued June 12, 2024) were excluded. Statistical analysis by X use and gender was performed using Wilcoxon rank sum and chi-square (or Fisher exact) tests for continuous and categorical variables, respectively. Analyses were performed using R (version 4.0.5; The R Foundation) with 2-sided tests with $P \leq .05$.

Ethical Considerations

This cross-sectional study used publicly available data and was therefore exempt from ethical approval per the Cedars-Sinai Medical Center institutional review board (STUDY00003292). STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) reporting guidelines were followed (Multimedia Appendix 1).

Results

In total, 2908 physicians' profiles were analyzed, of which 37% (n=1068) were on X (Table 2). There was a greater proportion of women (vs men) physicians on X in the Northeast (35.1% vs 27.1%) but a smaller proportion in the Midwest (32.2% vs 39.6%; *P*=.03; Table 2). X users accounted for a higher proportion of women (39% vs 35%; *P*=.05), were more likely to hold leadership titles (*P*<.001), and had an advanced dual degree (33% vs 25%; *P*<.001) than non–X users. Among those on X, women (vs men) were less likely to have "professor" status (25% vs 41%; *P*<.001) and leadership titles (*P*=.006) but more likely to have a master's in public health (9% vs 5%; *P*=.03).

Mention	86 (13.2)	70 (17.0)	

[a]*P* values were determined using the Wilcoxon rank sum test for continuous variables and chi-square or Fisher exact test for categorical variables, where appropriate.

Overall, women (vs men) had significantly fewer followers (mean 305 vs 390, *P*=.002) and tweets (mean 131 vs 169, *P*=.02). Adjusting for fewer years on X, women showed similar influence as men (mean 48 vs 55 followers per X-year, *P*=.12) but a higher rate of liking posts (mean 77 vs 46 per X-year, *P*=.02). Women (vs men) were more likely to mention being a parent in their biography (17% vs 10%, *P*=.002), but no differences were noted in other content variables (*P*>.05).

Discussion

Principal Results

In this cross-sectional study evaluating gender parity in the oncology workforce on social media, we observed women physicians on X being less likely to hold professor status and leadership titles. As seen on X, particularly in male-dominated fields of radiation and surgical oncology, the proportion of women was significantly higher than published workforce estimates (radiation oncology: 42% vs 31%, *P*=.04; surgical oncology: 51% vs 39%, *P*=.03) [2]. These data are suggestive of motivational and/or behavioral differences in X use by gender.

XSL•FO
RenderX

Comparisons With Prior Work

We observed that women were more likely to mention being a parent, consistent with studies describing higher engagement in fostering support and community [3]. Further, women "liked" more posts, which perhaps parallels the expected levels of "friendliness" and tone softening in women's professional communications, which has been associated with increased emotional labor. Indeed, content language analyses have demonstrated that women use exclamation points more frequently than men and as markers of "friendly interaction" [4]. Behavioral psychology studies report that women have higher engagement in emotional labor practices, which may drain resources without equitable rewards, contributing toward the underrepresentation of women in leadership positions [5]. These findings support continued evaluation of motivational and/or behavioral differences in professional social media use.

Men physicians are more likely to hold "verified" X accounts (verification is thought to add a degree of validity) [6] and report professional benefits from social media use, such as invited talks [7], consistent with studies reporting that women X users face challenges in popularity and influence at academic meetings despite comparable activity [8]. Thus, while social media offers a platform for connection and visibility [9], these findings underscore the need for ensuring equitable opportunities moving forward.

Limitations

Institutional websites may be inaccurate, incomplete, and/or outdated. Gender classification may be inaccurate and impart classification bias. Publicly available X data are more limited than prior studies [10]. Verified status was not analyzed due to low occurrence (0.2% of accounts).

Conclusions

Women oncologists are enriched on X, with higher self-engagement, suggestive of a heightened motivation for professional X use. Future longitudinal studies examining the role of emotional labor and network support in motives for social media use are warranted.

Acknowledgments

VT, SK, and KMA had full access to the data. MK reports receiving personal fees from Theragenics, Alessa, GTMedical, and Springer, outside the submitted work. KMA reports honoraria from OncLive, outside of the submitted work. The remaining authors have no disclosures. All authors have read and agreed to the published version of the manuscript.

Authors' Contributions

VT and KMA drafted the manuscript. VT, SK, MS, LB, MK, and KMA reviewed all analyses and edited the final manuscript.

Abstract

This paper advances the "eHealth Literacy 3.0" model following Norman and Skinner's 2006 original eHealth literacy 1.0 model and Norman's 2011 2.0 update, and introduces a corresponding revision to the eHealth Literacy Scale (eHEALS) measurement instrument (eHEALS-R).

(J Med Internet Res 2025;27:e70112) doi:10.2196/70112

KEYWORDS

eHealth literacy; eHealth literacy definition; eHealth literacy model; eHealth literacy measurement

Introduction

Digital technology is transforming, not just evolving. A landmark definition and model of eHealth literacy was developed by Norman and Skinner [1] during the early 2000s and updated by Norman [2] when digital technology involved far fewer ways to connect and interact. Two decades later, the proliferation of digital technology has become ubiquitous. Although there are now other definitions in the literature [3-6], Norman and Skinner's [1] version continues to be the most cited model [7,8]. An updated definition that better fits the current and foreseeable future of digital technology is overdue. This paper serves as a prompt for introducing and stimulating collaborative research on our "eHealth Literacy 3.0" model and revised eHealth Literacy Scale (eHEALS-R).

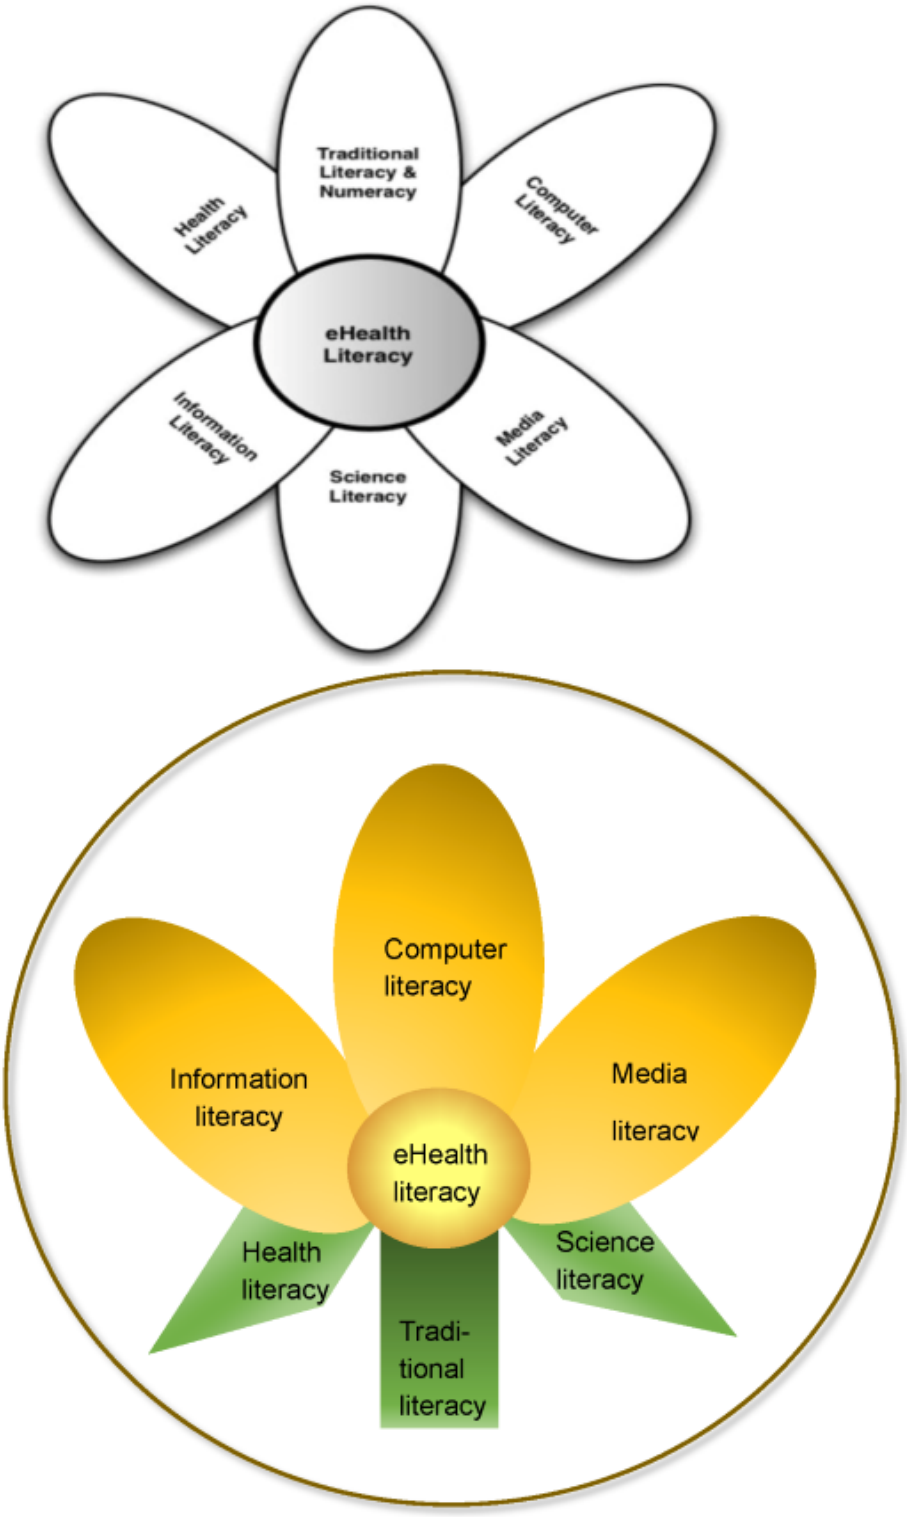
Methods

We reviewed the published literature on eHealth literacy to consolidate the critiques and suggestions regarding Norman and Skinner's [1] eHealth literacy definition or model. The consolidated themes were synthesized to bolster the original eHealth literacy conceptual model into version 3.0, which reflects current and anticipated use contexts.

Results

Norman and Skinner [1] defined eHealth literacy as "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem." We have revamped the definition of eHealth literacy as "the ability to engage with digital technologies in effective, safe, and helpful ways to achieve health goals."

This version encapsulates an expanded concept of the original model reflecting effectiveness, safety, and helpfulness. The core idea of the original lily model is that eHealth literacy is the fused "pistil" fed by the 6 literacies ("petals"), which ties them together [1]. The new model draws more elements from the lily flower's anatomy, whose positions and functions help to better



XSL•FO
RenderX

visualize the constructs of literacies and their interrelationships (Figure 1).

Traditional literacy (referring to reading, writing, and speaking skills) embodies the stalk, from which the other 6 literacies are stemmed. Traditional literacy is a precondition, without which no other literacies can grow.

Two sepals are representative of health and science literacies. As in flowers, the sepals' main functions are to protect and support the flowers. While health literacy implies understanding and engaging with the health system, science literacy implies understanding the key characteristics of science and how it is done. These two literacies serve as a strong ground for the other literacies above them, including eHealth literacy.

Figure 1. The 2006 lily model and the new lily model.

XSL•FO
RenderX

Three petals illustrate (1) computer literacy, (2) information literacy, and (3) media literacy. These petals are more pronounced in the new model, with their enhanced definitions encompassing technological advancement and contemporary paradigms. As with flower petals, which are typically the most attractive part of a flower, computer literacy is needed to keep up with the mainstream development of digital technology. Information and media literacies serve as counterparts to optimize the outcomes of the technology while mitigating the potential risks and harms posed by technological advancement.

At the center of the flower lies the pistil, representing eHealth literacy. Being held, supported, and fed by the other literacies, a person uses eHealth literacy to interact with digital technology to bear the "fruit," that is, their health goals and needs.

Overall, the new model is shaped in a circle representing contextual factors that influence the way a person engages with digital technologies in an effective and safe manner.

Table 1 compares the original and new lily models. Modifications reflect current health technology trends with eHealth encompassing well-being, care, monitoring, and assessment, while introducing new security and privacy concerns. The modified constructs and their interrelationships are presented as initial steps, with theoretical elaboration and collaborative empirical research to follow.

Table 1. Comparison of two lily models. Key changes in the new model are highlighted in italics.

Element	Description	
	The 2006 lily model	The new lily model
Traditional literacy	Reading, writing, and speaking skills.	Reading, writing, and speaking skills.
Health literacy	The ability to understand and engage with the health system to make appropriate health decisions and act upon them.	The ability to understand and engage with *health source material* and the health system, make appropriate and *safe* health decisions, and act upon them.
Science literacy	The ability to understand the nature, objectives, methods, practice, limitations, and opportunities of science and/or knowledge.	The ability to understand the nature, objectives, methods, practice, limitations, perspectives and opportunities of science and/or knowledge.
Information literacy	The ability to seek, find, understand, appraise, and use information.	The ability to seek, find, understand, appraise, filter, use, and *create information ethically and safely.*
Computer literacy	The skills to use computers and to adapt to new technologies in solving problems.	*The skills to learn, adapt to, and engage with digital technologies to actively promote and support health, care and well-being.*
Media literacy	Critical thinking skills to analyze, evaluate, and use media content to form a judgment and guide actions.	*Critical thinking and conscious thinking skills* to analyze, evaluate, and use media content to form a judgment and guide actions. Critical thinking involves the use of logic to evaluate media content and guide decisions, while conscious thinking relies on self-awareness, sensory insight, clarity, and emotional control [9].
eHealth literacy	The ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem.	*The ability to engage with digital technologies in effective, safe, and helpful ways to achieve health goals.*

Discussion

As digital technology evolves, so does our understanding of the skills needed to navigate it for wellness and health care. While eHealth literacy's fundamental skills remain, model 3.0 reflects our expanded digital technology ecosystem and tool set. Greater emphasis is placed on the outcome: achieving health goals effectively and safely. Research is now needed to compare and validate model 3.0. Finally, model 3.0 has been used to develop a revised 10-item version of the eHEALS [10], with items measuring each element of the model.

Data Availability

We encourage collaboration on the evaluation and language adaptations of the new eHEALS-R (revised eHealth Literacy Scale) in diverse settings. Please contact CN and/or HS for details.

Abstract

In this national study of primary care practice–level factors associated with telehealth adoption in 2022, we found that training and assisting patients with the use of telehealth, broadband expansion efforts, and a higher proportion of low-income patients were associated with higher practice-level telehealth use, suggesting both opportunities for telehealth expansion and potential populations with higher need for its use.

(J Med Internet Res 2025;27:e70404) doi:10.2196/70404

KEYWORDS

telehealth; telemedicine; remote consultation; primary health care; general practice; internet access; health policy; health care economics and organizations; access to primary care; digital divide; vulnerable populations; medically underserved area

Introduction

In 2021, the National Academy of Medicine called for further study of telehealth to help strengthen primary care as part of their "Implementing High-Quality Primary Care in the United States" report [1]. Past studies highlight a range of patterns in telehealth use by patient-level factors [2], but primary care practice–level capabilities, such as resources to enable telehealth, have not been systematically assessed. Organizational and contextual factors, such as a federally qualified health center (FQHC) designation and a practice's neighborhood characteristics, may also be associated with telehealth use. We analyzed a national survey of US adult primary care practices to examine relationships between practice-level factors and telehealth adoption.

Methods

Overview

We analyzed cross-sectional data from the 2022-2023 National Survey of Healthcare Organizations and Systems, which surveyed practice leaders about telehealth use in 2021, practice payment models, and care delivery structures and processes (1245/3499 people responded to the survey, for a 36% response rate). Survey administration information and data sources are described in Multimedia Appendix 1.

XSL•FO
RenderX

The primary outcomes are the proportion of all outpatient visits done via telehealth (real-time audiovisual or audio-only, eg, telephone) and the proportion of telehealth visits done audio-only. We categorized practices by quartile of telehealth use to compare practice-level differences by characteristic. We estimated multivariable linear regression models for all cases (N=1071) and used average marginal effects to generate estimates and 95% CIs for the primary outcome measures. Model covariates included practice ownership, clinician staffing, FQHC status, and telehealth-enabling resources. All analyses were completed in Stata (version 17; StataCorp), and all models used robust estimates of variance and 2-tailed *P* values, with *P*<.05 set as the threshold for significance. Weights were used in all analyses to account for nonresponse probabilities, detailed in Multimedia Appendix 1.

Ethical Considerations

This study was deemed exempt by the Dartmouth College Committee for the Protection of Human Subjects (00032337). As practices were the unit of analysis, participants received an information sheet in lieu of informed consent. Practices were deidentified prior to analysis.

Results

The median use of telehealth for practice encounters was 20% (IQR 10%-35%), and the median proportion of audio-only telehealth visits was 29% (IQR 17%-50%). High-telehealth-use practices were more likely to care for a high proportion of uninsured patients, to have expanded broadband access for patients, and to have trained patients to use telehealth (Table 1).

In multivariable regression analyses (Figure 1), a high payer mix of uninsured patients and high broadband expansion corresponded to higher telehealth use (*P*=.02 and *P*=.008, respectively), while rurality corresponded to lower telehealth use (*P*=.008). Audio-only telehealth use was higher among FQHCs compared to other practices (*P*=.02), and assisting patients with using telehealth was associated with both higher telehealth use and a smaller proportion of audio-only telehealth use (*P*=.002 and *P*=.001, respectively).

[a]Characteristics are reported as weighted percentages unless otherwise noted. Details on weighting are provided in Multimedia Appendix 1.

[b]Differences between quartiles; generated via the χ^2 test with the exception of download and upload speed, which were generated with the adjusted Wald test.

[c]Includes any engagement in accountable care organization and capitated payment contracts, which are alternatives to fee-for-service billing.

Figure 1. Adjusted Telehealth Use Rates and Audio-Only Telehealth Proportions by Select Factors. Covariates included in the multivariable linear regression model were as follows: practice ownership type, US census region, clinician staffing size, Area Deprivation Index quartile, median download speed at the census tract level, reported financial health, whether a practice reported impacts from staff shortages, alternative (to fee-for-service) payment model participation, and a payer mix that was >20% Medicare. Each covariate was significant in univariate regression at the *P*<.1 level; in preliminary runs when 2 factors had a Spearman correlation coefficient >0.5 or <–0.5, the least significant factor was excluded. EHR: electronic health record.

Discussion

In this national study of primary care practices in 2022, we found that respondent practices serving the uninsured reported greater use of telehealth for patient encounters, and FQHCs used more audio-only telehealth. This suggests that low socioeconomic status populations had a higher need for telehealth and that cuts to audio-only reimbursement would disproportionately impact care for such patients. The "digital divide," systematic barriers for accessing and using technology and telehealth among various populations [3], is a known issue for FQHC and rural populations [4,5], and our study provides national evidence that these practice-level factors are significantly associated with lower adoption of video-based telehealth.

Importantly, we found that the telehealth-enabling practices of training and assisting patients with using telehealth and broadband expansion were associated with higher telehealth adoption. In contrast, electronic health record integration for video visits, participation in alternative payment models that incentivize care quality, and practice ownership were not significant practice-level factors, contrasting with a prior study suggesting health system integration was linked to higher telehealth use at the physician level [6].

Limitations include potential nonresponse bias due to the modest response rate, though we used weights to account for this (sensitivity analyses of missing data are in Multimedia Appendix 1); that telehealth use is reported in aggregate rather than calculated from visit data, so could not be verified; and an inability to draw causal inference from cross-sectional analysis. Longitudinal analyses or controlled trials would provide stronger

XSL•FO
RenderX

evidence and be able to describe any changes in significance of the identified factors for telehealth use over time.

These findings provide important national data for the design of policy and practice interventions to expand telehealth use. Practices focused on enabling telehealth appear able to meaningfully increase its uptake [7]. Federally, renewing the lapsed support for broadband accessibility is an important means to address the digital divide [8,9].

Abstract

Background: The rapid shift to video consultation services during the COVID-19 pandemic has raised concerns about exacerbating existing health inequities, particularly for disadvantaged populations. Intersectionality theory provides a valuable framework for understanding how multiple dimensions of disadvantage interact to shape health experiences and outcomes.

Objective: This study aims to explore how multiple dimensions of disadvantage—specifically older age, limited English proficiency, and low socioeconomic status—intersect to shape experiences with digital health services, focusing on video consultations.

Methods: Following familiarization visits and interviews with service providers, 17 older people with multiple markers of disadvantage (older age, low socioeconomic status, and limited English proficiency) were recruited in the Redbridge borough of London. Data collection included narrative interviews and ethnographic observations during home visits. Field notes captured participants' living conditions, family dynamics, and technological arrangements. Guided by intersectionality theory and digital capital concepts, interviews explored participants' experiences accessing health care remotely. Intersectional narrative analysis was used to identify key themes and examine how different forms of disadvantage interact. We developed theoretically informed narrative portraits and user personas to synthesize findings.

Results: Analysis revealed that the digitalization of health care can exacerbate existing inequities, erode trust, compound oppression, and reduce patient agency for multiply disadvantaged patient populations. Examining intersectionality illuminated how age, language proficiency, and socioeconomic status interact to create unique barriers and experiences. Key themes included the following: weakened presence in digital interactions, erosion of therapeutic relationships, shift from relational to distributed continuity, increased complexity leading to disorientation, engagement shaped by previous experiences of discrimination, and reduced patient agency.

Conclusions: This study provides critical insights into how the digitalization of health care can deepen disparities for older patients with low income and limited English proficiency. By applying intersectionality theory to digital health disparities, our findings underscore the need for multifaceted approaches to digital health equity that address the complex interplay of disadvantage. Recommendations include co-designing inclusive digital services, strengthening relational continuity, and developing targeted support to preserve agency and trust for marginalized groups in an increasingly digital health care landscape.

Introduction

Overview

While existing research has explored digital health disparities [1-5] and the application of intersectionality theory in health care [6-8] separately, there remains a critical gap in understanding how multiple dimensions of disadvantage intersect specifically in the context of digital health services. Previous studies have largely focused on single-axis analyses of digital exclusion [9-11]. For example, Ramsetty and Adams [9] examined socioeconomic status as a determinant of digital health access through quantitative analysis of technology ownership and internet connectivity rates. Eberly et al [10] used a large-scale quantitative study to analyze telemedicine access solely through the lens of age, finding lower video visit completion rates among older adults. Similarly, Donaghy et al [11] investigated the acceptance of video consultations primarily through the single dimension of technological literacy using survey data. While these quantitative studies provide valuable insights into individual factors, they have not adequately examined the compounded effects of age, language proficiency, and socioeconomic status on experiences with digital health technologies, particularly video consultations. Furthermore, there is a lack of in-depth, qualitative research that captures the lived experiences of multiply disadvantaged patients navigating these digital health spaces [12]. This study aimed to address this gap by applying an intersectional lens to explore how various forms of disadvantage interact and manifest in the context of video consultations, providing a more nuanced and comprehensive understanding of digital health disparities among susceptible populations.

We adopted an intersectional perspective from feminist studies to highlight the intersection and entanglement between digital technology, structural stratifications, and ingrained tendencies of "othering" in societies. This approach allowed us to move beyond simplistic notions of digital divisions to examine how digital technology is implicated in complex and intersectional systems of power. Drawing on narrative interviews with older, low-income individuals with limited English proficiency, we examined intersectionality and how video consultations can exacerbate existing inequities for multiply disadvantaged patient populations.

Our analysis revealed that digital health disparities operate at the intersection of multiple fracture lines of difference that mediate various spaces of inclusion and exclusion. We argue that addressing digital health disparities requires moving beyond single-axis analyses to consider how different aspects of disadvantage intersect in individual lives. This paper contributes to information systems (ISs) literature by providing a richer theorization of digital inequity, highlighting the need for intersectional approaches to digital health equity. We propose a research agenda that calls for IS scholars to reconceptualize actors beyond simplistic notions of "users," to consider positioning rather than contextualizing, and to examine how digital health technologies are intertwined with producing and reproducing social orders and stratifications. Our findings have important implications for policy and practice in designing and implementing more inclusive and equitable digital health services.

Background and Literature Review

Overview

In the United Kingdom, video consultation uptake has increased significantly since the COVID-19 pandemic. National Health Service (NHS) England reported that before the pandemic, <1% of primary care appointments used video, but this number rose sharply during early 2020 to approximately 13% as part of the NHS Long Term Plan to expand digital-first care [13]. By 2023, about 9% of consultations in general practice continued to use video, reflecting an enduring shift toward remote health care delivery despite a return to face-to-face appointments as the dominant mode (65%) [14,15]. However, the use of video consultations varies significantly across demographic groups. Research indicates that older patients (aged >65 years) are less likely to use video services, with adoption rates around 7%, compared to 20% among younger adults aged between 18 and 34 years. Similarly, individuals from lower socioeconomic backgrounds and those with limited English proficiency face notable barriers, demonstrating uptake rates <10% [14,16].

Digital Health Inequalities and the Digital Divide

The IS literature has long engaged with the concept of the digital divide, traditionally focusing on accessibility, literacy, and adoption of digital technologies [17]. This discourse often conceptualizes individuals as "users" of technology, assigning them to specific group categories such as "the excluded" or based on binary divisions of "haves" and "have-nots" [18]. However, this notion of the digital divide fails to account for the multifaceted and compounded nature of digital inequality [12,19]. Recent scholarship has recognized that digital exclusion is a complex and dynamic phenomenon influenced by various factors beyond access to technology, including age, gender, education, and socioeconomic status [20-25]. As health care becomes increasingly digitalized, there is a growing need to understand how these broader digital inequalities manifest in health contexts. The concept of digital health equity has emerged as a critical area of study, examining how social determinants of health intersect with digital access and skills to shape health outcomes. This evolving field calls for more nuanced, intersectional approaches to understanding and addressing disparities in digital health access and use.

Intersectionality Theory

To address the limitations of single-axis analyses of digital exclusion, we turn to the concept of intersectionality from feminist studies. Originally proposed by Crenshaw [26] to expose the marginalization of Black women under both sexism and racism, intersectionality stands against the tendency in critical social theorizing to treat individuals in independent categories. It emphasizes that systems of oppression are inherently bound together, creating singular social experiences for people who bear the force of multiple systems [27]. While IS research has explored the relationship between IT and identity [28,29], most studies focus on the individual or group level, investigating how IT mediates or shapes identities. However, an intersectional perspective views subjectivity as emerging

XSL•FO
RenderX

from differential experiences produced by multiple and intersecting power structures [26]. This approach moves beyond a behavioral, individualistic sense of identity to one of the "social positioning" of individuals within social structures [30]. Applying intersectionality to digital health inequalities allows us to examine how various dimensions of disadvantage—such as age, language proficiency, and socioeconomic status—interact and compound to shape individuals' experiences with digital health services.

Digital Capital Theory

The concept of digital capital by Ragnedda and Ruiu [31], an extension of the cultural capital theory by Bourdieu [32], offers another valuable lens for examining digital health disparities. Bourdieu [32] applied the idea of capital to signify the internal (eg, abilities and attitudes) and external (possessions and attributes) resources that people mobilize to achieve their goals in social life. He highlighted cultural capital as a form of capital that can be accumulated and transformed into other forms of capitals. Digital capital is made up of both digital competencies and digital technologies, which Ragnedda and Ruiu [31] argue is a form of capital in its own right and is essential for building up social, economic, and cultural resources in the digital world we live in today. Disparities involving digital skills originate in inequalities of access but are mediated by orientations that can only be understood in relation to total life contexts (eg, education, income bracket, age, location, and social support all influence a person's access to digital technologies and the level of digital skills they can acquire) [33]. Digital capital is a relatively new concept that scholars have begun to explore empirically through various methodological approaches [34]. Digital capital may be estimated, for example, at the individual level by assessing a person's digital literacy and skills, at the organizational level by measures of digital infrastructure (including the digital competence of personnel), and at the locality level in terms of the quality of the area's IT infrastructure.

Digital capital theory points us to the hypothesis that traditional forms of capital (such as economic, cultural, and social) are converted into digital capital and vice versa and provides the conceptual tools to examine how and to what extent this occurs, thereby illuminating how social inequality relates to digital inequality. If digital spaces—due to social inequality and underlying power structures—become increasingly stratified, there will be significant impacts on how individuals from differing backgrounds gain accumulated forms of capital through the digital realm. In other words, digital capital theory offers an explanation as to why people who already face systemic inequities find that these disparities widen when services are digitalized.

Recent studies have begun to explore how digital capital interacts with other forms of capital to influence health outcomes and access to digital health services [35]. However, there remains a need for more in-depth, theoretically informed research on how digital capital intersects with other dimensions of disadvantage in shaping experiences with digital health technologies.

In the context of this study, intersectionality works as an overall guiding principle for understanding how people's lives and characteristics stem from and lead to multiple axes of disadvantage, while digital capital theory helps us understand how these axes of disadvantage play out in terms of access to and use of digital resources.

Research Gap and Objectives

Our previous narrative review [12] highlighted that while existing literature recognizes the multifaceted nature of digital inequality, there is a critical lack of in-depth, theoretically informed studies examining how different dimensions of disadvantage combine to affect digital health disparities. The review found the available literature on digital health disparities, particularly in relation to video consultations, to be sparse and primarily descriptive rather than explanatory. Most research has focused on identifying barriers and enablers without adequately exploring the complex interplay of factors contributing to these disparities.

Importantly, our review revealed no theoretically informed studies that examined how different dimensions of disadvantage combined to affect digital health disparities. This gap in the literature limits our understanding of how multiple disadvantages intersect and compound to shape individuals' experiences with digital health services.

Building on these findings and responding to the recommendations of our narrative review, this study aims to address these critical gaps. By doing so, we seek to move beyond the descriptive accounts that have dominated the field and provide a richer, more nuanced theorization of digital health disparities. This approach allows us to explore the complex ways in which different aspects of disadvantage interact, compound, and manifest in the context of digital health services. Our goal is to contribute to the development of more inclusive and equitable digital health services by offering insights into the lived experiences of multiply disadvantaged individuals, as called for in our previous work.

This study represents a direct response to the research agenda proposed in our narrative review, aiming to deepen our understanding of digital health disparities and inform more effective, equitable strategies for digital health implementation.

Methods

Overview

This study used a qualitative, interpretive approach to explore the intersecting effects of age, socioeconomic status, and limited English proficiency on experiences with digital health services. The focus on age, language proficiency, and socioeconomic status was informed by our aforementioned narrative review [12], indicating these as key predictors of lower digital service uptake and barriers to access. We adopted narrative inquiry [36] as our primary methodology, which aligns with our aim to center the voices and experiences of marginalized patients. The study was conducted in Redbridge, one of London's most diverse boroughs. It has >65% of its residents from Black and minority ethnic communities, predominantly Asian (42%). Over 90 different languages are spoken in the borough, with nearly a

XSL•FO
RenderX

quarter of residents having a first language other than English. The borough includes several areas ranked among the 20% most deprived in England, with an unemployment rate (8%) exceeding London's average. This demographic and socioeconomic profile made Redbridge an ideal setting to examine intersecting dimensions of disadvantage in digital health care access. Participants were recruited through the Redbridge Respiratory Service within the North East London NHS Foundation Trust, community organizations, and snowball sampling.

Inclusion criteria for participants were as follows: (1) aged ≥65 years, (2) limited English proficiency (self-reported or identified by health care providers), (3) living within an Index of Multiple Deprivation decile of 1 to 5, (4) having attempted ≥1 video consultation, and (5) residing within the Redbridge borough.

As this was a doctoral research project, the primary investigator, LH, conducted all interviews and primary analysis, with regular supervision and analytical discussions with her supervisory team to challenge interpretations and biases throughout the research process. Semistructured narrative interviews were conducted with 17 participants between July 2022 and January 2023. All (17/17 100%) study participants had access to health care through the NHS despite being multiply disadvantaged. The interview guide was designed to elicit rich narratives about participants' experiences with digital health services, particularly video consultations. Questions explored their overall health care journey; experiences with digital technologies; and perceptions of how their age, language abilities, and financial situation affected their access to and use of digital health services. As a multilingual researcher fluent in Hindi, Urdu, and English, LH conducted all interviews directly in participants' preferred languages. Participants could freely switch between languages during interviews, which many did. This linguistic flexibility allowed participants to express themselves more fully and comfortably when discussing their experiences. All non-English segments were translated to English during transcription by LH, while "broken English" was transcribed verbatim when the meaning was clear. In addition to interviews, LH conducted ethnographic observations with 9 (53%) of the 17 participants, including home visits and participation in daily routines. These observations provided valuable contextual insights into participants' living conditions, family environments, and technological exposure. The ethnographic data were analyzed alongside interview transcripts to provide richer context to participants' narratives and to understand how their home environment and daily routines influenced their experiences with digital health care.

LH used thematic narrative analysis [37] using an intersectionality lens to identify key themes while preserving the integrity of individual stories. The analysis process involved the following: (1) familiarization with the data through repeated reading of transcripts, (2) open coding to identify initial themes and patterns, (3) development of a coding framework informed by intersectionality theory, (4) axial coding to explore relationships between themes, and (5) selective coding to refine and integrate themes into a coherent narrative.

To enhance the intersectional analysis, a modified version of the Equity Design Collaborative's meta-empathy mapping approach was incorporated [38]. This approach focuses on understanding users' needs through transformative empathy, moving beyond surface-level observations to deeply understand how systemic barriers and power structures affect user experiences. This modified approach shaped the analysis in 3 key ways.

First, it guided us to examine both immediate barriers (ie, language difficulties) and deeper structural challenges (ie, how health care systems may inadvertently privilege certain cultural norms). Second, it helped identify power dynamics in health care relationships. Third, it informed how outputs such as user personas (discussed in subsequent sections) were structured to capture both individual circumstances and systemic influences on participants' experiences. This methodological lens helped ensure findings reflected not only individual experiences but also broader systemic factors affecting remote care access.

Several strategies were used to ensure the trustworthiness of findings [39], including prolonged engagement with participants through multiple interactions, triangulation of data sources, member checking with participants to verify our interpretations, and maintaining a reflexive journal to document the decision-making process and potential biases.

Particular attention was paid to ensuring that participants fully understood the nature of the research and their rights, given potential language barriers and vulnerabilities. As researchers, we also acknowledge our own positionalities and how they may influence the research process. LH is a female Muslim of South Asian descent, which facilitated trust building with many participants but also required ongoing reflexivity to avoid assumptions based on shared cultural backgrounds. To synthesize findings, LH developed 4 [40] theoretically informed narrative portraits and user personas that captured key intersecting dimensions of disadvantage, including how age, language barriers, socioeconomic status, cultural factors, and health conditions combined to shape participants' experiences with digital health care. These are reported in detail in our previous paper [40] and serve as complementary outputs that distill key themes into accessible archetypal stories, balancing the need to honor individual perspectives with extracting cross-cutting insights about the interplay of technology and disadvantage.

Ethical Considerations

The study received ethics approval from the NHS Research Ethics Committee and the University of Oxford's Central University Research Ethics Committee. Informed consent was obtained from all participants, and pseudonyms were used to protect their identities. Ethical approval was obtained from East Midlands—Leicester South Research Ethics Committee and UK Health Research Authority (September 2021, reference number: 21/EM/0170; Integrated Research Application System project ID 300719).

Results

Overview

The analysis revealed 8 key themes that illuminate how multiple dimensions of disadvantage intersect to shape experiences with

XSL•FO
RenderX

digital health services, particularly video consultations. These themes highlight the complex ways in which the digitalization of health care can exacerbate existing inequities, erode trust, compound oppression, and reduce patient agency for multiply disadvantaged patient populations.

Digital Interactions May Have a Weak Presence

The concept of "absent presence," originally developed by Gergen [41] to describe technology-induced distraction in face-to-face interactions, takes on new significance in the context of digital health care. The analysis found that participants consistently reported a sense of diminished presence in digital health care interactions, particularly in video consultations. This weakness of presence manifested in 3 key ways: delayed responses, mechanical intonation, and perceived motionlessness.

Delayed responses were frequently noted by participants as a sign of disengagement. Maneshi, an Indian immigrant aged 83 years, articulated this experience as follows:

> *If my doctor is doing twenty other things on his side of the screen while I'm talking, even if he is technically listening, it just doesn't feel like a genuine conversation to me...When I go to the GP [general practitioner] in person, those distractions aren't there. I know the GP is looking at me and having a conversation with me.*

This account illustrates how the perceived divided attention of health care providers during video consultations can erode the sense of a genuine, engaging interaction. The lack of immediate responsiveness disrupts the natural rhythm of conversation, leading to a feeling of disconnection.

Mechanical intonation was another aspect that contributed to the sense of weak presence. Fowzia, a recently widowed immigrant from Pakistan, expressed this concern as follows:

> *The absence of eye contact and non-verbal cues makes you feel...I don't know it's off putting. It feels like I'm talking to a computer program instead of a real doctor. They used to, the doctors, they would bring a lot of comfort and assurance; now, it's replaced with a sense of disinterest. It just makes you think you know? Do they even care?*

Participants described feeling as though they were interacting with a "computer program" rather than a real person, noting the flat, unemotional tone often used by health care providers during video consultations. Recent research in general practice has shown that video-mediated communication affects sensory conditions in clinical interactions, technical issues such as delayed facial expressions and sound can disrupt natural conversation flow, and the screen interface limits health care providers' ability to read and respond to patient cues [42]. This lack of vocal vitality, as conceptualized by Stern [43], can significantly impact the patient's perception of the provider's engagement and empathy.

The third manifestation of weak presence was perceived motionlessness. Abed, a recently retired repairman aged 69 years, highlighted this issue as follows:

> *His movements don't signal any interest. I mean I guess that could just be because I'm seeing his face and can't tell over video call how much he's actually moving. But I'm not seeing hand movements or his head moving much you know.*

In face-to-face interactions, body language and subtle movements play a crucial role in conveying attention and engagement. However, in video consultations, the limited visual field and potential technical constraints can result in an appearance of stillness that patients interpret as a lack of involvement or interest. Basmah, a Bangladeshi immigrant aged 73 years with arthritis and limited mobility, noted the following:

> *Back in the day, a doctor's touch and a comforting pat on the back meant so much. Now, it's different, you just hear typing with those hands.*

This triad of delayed responses, mechanical intonation, and perceived motionlessness collectively contributed to a sense of "absent presence" in digital health care interactions. Therefore, many (11/17, 65%) participants reported feeling disconnected and unheard during video consultations, potentially impacting the quality of care and patient satisfaction. Mohammad, a Sri Lankan immigrant aged 70 years with multiple chronic conditions and living with his extended family, starkly put the following:

> *Facial expression and body language is so important. When you talk to people you can see what's wrong and things like that and some of the things you don't know whether when the GP say things, how they mean it because I can't tell over remote. I don't think the whole system is fracturing, I think it's completely collapsing.*

While all patients may experience reduced presence in video consultations, this sense of disconnection is particularly problematic for patients with limited English proficiency, who rely heavily on nonverbal cues and physical presence to support communication and understanding. The technical barriers to presence can additionally compound existing language barriers, potentially leading to misunderstandings or missed clinical information.

Digital Encounters May Weaken Relationships

Analysis revealed that digital encounters, particularly when there was no previous in-person relationship, often weakened the therapeutic relationship between patients and health care providers. Participants consistently expressed difficulty in forming bonds through screens, highlighting the importance of relational foundations for ethical care.

Rajpreet, a first-generation Indian woman experiencing economic hardship and multiple chronic conditions, articulated this challenge as follows:

> *Doing this by video makes it harder. If I met her in person, maybe we could connect more...but I know women like her, that's not to say in a bad way, just that she doesn't really struggle with the same things that I do, it's very different when two women come*

XSL•FO
RenderX

> *from...I don't know how to say...just that...she's of a different social class...if that makes sense.*

This quote illustrates how the lack of physical presence can exacerbate perceived social and cultural differences, making it more difficult to establish a connection and mutual understanding.

The importance of preexisting relationships was emphasized by many (14/17, 82%) participants. Fatima, an Afghan woman aged 81 years with diabetes and heart conditions, who relies on her children for translation, explained the following:

> *I think it [video consultation] was easier because I had met Dr. Samari before. So I already had that initial relationship with her. I've seen her a few times. I felt comfortable with her. I think it would have been a bit more awkward if it had been like a first meeting.*

Conversely, participants who had video consultations with unfamiliar clinicians often reported fewer positive experiences. Ramnik, an Indian immigrant aged 78 years with hypertension and diabetes, who lives alone and relies on community support services, explained the following:

> *You stay in the online waiting room being all confused and then they let you into the call. And its someone you've never seen before. And he just wants yes or no. Then it's finished. You can go. That's it. You know? So I don't know. I don't like it. I don't. This is why I don't want to see the GP unless it's really bad. When I did it [video consultation] with my own specialist it wasn't like this. That time was good because he knew me and I knew him.*

This account highlights how the lack of a prior relationship can lead to a sense of disconnection and dissatisfaction with the consultation process.

Some (5/17, 29%) participants stressed the need for occasional in-person visits to establish and maintain a connection:

> *It'd be nice if they could see a person like myself every three months or normal patients at least once every six months. Yeah, so you know, so then you know them. So that builds up some, like, friendship as well. Now there's no friendship. But that's why, you know, it's important we get to know who the person is. Here there's no chance to do that.*

This suggestion underscores the perceived value of face-to-face interactions in building and sustaining therapeutic relationships.

The findings indicate that even when participants had successive video consultations with the same health care provider, they rarely developed a sense of building a strong and positive therapeutic relationship. This contrasts with face-to-face environments, where the patient-provider relationship typically strengthens with each encounter. Some (4/17, 23%) participants even described a deterioration in their relationship over repeated remote encounters, unless preceded by face-to-face meetings.

The weakening of therapeutic relationships through video consultations has consequences for marginalized older adults who often rely on trusted health care provider relationships to maintain engagement with health services. Limited English speakers face additional barriers to relationship building in digital settings, where language difficulties are compounded by technical constraints.

The Shift From Relational to Distributed Continuity

The analysis also revealed a significant shift from relational to distributed continuity as digitalization increased after the COVID-19 pandemic. This transition often left patients feeling lost, unsupported, and struggling to navigate their care effectively. The loss of relational continuity was particularly pronounced for marginalized older adults who had previously relied on long-standing relationships with health care providers.

Tasneem, a Bengali immigrant aged 75 years, expressed this loss as follows:

> *Dr. Talib has seen me through so much. I could speak to her about anything, and she really listened and understood me.... [Now] I don't even know my doctor's name. How can I trust someone I don't even know?*

This quote encapsulates the profound impact of losing a trusted health care relationship and the challenge of building trust in a system of distributed care.

The fragmentation of care was a recurring theme among participants. Arjun, a retiree aged 72 years, described his frustration with the depersonalization of care as follows:

> *It's becoming less and less personal. It's like you are not a person there you are just a face. For example, the company I work for we went through the same sort of process, I joined in '87 with BT and then in 1993 they brought this employee individual identification numbers they're called right, so you're given a nine digit number and then after that whenever you wanted to talk to the HR department or pay group or something like that, that's the thing that you gave them and that's it. So you only become a number, in this case you're only becoming a face to the GP, always a new number, new face, new GP, it's not who you are or what you are.*

This shift to distributed continuity often resulted in communication breakdowns and potential risks to patient care. Priya, a Punjabi woman aged 71 years with diabetes, expressed her concerns as follows:

> *Ordering repeat medicine with the GP always main problem. They are, you know, taking so long and even sometimes they don't know your condition there because communication, everything is so broken. They just forget everything. Like you are the new person to them. You know that's the problem with the GP always.*
>
> *They don't know my history or me. I feel scared they'll make a mistake with the dosage but what can I do?*

The loss of community connections was another significant aspect of this shift. Another participant highlighted how digital triaging erased the familiarity and efficiency of previous care arrangements:

XSL•FO
RenderX

> *[B]efore, you know, they knew everything already. They knew you. And they had my history. Whereas. Where I am now, as I said, the first five minutes of any session are taken up with me explaining who I am, what my situation is. And then, you know, explaining what the problem is, why I'm seeing them all the rest. And this is repeating after filling out a whole econsult first. It's a right shame.*

The fragmentation of care extended beyond primary care to specialist services. Najma, a Pakistani immigrant aged 66 years with limited English proficiency and respiratory conditions, living in council housing, described her frustration with revolving specialists and poor communication:

> *Now my specialist has also now changed. Three of them I went through. At the moment one, I think one is they know she's the main one. She was good, but now I don't know which one. Last two weeks ago they giving me one medicine which is a high dose they asked me to stop and they my daughter she sent a lot of e-mail to her but she don't reply anything here so this one [the new specialist] I think she's not so good. Communication is not good. You keep chasing them, you know?*

These experiences highlighted how the shift to distributed continuity has disrupted the holistic, coordinated care that many patients, especially those from marginalized communities, relied upon. The fragmentation of care across digital platforms has created new challenges in maintaining consistent, personalized health care relationships and effective communication between health care providers and patients.

Digital Interactions May Compound Oppression

Findings revealed that digital health services often compounded existing forms of oppression and discrimination, particularly for participants with limited English proficiency and low digital literacy. These individuals faced multiple, intersecting barriers in accessing and navigating digital health platforms, which exacerbated their existing challenges in health care settings.

Rajpreet, a first-generation Indian woman aged 74 years living in council housing with multiple chronic conditions, articulated this challenge:

> *I told her, don't mind me saying this Dr. Kaur, but you don't really know what it's like, you come from a different background or world whatever you want to call it [laughs], you know medically sure, but over video you can't grasp it, you won't understand because you don't have it either, my condition, what surrounds it, that sort of thing...*

This quote illustrates how digital interactions can amplify cultural and experiential gaps between patients and health care providers, making it more challenging to discuss sensitive health issues.

Language barriers were particularly problematic in digital settings. Samiyah, a Pakistani grandmother aged 69 years, with limited English proficiency and chronic pain conditions who recently moved in with her son's family, noted the following:

> *It's already hard to explain my symptoms in English, but over video, it's even worse. I can't use gestures or show them exactly where it hurts. Sometimes I feel like they don't understand me at all.*

Low digital literacy compounded these challenges. Tasneem shared the following:

> *I struggle with technology, and now I have to figure out how to use these apps just to see my doctor. It makes me feel stupid and left behind. Sometimes I just give up.*

The shift to video consultations also highlighted existing inequalities in access to technology. Mohan, living on a basic pension in social housing with diabetes and heart disease, explained the following:

> *They tell us to do video calls, but I don't have a smartphone or good internet. It's like they're saying healthcare is only for people who can afford fancy gadgets.*

Participants from marginalized groups often found themselves at the intersection of multiple disadvantages—language barriers, cultural differences, low digital literacy, and limited access to technology—all of which were amplified with video consultations.

Digitalization May Erode Trust in Health Providers and Systems

Findings revealed that the shift to video consultations also frequently eroded participants' trust in health care providers and systems. This erosion of trust was often rooted in a sense of depersonalization and lack of continuity in care, particularly for marginalized and susceptible populations. Research has also documented how marginalized communities may have lower trust in health care providers due to several factors, including historical medical mistreatment, documented disparities in quality of care, and systemic barriers to culturally and linguistically appropriate services [44,45]. In this study, this broader context of health care mistrust appeared to be exacerbated by the shift to video consultations, particularly when patients could not establish consistent relationships with health care providers.

Hasan, with his multiple chronic conditions and previous negative health care experiences, articulated this sentiment strongly in the following manner:

> *You don't wanna be a part of this system. Like you can't trust these people in the NHS... Because I need the GP, but to be honest, I don't trust that like you know, she's not very good and she she doesn't really care, right? That's the impression I get so I try not to go but then it gets worse.*

This quote illustrates how the perceived lack of care and attention in digital interactions can lead to a cycle of disengagement and worsening health outcomes.

The impersonal nature of video consultations was a recurring theme. As Fowzia explained the following:

XSL•FO
RenderX

> *The personal connection is not the same. I miss the stuff that didn't require words, stuff you could just see and feel and the comfort of being physically there in the same room. It's harder to build that trust through a screen.*

This highlighted the importance of nonverbal cues and physical presence in building trust, which many felt was lacking in digital interactions.

The erosion of long-standing relationships with health care providers was particularly distressing for some participants. Fatima shared the following:

> *Thing is you can't even think about trusting the GP now even if you wanted to this way [over video consults]. These things take a lot of time, beta, my old GP, I knew him for 10 years, every small flu, back ache, little cold he knew it all. I don't even know if I have another 5 years left in me and if I keep seeing a different GP over a different platform where does that leave me, beta?*

This account underscores how the fragmentation of care across multiple health care providers and platforms can disrupt the accumulation of shared knowledge and understanding that forms the basis of trust in health care relationships.

The erosion of trust sometimes led to nonadherence to medical advice. Zainab, a Pakistani immigrant aged 73 years with heart disease, who had previously experienced dismissive treatment from health care providers, explained the following:

> *I mean why should I take it [the medication], ok yeah they prescribe it but they don't even bother listening to me, click clacketing away at their keyboard, not even looking at the screen, they think they know what's wrong with me just like that? I don't trust it one bit course I'm not gonna take it.*

For some, the distrust in the health care system led to anxiety and avoidance. Hamida, a Bangladeshi mother aged 75 years living with her daughter's family and experiencing both physical health conditions and growing anxiety about health care interactions, shared the following:

> *My daughter thinks I have anxiety because I don't want to deal with the NHS. I don't know, maybe I do. But to me it's more about the fact that they can't be trusted.*

However, it is important to note that not all participants experienced an erosion of trust. In a notable disconfirming case, 1 participant reported high levels of trust in video consultations due to a preexisting, long-term relationship with her general practitioner. This suggests that strong, preexisting therapeutic relationships may buffer against the potential erosion of trust in digital interactions.

These findings highlight the complex relationship between digitalization and trust in health care. Video consultations can risk eroding the personal connections and continuity of care that many patients, particularly those from marginalized groups, rely on to build trust with their health care providers. This erosion of trust can have serious implications for patient engagement, adherence to treatment, and overall health outcomes.

Digitalization Increases Complexity, Which May Lead to Disorientation

The analysis highlighted that the introduction of multiple digital platforms and access points often led to increased complexity and disorientation for participants. Many (12/17, 70%) struggled to navigate the various digital pathways and processes, leading to frustration and, in some cases, disengagement from health care services.

Mukesh, a man aged 85 years with cognitive challenges, articulated this complexity in the following manner:

> *The health system as a whole there is a lack of communication and sharing between the different functions. I mean I've got access to a long COVID clinic. Then I also deal with my GP and there should be some information exchange between the two. Not me filling them both in on my own. And then with the hospital, they're not connected in a way that they can get anything from my GP to the hospital and it has been very frustrating.*

This quote highlights how the fragmentation of digital systems can place an additional burden on patients, particularly those with complex or multiple health conditions.

The sense of being overwhelmed by digital options was a common theme. Ramnik expressed the following:

> *I felt like I was drowning in all the options, do I call the practice, do I do this econsult thing, do I use the NHS app, do I first check the website, but then the website it too complicated anyways and then I'm back to square one. It's overwhelming, especially when you're already struggling with other things, this is the last thing I should have to worry about.*

This account illustrates how the proliferation of digital access points, while intended to improve accessibility, can paradoxically create barriers for some patients.

The disorientation experienced in digital health care settings was often compounded by language barriers and limited digital literacy. As Samiyah shared the following:

> *I wouldn't know the first thing about doing a video call. He [son] set it up for me, clicked some stuff, and had it up and running and I just sat there. They did all the talking without me, but it probably was for the best anyways because I don't know if I could've even said what I needed to properly, the language issue, the screen issue, just looking at it all was too much for me.*

This quote underscores how digital health care can inadvertently exclude patients who lack the necessary language skills or technological proficiency, potentially exacerbating existing health inequalities.

The complexity of digital systems also led to challenges in maintaining continuity of care. Mohammad noted the following:

XSL•FO
RenderX

> *Look I've got more health issues than I can count on both of my hands, navigating through different services and providers, half remote, half in person, half on the phone, I just feel like I'm lost in a maze. I'm constantly juggling between appointments with different specialists, trying to piece together the whole story for myself and for the providers too because they themselves don't know the full story. It's exhausting and overwhelming.*

This account highlights how the fragmentation of care across various digital and in-person platforms can create a significant cognitive and emotional burden for patients, particularly those managing multiple health conditions.

The disorientation caused by digital complexity was often exacerbated by socioeconomic factors. As Maneshi explained the following:

> *Not having the money to go private adds another layer of hard to the mix. I can't afford the luxury of choosing the most convenient healthcare option. No. Instead, I'm forced to navigate through a patchwork of NHS resources that takes weeks, months, even years and it's just getting worse because they're trying to move things online now and my brain is already just scattered from long-covid first and then the mess that is the NHS trying to be something they aren't so this is just the cherry on top.*

This quote illustrates how the digitalization of health care, when not adequately supported or implemented, can compound existing health inequalities and create additional barriers for those already struggling to access care.

Engagement With Digital Services May be Shaped by Previous Experiences of Racism and Discrimination

Findings revealed that participants' willingness to engage with digital health services was often profoundly influenced by their previous experiences of racism and discrimination within the health care system. These past negative experiences created a foundation of mistrust that often extended to new digital health initiatives.

Hamida, with her growing anxiety, articulated this heightened vigilance as follows:

> *So I'm literally now I'm very vigilant. I will check every single medication. I will read the leaflet 3 times, I will Google it because I don't trust these people they already prescribed the wrong one [medication] to me once before.*

This quote illustrates how past negative experiences can lead to a deep-seated mistrust that influences future interactions with health care services, including digital platforms.

The intersection of racial identity and socioeconomic status in shaping health care experiences was highlighted by Abed in the following manner:

> *Well, yes. At the end of the day, yes, I do think that if I was a white person from a rich background, instead of brown and poor, I might have been treated differently.*

This perception of differential treatment based on race and class extended to video consultations, with participants expressing concern that these biases would persist in digital interactions.

Some (9/17, 53%) participants described a resigned acceptance of interpersonal racism from health care staff:

> *You know, sometimes you can tell they're a little bit... racist, but it's OK, you know, it's not a big deal.*
>
> *And sometimes you get certain doctors who are racist. But it's whatever, I'm used to that.*

These statements reveal a troubling normalization of discriminatory treatment, which may influence patients' expectations and engagement with digital health services.

Language barriers were identified as a particular challenge in video consultations, often intersecting with perceptions of racial discrimination:

> *They make it such that you know she's not given one [appointment for his wife]. If you know what I mean. It's I think it's easier for them to treat people who, for example, who they can see is very much quite different. For example, if you have really great English and you're able to communicate, you're able to get your points across, you won't deal with it [racism] as much as you will for example, if, it's just ok.*

This quote highlights how language proficiency can intersect with racial bias to create additional barriers to accessing health care, including digital services.

Some (6/17, 35%) participants, like Mukesh, expressed concern that video consultations might amplify existing biases:

> *Not too long ago my wife she had a video appointment because she had an issue with the hand. So the doctor like any questions we asked, he was just reluctant to answer and he had the, you know, the sarcasm.... So you just know where some doctors, you don't know whether it's racist or not, but like because we call it that because we feel that way.*

This account suggests that the physical distance in video consultations may exacerbate perceptions of dismissive or discriminatory treatment.

The cumulative effect of these experiences led participants like Tasneem to express extreme distrust in the health care system:

> *This is what I mean. And that's why I can't trust these people with your life. You can't. You can't. You you'd rather die than trust some idiot with your life because you're gonna die anyway.*

This level of distrust poses significant challenges to the adoption and effective use of digital health services among marginalized communities.

Digital Interactions May Reduce Patient Agency

The study revealed that the cumulative effect of the previously discussed factors often resulted in reduced patient agency. Many

XSL•FO
RenderX

(14/17, 82%) participants, particularly those facing multiple disadvantages, felt disempowered and unable to effectively advocate for themselves in digital health care interactions:

> *I'm not very happy with the new GP, but I'm scared to change. The next one might be even worse.*

This quote illustrates how the lack of options and fear of further negative experiences can trap patients in unsatisfactory care arrangements, reducing their ability to seek better alternatives.

The complexity of digital systems often led to confusion and reliance on others, as Najma described the following:

> *I can't tell you how many times I've tried using the website or app and just ended up more confused. Which link was I supposed to click? How do I even describe my symptoms properly in writing? I don't know half these medical terms they're asking. My English is no good. Eventually I just give up and tell my son to figure it out for me instead.*

This account highlights how language barriers and limited digital literacy can significantly undermine patients' ability to independently navigate their care.

The lack of physical presence in video consultations was also cited as a factor reducing patient agency. Mukesh, who experiences complex neurological symptoms, shared the following:

> *I mean doctors have it tough now seeing us all through video calls. But it almost feels pointless for me. He's just staring at notes on some other screen barely listening. I can't really show him what's going on with my body in a genuine way. And to be quite honest it just feels like he's already decided before properly hearing me out.*

This quote underscores how the limitations of video consultations can leave patients feeling unheard and unable to effectively communicate their concerns.

The reliance on family members further eroded the personal agency of participants like Samiyah, who explained the following:

> *At my age, it's impossible to keep track of the different numbers to call or steps to do appointments online. My children handle everything now—they email test results, book consultations, order medications for me. I feel so helpless relying entirely on them, but I don't really have much of a choice.*

This dependence on others for health care management significantly diminishes patients' autonomy and control over their own care.

Some participants, like Mohammad, felt entirely excluded from digital health care due to lack of access to necessary technology:

> *We don't have good internet like that or one of those fancy smartphones they keep saying to use, you see that phone? [points to older Samsung phone with cracked screen] That's what I have and it only works when we can pay for the you know [data]. My nephew always talking about this gadget and that, we just can't afford it. I know they started some phone video service during corona, but it wasn't for me. It feels like they are saying either we have to use this stuff or else we don't deserve to get treatment.*

This quote highlights how socioeconomic factors can create barriers to accessing digital health services, further reducing patient agency.

These 8 themes collectively illustrate the complex and intersecting ways in which the digitalization of health care can exacerbate existing inequities for multiply disadvantaged patients.

Discussion

Principal Findings

Overview

This study provides critical insights into how multiple dimensions of disadvantage intersect to shape experiences with digital health services, particularly video consultations, among older, low-income, individuals with limited English proficiency. The findings revealed a complex interplay of factors that contribute to digital health disparities, extending beyond notions of access and skills to encompass issues of presence, trust, continuity, oppression, complexity, and agency. The analysis revealed that the digitalization of health care can exacerbate existing inequities, erode trust, compound oppression, and reduce patient agency for multiply disadvantaged patient populations. Video consultations often created dynamics of "absent presence," where patients perceived health care providers as distracted or disengaged, leading to a sense of disconnection. The lack of previous in-person rapport negatively shaped patients' perceptions of subsequent video consultations with unfamiliar clinicians, which led to weakened relationships. The shift eroded established continuities of care for some, with the fragmentation of relational continuity becoming apparent. Digital interactions compounded experiences of oppression for patients navigating multiple, intersecting forms of structural disadvantage, such as age, ethnicity, and socioeconomic status. The complexity of navigating multiple digital platforms and pathways led to profound disorientation and fragmentation of care, especially for those with limited digital literacy or language proficiency. Experiences of racism and discrimination within health care settings shaped patients' engagement with digital services, often leading to disengagement and mistrust. The cumulative effect of these factors resulted in a significant reduction in patient agency, particularly for marginalized individuals, undermining their ability to effectively navigate their care and make informed decisions.

The experiences of our participants suggest that digital health technologies, rather than being neutral tools, act as both mirrors and magnifiers of existing social inequalities. This aligns with the concept of the "digital poorhouse" by Eubanks [46], where technology reinforces and exacerbates existing patterns of marginalization. In this study, the shift to video consultations not only reflected existing disparities in health care access but also often amplified them, creating new barriers for those already struggling to navigate the health care system. This

XSL•FO
RenderX

finding challenges the often-optimistic rhetoric surrounding digital health innovations [47,48]. While proponents argue that digital technologies can democratize access to health care [49,50], our results suggest a more nuanced reality. For multiply disadvantaged patients, the digitalization of health care services can create a cascade of exclusionary experiences, from difficulties in accessing technology to challenges in effectively communicating health needs in a digital environment.

Extending Intersectionality Theory in Digital Health Contexts

This research extends intersectionality literature by applying its insights to the study of digital health disparities, revealing specific mechanisms through which the increasing digitization of health care creates new forms of inequity and exclusion. The findings highlight how digital access disparities effectively excluded individuals with low digital literacy from video consultation, while limited English proficiency significantly reduced older adults' engagement with health services in the digital space. Importantly, we found that digital competency and digital access do not always go hand in hand, demonstrating how digitalization, while improving health care access for some, simultaneously creates new vectors of exclusion that intersect with and exacerbate existing social inequities. Moreover, while earlier intersectionality research has focused primarily on traditional axes of oppression such as race, class, and gender, this study highlights the emergence of new vectors of disadvantage related to digital access, literacy, capital, and competency. This underscores the need for an expanded understanding of intersectionality that accounts for the growing centrality of digital technologies in shaping health outcomes and experiences.

This study shows that digital health disparities do not operate along independent axes of division but often overlap, interlink, and interact, demonstrating how patterns of dominance and vulnerability intersect to shape people's experiences with digital health care. We argue that inequity and digital health exclusion are relational and occur along multiple fracture lines, which differentiate people's spaces of opportunities, well-being, and level of agency. These disparities are produced and reinforced through complex social relationships and interactions within health care systems and broader societal structures. The COVID-19 pandemic may have brought out new instantiations and shed light on what was less visible before; however, the roots of digital health inequity are deeply entrenched in systems of power and social order.

The Constellation of Challenges for Multiply Disadvantaged Patients

The findings from this study revealed that video consultations created a constellation of challenges for older patients with multiple disadvantages. Participants described feeling profoundly disoriented in digital spaces, struggling to navigate unfamiliar platforms and processes. This disorientation was compounded by disrupted continuity of care, as they cycled between health care providers in fragmented digital encounters. The remote modality also engendered a weak sense of presence and connection—many (13/17, 76%) felt their health care providers were not fully attentive or did not understand their needs. Crucially, the digital interfaces exacerbated feelings of disempowerment and loss of agency. Participants felt adrift, unable to steer the direction of their care. Intersecting barriers reinforced the following: limited economic, social, and linguistic resources; social and cultural isolation; low digital, health, and health care system literacy; and physical impairments of illness and age. Some (9/17, 53%) perceived the digital challenges as yet another form of discrimination. These intersecting factors fed into a cycle of growing disengagement and mistrust toward individual providers and the health care system as a whole.

Digital Capital and Health Equity

Our results also contribute to the emerging literature on digital capital [35] by illustrating how disparities in digital competencies and access intersect with other forms of disadvantage to shape health outcomes. The struggles of our participants to navigate complex digital health systems reflect not only a lack of technical skills but also a broader deficiency in the social and cultural capital needed to effectively engage with digitalized health care. This finding aligns with the theory of capital conversion by Bourdieu [32], suggesting that disadvantages in 1 domain (eg, socioeconomic status) can translate into disadvantages in another (eg, digital health access).

Trust, Presence, and the Digitalization of Care Relationships

Our findings on the erosion of trust and the sense of "absent presence" in video consultations raise important questions about the nature of care relationships in digital environments. Drawing on the work by Giddens [30] on trust in modern societies, we can interpret these experiences as reflective of the disembedding of social relations that occurs with increased digitalization. The loss of physical copresence in health care interactions appears to disrupt established mechanisms for building and maintaining trust, particularly for patients who may already have reasons to distrust health care institutions.

This erosion of trust and presence challenges dominant narratives about the efficiency and convenience of digital health services. While video consultations may offer logistical benefits, our findings suggest they may come at the cost of the relational aspects of care that are particularly important for susceptible patients. This aligns with the critique of the logic of choice in health care by Mol [51], suggesting that the move toward digital health services may prioritize a transactional model of care over a relational one.

Compounding Oppression and Reduced Agency

Perhaps the most concerning finding is that digital health interactions can compound existing forms of oppression and reduce patient agency. This aligns with critical perspectives on technology that view it not as a neutral tool but as a social force that can reinforce existing power structures [52]. In the context of health care, where power imbalances between health care providers and patients are already pronounced [53], the addition of digital interfaces appears to further tilt the scales against marginalized patients. The reduction in patient agency observed in this study has important implications for patient-centered care and shared decision-making, which are increasingly recognized as crucial elements of high-quality health care [54].

XSL•FO
RenderX

Our findings suggest that current approaches to digital health may be undermining these important principles for certain patient populations.

Methodological Contributions

This research also makes significant methodological contributions to intersectionality literature by demonstrating the value of qualitative and narrative-based approaches to studying the lived experiences of marginalized groups. While quantitative approaches have dominated much of the existing research on digital health disparities, our research draws on feminist and critical race theories that emphasize the importance of storytelling and counternarratives as forms of epistemic resistance [55,56]. By using in-depth narrative interviews and persona development as key methodological tools [40], we provide a more nuanced and contextualized understanding of how digital health disparities are experienced and navigated by multiply disadvantaged individuals.

Implications for Practice and Policy

Viewed through the lens of health equity and social justice, our findings suggest that the rapid digitalization of health care risks exacerbating existing health disparities. This aligns with the concept of "digital redlining" proposed by Gilliard and Culik [57], where digital systems create new forms of discriminatory exclusion. The compounding of oppression and reduction in patient agency experienced by our participants raise serious concerns about the potential for digital health technologies to undermine principles of equity and patient-centered care.

However, these findings also point to potential avenues for intervention. Through reconditioning the intersectional nature of digital health disparities, policy makers and health care providers can develop more flexible, targeted approaches to support susceptible patients. This might involve not only addressing technical barriers to access but also working to build the broader forms of capital needed to effectively navigate digital health systems. For example, offering a range of communication options, including in-person visits, and providing additional support for patients navigating digital systems.

In addition, our results underscore the importance of maintaining and strengthening relational continuity in health care, even as care becomes increasingly digitalized. This might involve strategies to ensure patients can maintain relationships with preferred health care providers across digital and in-person interactions. Third, our findings point to the need for greater attention to issues of structural competency in the design and implementation of digital health systems. This could involve training health care providers in culturally competent digital communication and the development of digital health interfaces that are more inclusive and culturally sensitive. Finally, our results suggest that efforts to address digital health disparities must go beyond simply providing access and skills training to address deeper structural inequalities. This aligns with calls for a "digital determinants of health" framework that recognizes the broader social, economic, and political factors shaping digital health equity [58].

Limitations and Future Research

While this study offers valuable insights, several methodological limitations warrant consideration. The relatively small sample size (N=17) and geographical confinement to Redbridge, London, limit the generalizability of our findings. Our reliance on narrative interviews may have introduced recall and social desirability biases, potentially skewing participants' accounts of their digital health experiences. The inclusion criterion of having attempted ≥1 video consultation may have inadvertently excluded those facing the most severe barriers to digital health access. In addition, our study focused primarily on video consultations, potentially overlooking other forms of digital health interventions.

Looking ahead, several key areas warrant further investigation to address these limitations and expand our understanding of digital health equity. Longitudinal studies are needed to track the long-term impacts of digital health services on marginalized populations, providing insights beyond the snapshot our study offers. Intervention studies should evaluate targeted approaches to address identified barriers, such as building digital capital and fostering trust, which could help overcome some of the access issues noted in our limitations.

To address the geographical limitations of our study, comparative analysis across different health care systems and cultural contexts could identify transferable principles and context-specific challenges in promoting digital health equity. This broader perspective would enhance the generalizability of findings and inform more universally applicable strategies.

From a policy perspective, there is a pressing need to examine how existing health policies and digital strategies impact health disparities. The study analysis could provide valuable context for understanding the systemic factors influencing digital health equity, beyond the individual experiences captured in our study.

Finally, to complement this study's qualitative insights and address the limitations of our small sample size, future work should focus on developing and validating quantitative measures for intersectional digital health disparities. This would enable population-level tracking and more comprehensive evaluations of digital health interventions, providing a broader evidence base to complement in-depth qualitative studies like our study.

These research directions will contribute to a more nuanced understanding of digital health equity and inform evidence-based strategies for inclusive health care digitalization. By addressing the limitations of this study and expanding the scope of the investigation, future research can build a more comprehensive picture of the challenges and opportunities in promoting equitable access to digital health services.

Conclusions

This study provides critical insights into how the digitalization of health care can deepen disparities for older, low-income, individuals with limited English proficiency. By applying an intersectional lens to the study of digital health inequalities, our research reveals the complex, overlapping, and mutually reinforcing nature of digital exclusion. Our findings underscore

XSL•FO
RenderX

the need for intersectional approaches to digital health equity that address the multifaceted nature of disadvantage.

This study makes several unique contributions to the field. First, it extends the application of intersectionality theory to digital health disparities, demonstrating how multiple dimensions of disadvantage interact to shape experiences with digital health services, particularly video consultations. This approach has revealed nuanced insights into how different forms of marginalization compound to create unique barriers to accessing and benefiting from digital health innovations.

Second, our development of theoretically informed user personas [40], grounded in intersectionality and digital capital theories, offers a novel methodological approach for representing the complex lived experiences of multiply disadvantaged patients. These personas provide a powerful tool for humanizing research findings and informing patient-centered service design in digital health contexts.

Finally, by centering the voices of marginalized patients, our research exposes how the rapid shift to video consultations has inadvertently exacerbated existing inequities and eroded trust for some susceptible groups. This challenges prevailing narratives about the universally positive impact of digital health innovations and highlights the need for more nuanced, context-sensitive approaches to digital health implementation.

Furthermore, our findings on the erosion of trust, the sense of "absent presence" in digital consultations, the shift from relational to distributed continuity of care, the weakening of patient-provider relationships, the compounding of oppression, the increased complexity leading to disorientation, the influence of previous experiences of discrimination on engagement, and the reduction in patient agency contribute new insights to the ongoing discourse on the impact of health care digitalization.

In conclusion, as health care continues to digitalize, it is imperative that we remain vigilant to the unintended consequences of technological change and work to ensure that the benefits of innovation are equitably distributed. This will require a fundamental rethinking of how we design, deploy, and evaluate digital health interventions, as well as a renewed commitment to the principles of social justice and health equity.

Acknowledgments

This was an empirical doctoral study by LH, based in UK primary care and linked to the Remote by Default 2 study [59]; the PhD is supported by the Health Foundation's grant to the University of Cambridge for the Healthcare Improvement Studies Institute. The study was overseen by the independent advisory group of the Remote by Default 2 study.

Abstract

Background: In recent years, health care has undergone a rapid and unprecedented digital transformation. In many fields of specialty care, such as rheumatology, this shift is driven by the growing number of patients and limited resources, leading to increased use of digital health technologies (DHTs) to maintain high-quality clinical care. Previous studies examined user acceptance of individual DHTs in rheumatology, such as telemedicine, video consultations, and mHealth. However, it is essential to conduct cross-technology and continuous analyses of user acceptance and DHT use to maximize the benefits for all relevant stakeholders.

Objective: This study aimed to explore the current acceptance, use, and preferences regarding DHTs among patients in rheumatology care in Germany.

Methods: Rheumatology patients from 3 clinics in Germany were surveyed to understand their perspectives on DHTs. The survey included main themes, including acceptance, preferences, COVID-19's impact, potential, and barriers related to DHTs. The data were analyzed using descriptive statistics and correlation analysis.

Results: Out of 337 participants, 53% (179/337) reported using DHTs. Specific technologies included wearables (72/337, 21%), mHealth apps (71/337, 21%), digital therapeutics (32/337, 9%), electronic prescriptions (30/337, 9%), video consultations (15/337, 4%), and at-home blood self-sampling (3/337, 1%). Nearly two-thirds (220/337, 65%) found DHTs useful, and 69% (233/337) held a generally positive attitude toward DHTs. Attitudes shifted positively during the COVID-19 pandemic for 40% (135/337) of participants. Higher education was more prevalent among DHT users (114/179, 63.7%) compared with nonusers (42/151, 27.8%; *P*=.02). The main potential benefits identified were location-independent use (244/337, 72%) and time-independent use

XSL•FO
RenderX

(216/337, 64%). Key barriers included insufficient user knowledge (165/337, 49%) and limited information on DHTs (134/337, 40%).

Conclusions: Patient acceptance and use of DHTs in rheumatology is increasing in Germany. A prospective, standardized monitoring of digital transformation in rheumatology care is highly needed.

Introduction

Health care is undergoing a multidisciplinary digital transformation, which refers to "a process that aims to improve an entity by triggering significant changes to its properties through combinations of information, computing, communication, and connectivity technologies" [1].

Within the realm of rheumatology care, a notable surge in digital technologies has transpired in recent years [2,3]. This occurrence stems from the existing global disparity between the increasing number of patients with rheumatic and musculoskeletal disease (RMD) [4] and the static or even decreasing availability of human resources in the field of rheumatology care [5,6].

Consequently, Miloslavsky and Bolster [7] have discerned the amplified use of telemedicine as a prospective remedy to ensure the continuity of rheumatological care in the future [7]. Concurrently, and accelerated by the COVID-19 pandemic, the European Alliance of Associations for Rheumatology (EULAR) has recently published points to consider for remote care in RMD [8].

In Germany, a country struggling with a shrinking and aging population and a shortage of health care professionals, digital health technologies (DHTs) in rheumatology care have proven effective in improving rheumatology care [2,9]. Prominent among the prevailing DHTs are video consultations, sensors, wearables, digital health applications, and digital therapeutics with varied objectives (symptom checkers, ePRO [electronic patient-reported outcome] documentation, or patient education), social media platforms or messenger platforms [10], which can also be combined with home-based self-sampling [11-13].

Past studies have assessed patients' and physicians' acceptance of DHTs in the domain of rheumatology within Germany. These investigations primarily centered on individual digital modalities, such as telemedicine [13,14], mHealth [15], and video consultations [16,17]. Following the onset of the COVID-19 pandemic, the influence of this global crisis on the adoption of DHTs was also scrutinized [3,17]. It remains essential to continuously analyze the digital transformation in rheumatology to maximize the benefits for all relevant stakeholders. In particular, the patient perspective is critical to ensuring that DHTs actually improve health care, meets patient needs, and builds patient trust in the use of DHTs. Thus, the aim of this study was to explore the current acceptance, use, and preferences regarding DHTs among patients in rheumatology care in Germany.

Methods

Overview

To explore the patients' perspectives and preferences regarding digital health systems in rheumatology care, we recruited rheumatology patients in 3 outpatient clinics. Inclusion criteria were being aged ≥18 years, literate in German, having the physical and mental ability to fill out a paper-pencil questionnaire, and having a diagnosis of RMD. The survey was conducted between February 2023 and April 2023. The 3 clinics were sent 125 questionnaires with the request to distribute the questionnaires to eligible patients.

The questionnaire was created based on a literature review and the results of a qualitative study with health care providers (HCPs) and nurses. The questionnaire addressed the following topics: acceptance of DHTs, use of DHTs, preferences for DHTs, the impact of COVID-19 on digital transformation, potential benefits, and barriers regarding DHTs, and sociodemographic characteristics. The survey was pilot-tested with 10 patients to detect necessary formatting and wording changes. Minor revisions were made accordingly. Please refer to Multimedia Appendix 1 for the German version of the questionnaire and Multimedia Appendix 2 for the translated version in English.

Data were analyzed using quantitative descriptive analysis and correlation analysis supported by SPSS (version 23.0; IBM). For correlation analyses, the data were converted into scores, and the Spearman rank correlation coefficient was calculated. The α error distribution was chosen to be 2-sided, as an undirected correlation is assumed to be open to hypotheses. These correlations had a correlation coefficient higher than 0.29.

Ethical Considerations

This study was approved by the ethics committee of Brandenburg Medical School (E-02-20211028). All patients provided informed consent. The rheumatology clinics received an expense allowance of €150 (US $ 158) for the distribution and return of the questionnaires. The study data are anonymous. The questionnaires were digitized and then stored at the Center for Mental Health at Brandenburg Medical School.

Results

Patient Characteristics

In total, 337 patients with RMD completed the questionnaire. The number of patients rejecting participation was not measured. The study sample's demographics are shown in Table 1. The mean age was 52.5 (SD 14.2) years; 64% (219/337) were female, 32% (108/337) were male, 1% were (3/337) nonbinary, and 2% (7/337) did not give any information on gender. On average, participants had been receiving rheumatologic treatment for a median 8 years (mean 9.35 years, SD 7.63; range: 1 month-399 months), and the median time with the diagnosis was 8.9 years (mean 10.2 years, SD 8.33; range: 3 months-579 months).

Attitudes Toward DHTs

About half of the patients used DHTs overall (179/337, 53%) (Table 2). Overall, most patients (220/337, 65%) rated DHTs as useful, while a third remained neutral in their assessment of usefulness. Almost two-thirds of the patients (233/337, 69%) were positive or rather positive toward DHTs. Among all participants, 55% (185/377) stated that their attitude toward DHTs had not changed due to the COVID-19 pandemic. However, 40% (135/337) mentioned that their attitude had become more positive.

Table 2. Attitudes toward digital health technologies.

Items	Participants (N=337), n (%)
Do you use digital health technologies?	
Yes	179 (53)
No	151 (45)

Yes, the attitude has become more negative	8 (2)
No	185 (55)
No data	9 (3)

Use of DHTs

Almost half of the patients (143/337, 42%) were already using email for communication with physicians before the COVID-19 pandemic (Table 3). Currently, this value has increased to 58% (195/337). The number of patients using video consultations was very low: 4% (15/337). However, 14% (48/337) stated that they would use video consultations in the future. We found that 9% (32/337) were using reimbursed digital health applications (German: Digitale Gesundheitsanwendung; DiGA). Overall, 21% (71/337) were using other mobile health apps. Only 1% (3/337) had used blood self-sampling. Almost a quarter (78/337, 23%) stated that they wanted to use electronic prescriptions in the future.

[a]DiGA: digital health application.

Potential Benefits of and Barriers to DHTs

Independence in terms of location (244/337, 72%) and time (216/337, 64%) and generally increased flexibility (170/337, 50%) were cited most often by patients as potential benefits of digital health. The detailed results are displayed in Table 4.

The biggest barrier at present is the lack of information. Thus, 49% (165/337) stated that they do not have sufficient knowledge, and 40% (134/337) stated that they are not sufficiently informed about DHTs. A third (118/337, 35%) stated that technical equipment is a barrier to using the tools.

Table 4. Potential benefits and barriers of digital health technologies.

Items	Participants (N=337), n (%)
Potential benefits	
Location independent use	244 (72)
Time-independent use	216 (64)
Detailed documentation of the course of the disease	139 (41)
Cost savings	134 (40)
More options for accessing information, diagnostics, and therapy	125 (37)
Accessibility	85 (25)
More flexibility	170 (50)
Better preparation for the physician-patient consultation	139 (41)
Needs-based care	68 (20)
No potential benefits	32 (9)
Barriers	
Limited information about digital health services	134 (40)
Insufficient evidence of the benefits of the offers	39 (12)
Poor quality of current offers	32 (9)
Gaps in data protection	92 (27)
Lack of user-friendliness	84 (25)
Lack of accessibility	12 (4)
High costs	12 (4)
Lack of technical equipment (eg, poor Internet connection, old end devices)	118 (35)
Lack of knowledge among users	165 (49)
No need because satisfied with the current analogue solutions	57 (17)

Correlation Analyses

While correlation analysis revealed some relationships between content items (Table 5), no significant correlations between the content items and sociodemographic data were observed.

Discussion

To explore the current patient acceptance, use, and preferences for DHTs in rheumatology care, we performed a paper-pencil questionnaire survey among patients with RMD in Germany.

Principal Findings

More than half (179/337, 53%) of 337 patients reported that they use DHTs. Overall, 21% (72/337) used wearables, 21% (71/337) used mHealth apps, 9% (32/337) used digital therapeutics (DiGA), 9% (30/337) used electronic prescriptions, 4% (15/337) used video consultations, and 1% (3/337) used at-home blood self-sampling. Nearly two-thirds of the patients with RMD (220/337, 65%) rated DHTs as useful. While 69% (233/337) reported a generally positive attitude toward DHTs, about 40% (135/337) mentioned their attitudes became more positive due to the COVID-19 pandemic. The main potential benefits of DHTs reported by the patients were location-independent use (244/337, 72%) and time-independent use (216/337, 64%). The main barriers included insufficient

XSL•FO
RenderX

knowledge among users (165/337, 49%) and limited information about digital health services (134/337, 40%).

Comparison With Previous Work

Our findings are aligned with previous studies that have examined patients' acceptance of DHTs in rheumatology [3,14-19]. Comparing our results with previous findings, clear trends emerge that further underscore the growing acceptance of DHTs among patients with RMD.

In a survey conducted from September 2019 to December 2019 among 766 German patients with RMD [18], only 51% (364/718) of participants indicated familiarity with the term "telemedicine." A mere 30% (210/690) expressed intentions to try telemedicine in the future, and a total of 21% (139/663) expressed a desire for their rheumatologist to offer telemedicine. In this study, conducted from February 2023 to April 2023, that is, after the COVID-19 period, 53% (179/337) of participants reported using DHTs. It should be noted, however, that while the terms telemedicine and DHTs are closely related, they are not synonymous.

In the 2019 survey, 0.3% of patients with RMD reported having experienced a video consultation with a physician. The current results reveal a 4% (15/337) use rate of video consultations, still representing a modest figure, suggesting that video consultations in rheumatology care remain an exceptional practice. These findings corroborate the outcomes observed by Richter et al [17]. In a survey of rheumatologists in Germany, 27% (55/205) reported offering video consultations during COVID-19 lockdown phases, with the frequency of provided video conferences diminishing as the pandemic progressed.

Knitza et al [15] reported that in 2018/2019, most patients with RMD (68%) believed that using medical apps could be beneficial for their own health [15]. However, out of 193 patients, only 8 (4%) were currently using medical apps. In the fall of 2020, Kernder et al [3] explored patient and rheumatologist attitudes toward digital technologies, particularly digital health applications. Even a higher rate of patients (222/299, 74%) and also rheumatologists (98/129, 76%) believed that digital health apps were valuable for managing RMDs. Compared with Knitza et al [15], our results reveal that digital health app use increased notably (71/337, 21%). In our study, a distinction was made between certified and prescribed digital therapeutics (DiGA) and other nonreimbursed digital health apps. Interestingly, patients reported less use of prescribed DiGAs (32/337, 9%) compared with other noncertified mHealth apps (21%). This discrepancy could be attributed to the absence of DiGAs explicitly tailored for RMDs, whereas non-DiGA mHealth apps fill this gap. A first pilot study evaluating DiGA use in rheumatology [20] revealed high patient acceptance and some clinical benefits, yet poor adherence as a major limiting barrier.

According to Kernder et al [3], 38% (112/299) of patients reported a positive change in attitude due to COVID-19, comparable to 40% (135/337) in this study. The most commonly cited advantages of DHAs were their independence from time and place, which were also expressed by participants in our study.

Our study also inquired about the use and acceptance of blood self-sampling, a prospect that has recently gained significance in future rheumatological care [11-13]. However, our results suggest that self-sampling currently remains largely confined to research settings.

In a recent secondary data analysis [21], we demonstrated that, specifically, older patients with RMD residing in rural areas, who could potentially benefit from telemedicine, currently lack the motivation to embrace it and appear to require additional support. However, these relationships were not confirmed by this study. Nevertheless, our data reaffirm the profound relevance of knowledge in the use of digital technologies in rheumatology care. In line with earlier findings [3,14,19,21], our participants identified "lack of knowledge among users" as the main barrier to use. Besides the patient perspective, the viewpoint of HCPs is also pertinent to the implementation of digital technologies. Lack of knowledge among rheumatologists was previously identified as a major barrier to implementing ePROs in routine care [22]. Conveniently, recent surveys also indicated a positive inclination of HCPs toward digital technologies in rheumatology [3,14,16,19].

Limitations

Our study has several limitations. Despite our best efforts, it is possible that our survey did not capture all important emerging technologies relevant to rheumatology. In addition, the terminology used in this survey for DHTs may have caused confusion among participants, potentially leading to information bias. In addition, our survey reached a selected population from 3 outpatient clinics. This also applies to the selection of study participants, as we assume that individuals with a specific interest in digital health were more likely to have completed our questionnaire. A strength of previous surveys [3,16,17,19,22] is that the survey was paper-pen–based (instead of digital) to minimize selection bias.

Finally, it is essential to acknowledge that numerous research groups are focusing on measuring the use and acceptance in the domain of digital rheumatology. However, these studies often use varying approaches and terminologies and refer to different study populations. Therefore, the comparability of data across studies for the purpose of continuous monitoring of the digital transformation in rheumatology remains limited.

Implications

Considering the heterogeneity regarding digital rheumatology surveys and fast transformation, we advocate for a standardized, regular, survey-based monitoring of the digital transformation in rheumatology from the perspectives of both patients with RMD and HCPs. Ideally, this monitoring should be conducted on an international level, including dedicated societies such as EULAR and the Digital Rheumatology Network. Furthermore, the specific digital technologies, their nomenclature, and other questionnaire content should be harmonized through Delphi studies in collaboration with an international expert board involving input from patients.

The results depict high acceptance regarding DHTs, which is currently limited mainly by a lack of knowledge. Dedicated

XSL•FO
RenderX

education for patients with RMD and the treating HCPs is necessary to foster implementation in routine clinical practice.

Conclusions

The digital transformation in rheumatology care in Germany is progressing. Patient acceptance and use is increasing. This provides hope that, despite the rising burden of disease and stagnating human resources, digital health can continue to ensure high-quality care for patients with RMD in the future. A prospective, standardized monitoring of digital transformation in rheumatology care is highly needed.

Acknowledgments

The authors would like to thank all participants of this study. We also owe special gratitude to the 3 outpatient clinics and their teams that supported this study and distributed the questionnaires.

This study was conducted in cooperation with RheumaDatenRhePort GbR (RHADAR) and uses data from a health care analysis commissioned by AbbVie Deutschland GmbH & Co KG.

Authors' Contributions

FM and SM had full access to all the data in the study and take responsibility for the integrity of the data and accuracy of the data analysis. FM, SM, MW, PA, and JH conceptualized and designed the study. FM, SM, MW, PA, JH, PSK, HK, JK, and PK were involved in the acquisition of data. FM, SM, RD, JK, KB, MH, NV, and PP were involved in the analysis and interpretation of data. All the authors were involved in drafting the manuscript and critically revising it for important intellectual content, and they approved the final version of the manuscript to be submitted for publication.

Conflicts of Interest

MW reports support and grants for projects, talks, and discussions by Abbvie, BMS, Boehringer, Galapagos, Gilead, GSK, Hexal, Janssen, Novartis, Pfizer, and UCB. MW is also a member of RHADAR (RheumaDatrenRhePort).

Abstract

Background: Mobile health apps often require the collection of identifiable information. Subsequently, this places users at significant risk of privacy breaches when the data are misused or not adequately stored and secured. These issues are especially concerning for users of reproductive health apps in the United States as protection of sensitive user information is affected by shifting governmental regulations such as the overruling of *Roe v Wade* and varying state-level abortion laws. Limited studies have analyzed the data privacy policies of these apps and considered the safety issues associated with a lack of user transparency and protection.

Objective: This study aimed to evaluate popular reproductive health apps, assess their individual privacy policies, analyze federal and state data privacy laws governing these apps in the United States and the European Union (EU), and recommend best practices for users and app developers to ensure user data safety.

Methods: In total, 4 popular reproductive health apps—Clue, Flo, Period Tracker by GP Apps, and Stardust—as identified from multiple web sources were selected through convenience sampling. This selection ensured equal representation of apps based in the United States and the EU, facilitating a comparative analysis of data safety practices under differing privacy laws. A qualitative content analysis of the apps and a review of the literature on data use policies, governmental data privacy regulations, and best practices for mobile app data privacy were conducted between January 2023 and July 2023. The apps were downloaded and systematically evaluated using the Transparency, Health Content, Excellent Technical Content, Security/Privacy, Usability, Subjective (THESIS) evaluation tool to assess their privacy and security practices.

Results: The overall privacy and security scores for the EU-based apps, Clue and Flo, were both 3.5 of 5. In contrast, the US-based apps, Period Tracker by GP Apps and Stardust, received scores of 2 and 4.5, respectively. Major concerns regarding privacy and data security primarily involved the apps' use of IP address tracking and the involvement of third parties for advertising and marketing purposes, as well as the potential misuse of data.

Conclusions: Currently, user expectations for data privacy in reproductive health apps are not being met. Despite stricter privacy policies, particularly with state-specific adaptations, apps must be transparent about data storage and third-party sharing even if just for marketing or analytical purposes. Given the sensitivity of reproductive health data and recent state restrictions on abortion, apps should minimize data collection, exceed encryption and anonymization standards, and reduce IP address tracking to better protect users.

data privacy policy; reproductive health apps; Transparency, Health Content, Excellent Technical Content, Security/Privacy, Usability, Subjective; THESIS; THESIS evaluation; women's health; menstrual health; mobile health; mHealth; menstruating persons' health; mobile phone

Introduction

Background

The rights of menstruating persons in the United States have been at the center of major midcentury movements throughout history, whether that has been equal voting rights, safe working conditions ignited by the events of the Triangle Shirtwaist Factory fire, and freedom over their body autonomy. However, these rights and freedoms were further compromised in the 2022 *Dobbs v Jackson Women's Health Organization* case, where the US Supreme Court overturned the 1973 *Roe v Wade* ruling, which guaranteed a constitutional right to abortion [1-3]. One year after the overruling, the nation's perspective on reproductive health and the practice of collecting data through mobile apps designed to manage reproductive health have both deteriorated. Not only has the overruling threatened menstruating persons' rights over their own bodies in terms of pregnancy, but it has also posed a risk to the safety of the information that menstruating persons share on such digital platforms.

The emergence of mobile health (mHealth) apps, coined as such by Robert Istepanian in 2008, has drastically shifted the way in which society approaches disease diagnosing, maintenance, monitoring, and management [4]. Such a shift has eased travel times and made selection of health care providers easier. While it was previously necessary to schedule physicians' appointments to measure the health of an athlete or a patient with prediabetes, that is all simply done now through wearable devices such as Fitbit and Apple Watch or at-home glucose monitors that automatically update and transfer data from the user to the health care provider and alert users of irregularities detected, such as lowered oxygen levels and heightened heart rates. Due to the ease of use, users are increasingly turning to digital technologies such as mHealth apps for their health information and monitoring needs. However, smartphone technology use has been found to vary between nonmenstruating and menstruating persons, with 51% of nonmenstruating and 56% of menstruating persons using smartphones [5]. This trend is also reflected in health app use, with menstruating persons being more than twice as likely as nonmenstruating persons to turn to these apps for health information [5]. Over the past 6 years, the number of downloads for health and fitness apps alone has increased from over 1 billion in 2017 to 4.2 billion in 2023 [6].

This steady increase has also been observed with period trackers and reproductive health apps in particular, with a 2019 Kaiser Family Foundation study counting a third of American menstruating persons as users [7]. Additionally, in a study conducted among 360 health care providers, approximately 33% referred or provided information to their patients about sexual or reproductive health apps, and approximately 41% of those health care providers were confident and informed about sexual health apps [8]. Although there is continual discussion regarding security and confidentiality, the health care professionals indicated that there are potential benefits of sexual and reproductive health apps, such as being available to inform and assist underserved populations, engagement with and building of communities, training and education, and other health benefits. Reasons for use of sexual and reproductive health apps vary from menstruation monitoring, such as symptoms, changes, possible concerns, and cycle predictability, to fertility and conception tracking (ovulation) and organization of reproductive health information to pass on to health professionals during annual visits [9]. Such use has also allowed most menstruating persons to feel prepared, informed, and in control of their menstruation cycle in comparison to antiquated ways of tracking such as calendar markings [10]. Despite their ease of use and associated benefits, many apps rely on common yet sometimes inefficient methods to ensure that users read the terms and conditions and privacy policies. For example, the clickwrap (click-accept) approach, as observed in many apps, does little to ensure that users are actively reading the terms of use of each app. While there is no guarantee that users will read these terms, other approaches such as the scrollwrap (scrolling to the bottom to accept) approach may be better suited for mobile apps that deal with more sensitive data so that users are more inclined to read through highlighted areas and make educated decisions.

The convenience of reproductive health apps has posed challenges to users. Following the leak of the Supreme Court overruling draft in May 2022, many menstruating persons were left questioning what apps were safe to use. This led to an influx of users switching to reproductive health apps with more promising data privacy policies and practices, such as Clue and Stardust [11-13]. Given the sensitive information that these apps collect and store, in addition to recent shifts in the Supreme Court's response to reproductive rights, the safety, confidentiality, and privacy of menstruating persons have taken center stage as potential risks associated with data misuse have become a growing concern [14]. These potential risks have become even more prominent in light of lapses in user policies designed to protect consumers and manage the flow of their data (data collection, data sharing, and data monitoring). Those in historically inequitable health situations, such as low-income, rural, and Black and other minoritized communities, have an increased risk of both using health apps as supplements for access to quality health care and being targeted and criminalized for seeking certain types of reproductive health care [15,16]. Professionals in the field, including legal scholars from the American Bar Association, have also expressed their concern about the potential misuse of advertising data [17,18]. In addition, while there has been misinformation regarding the misuse of private reproductive health data, it is vital for users of these apps to know and understand what data are collected, how they may be used, which companies may not meet their expectations and promises, and how they can protect their

XSL•FO
RenderX

sensitive reproductive data by choosing apps that prioritize consumer safety [18].

Policy Evaluations and Legal Framework

Although there are currently no comprehensive federal laws governing data privacy in the United States, certain case proceedings, agencies, and constitutional protections—such as the Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule [19], the Fourth Amendment [20], the Food and Drug Administration [21] monitoring of medical devices, and the Federal Trade Commission (FTC) [22]—aim to protect individual privacy and medical records associated with identifiable health information. However, there is a lack of clarity regarding how these guidelines extend to mHealth apps and internet resources; for example, HIPAA does not restrict how apps may use health information that has been disclosed pursuant to the user's right of access and how certain court rulings apply to and ensure privacy in personal, home, or public settings. In addition, privacy policies and data protections vary depending on an app's country of origin. For instance, the European Union (EU) enforces comprehensive data privacy laws, providing a robust framework for identifying gaps in existing user data protection and highlighting areas for potential improvements. A comparative view of US and EU data privacy laws is presented in Multimedia Appendix 1 [19-37].

Although many apps require users to input identifiable information, certain users are at risk when such information is misused or not properly stored, secured, or shared. With reproductive health apps in the United States, the sensitive information required from users, coupled with recent legislative changes such as the overruling of *Roe v Wade*, underscore the importance of assessing the privacy policies and practices of sexual and reproductive health apps. So far, limited studies have analyzed the data privacy policies of these apps and addressed the safety issues associated with insufficient user protection. Therefore, this study aimed to (1) evaluate popular reproductive health apps and their respective data privacy policies, (2) compare data privacy laws governing these apps in the United States and the EU, and (3) recommend best practices for users and app developers to ensure user data safety.

Methods

Study Design

We conducted a qualitative content analysis between January 2023 and July 2023 on reproductive health apps available on the Apple App Store and Google Play Store and their publicly available privacy policies. The Transparency, Health Content, Excellent Technical Content, Security/Privacy, Usability, Subjective (THESIS) evaluation tool was used to assess the privacy policies and user agreements of the apps and compare the data privacy laws governing these apps in the United States and the EU [38].

Ethical Considerations

This project did not involve human participants, and the City University of New York Graduate School of Public Health and Health Policy determined that it is not considered human participant research and, therefore, an institutional review board review was not required.

App Selection

To identify apps that would offer the most comprehensive insights into data protection, we conducted a Google search for the leading apps available on both the Apple App Store and Google Play Store. The most commonly mentioned and popular reproductive health apps included Clue [39], Flo [40], and Period Tracker by GP Apps [41]. These selections were informed by recommendations from the *Women's Health* magazine, which based its choices on obstetrician and gynecologist recommendations, and Healthline, which considered customer ratings and reviews, price, availability and accessibility, tools, and features [42,43]. Furthermore, we included a convenience selection with Stardust, which experienced a surge in users and became one of the most downloaded reproductive health apps following the *Roe v Wade* overruling due to its promise of data security using end-to-end encryption [44]. These 4 apps also appeared in the top 15 search results in both app stores based on their consumer ratings, reviews, and download numbers. Consumer ratings, reviews, and app downloads determine the popularity and acceptability of and satisfaction with the apps [45]. Furthermore, these 4 apps were specifically chosen because they provide a good understanding of how policies differ between the United States and the EU and, subsequently, how that affects app data use practices in the 2 regions.

The term *reproductive health app* is used consistently throughout this paper to refer to this category of mobile apps. The selected apps, along with others cited in previous sources, allow users to not only track menstruation cycles but also monitor pregnancy and sexual activity. The data stored on these apps are more sensitive than those stored on other mHealth apps as they often include email addresses, age, name, and date of birth. This sensitivity increases the risk to users if the data are shared or improperly stored.

Data were gathered from the Google Play Store and Apple App Store platforms for each app. App characteristics, including reviews, content rating, and update frequency, were evaluated on both iOS (Apple) and Android systems to identify any differences (Table 1). Notably, certain information is platform specific; for instance, the number of downloads is available only for Android users, whereas app rankings are accessible only to iOS users. This assessment aimed to determine whether apps regularly update their practices in response to the evolving landscape of privacy laws. App characteristics were initially evaluated in May 2023 and updated again in July 2023. It should be noted that these characteristics are subject to change.

[c]Not available.

Downloading, Registering, and Using

In total, 2 researchers (NZ and KSW) downloaded and registered on all 4 apps (Clue, Flo, Period Tracker by GP Apps, and Stardust) using both an iOS and Android system between May 2023 and July 2023. All apps had a "log in" and "create an account" option that used an email and password or an existing Google or Facebook account and a passive or explicit agreement with the privacy policy and terms of service. The passive agreements had language such as the following—"by creating an account you are agreeing..."—whereas explicit agreements required a button to select "agree" before continuing with the registration. These steps can be observed in Figure 1. Enrollment flow varied between apps, with common information required for signing up being email, age, date of birth, and phone number.

XSL•FO
RenderX

Figure 1. Visualization of the reproductive health app selection and the registration on each app between May 2023 and July 2023.

Data Analysis: THESIS Evaluation Tool

To properly assess the reproductive health apps chosen, particularly regarding their privacy and security, it was important to find an evaluation tool that addressed these qualities. Unlike the commonly used Mobile App Rating Scale assessment tool that rates apps based on subscales, items, descriptors, and anchors, the THESIS evaluation tool dedicates one of its domains specifically to app privacy and security [47]. The THESIS evaluation tool consists of 6 domains on which an app is rated on a scale from 1, the lowest, to 5, the highest: transparency, health content, technical content, security and privacy, usability, and subjective rating. Due to the objective of this research being the security of user data, the security and privacy domain, consisting of 6 subcategories, was the part of the evaluation tool used. The subcategories and their rankings are shown in Textbox 1.

XSL•FO
RenderX

Textbox 1. Subcategories of the security and privacy domain of the transparency, health content, excellent technical content, security and privacy, usability, and subjective evaluation tool and their rankings.

- Protection against theft and viruses: does the app follow best practices in security with optimal antivirus and safeguards against breaches? This is found in the privacy policy of an app.
- Authentication: is the authentication procedure optimal? User experience is based on receiving an email or SMS text message notifications for creating an account, in addition to password protection for accessing the user's profile.
- Data sharing: when sharing information, does the app use best practices? This is found in the privacy policy of an app.
- Maintenance: does the app have regular cycles to update and patch its security? This is found in the Apple App Store or Google Play Store under "version history" for each app—last update occurred during the month of rating or the month before (the update schedule is very consistent; rating of 5), last update occurred 2 months before the time of rating (the update schedule is generally consistent; rating of 4), last update occurred between 3 and 5 months before the time of rating (the update schedule is a little inconsistent; rating of 3), last update occurred between 6 months and a year before the time of rating (the update schedule is completely inconsistent; rating of 2), and last update occurred >1 year before the time of rating (rating of 1).
- Signaling of breaches: if a breach occurs, does the app have a method to notify its users? This is found in the privacy policy or the terms and conditions of an app.
- Anonymization: does the app appropriately anonymize individuals? This is found in the privacy policy or the terms and conditions of an app [38].

  To note, the Federal Trade Commission (FTC) has expressed concern regarding the legitimacy of data anonymization as promised by multiple apps, not just reproductive health apps, calling claims as potentially deceptive trade practice and violating the FTC Act when untrue. Significant research has shown that anonymized data can often be reidentified, especially in the context of location data. One set of researchers demonstrated that, in some instances, it was possible to uniquely identify 95% of a dataset of 1.5 million individuals using 4 location points with time stamps [48].

The evaluation tool includes 2 additional columns dedicated to rationalizing the pros and cons of specific ratings. The Why Not −1 column indicates why points were not deducted from the app's score, whereas the Why Not +1 column indicates why points were deducted from the final score.

Results

Reproductive Health App Privacy Policy Summaries

With 1.8 million mobile apps available on the Apple App Store and 2 million available on the Google Play Store, both platforms have released their own guidelines for developers seeking to launch their apps [49,50]. The Apple App Review Guidelines have a specific section dedicated to privacy policy requirements, stating that all apps must provide their users with a privacy policy either within the app or as a link when developing for iOS. These privacy policies must "identify what data, if any, the app or service collects, how it collects and uses that data, confirm that any third party with whom an app shares user data (in compliance with these Guidelines)—such as analytics tools, advertising networks and third-party SDKs, as well as any parent, subsidiary or other related entities that will have access to user data—will provide the same or equal protection of user data as stated in the app's privacy policy and required by these Guidelines, and explain its data retention/deletion policies and describe how a user can revoke consent and/or request deletion of the user's data" [51]. These guidelines also include more information on secure user consent, data minimization, and data collection. The Google Play Store guidelines are similar, posted on the Google Play Console Help Center, and require developers to state how private user data are collected, protected, and handled. However, the expansion of the privacy policy requirement to all mobile apps released through the Google Play Store is recent, as of 2022 [52]. In addition to this, in July 2021, the Google Play Store began requiring apps to fill out a data safety form that needs to align with the apps' actual data use. That being said, the only Google Play Store requirements are that information such as where the data are sold to and how they are shared be stated in the data safety form. On the basis of this information, Google does not clearly state its concern for the privacy of its users. The same pattern was observed on the Apple App Store, with the only difference being Apple's location tracking option that pops up with every app downloaded. Because of these guidelines, the 4 reproductive health apps evaluated have their own data privacy policies separate from their terms and conditions that must be agreed to before use of the app.

Multimedia Appendix 2 [39-41,46] shows the analysis of each reproductive health app regarding its privacy policy, the type of data collected, how they are protected (varying types of encryption vs none at all to store sensitive data and protect them from being stolen, changed, or compromised), who they are shared with, what options are available for users seeking to delete or opt out of data sharing, and potential concerns that remain. In addition to this, a column was dedicated to assessing the accessibility of privacy policies to users, which often affects the probability of users reading through them rather than simply clicking on Agree to access the app functions, otherwise known as the clickwrap approach. Furthermore, both anonymization and end-to-end encryption are included in one section because they are used with differing data, such as anonymization for metadata such as IP addresses and end-to-end encryption for data input into the app by the user, and, thus, vary in data protection. Assessment of these apps was first conducted at the beginning of the research in November 2022 and then updated twice, once in May 2023 and again in July 2023 for the most up-to-date assessment. The final column of the table addresses concerns related to the methodology used by each app.

XSL•FO
RenderX

THESIS Evaluation Tool

After analysis of individual app policies, the THESIS evaluation tool allowed for a thorough comparison of the security and privacy of the 4 mobile apps selected. The tool was first used to assess the EU apps, Clue (Table 2) and Flo (Table 3), with Clue being the first due to its earlier release date, followed by the assessment of the US app Period Tracker by GP Apps first due to its earlier release date and then of Stardust as that is the most recently released app evaluated. This chronological order allowed for a better understanding of the changes made in the app privacy policies with the changing landscape of reproductive health rights. Scoring was based on an initial analysis of the apps in May 2023 that was repeated in July 2023 to see whether any changes were made as more state privacy laws were introduced. A description is provided for every score to explain the reasoning behind each grade. The subcategories are those of the THESIS evaluation tool and its score guide.

Table 2. Transparency, health content, excellent technical content, security and privacy, usability, and subjective evaluation of Clue, a European Union (EU) app that falls under General Data Protection Regulation protections, based on an initial analysis of the app in May 2023 repeated in July 2023. Score: 3.5 for the security and privacy domain.

Subcategory	Score	Why not –1	Why not +1
Protection against theft and viruses	1	—[a]	Not enough information available anywhere in policies or documents
Authentication	4	For verification, the app sends an email to the address used for registration, and the user is unable to input information into the app calendar without this verification; PIN[b], Touch ID (iPhone 5S-8), or Face ID (iPhone X-13) authentication is available and is intended to automatically encrypt Clue data and prevent someone else from accessing users' information through a user's device	Information on this feature is not explicitly stated; requires a look through the privacy policy on the app's website.
Data sharing	3	Data-sharing practices seem to be more transparent than those observed on other apps. The creators make it a point to state that privacy is one of their top priorities. It also follows guidelines of EU data privacy laws, which are said to be the strictest in the world.	However, Apple has its own ranking of data based on the analytics the app creators provide them with. This portion is contradictory as it states the following: "Data linked to you may be collected and linked to your identity: contact info, health and fitness, location, etc" [53]. Data are also stored, which poses threats if subpoenaed.
Maintenance	5	The app is updated almost every week. The last update occurred 5 days before rating.	—
Signaling of breaches	1	—	Not enough information available anywhere in policies or documents
Anonymization	3	The app states not to use any identifiable information of the users for any purposes, including data analyses. Encryption is used.	IP address collection poses a threat to user safety. HTTP is not the safest encryption method and "the data that is transferred over an HTTP connection is not encrypted, so you run the risk of third-party attackers stealing the information" [54].

[a]None.

[b]PIN: personal identification number.

XSL•FO
RenderX

Table 3. Transparency, health content, excellent technical content, security and privacy, usability, and subjective evaluation of the Flo app data use practices in July 2023. Score: 3.5 for the security and privacy domain.

Subcategory	Score	Why not –1	Why not +1
Protection against theft and viruses	4	General information provided, such as an email for the data protection officer. The website mentions vulnerability testing and system monitoring or alerting.	Difficult to test accuracy in real-life settings unless issues arise.
Authentication	4	The app sends an email to the address used for signing up for verification, and the user is unable to input information into the app calendar without this verification. There is an option to password protect the app to enable secure access.	Secure access is not a pre–set up option; users have to know how to access it and turn it on. This is only mentioned in the app's web page rather than being originally included in the app.
Data sharing	2	At first glance, it looks good, and data are not said to be sold to other companies. A user's cycle can be linked to other apps. There is an emphasis on sharing rather than selling. The data stored are also encrypted.	It is said that personal data may be processed in relation to the company's interests in providing services, commercial interests, and "wider societal benefits." The app connects with AppsFlyer for marketing and promotions and requires consent, but consent is required to make an account regardless. This involves a lot of technical identifiers. The "security of personal data" section is contradictory as it says that the data are encrypted [40]. It is important to note that encryption does not mean that data are not accessible by the company doing the encryption. It just means that the data do not reside on their servers in plain-text format. Use of the term "encrypted" gives the impression that the company cannot see the data, whereas in reality, it just means that the data are not stored in a plain-text format.
Maintenance	5	The app is updated almost every week. The last update occurred 5 days before rating.	—[a]
Signaling of breaches	4	There is a separate section in the policy for security breaches and what steps the app will take if that occurs. A notification is said to be sent out, and the app will take steps such as deleting user information, resetting passwords, and logging out of user devices if such a breach occurs.	Does not seem to be responsible for third-party data breaches (although it states otherwise) given a previous data breach with third-party Facebook Analytics tool despite existing safeguards.
Anonymization	3	The app states not to sell any identifiable information. The app also gives the option to be used in anonymous mode. There is an option to not allow the app to track Apple Health or Fitbit statistics. All data are encrypted using KMS[b] [55].	IP address and unique device identifiers (IDFA[c]) are collected. The Apple App Store also has contradictory information saying that data are linked to a user, such as location, contact information, identifiers, user content, and sensitive information.

[a]None.

[b]KMS: Key Management Service.

[c]IDFA: identifier for advertisers.

Flo users in the United States are subject to US laws, but the company must also comply with EU laws for EU-based users. In Table 3, scoring was based on an initial analysis of the app that was repeated 2 months later to see whether any changes were made as more state privacy laws were introduced. A description is provided for every score to explain the reasoning behind each grade. The subcategories are those of the THESIS evaluation tool and its score guide. A major concern is the app's use of IP address tracking as well as the use of data by third parties for advertising and marketing.

Period Tracker by GP Apps (Table 4) is a US-based app potentially required to adhere to the General Data Protection Regulation because of its European users. Scoring was based on an initial analysis of the app in May 2023 that was repeated in July 2023 to assess changes as more state privacy laws were introduced. A description is provided for every score to explain the reasoning behind each grade. The subcategories are those of the THESIS evaluation tool and its score guide, as seen in the previous 2 evaluations.

XSL•FO
RenderX

Table 4. Transparency, health content, excellent technical content, security and privacy, usability, and subjective evaluation of Period Tracker by GP Apps' data use practices in July 2023. Score: 2 for the security and privacy domain.

Subcategory	Score	Why not –1	Why not +1
Protection against theft and viruses	2	Some security is listed on the app's website, such as limiting access to information to authorized employees and contractors.	Does not seem to be held accountable for any breaches or collection of data that may occur.
Authentication	3	Option to turn on finger ID or passcode is available.	It is not clearly stated where this option is and how to actually use it.
Data sharing	2	—[a]	Limited information available, which makes it seem even more as though the app does not want to disclose its privacy and data sharing information. Nothing about unidentifiable information or how sharing occurs is noted.
Maintenance	2	—	Last update and bug fix was 6 months before rating. Seems to be an update pattern based on the version history available on the app store.
Signaling of breaches	2	It does say that users will be informed of any changes occurring within the system; this may mean breaches as well.	No information on breaches is available other than the app stating that they are possible and they are not responsible.
Anonymization	2	Option for using without an account is possible but extremely limited.	Nothing else is noted about anonymization from the app itself. However, the app store does say that one can disable their information being used by third parties, but this is written in tiny letters on the website.

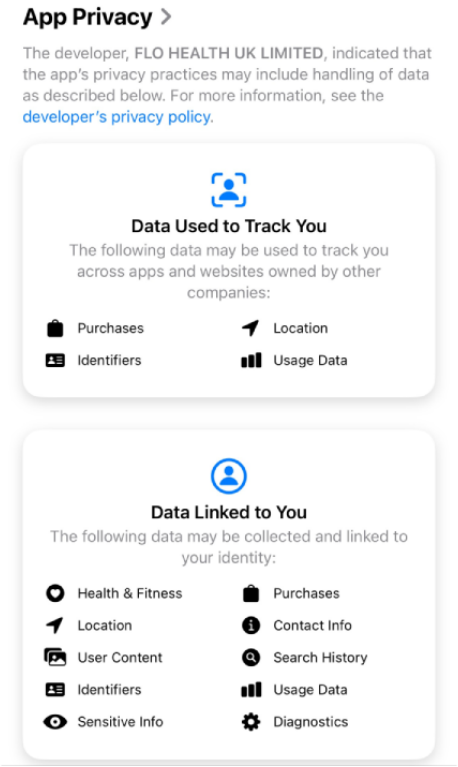
[a]None.

The final app evaluated was Stardust (Table 5), an app that underwent internal data storage and use and account creation modifications as a response to *Dobbs v Jackson* and the wave of worry among menstruating persons using reproductive health apps [56]. Stardust was purposely chosen because of its recent emergence and emphasis on user data protection and different account creation practices. Stardust emphasizes end-to-end encryption and minimal data collection. Table 5 scoring was based on an initial analysis of the app in May 2023 that was repeated in July 2023.

Table 5. Transparency, health content, excellent technical content, security and privacy, usability, and subjective evaluation of the Stardust app's data use practices in July 2023. Score: 4.5 for the security and privacy domain.

Subcategory	Score	Why not –1	Why not +1
Protection against theft and viruses	3	Some information regarding theft was provided.	General statement: "We take all reasonable and appropriate measures (including encryptions) to protect all collected Personal Data from loss, theft, misuse, and unauthorized access" [46].
Authentication	5	The app sends an email to the address used for signing up for verification, and the user is unable to input information into the app calendar without this verification. Uses Rownd, a privacy-first authentication platform.	—[a]
Data sharing	4	Data-sharing practices seem to be more transparent than those observed on other apps, closer to what is observed in the EU[b]. Data are said to be encrypted.	However, data are still said to be potentially provided if required by government agencies. It is not clear what that includes.
Maintenance	5	The app is updated almost every week. The last update was 1 day before rating.	—
Signaling of breaches	1	—	No information available anywhere in policies or documents
Anonymization	5	End-to-end encryption that is only accessible to the user. The policy states to also not track or use IP addresses. Even if the government asks for the information, it should not be linked to a specific user. Users are also able to come up with their own username and are not required to use their legal name.	—

[a]None.



[b]EU: European Union.

App Store Information Discrepancies

Another important aspect to consider are the discrepancies observed between data collection information on the Apple App Store and on the apps themselves. Despite app promises of data privacy, there are notable differences between their respective privacy policies and what is stated in the Apple App Store. As shown in Figure 2 [57], the Apple App Store included its own description of potential data collection based on each app. While Flo has a history of violating the privacy policy promised to its users, the data that may be collected as listed by the Apple App Store are different from those listed in the app's privacy policy.

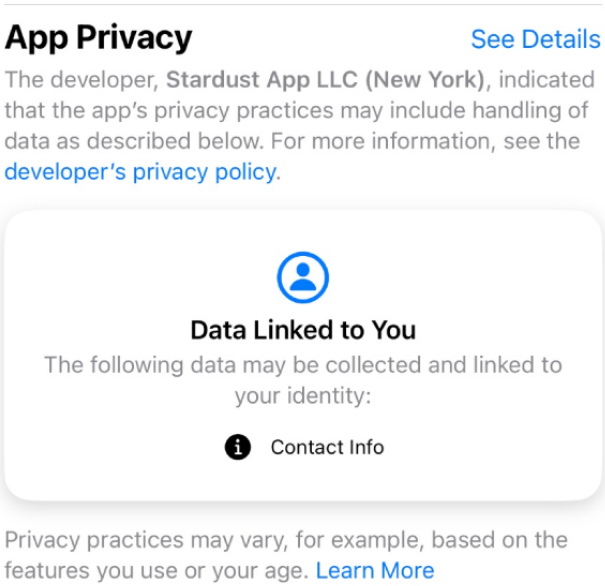

Figure 2. Apple App Store description of Flo data collection and sharing.

This is in comparison to the app privacy summary of Stardust, which more closely aligns with the information provided in the app's own privacy policy.

Such discrepancies make it difficult for users to determine what data are being collected and shared and, thus, cause confusion when deciding what reproductive health app should be used. These discrepancies are also reflected in Figures 2 and 3 analyzing the apps, where contradictory information alters app ratings.

Figure 3. Apple App Store description of Stardust data collection and sharing for comparison with that of Flo [39].

XSL•FO
RenderX

In addition, another notable discrepancy is the content rating for the apps as observed on the Apple App Store and Google Play Store. While 75% (3/4) of the apps have ratings of 12+ on the Apple App Store, all 4 apps are rated E for Everyone on the Google Play Store. Given the content of the apps and the sensitivity of the data provided, the Apple App Store rating should be considered the more suitable one. It is interesting to note that a statement on the Google Play Store mentions that "content ratings on Google Play are provided by the International Age Rating Coalition (IARC) and are designed to help developers communicate locally relevant content ratings to users" and, thus, makes it difficult to understand what causes the discrepancy in content rating on both platforms [59].

Discussion

Principal Findings

This study evaluated popular reproductive health apps and their respective data privacy policies, compared data privacy laws governing these apps in the United States and the EU, and recommended best practices for users and app developers to ensure user data safety. The characteristics of reproductive health app data privacy, safety, and use were indicated. Using the THESIS evaluation tool, the privacy and security features of 4 reproductive health apps were identified, and the determined discrepancies in these features were described in the previous sections. Although there are successes and good practices in app user data management, potential concerns remain. Adopting best practices from multiple sources, such as end-to-end encryption, can help enhance the privacy and security of user data on reproductive health apps.

Potential Concerns

A careful evaluation of the 4 selected reproductive health apps identified Stardust as the most privacy-centered app at the time of this qualitative content analysis. It should be noted that policies and data use practices are continually evolving as apps adapt to new requirements and guidelines. Although Stardust has lower ratings on both the Google Play Store and Apple App Store, which is attributed to its recent release and interface issues, it provides the most comprehensive data protection to its users. This is due to its limited data collection, such as excluding IP tracking; transparent privacy policy; specified encryption methods; options for deleting previously shared data; and the use of third-party platforms that assess deidentified data in a secure manner. While Clue, Flo, and Period Tracker by GP Apps collect IP address data, Stardust focuses on location data, such as country and time zone data, which minimizes the likelihood of connecting a user to a specific location and any reproductive health information. Furthermore, the app is transparent about the third parties it engages with and how user data are used. Although Flo and Clue use encryption to protect the confidentiality of the digital data stored across various platforms, the combination of IP address collection and the extensive use of third-party data brokers for analytics may pose unique risks to users, especially when linked with sensitive information such as missed periods and unique device identifiers [18].

When comparing the privacy and security of the data collected on all 4 apps—Clue, Flo, Period Tracker by GP Apps, and Stardust—determining what factors make one reproductive health app during this time a better and safer choice for users than others was critical. Although existing privacy policies attempt to combat the easy accessibility of user data and ensure stricter regulation on data sharing and breaches, the ultimate responsibility to ensure the safety of reproductive health information and app users falls on the app developers themselves. In this assessment, these factors included how accessible the privacy policy of each app is; what data are collected and how they are made secure; which, if applicable, third parties data are shared with and for what purposes; and the ease with which users may have their data deleted and opt out of future data collection.

In addition to this, a common trend among all apps was the questionable access to privacy policies and user agreements that does little to assure and encourage users to read through these agreements rather than selecting "Accept" just to gain access to the apps' functions.

Despite identified potential concerns, for users in regions without strict abortion regulations, Clue and Flo may be safe choices considering that IP address tracking alone, without any other identifiable data-point tracking as the apps promise, should not pose a significant threat. For full protection, users should create anonymous accounts, as facilitated in Flo and anticipated in Stardust, and enable password protection where available. Most importantly, users are advised to avoid reproductive health apps such as Period Tracker by GP Apps due to its infrequent system updates, lack of accountability, inadequate encryption in data collection and sharing, and insufficient transparency in their privacy policies. Using an app that does little to protect individual users may make it prone to data breaches and risks data use for things that the user is not aware of, such as during subpoenas or other investigations.

Comparison With Other Work

The findings of this study have also been supported by previous data privacy research, systematic reviews, and scoping reviews conducted in relation to numerous mHealth apps, including mental health, diabetes management, and physical activity tracking. Although they used different analysis methods from the THESIS evaluation tool, Benjumea et al [60] also concluded that the re-evaluation of the data collected on these apps, stated as "minimization" by the General Data Protection Regulation, is necessary to determine whether the scope of the personal information collected on these apps is beneficial to the users or may be limited to protect user data. In addition, the research conducted by Alfawzan et al [61] involving the 23 most popular mHealth apps for menstruating persons emphasized the threats associated with third-party data sharing, determining that 87% of the apps assessed were found to partake in such sharing and stating that "user consent, especially about sharing data in general or with a third party, is a concern for women's privacy...research indicates that end users do not have full awareness of what their consent entails." Furthermore, key findings of the analysis of reproductive health apps, including Flo, in the article "In Post Roe v Wade Era, Mozilla Labels 18

XSL•FO
RenderX

of 25 Popular Period and Pregnancy Tracking Tech With *Privacy Not Included Warning" by the Mozilla Foundation concluded that there is no clear stand on data sharing with law enforcement; password requirements are especially low; and there is an absurd amount of personal information being collected ranging from device IDs and IP addresses to pregnancy symptoms and physicians' appointments [62].

Other articles, such as "Mobile Health and Fitness Apps: What Are the Privacy Risks" by Privacy Rights Clearinghouse, outline discussed concerns about data collection for advertising purposes, stating that "mobile applications, especially apps that you download for free, depend on advertising to make money...they may share personally identifiable information with advertisers, or allow ad networks to track you...if an application collects your universal device ID (UDID) or embeds a unique ID in the application you download, analytics data can be traced back to you personally" [63]. This concept closely relates to the accusations previously made against Flo regarding their user data sharing between 2016 and 2019.

Importance of Encryption and Real-Life Application

Following the overruling of *Roe v Wade*, major reproductive health apps such as those assessed in this study have taken it upon themselves to work toward a safer way for menstruating persons to track, monitor, and maintain their reproductive health. With the introduction of end-to-end encryption in the late 90s, these apps have adopted a way to provide users with data privacy while also collecting enough user analytics to better their own apps [64]. Such encryption methods, as observed in Stardust, are meant to ensure that sensitive data such as personal health information are protected from unauthorized disclosure. "In [end-to-end encryption], the data is encrypted on the sender's system or device, and only the intended recipient can decrypt it. As it travels to its destination, the message cannot be read or tampered with by an internet service provider (ISP), application service provider, hacker or any other entity or service" [65].

One of the issues that only Stardust addressed is the collection of IP addresses and location tracking. Despite end-to-end encryption dispersing and disconnecting user data from user profiles, IP location tracking and mobile ID tracking leads to the risk of connecting deidentified user information with specific locations and phone use. For example, if a user is located in a US state that has banned abortions, such as Alabama, Idaho, Tennessee, and Texas, there is a risk that state officials could obtain personal data that reveal pregnancy or potential termination of pregnancy based on period or symptom tracking [66-68]. In addition to this, the location data tracked through these apps could also reveal a user's visits to abortion clinics via IP addresses. If state agencies receive a subpoena, they may obtain this information regarding users and the medical professionals providing banned procedures. In states where abortions are illegal, lack of proper data protection raises implications that could endanger users after the overruling of *Roe v Wade*, especially among those with historically inequitable health situations [69]. Increased risk of government officials legally obtaining personal information, even IP addresses that may directly link data points to an individual user, due to these laws has led to the assessment of the data safety provided by individual apps and what steps may be taken from the users' and the developers' side to ensure future security. In addition to this, some companies such as Flo and Clue have developed the option for users to create passwords to protect their app accounts through encryption methods that ensure access to the app only through the user's phone. Analyzing the proper steps that Flo, Clue, and Stardust have taken to heighten their users' safety allowed for the assessment of data privacy lapses in Period Tracker by GP Apps.

Prioritizing Marketing Over User Protection

Evaluation of privacy policies also shed light on what role data collection plays apart from direct user experience improvement. For all the apps except Stardust, it is explicitly stated that some data are shared with third-party apps for marketing purposes, such as reaching potential users based on current user preferences. The issues associated with this are similar to what happened with Flo sharing its user information with Facebook Analytics services that resulted in a data breach. Flo's statement on this data breach allows for insights on what user data have been used for recently—insights from Facebook Analytics found "that it's challenging for [Flo] users to log childbirth and enter postpartum mode...This finding was driven by the insights from analytical systems, and with its help [Flo] managed to improve user experience and stressless" [70]. However, many, including the FTC, have speculated "...that Flo's data-sharing practices had allowed third-party companies to use said personal health information expansively, including for advertising..." [71]. Apart from Flo, apps such as Clue also state that they use data for promotional purposes. With the sensitivity of the data at hand on these apps, reproductive health app developers may consider limiting their marketing resources and turning to internal analytics without the use of third parties unless third parties have their own practical user privacy tools that may be trusted and proper business associate agreements are in place.

Recommendations

With the thorough analysis of the 4 most popular reproductive health apps available on both the Apple App Store and Google Play Store, it is possible to make recommendations for app developers, major app platforms, and individuals looking to use reproductive health apps.

First, to ensure user data safety, developers should prioritize the access to and reading ease of privacy policies. While users are currently required to agree to the terms and conditions of reproductive health apps before the use of the apps' features, there is no guarantee that these policies are actually being read and not just bypassed. Although court cases such as *Bassett v Electronic Arts Inc* currently require terms and conditions to be clearly visible to users (ie, not hidden by fonts or an unclear location of the link), all the apps evaluated used the clickwrap approach for user privacy policy consent [67,72]. To make it more probable that users are actively reading the conditions they are agreeing to, using a scrollwrap approach, one that requires users to scroll through the entire policy agreement before checking off an "I accept" button that becomes active only once the scrolling is completed, is preferable [73]. With this method, app privacy policy writers should opt to highlight the most important aspects of the agreement in layman's terms

XSL•FO
RenderX

to capture the user's attention. While this does not guarantee that users are actively reading what they are agreeing to, if information is highlighted, it may catch users' attention better. App developers may also consider shifting to preset anonymous modes of user profiles, as observed as an option in Flo, as well as requiring virtual private network use to access the app functions to limit the chances of data being specifically linked to individual users.

Second, the evaluation of previously enacted policies also requires adaptation to the ever-changing field of technology that poses new threats to mHealth app users.

Third, users should be encouraged to make educated decisions when selecting reproductive health apps for personal tracking, monitoring, and management. Users should be aware of what data are collected; where those data go; and what risks arise if their personal information is shared, handled, or stored differently than what is expected or promised. This could be made possible by major app platforms such as the Apple App Store and Google Play Store closely monitoring the collection of data on reproductive health apps and making sure that apps are constantly updating their users on changes to data privacy settings, as well as adhering to data-sharing restrictions stated in individual app policies. Platforms should also consider altering their rating criteria, making data privacy one of the most crucial qualities of a highly rated app and, thus, increasing user health literacy and guiding them to the secure apps.

Finally, end-to-end encryption and data anonymization methods should both be used to protect not only the reproductive health data that users have provided to the apps but also the data collected by the apps themselves, including device IDs and IP addresses. Such practices would further ensure that deidentified personal health information may not be linked to a specific user while also providing developers with enough user analytics to continue updating the app's functionality. Furthermore, it is vital for apps to follow anonymization rules set out by the FTC and other regulatory systems rather than make false promises that do little to protect user data.

Strengths and Weaknesses

While many other studies have assessed the data protection aspects of reproductive health apps, this is one of the first that takes a comprehensive approach to data privacy, from the analysis of existing data privacy policies to individual encryption methods. In addition to this, having more than one researcher assess each individual app allowed for limitation of bias and increase in reliability and validity. However, there are a few weaknesses concerning this study. These include the lack of generalizability as only 4 apps were assessed, whereas there are >25 reproductive health apps on both the Google Play Store and Apple App Store platforms; the constant updates of Clue, Flo, and Stardust that change the way in which each protect, collect, and share data; and the ever-changing field of data privacy, with company statements and policies changing since the beginning of this study in 2022. Furthermore, a limitation is the convenience sampling conducted through which the 4 apps were chosen as there was no systematic search of apps conducted apart from that of country of origin for the 2 EU apps listed. Finally, what was true last year regarding these apps may not be true today. With the changing landscape of data privacy policies and federal and local governments changing platform requirements, these apps may have taken steps to further protect user data. In addition, most apps are constantly updating their own policies and interfaces.

Conclusions

As stated by Ritesh Kotak, a Toronto cybersecurity and technology analyst quoted in CBC Canada's "Americans are being urged to delete period tracking apps. Should Canadians do the same?" article, "When you downloaded that app, how much did you pay for it? What's your monthly subscription fee? If the answer is zero, if you're not paying for the product, then you are the product" [68]. Moving forward in a technology-based society heightens the risk of information sharing and data security violations, which becomes of increased concern when combined with reproductive health changes within the Supreme Court and local government agencies. Because of this, it is crucial for the landscape of data privacy protection to reflect the changes being made and prioritize the safety and protection of users. More studies emphasizing the use of data collected by reproductive health apps and long-term threats caused by the sharing of such data, in addition to lapses in outdated policies in place, will further assist users in making smart app selection decisions and encourage app developers to assert user data protection as their top priority. Reproductive health apps are meant to function as resources available to the general population designed to make their day-to-day lives and activities simpler; they are not meant to be guidelines for maternal or menstruating health and, thus, should be treated as such. That is why limiting the data collected by these apps and taking precautions to ensure data privacy is in the best interest of users and app developers.

Abstract

Background: Increasing life expectancy has led to a rise in nursing home admissions, a context in which older adults often experience chronic physical and mental health conditions, chronic pain, and reduced well-being. Nonpharmacological approaches are especially important for managing older adults' chronic pain, mental health conditions (such as anxiety and depression), and overall well-being, including sensory stimulation (SS) and therapist support (TS). However, the combined effects of SS and TS have not been investigated.

Objective: This randomized controlled trial examines the specific and combined effects of brief SS and TS interventions on older adults' physical and mental health and pain intensity levels, among individuals living in nursing homes.

Methods: A total of 96 patients aged 65-99 years from a nursing home were randomly assigned to 3 groups: SS, TS, and combined SS+TS interventions, each delivered as four 20-minute sessions. SS was implemented using a multisensory Snoezelen room. Pain intensity levels (per a Visual Analog Scale), blood pressure, heart rate, blood oxygen saturation, and hand grip strength (using a Jamar hand dynamometer) were measured before and after each of the 4 weekly therapeutic sessions. In addition, life satisfaction (per the Satisfaction with Life Scale) and anxiety (per the 7-item General Anxiety Disorder Scale) were evaluated before and after the whole intervention. Mixed model analyses tested the relative efficacy of the 3 interventions, applying simple slope analysis with Tukey correction. Study rationale and analytical plans were preregistered.

Results: The combined intervention of SS and TS (SS+TS) resulted in reduced pain levels compared with SS (B=0.209, P=.006) and TS alone (B=0.23, P=.002) over 4 sessions ($F_{6,266}$=2.62; P=.017; R^2=0.23). Further, the combined SS+TS intervention resulted in reduced systolic blood pressure versus SS (B=0.09, P=.01) and TS alone (B=0.016, P<.001) groups ($F_{6,272}$=5.42; P<.001; R^2=0.29). In addition, the combined SS+TS intervention resulted in an increased grip strength versus SS (B=–0.35, P=.003) and TS alone (B=–0.032, P=.008) groups ($F_{6,273}$=2.25; P=.04; R^2=0.19). Moreover, combined SS+TS resulted in an improvement in life satisfaction (B=–4.29, P<.0001) compared with SS (B=–2.38, P=.0042) and TS alone (B=–1.20, P=.13) groups ($F_{2,39}$=3.47; P=.04). Finally, SS+TS demonstrated greater improvement in symptoms of general anxiety disorder (B=10.64, P<.0001) compared with SS (B=3.30 P=.01) and TS alone (B=1.13, P=.37) ($F_{2,38}$=13.5; P<.001) groups. No differences between the interventions

XSL•FO
RenderX

were shown for blood oxygen saturation ($F_{6,273}$=2.06; P=.06), diastolic blood pressure ($F_{6,272}$=1.12; P=.35), and heart rate ($F_{6,273}$=1.33; P=.23).

Conclusions: The combined intervention of SS and TS showed therapeutic benefits for pain management and physical and mental health of older adults living in nursing homes, relative to each therapeutic component in isolation. This brief intervention can be readily implemented to improve well-being and optimize therapeutic resources in nursing home settings.

KEYWORDS

Snoezelen room; mental health; sensory stimulation environment; social support; nursing homes; older adults

Introduction

The global population is witnessing a notable rise in life expectancy, leading to an expanding aging population. According to the World Health Organization (WHO), older adults (aged 65 and above) made up 12.3% of the global population in 2017, with this proportion expected to surpass 22% by 2050 [1]. Similar trends are evident in the Middle Eastern region. For example, Israel's older adult population (aged ≥65 years) accounted for approximately 12%-13% of its total population in 2020, mirroring trends observed in other developed countries. While the United Nations defines older persons as those aged 60 years and older, this study follows the widely accepted threshold of 65 years and older, commonly used in health-related studies and policies. This demographic shift has driven a significant increase in the number of nursing home beds globally, with the availability of hospital beds in nursing homes rising by more than 200% between 1988 and 2015 [2-5].

Individuals living in nursing homes often encounter challenges related to functional and cognitive impairments, stemming from the natural aging process, polypharmacy, and various health conditions [3,6]. Additionally, they may struggle with loneliness and emotional distress [7]. Therefore, a key therapeutic focus is on preserving and enhancing functional and cognitive abilities while promoting life satisfaction and overall quality of life [2].

Multisensory interventions, such as Snoezelen room therapy, alongside social support, are essential components of care for older adults in nursing homes [8]. Snoezelen room therapy is a form of multisensory stimulation (multi-SS) that involves the gradual application of sensory stimuli to enhance an individual's sensory perception and integration. Numerous studies have emphasized the unique benefits of multi-SS interventions combined with therapist support (TS) in improving physical and mental health outcomes. These include positive effects on heart rate, blood pressure, blood oxygen saturation, depression, anxiety, and pain management [1,2,6,8].

In recent decades, there has been an increasing interest in using multisensory treatment approaches—incorporating visual, auditory, olfactory, and tactile stimulations—to improve the well-being of older adults. Originally developed in the 1960s and 1970s in the Netherlands and the United States for children with learning difficulties and developmental intellectual disabilities, multi-SS environments (MSSEs) have consistently shown benefits across diverse populations. Over time, the scope of MSSE has broadened to include older adult populations, demonstrating success in addressing conditions such as dementia and Alzheimer disease, as well as mental health concerns and other geriatric conditions [1,2,4,6].

In recent years, an expanding body of evidence has suggested that MSSE, especially through Snoezelen room therapy, shows promise as a valuable intervention for enhancing the well-being of older adults. MSSE interventions have been shown to improve communication with patients experiencing various communication disorders and a lack of expression, a common challenge among older adults living in nursing homes (eg, dementia) [1,7]. It creates a "listening" channel to internal sensations by enhancing individuals' sensory regulation, which may serve as an alternative to verbal communication [8].

Previous research has consistently indicated that MSSE interventions, particularly Snoezelen room therapy, can lead to significant improvements in both physical and mental health. Physiological measures, such as heart rate and blood oxygen saturation, have shown positive changes after MSSE sessions [8-10]. Moreover, these interventions have been shown to be effective in enhancing psychosocial abilities and reducing agitation, behavioral disorders, anxiety, and depression among older adults. This, in turn, contributes to overall improvements in life satisfaction and fosters better social relationships and participation in meaningful activities [1,2,8,11].

An effective therapeutic tool within the MSSE approach is Snoezelen room therapy [8,11], which provides concentrated multi-SS while personalizing the intensity of the experience (Figure 1) [1,12,13].

XSL•FO
RenderX

Figure 1. Demonstration of the Snoezelen room therapy.

The Snoezelen room is a specially designed space equipped with various sensory systems, providing a unique therapeutic environment for individuals. This innovative therapy involves the careful integration of lighting, sound, smell, and touch elements to create a multisensory experience. Guided by qualified therapists, individuals can participate in Snoezelen room sessions that evoke feelings of success, tranquility, pleasure, and contentment. One of the key strengths of the Snoezelen room intervention is its nonjudgmental and nonevaluative nature, offering a safe space where participants can explore their senses without fear of failure or criticism [4,14]. Beyond the previously mentioned benefits, Snoezelen room therapy has also been found to reduce pain sensations and enhance motivation, which is a crucial factor for participation in various daily activities [15].

Older adults may often experience social isolation and reduced social connections [16]. Social support has proven effective in alleviating depression, anxiety, and loneliness among older adults living in nursing homes, and it has also been shown to be a protective factor against depression [17,18]. Additionally, social support and social touch have a positive impact on reducing stress and pain intensity [19,20].

The role of therapists' social support in enhancing the well-being of older adults, especially those in nursing homes, is increasingly recognized as a valuable intervention. Numerous studies have shown that the presence of dedicated and compassionate therapists can lead to significant improvements in self-esteem, pain perception, and overall quality of life among older adults [16,21]. A lack of social support among older individuals experiencing chronic pain can contribute to worsened mental health conditions and an increased risk of suicide [19,22]. In the context of nursing home care, there is a pressing need for targeted interventions that emphasize TS to effectively enhance the mental and physical well-being of older adults [16,17,23].

While both multi-SS and TS have been individually recognized for their potential to improve the well-being of older adults, the integration of these interventions remains relatively unexplored. Combining multi-SS with dedicated TS has the potential to create a more profound impact on the overall well-being of older individuals compared with each intervention used alone. By synergistically addressing both the sensory and social needs of older adults, this integrated approach may lead to better pain management and improved mental health outcomes.

In this study, we aim to address the existing research gap by exploring the potential benefits of an integrated intervention that combines multi-SS with TS for the care of older adults. This pilot randomized controlled trial (RCT) is designed to primarily assess the feasibility of implementing this combined intervention and to provide preliminary insights into its effectiveness. Our objectives are 2-fold: first, to determine whether this approach can be successfully implemented in nursing home settings, and second, to gather initial evidence on its potential for future large-scale trials. We will also evaluate the combined impact of SS and TS on pain management, as well as the overall physical and mental health of older adults. We hypothesize that the synergistic effect of integrating SS with TS will lead to more significant improvements in pain reduction and physical and mental health outcomes compared with either intervention applied in isolation.

Methods

Study Design

A randomized clinical trial was conducted over 1 year to examine the combined effect of SS and TS on pain intensity, as well as the mental and physical health of older adults living in nursing homes. The study specifically targeted older adults residing in these settings. All participants were randomly assigned into 3 groups by the supervising researcher using a stratification strategy to ensure balanced groups (see the "Randomization" section). The executing researcher and research staff responsible for assessments were blinded to the randomization process.

XSL•FO
RenderX

Sampling Method and Randomization Process

Participants were recruited using a convenience sample from Ahuzat Hazafon Geriatric Nursing Hospital. Eligible participants were residents aged 65 years or older who had lived in the facility for at least three months and were capable of participating. Exclusion criteria included uncontrolled epilepsy and severe behavioral disturbances. Following eligibility screening, participants were assigned to 1 of 3 groups—SS, TS, or the combined SS+TS group—using stratified randomization. Stratification was based on age, sex, and cognitive level to ensure balanced groups. Randomization and allocation were overseen by an independent researcher who was not involved in the trial's day-to-day activities. Additionally, research staff responsible for conducting baseline and postintervention assessments were blinded to group assignments to minimize assessment bias.

Research Process

Patients, with the approval of their custodians, were invited to participate in the study. Each eligible participant attended 4 weekly therapeutic sessions based on their group assignment: SS (SS intervention using Snoezelen room therapy, involving gradual multi-SS without social interaction), TS (therapist's social support intervention only, without SS), or SS+TS (a combined intervention of both SS and therapist's social support). Each session lasted 20 minutes. Immediately before and after each session, we collected objective measures, including pain intensity, blood pressure, blood oxygen saturation, hand grip strength (HGS), and heart rate, from each participant. Additionally, eligible participants completed subjective assessments (Multimedia Appendix 1) to measure their satisfaction with life and anxiety levels at the beginning and end of the study.

Sample Size

A prestudy power analysis was conducted, and the sample size was calculated based on an effect size of Cohen d=0.40, with a power of 0.80 and a type I error rate of 0.05/6 (0.0083) to account for 6 primary outcomes [18]. This analysis resulted in an estimated sample size of 102 participants.

Outcome Measures

The objective measures included systolic and diastolic blood pressure, heart rate, blood oxygen saturation, and HGS. These metrics were assessed before and after each session. Patient-reported outcomes included life satisfaction, current pain, and general anxiety. Life satisfaction and general anxiety were assessed before the first session and after the last session, while pain was evaluated before and after each session.

Research Tools

The following tools and instruments were used in this study:

- Blood pressure, heart rate, and blood oxygen saturation were measured using the "Welch Allyn" measuring instrument, a commonly used tool in clinical and research settings [24].
- HGS was assessed using the Jamar hand dynamometer, a valid and reliable tool for measuring muscle strength [25,26].
- Life satisfaction was measured using the Satisfaction with Life Scale (SWLS), a short 5-item instrument with high internal reliability (Cronbach α=0.93) and good test-retest reliability (0.84/0.80 for immediate/over a month interval) [27,28]. The SWLS has been translated into Hebrew and validated in multiple studies within the Israeli population, including older adults [29].
- Pain intensity was evaluated using the Visual Analog Scale, a 10-cm ruler with facial illustrations, which has been validated for pain assessment in older adults [30,31].
- General anxiety was assessed using the 7-item General Anxiety Disorder (GAD-7) Scale. The scale is considered valid and reliable for both clinical and research use, with a high level of internal reliability (Cronbach α=0.89). The literature demonstrates the effective use of the GAD-7 in the older population [32,33].
- The MMSE is widely used in Israel and has been validated in several studies involving older Israeli adults [34]. The Hebrew version of the MMSE demonstrated strong psychometric properties, including good internal consistency (Cronbach α=0.82) and excellent test-retest reliability across cognitive domains. It has been found to be a valid tool for assessing dementia in the Israeli older adult population [34].

Prevention and Treatment of Selection Bias

To minimize selection bias, participants were recruited through a convenience sample, and stratified random assignment was used to evenly distribute potential confounders among the study groups. Additionally, the researcher conducting the study was blinded to the group assignments to reduce bias in data collection and analysis.

Treatment of Confounders and Modifiers

To address confounding variables, statistical control was applied. Sex and age, known universal variables that can act as confounders, were included as control variables in the statistical analysis. This approach ensured that any observed group differences were not solely influenced by these variables.

Data Analysis Methods

Group differences were examined using the chi-square test for categorical variables and a 1-way analysis of variance for continuous variables. For session-level outcomes, including blood pressure, blood oxygen saturation, heart rate, HGS, and pain intensity, percentage changes from presession to postsession were calculated. These changes were then analyzed using mixed models to test the differences between treatments over time, defining an interaction between time and treatment. Tukey-corrected post hoc analysis was applied for significant interactions. Pairwise contrasts were used to compare group differences at each session, with participant-based random intercepts and session slopes defined. The analysis of anxiety and life satisfaction outcomes was conducted using mixed effect models to compare pre- and postintervention differences across groups. When significant differences were detected, intervention-specific slopes were further examined using Tukey correction to account for multiple comparisons.

XSL•FO
RenderX

Ethical Considerations and Approval

Participants were recruited by an occupational therapist who contacted all eligible patients living in the nursing home. The researcher explained the purpose of the study, ensured voluntary participation, and clarified that nonparticipation would not affect the patients' or therapist-patient relationship. Informed consent was obtained from participants or their custodians, particularly for those lacking sufficient cognitive capacity. The study was preregistered with ClinicalTrials.gov (registered ID NCT05394389) and received ethical approval from the Faculty of Social Welfare & Health Sciences Ethics Committee at the University of Haifa (approval number [112/21]).

Resources, Equipment, and Physical Tools

The study was conducted at Ahuzat Hazafon Geriatric Nursing Hospital, which provides medical, nursing, and paramedical services to its residents in mentally ill and nursing wards. The Snoezelen room where the study was conducted was a white, furnished space equipped with various SS systems, including lighting, audio, odor distribution, and massage systems. The room already had visual, auditory, tactile, and aromatic SS systems in place, which were used during the study.

Results

Participants

The mean age of participants was 82.2 (SD 7.92) years, with the majority being women (62/96, 65%; Table 1). Most participants exhibited some degree of cognitive decline (mean Mini-Mental State Examination [MMSE] score 15.4, SD 8.45). The analysis indicated no significant differences between the groups in MMSE scores ($F_{2,93}$=1.51; P=.32). Additionally, no significant differences were found among the 3 intervention groups for gender, age, cognitive state, or pain intensity (all Ps>.2). Complete statistical analysis is presented in Multimedia Appendix 2. Participant recruitment is detailed in Figure 2.

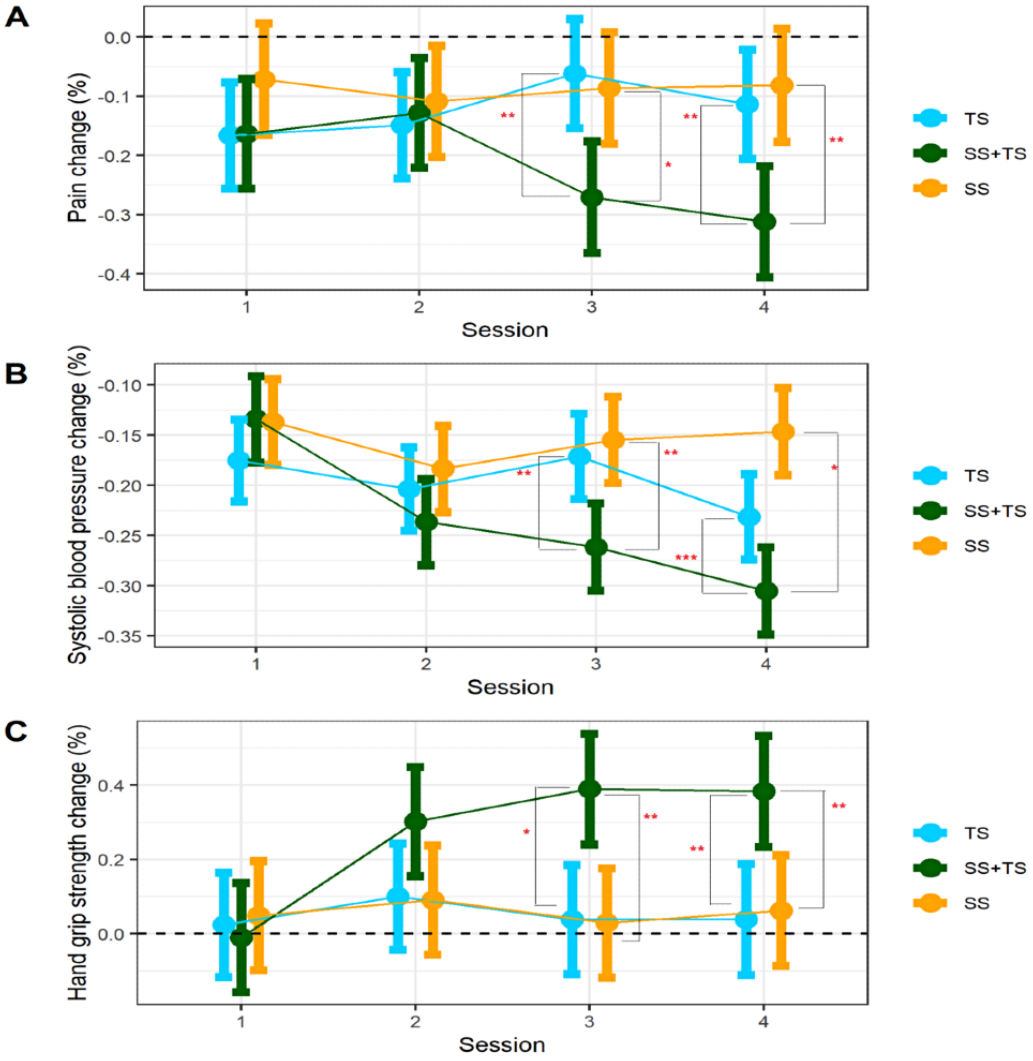
Comparing the Effect of SS, TS, and SS+TS Interventions on Physical Health

Blood Pressure

Intervention groups showed different temporal patterns of systolic blood pressure over the 4 sessions ($F_{6,272}$=5.42; P<.001). The SS+TS group demonstrated a stronger reduction in systolic blood pressure compared with the SS alone group at session 3 (B=0.09; SE 0.03; t_{272}=2.933; P=.01; Cohen d=0.97) and session 4 (B=0.073; SE 0.03; t_{272}=2.4; P=.045; Cohen d=0.8). The SS+TS group also showed a stronger reduction in systolic blood pressure compared with the TS group at session 3 (B=0.107; SE 0.03; t_{272}=1.71; P=.002; Cohen d=1.15) and session 4 (B=0.16; SE 0.031; t_{272}=5.1; P<.001; Cohen d=1.70). All other group differences were not significant (all P>.2).

For diastolic blood pressure, the groups showed a similar pattern of improvement associated with the intervention ($F_{6,272}$=1.12; P=.35).

Hand Grip



Intervention groups showed different temporal patterns of dominant HGS over the 4 sessions ($F_{6,273}$=2.25; P=.04). In the post hoc analysis, the SS+TS group demonstrated a stronger improvement in dominant HGS compared with the SS alone group at session 3 (B=–0.35; SE 0.106; t_{353}=–3.30; P=.003; Cohen d=0.89) and at session 4 (B=–0.34; SE 0.107; t_{354}=–3.21; P=.004; Cohen d=0.87). The SS+TS group also showed stronger HGS improvement compared with TS at session 3 (B=–0.36; SE 0.107; t_{353}=–3.87; P=.02; Cohen d=0.91) and at session 4 (B=–0.032; SE 0.107; t_{354}=–2.99; P=.008; Cohen d=0.81). No significant differences were found in other comparisons between the groups (all P>.11). Nondominant HGS did not show group differences in temporal dynamics over the 4 sessions ($F_{6,271}$=1.27; P=.27).

Pain

Intervention groups showed different temporal patterns of pain reduction ($F_{6,266}$=2.62; P=.02). The SS+TS group demonstrated stronger pain reduction compared with SS alone, at session 3 (B=0.209; SE 0.067; t_{307}=3.12; P=.006; Cohen d=0.91) and at session 4 (B=0.20; SE 0.067; t_{307}=2.96; P=.009; Cohen d=0.87). Additionally, the SS+TS group showed stronger pain reduction compared with the TS alone group, at session 3 (B=0.18; SE 0.068; t_{307}=2.73; P=.02; Cohen d=0.81) and at session 4 (B=0.23; SE 0.068; t_{307}=3.38; P=.002; Cohen d=1.01). No significant differences were found in all other pairwise group comparisons (P>.32 in all cases; Figure 3).

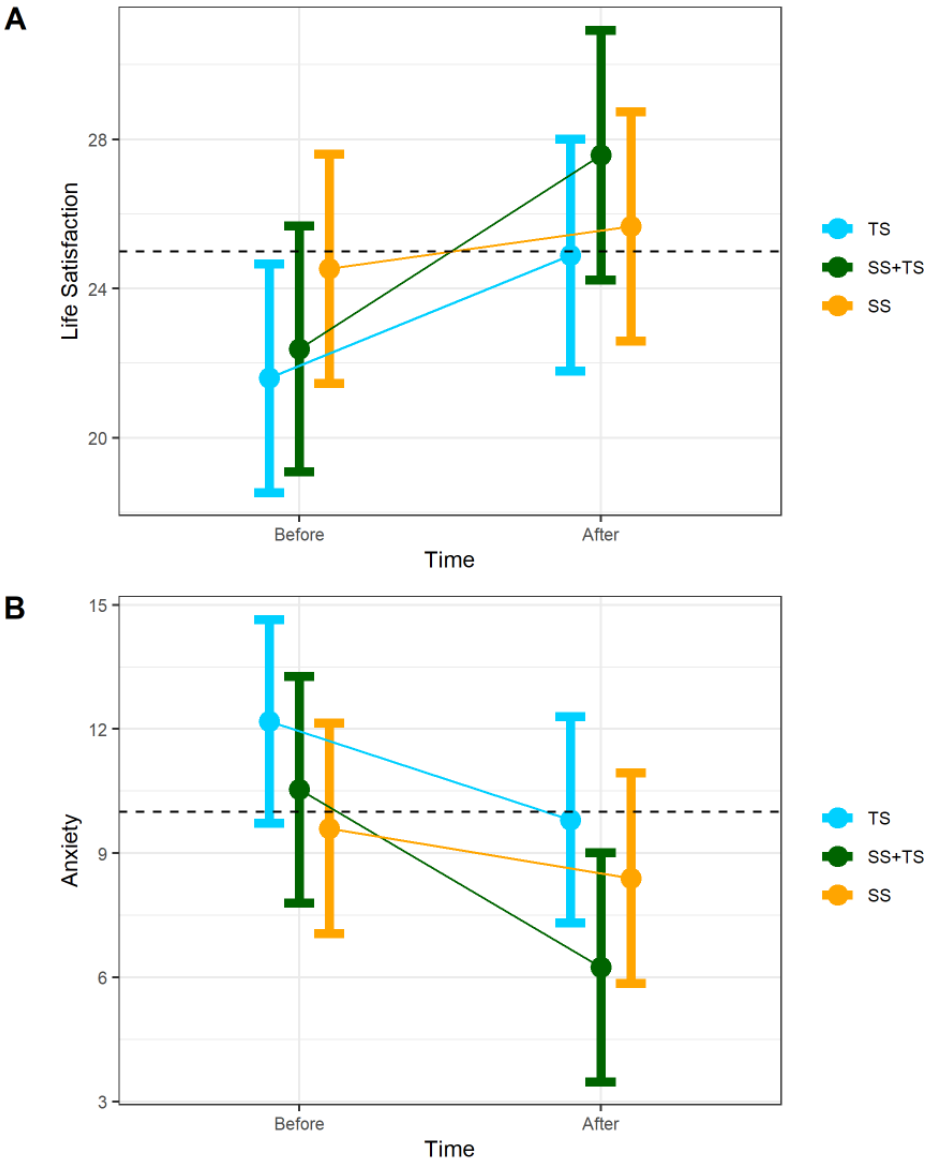
Figure 3. Fluctuations over 4 sessions for physical health measures: (A) pain intensity levels, (B) systolic blood pressure, and (C) hand grip across 3 interventions: (1) therapist support (TS), sensory stimulation (SS), sensory stimulation and therapist's support (SS+TS). TS+SS demonstrated relative improvement in all 3 outcomes at sessions 3 and 4. *P<.05, **P<.01, ***P<.001.

Comparing the Effect of SS, TS, and SS+TS Interventions on Emotional Health

Anxiety



The analysis revealed different temporal patterns of anxiety reduction among the intervention groups ($F_{2,38}$=13.5; P<.001). As hypothesized, the SS+TS group demonstrated a significant reduction in anxiety (B=10.64; SE 1.41; $t_{38.8}$=7.57; P<.001; Cohen d=1.57). By contrast, the SS and TS alone groups showed no significant improvement in anxiety (SS, P=.15; TS, P=.38).

Satisfaction With Life

The analysis indicated different temporal patterns of satisfaction with life among the intervention groups ($F_{2,39}$=3.47; P=.04). As hypothesized, the SS+TS group showed significant improvement in life satisfaction (SWLS; B=–4.29; SE 39.5; $t_{39.5}$=–4.89; P<.001; Cohen d=1.44). Additionally, the SS group showed significant improvement in the SWLS (B=–2.38; SE 0.78; P=.004; Cohen d=0.99). However, the TS group did not show a significant improvement (P=.13; Figure 4).

XSL•FO
RenderX

Figure 4. Mental health outcomes before/after 3 interventions: (1) therapist support (TS), (2) sensory Stimulation (SS), and (3) sensory stimulation and Therapist's support (SS+TS). (A) Life satisfaction; (B) anxiety. The dotted line at life satisfaction=25 represents the cut-off for satisfied/extremely satisfied (above the line). The dotted line at anxiety=10 represents the cut-off for severe anxiety (above the line).

Secondary Outcomes

The analysis revealed that the groups showed a similar pattern of improvement related to the intervention for heart rate ($F_{6,271}$=1.33; P=.23) and blood oxygen saturation ($F_{6,274}$=2.06; P=.06).

Discussion

Principal Findings

This pilot randomized clinical trial is the first to investigate the combined effects of multi-SS in a Snoezelen room and TS (SS+TS) on the health of older adults living in nursing homes. Our findings indicate that the SS+TS intervention significantly reduced pain levels, lowered systolic blood pressure, and improved HGS compared with the SS and TS interventions individually. Additionally, the SS+TS intervention enhanced life satisfaction and reduced anxiety, with these effects being more pronounced than those observed with SS or TS alone [12,15,22].

Our findings supported the primary hypothesis, showing that the combined intervention of SS in a Snoezelen room, along with TS, had a more profound effect on pain intensity and physical and mental health outcomes compared with each intervention component delivered in isolation. Specifically, the SS+TS intervention led to reduced pain levels, lower systolic blood pressure, and increased HGS during sessions 3 and 4, surpassing the effects of SS and TS alone. Additionally, the SS+TS intervention showed greater improvements in life satisfaction and anxiety compared with the other interventions.

Effect of Multisensory Stimulation and Therapist's Support on Pain

The therapeutic impact of the combined SS+TS intervention notably improved pain experience during the latter half of the intervention. Previous research has highlighted the unique positive effects of SS and TS on pain perception [1,15].

XSL•FO
RenderX

Pharmacological interventions, particularly opioids and other pain medications, can have adverse effects on older adults, including falls, cognitive impairment, constipation, and addiction [23,35]. Nonpharmacological methods for pain management, such as the Snoezelen room integrated with enhanced TS, offer a safer alternative and are often more cost-effective in the long term compared with continuous pharmaceutical treatments [23,33,34].

Our findings, combined with existing literature on the Snoezelen room intervention, support the multidimensional effects of the SS+TS intervention on pain intensity. Alleviating pain is crucial, as the experience of pain can lead to decreased mobility, sleep disturbances, emotional distress, and, consequently, a reduced quality of life among older adults [23,35,36].

Interestingly, our results revealed that the therapeutic effects of the combined intervention were most pronounced during sessions 3 and 4. This observation aligns with prior research indicating that pain reduction following nonpharmacological interventions can be delayed [1,15,37-39]. For example, pain reduction resulting from physical exercise for low back pain is often gradual and occurs over time [40,41].

Additionally, social support–focused interventions have been associated with delayed pain relief [23,37]. This delay may be due to the gradual implementation and refinement of coping strategies. It can take time for participants, particularly older adults, to adjust to a new type of therapy that includes multiple elements. This adaptation period may delay the positive interpretation of bodily sensations [37,42-46]. Further investigation is warranted to explore the temporal dynamics and long-term effects of the intervention.

Effect of Multisensory Stimulation and Therapist's Support on Physical Health

We observed an increased impact of the combined SS+TS intervention on systolic blood pressure and HGS. Previous studies have shown that SS, especially olfactory and visual stimulation, can effectively reduce blood pressure and enhance overall health [12,47,48]. Another study highlighted that TS can enhance physical health by providing a safe and nonjudgmental space for older adults to share their concerns, fears, and anxieties. Such support can help reduce stress, which is linked to various physical health issues, including hypertension, heart disease, and compromised immune function [17,23,38,49-52].

Our findings underscore the importance of interventions that address the mind-body connection. Recent studies have shed light on the physiological mechanisms through which mental processes impact the immune system and other bodily functions [47,53-55]. Moreover, some multisensory interventions include resistance training and muscle-strengthening exercises. Participating in these activities can help older adults maintain or even improve muscle strength and endurance, leading to better physical health and greater independence in daily activities [54,56].

Contrary to our initial hypothesis, we did not find that the combined SS+TS intervention provided greater benefits compared with SS and TS alone in terms of heart rate, blood oxygen saturation, and diastolic blood pressure. None of the interventions showed improvements in these metrics. It is plausible that the duration of our intervention (4 sessions lasting 17-20 minutes each) was insufficient to detect changes in these outcomes. Moreover, existing research supports the notion that similar interventions focusing on sensory processing and social support may not effectively improve heart rate and blood oxygen saturation in advanced age [8,21]. Additionally, stable diastolic blood pressure among older adults is often indicative of good health, and reducing diastolic blood pressure could even pose a risk factor for heart disease [57,58].

Improving Mental Health Through Multisensory Stimulation and Therapist Support

Our study yielded promising findings regarding the therapeutic benefits of a brief SS+TS intervention for enhancing mental health among older individuals residing in nursing homes. This intervention showed potential for improving life satisfaction and reducing anxiety, without exacerbating the common issue of polypharmacy in the geriatric field. It is well-established that better mental health in this population is closely linked to improvements in physical well-being [49]. Previous research has consistently highlighted that multi-SS, which often includes elements such as soothing music, aromatherapy, and tactile sensations, can reduce stress levels, alleviate anxiety, and promote a sense of calm. For individuals dealing with anxiety disorders, such as generalized anxiety disorder or posttraumatic stress disorder, multisensory interventions can serve as valuable coping mechanisms.

Multisensory experiences can trigger the release of endorphins and other feel-good neurotransmitters, leading to improved mood and emotional well-being. Furthermore, chronic pain has been associated with an increased aversiveness to unpleasant multi-SSs, suggesting shared mechanisms between pain intensity and multisensory processing [15,59]. For older individuals who may struggle with depression or mood disorders, regular participation in multisensory activities can offer a natural, nonpharmacological approach to improving their mood. Additionally, multisensory activities that encourage social engagement can help mitigate feelings of isolation and loneliness, providing residents with a sense of belonging and companionship [19,21,32,60]. Moreover, these improvements have been shown to contribute to an enhanced sense of well-being and increased social engagement [60]. An extensive body of research has demonstrated the significant role of TS in improving various markers of mental health [17,18,20,61]. TS is widely regarded as a valuable component for addressing emotional and social needs, which are often critical for older adults facing mental health challenges. Emotional support and empathy can significantly enhance treatment outcomes for older adults experiencing depression, anxiety, and reduced life satisfaction [18,20,62,63].

An intriguing question arises from our study: What makes the combined SS+TS intervention particularly effective? We propose that the therapeutic state of mind fostered by the relaxing environment created through SS plays a crucial role. This environment prepares the groundwork for the TS to have a greater impact by reducing patient resistance. Supporting this

XSL•FO
RenderX

notion, previous research has demonstrated that SS creates a more conducive analgesic environment compared with standard settings [15,64]. This shift in environment may be particularly therapeutic for older individuals living in nursing homes, where the atmosphere often mirrors that of a hospital, characterized by medications and medical procedures that can heighten feelings of discomfort and anxiety.

The observed effects of the SS+TS intervention may result from an interactive synergy between SS and TS. Rather than being merely additive, these interventions appear to enhance each other, leading to greater therapeutic outcomes. The soothing environment created by SS likely amplifies the effectiveness of TS, enabling a more profound impact on participants' health. This combined effect underscores the potential of the SS+TS intervention to be particularly effective in settings such as nursing homes, where establishing a calming, supportive environment is crucial.

In exploring the nature of the combined effects of SS and TS, a critical question arises: Do these interventions provide additive or interactive benefits when applied together? An additive effect would suggest that the benefits of the combined SS+TS intervention are simply the sum of the individual impacts of SS and TS when applied separately. By contrast, an interactive effect would indicate a synergistic relationship, where the combined SS+TS intervention produces outcomes that surpass the sum of its individual components. Although a no-treatment control group would offer a more definitive basis for distinguishing between these possibilities, our current analysis, based on a visual examination of pre-to-post intervention changes, suggests the presence of an interactive effect. This observation suggests that the combination of SS and TS may activate mechanisms that go beyond their individual contributions, leading to enhanced therapeutic outcomes. This synergy could stem from how SS prepares individuals mentally and physically for more effective engagement with therapeutic support, or vice versa. Future research with a more comprehensive experimental design, including a control group and separate groups for each intervention, would be invaluable for confirming and further elucidating these effects.

Limitations and Recommendations for Future Studies

Although our study has provided valuable insights, it is important to acknowledge its limitations. Conducted in a single nursing home, our findings may not fully represent the broader population.

First, the use of a convenience sample from a single nursing home may introduce selection bias, as participants may not fully represent the broader population of older adults in similar care settings. For instance, participants with behavioral issues were excluded, which limits the generalizability of the findings to this wider population. Additionally, the voluntary nature of participation may introduce selection bias, as participants who chose to join the study may have been more motivated or in better health, potentially influencing the outcomes. Future studies should aim to replicate our findings across multiple settings, explore additional measures of physical and mental health, and extend the intervention period to assess long-term effects.

Second, the sustainability of the observed effects was not assessed, as follow-up data were not collected. Consequently, while our findings suggest potential benefits of the combined SS+TS intervention, the duration of these effects remains unknown.

Third, the study's modest sample size may limit the power to detect small effect sizes. Further research with larger sample sizes and extended follow-up periods is needed to validate these preliminary findings. Furthermore, exploring the impact of the SS+TS intervention on medication use, particularly for mental health conditions, as well as on sleep quality among nursing home residents, would provide additional valuable insights into the intervention's effectiveness.

Conclusion and Implications for Clinical Practice

Our study highlights the therapeutic potential of the combined SS+TS intervention for managing pain and enhancing the physical and mental well-being of older adults in nursing homes. The results indicate that this intervention not only improves key health outcomes but also has the potential to reduce reliance on medications, addressing concerns related to polypharmacy. The scalability and ease of implementation make SS+TS a valuable nonpharmacological option for nursing homes, potentially enhancing patient care and resource efficiency. Future research should focus on larger-scale studies and long-term follow-up to confirm these findings and explore the broader applicability of the intervention.

Acknowledgments

We thank the Ahuzat Hazafon Geriatric Nursing Hospital for their support in conducting the RCT at the Snoezelen Room within the Occupational Therapy Department. We extend our gratitude, in particular, to the occupational instructors for their invaluable assistance in facilitating the research. This study was supported by the Israeli Science Foundation (grant 2608/22) and The Israel Data Science Initiative (IDSI) of the Council for Higher Education in Israel and the Data Science Research Center at the University of Haifa (PG). This work was also supported by the National Institute on Aging of the National Institutes of Health (grant R24AG064191) and the National Institute of Aging (grants 1P30AG064198-01 and 5P30AG022845-19 to YA). The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; or decision to submit the manuscript for publication.

Abstract

Background: Heart failure (HF) is one of the most common causes of hospital readmission in the United States. These hospitalizations are often driven by insufficient self-care. Commercial mobile health (mHealth) technologies, such as consumer-grade apps and wearable devices, offer opportunities for improving HF self-care, but their efficacy remains largely underexplored.

Objective: The objective of this study was to examine the feasibility, acceptability, safety, and preliminary efficacy of a patient-centered mHealth intervention (iCardia4HF) that integrates 3 consumer mHealth apps and devices (Heart Failure Health Storylines, Fitbit, and Withings) with a program of individually tailored SMS text messages to improve HF self-care.

Methods: We conducted a phase 1 randomized controlled trial. Eligible patients had stage C HF, were aged ≥40 years, and had New York Heart Association (NYHA) class I, II, or III HF. Patients were randomly assigned to either iCardia4HF plus usual care or to usual care only and were observed for 8 weeks. Key feasibility measures were recruitment and retention rates. The primary efficacy outcome was change in HF self-care subscale scores (maintenance, symptom perception, and self-care management) at 8 weeks, assessed with the Self-Care Heart Failure Index (SCHFI; version 7.2). Key secondary outcomes were modifiable behaviors targeted by the intervention (health beliefs, self-efficacy, and HF knowledge), health status, and adherence to daily self-monitoring of 2 core vital signs (body weight and blood pressure).

Results: A total of 27 patients were enrolled in the study and randomly assigned to iCardia4HF (n=13, 48%) or usual care (n=14, 52%). Of these 27 patients, 11 (41%) in the intervention group (iCardia4HF) and 14 (52%) in the usual care group started their assigned care and were included in the full analysis. Patients' mean age was 56 (SD 8.3) years, 44% (11/25) were female, 92% (23/25) self-reported race as Black, 76% (19/25) had NYHA class II or III HF, and 60% (15/25) had HF with reduced left ventricular ejection fraction. Participant retention, completion of study visits, and adherence to using the mHealth apps and devices for daily self-monitoring were high (>80%). At 8 weeks, the mean group differences in changes in the SCHFI subscale scores favored the intervention over the control group: maintenance (Cohen *d*=0.19, 95% CI –0.65 to 1.02), symptom perception (Cohen *d*=0.33, 95% CI –0.51 to 1.17), and self-care management (Cohen *d*=0.25, 95% CI –0.55 to 1.04). The greatest improvements in terms of effect size were observed in self-efficacy (Cohen *d*=0.68) and health beliefs about medication adherence (Cohen *d*=0.63) and self-monitoring adherence (Cohen *d*=0.94). There were no adverse events due to the intervention.

Conclusions: iCardia4HF was found to be feasible, acceptable, and safe. A larger trial with a longer follow-up duration is warranted to examine its efficacy among patients with HF.

Introduction

Heart Failure and Self-Care

Heart failure (HF) is a complex chronic condition with symptoms and signs that result from any structural or functional impairment of ventricular filling or ejection of blood [1]. HF affects >64 million people worldwide [2]. In the United States, approximately 6.7 million Americans aged >20 years have HF, and recent estimates indicate that by 2030, the prevalence of HF will increase to 8.5 million [3]. Black Americans have the highest incidence of HF among all racial and ethnic groups and approximately 45% greater risk of death or decline in functional status than White Americans [4]. The risk of developing HF is similar for women and men, but women are underrepresented in HF research [5].

Although considerable progress has been made over the years in both invasive and noninvasive treatments for the management of the disease [6], HF outcomes remain poor. HF is a leading cause of hospitalization and death among middle-aged and older adults in the United States [7,8]. Nearly 1 in 4 patients are readmitted within 30 days, and approximately 50% are readmitted within 6 months following an HF hospitalization [8-10]. Hospital readmissions result in significant costs to the health care system and are directly linked to poor health-related quality of life and depression [11,12]. The total cost for HF was US $30.7 billion in 2012 and is expected to reach US $69.7 billion by 2030 [13]. Therefore, attempts to decrease its societal and economic burden have become a major public health priority.

Self-care is considered essential for patients with HF, and therefore, improving self-care has increasingly become a major focus of multidisciplinary HF management programs and research worldwide [14]. HF self-care refers to behaviors and actions centered on 3 separate but linked concepts: *maintenance*, *symptom perception*, and *self-care management* [15]. The first concept, *maintenance*, refers to those behaviors that patients incorporate in their daily lives to maintain physiological stability and well-being (eg, taking medications as prescribed, following a heart-healthy diet, restricting sodium intake, and being physically active). *Symptom perception* involves daily self-monitoring and recognition of HF signs and symptoms (eg, sudden weight gain, increased blood pressure (BP), fatigue, shortness of breath, and chest pain) for early detection of deterioration. *Self-care management* refers to the strategies that one can use to respond to HF signs and symptoms when they occur (eg, adjusting diuretics, restricting fluid intake, adapting diet, and calling a care provider for guidance) to prevent hospital admission and increased mortality. A growing body of literature has shown that patients with HF who consistently engage in adequate HF self-care are more likely to be clinically stable, have better health-related quality of life, and have better event-free survival [16-20]. However, self-care in patients with HF is frequently poor, especially among racial and ethnic minority patients due to socioeconomic factors that account for delays in seeking treatment for worsening symptoms, inadequate access to health care, noncompliance with follow-up appointments, and poor adherence to recommended treatments [1,4]. Even patients recently discharged from the hospital due to acute decompensated HF (ADHF), where they presumably received patient education about HF, demonstrate low rates of adherence to basic HF self-care behaviors, such as taking HF medications as prescribed, following a low-sodium diet, and self-monitoring for HF signs and symptoms [21]. Multidisciplinary HF disease management programs that involve hospital or clinic intervention (eg, regular follow-up visits and patient education) by a multidisciplinary team of cardiologists, advanced practice nurses, pharmacists, dieticians, or other HF specialists have been successful at reducing mortality and HF-related hospitalizations. However, such programs are not available to all patients and have limited reach due to limited health care resources and accessibility constraints [22]. Therefore, interventions have evolved toward a proactive, real-time technological model to better monitor and assist patients with HF self-care and management of symptoms at home. These interventions range from structured telephone support and noninvasive home telemonitoring [23,24] to remote patient monitoring (RPM) with implantable devices [25,26] and, more recently, the use of mobile health (mHealth) technologies for patient education [27] and HF self-care support [28-31].

mHealth Interventions

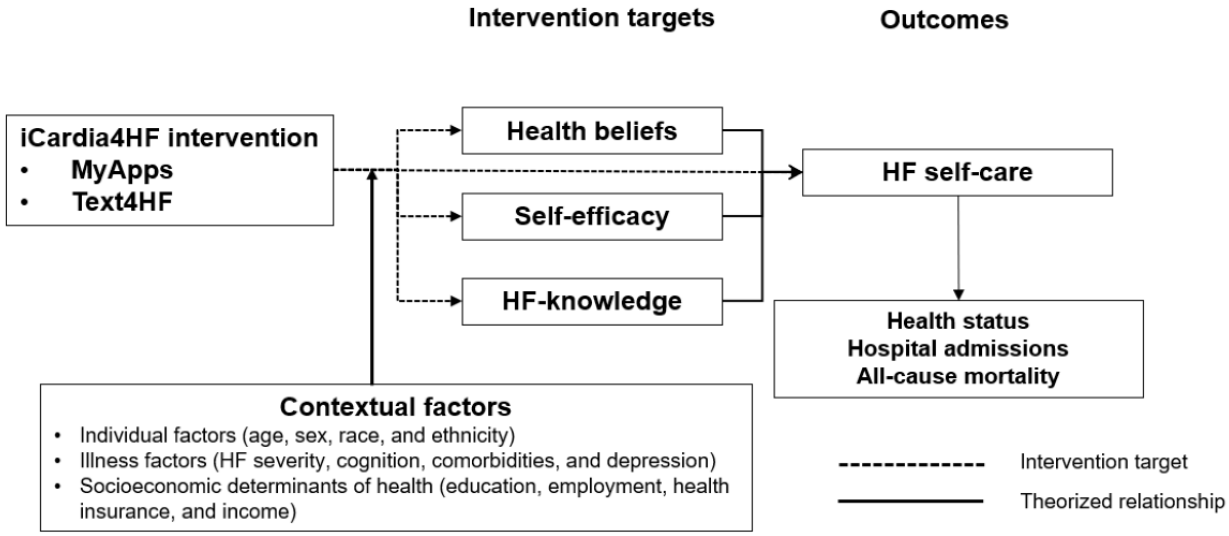
mHealth, which is defined as the use of mobile computing and communication technologies in health care and public health, is a rapidly expanding area within biomedical and health informatics with great potential for developing and delivering patient-centered behavioral interventions to improve self-care and chronic disease management [32-34]. The term *patient-centered* is used in this paper to refer to interventions that focus explicitly on the patient and in which the content of the intervention is selected or tailored to address the patient's salient characteristics (eg, health beliefs, knowledge, confidence, cultural background, and preferences) [35]. With the uptake of smartphone ownership among adults in the United States [36], there is a growing opportunity to capitalize on the use of mHealth apps, wearable sensor devices, and other connected health technologies to develop patient-centered HF self-care interventions that are more accessible and scalable. As patients carry their smartphones with them wherever they go, patient-centered mHealth interventions can fit more seamlessly into their daily routine and lifestyle to support their needs.

Consumer-grade mHealth technologies hold promise for engaging patients in better HF self-care and delivering patient-centered intervention, but their efficacy remains underexplored. A recent systematic review and meta-analysis

XSL•FO
RenderX

found that mHealth interventions for patients with HF reduced the risk of all-cause mortality and HF hospitalizations [29]. However, results were mainly driven by studies that implemented mHealth as part of a larger RPM system that focused on daily transmission of patient-generated health data to a clinical care team for review and delivery of actionable feedback. Fewer studies tested the effects of stand-alone mHealth interventions (without RPM) focused on improving self-care, and virtually no studies tested the efficacy of commercially available mHealth apps, despite their increasing availability and uptake [28]. Furthermore, none of the interventions were tailored to the patients' characteristics or needs, which is often one of the reasons for low engagement with and abandonment of mHealth apps and devices [37,38].

Study Objectives



To address this important knowledge gap, our team developed and tested a patient-centered HF self-care intervention (iCardia4HF) that integrates 3 commercial mHealth apps and devices (MyApps) with a program of individually tailored SMS text messages (Text4HF) to improve self-care in patients with HF. Tailoring of the text messages was guided by participants' health beliefs, knowledge, and confidence in performing HF self-care. The intervention was delivered through an innovative digital health platform (iCardia) [39], which allows for remote collection of patient-generated health data from the devices and apps and delivery of the tailored text messages. The objective of this study was to test the feasibility, acceptability, and safety of the iCardia4HF intervention and to determine the effects of the intervention on HF self-care (primary outcome) and other health outcomes over 8 weeks, compared with usual care.

Theoretical Basis and Development of the Intervention

Details regarding the structure, content, and delivery of the intervention are provided in the Methods section. Here, we briefly describe the theoretical basis and development of the intervention.

Figure 1 presents the conceptual framework that formed the basis for the iCardia4HF intervention. The intervention is based on the situation-specific theory of HF self-care [15] and the Health Belief Model [40]. In the situation-specific theory, HF self-care is defined as a naturalistic decision-making process involving routine behaviors and actions that maintain physiological stability *(maintenance)*, facilitate self-monitoring and identification of HF symptoms *(symptom perception)*, and direct the patient's response to those symptoms *(self-care management)*. The Health Belief Model proposes that individuals' performance of a specific self-care behavior (eg, medication adherence or following a sodium-restricted diet) is determined by their beliefs regarding susceptibility to the disease, seriousness of the disorder, and perceived benefits and barriers of performing that self-care behavior. In addition to health beliefs, HF self-care decisions are influenced by knowledge about the disease (HF knowledge) [41,42] and confidence (self-efficacy) in performing HF self-care [43,44]. Confounding HF self-care decisions are contextual factors [21,45] which include the individual characteristics of a person (eg, age, gender, race, and ethnicity), the illness-related factors (eg, HF severity, comorbidities, and depression), and social determinants of health (eg, education, employment, health insurance, and income).

Figure 1. Conceptual framework providing the basis for the intervention. HF: heart failure.

The iCardia4HF intervention was developed iteratively following a user-centered design process [46], informed by the needs of key stakeholders (patients, clinicians, and researchers) and our team's expertise in mHealth and chronic disease management. For the MyApps component of the intervention, we selected 3 popular consumer-grade mHealth apps (Heart Failure Health Storylines [Self-Care Catalysts Inc], Withings Health Mate [Withings], and Fitbit [Google LLC]) and 3 connected health devices (Withings Body Cardio Scale, Withings Blood Pressure cuff, and Fitbit Charge 2 activity tracker). These apps and devices incorporate core functionalities and electronic tools (eg, adherence reminders, vital signs monitoring, symptoms tracking, and medication tracking) that support the main aspects of HF self-care (ie, maintenance,

XSL•FO
RenderX

symptom perception, and self-care management). For the selection of the mHealth apps and connected health devices that make up the MyApps intervention component, we relied on a systematic review of 30 HF self-care apps [28] and a cross-sectional survey study of 100 patients with HF [36] in which we assessed attitudes and perceptions toward mHealth technologies, including current use and preferences for mHealth apps and devices. We also relied on cumulative experience gained from other interventional studies we have conducted in people with cardiovascular disease and other chronic diseases, in which we used Fitbit and Withings devices for vital signs monitoring and promotion of physical activity and healthy lifestyle behaviors [47-50]. Fitbit devices are increasingly used in research [51] and have been noted to be valid, reliable, and user-friendly in monitoring physical activity [52,53]. Similarly, Withings scales and BP monitors are accurate and have received 510 (k) clearance by the US Food and Drug Administration. By using these mHealth apps and devices regularly, patients with HF can become more aware of how their bodies work and what is normal, identify health changes that may need medical attention, and stay motivated while making healthier lifestyle choices.

The Text4HF component of the intervention consists of individually tailored text messages that aim to promote HF self-care adherence by targeting patients' health beliefs about HF self-care (ie, perceived barriers and benefits to prescribed medications, sodium-restricted diet, self-monitoring of HF symptoms, and daily physical activity), including HF knowledge and self-efficacy. For the development of the Text4HF intervention component, we relied on and built upon the work of Dr Susan Pressler, an internationally recognized expert in health behavior interventions for patients with HF. First, we translated the original messages that were developed and tested in the *Heart Messages* [54] study and in the *Promoting Understanding and Management through Partnering: U and Your Physician* [55] study, into SMS text messages. Then, we developed additional text messages to strengthen the intervention. Finally, we refined the text messages based on clinical guidelines for the management of HF [56] and stakeholder input to ensure accuracy, readability, and cultural relevance [57].

Methods

Study Design

iCardia4HF was a phase 1 (feasibility and pilot) randomized controlled trial [58] with 2 arms (intervention and control), allocation concealment, and masking of outcome assessors to group assignment. The intervention duration was 8 weeks. Patient assessments were performed in person at baseline, 4 weeks (30 days), and 8 weeks (56-60 days). The primary outcome of interest was HF self-care. The duration of the intervention and selection of follow-up visits for the assessment of HF self-care and intervention target variables were chosen based on guidelines for feasibility studies and because improvements in HF self-care and other measures relevant to this study have occurred at similar times in other studies [55,58-60]. The trial was conducted between January 2019 and February 2020.

Population and Setting

Patients were recruited from the hospital and outpatient HF clinic of the University of Illinois Hospital and Health Sciences System (UI Health) in Chicago, Illinois. Inclusion criteria were (1) chronic HF (stage C); (2) New York Heart Association (NYHA) class I, II, or III; (3) aged ≥40 years; (4) ability to speak and read in English; (5) smartphone ownership; and (6) living within a 48-km radius from UI Health. Exclusion criteria were (1) on a waiting list for an implanted ventricular assist device or heart transplant; (2) advanced renal disease (hemodialysis or creatinine >4.0 mg/dL) (3) end-stage HF; (4) active cancer; (5) not able to perform self-care; (6) living in a setting other than home (eg, nursing home); (7) hospice candidate; (8) Montreal Cognitive Assessment score <22 [61]; and (9) major cognitive impairment (eg, dementia). Originally, the age eligibility criterion was set to ≥50 years in this study, but due to the large number of African American patients served by the UI Health system and the fact that on average HF occurs in Black patients 10 to 15 years earlier, we modified our study protocol to include patients aged ≥40 years [62]. On the basis of left ventricular ejection fraction (EF), HF is classified into 3 EF categories: HF with reduced EF (HFrEF), mildly reduced EF (HFmEF), and preserved EF (HFpEF), according to the EF ranges ≤40%, 41% to 49%, and ≥50%, respectively. Preserved EF now represents >50% of HF cases and can have outcomes as poor as those associated with HF with reduced EF and mildly reduced EF [1]. Therefore, we included patients from all 3 EF categories.

Sample Size

The primary purpose of a phase 1 study is to determine the feasibility of recruitment, retention, and intervention delivery and to collect preliminary data on the primary outcome measure to inform the design and sample size calculation for a phase 2 trial. Hence, an efficacy-based power analysis was beyond the scope of this feasibility study [63]. During the planning stages of the trial (grant proposal submission) and in the original protocol that we published in clinicaltrials.gov before the start of recruitment, we aimed at enrolling 40 patients (an average of 4 patients per month over a 10-month recruitment period), using the general rule of thumb of having 15 to 20 patients per group to obtain an estimate of the variance for the primary outcome. However, as the study progressed and we collected recruitment data, we revised the original accrual plan, taking into consideration the eligibility fraction (proportion of potential participants who undergo screening and are eligible to enroll), the enrollment fraction (proportion of people who are eligible for participation and who actually enroll for the trial), and the funding period for the study (12 months). Consistent with recommendations that a sample size of 12 participants per group is suitable for a phase 1 trial [64], we adjusted the anticipated enrollment in the study to 28 participants, accounting for an expected attrition rate of 15%. The revised justifications for this sample size were based on rationale about feasibility and precision about the mean and variance, as described in the study by Julious [64]. Specifically, we considered the degrees of

XSL•FO
RenderX

freedom required to ensure the 95th percentile for the variance has 50% power.

Screening and Recruitment Process

Patient screening and recruitment were performed in 2 stages. Stage 1 involved querying the hospital electronic medical record to identify and screen potentially eligible patients who were either admitted to the hospital due to HF or had an upcoming appointment at the outpatient HF clinic for follow-up. Patients found eligible on initial screening were approached in person by a study researcher who briefly described the study, invited participation, and further assessed patients for eligibility (stage 2). Eligible patients agreeing to participate provided written informed consent, and Health Insurance Portability and Accountability Act (HIPAA) authorization and were scheduled for baseline assessment and study orientation.

Randomization and Allocation Concealment

After completion of baseline assessment, patients were randomly assigned 1:1 to the intervention or the control group. For the randomization, we used the biased-coin minimization method by Pocock and Simon [65] with base probability set to 0.7 to achieve balance of important clinical covariates (age, biological sex, and NYHA functional class) between the 2 study groups. Randomization was performed centrally by a designated staff person using QMinim [66], password-protected web-based software hosted in a secure server at the University of Illinois Chicago. The person responsible for the randomization was not involved in patient recruitment and enrollment and did not have the ability to influence the execution of the randomization procedure. Investigators enrolling participants did not have access to the system or knowledge of the minimization algorithm and therefore could not foresee assignments.

iCardia4HF Intervention Group

Patients in the intervention group received the MyApp and Text4HF components of the iCardia4HF intervention, in addition to usual care. In the subsequent sections, we describe the content, structure, and delivery of the 2 intervention components.

Consumer mHealth Apps and Devices (MyApps)

Overview

MyApps consisted of 3 popular consumer-grade mHealth apps (Heart Failure Health Storylines [version 7.17], Withings Health Mate [version 4.1.1], and Fitbit [version 2.86]), and 3 connected health devices (Withings Body Cardio Scale [version 1751], Withings Blood Pressure cuff [version BP-801], and Fitbit Charge 2 activity tracker [version 22.58.0]). The mobile apps and devices interface with each other, offering patients an integrated set of self-monitoring and behavior change tools that support the 3 core elements of HF self-care (maintenance, symptom perception, and self-care management) [15]. There were no major changes or upgrades to the apps and devices during the study affecting their content or features. Also, no adaptations or changes were made to the consumer apps or devices used in the study as part of the intervention. Each app specializes in different preventative and healthy lifestyle behaviors, and collectively, the 3 apps and devices supported the following HF self-care activities:

Medication Adherence

Heart Failure Health Storylines has a medication tracking feature that allows patients to add the medications they are taking and schedule reminders in the form of push notifications for each medication. When a medication reminder is triggered on the phone, patients are prompted to respond whether they took their medication or not, and thus maintain a digital diary of medication adherence on their phone.

Vital Signs Monitoring

HF self-care requires daily monitoring of weight to check for weight gain caused by increased fluid [1]. It also requires lowering BP to make it easier for the heart to pump blood [1]. Monitoring of weight and body composition (fat mass, muscle mass, water mass, bone mass, and BMI) is captured by the Withings Body Cardio scale. BP, including heart rate, is captured by the Withings Blood Pressure monitor. Both devices interface with the Withings Health Mate app via Bluetooth and automatically transmit captured data whenever a new measurement is taken. For weight and body composition, the app provides patients with visual line graphs along with textual feedback to notify them of any fluctuations over time (eg, gaining weight +2.2kgs since last measurement or over a selected period). Similarly, BP measurements (systolic and diastolic) are presented in the app in tabular format and also as a line graph, using a color-coding scheme to classify each measure as normal (<120/80 mm Hg), elevated (120−129/<80 mm Hg), high BP or stage 1 hypertension (130-139/80-89 mm Hg), high BP or stage 2 hypertension (140-179/90-119 mm Hg), or hypertensive crisis (≥180/≥120 mm Hg), according to clinical guidelines [67]. In case BP>180/110 mm Hg, the app advises the patient to seek emergency care right away.

HF Symptom Monitoring

In addition to taking medications and tracking weight and BP, HF self-care involves monitoring HF symptoms. The Heart Failure Health Storylines app has a feature that allows patients to record the presence and severity of HF symptoms over time, using a 10-point Likert scale. Symptoms are timestamped and displayed in a weekly calendar format using a color-coded scheme. Symptom questions programmed in the app at baseline included chest pressure; coughing; difficulty in sleeping; swelling in the abdomen; swelling of legs, feet, and ankle; shortness of breath when lying down or at rest; shortness of breath with activity; and fatigue. Patients were asked to perform symptom tracking daily.

Sodium-Restricted Diet

Patients with HF typically need to restrict sodium intake to avoid fluid retention and episodes of ADHF. The Heart Failure Health Storylines app provides patients with generic information about heart healthy eating and guidelines for lowering sodium intake.

Physical Activity

The Fitbit app and Charge 2 activity tracker provide patients with several tools that support daily self-monitoring of steps, intensity of physical activity, heart rate, and sleep. Also, Fitbit incorporates a variety of behavior change tools, such as goal setting, activity visualization with feedback, rewarding messages

XSL•FO
RenderX

when step goals are met, and prompts to move when sedentary (<250 steps) for >50 minutes.

All patient-generated health data captured by the connected health devices and mHealth apps are presented in the "My Storylines" dashboard of the Heart Failure Health Storylines app as visual graphs in a weekly calendar format with color-coded schemes. This helps patients identify preclinical measures of ADHF between time periods, correlate lifestyle behaviors with changes in their health, and modify their behavior accordingly.

We used a goal-based approach to promote self-care via the mHealth tools described earlier in concurrence with clinical guidelines for patients with HF. The primary goals communicated to patients at baseline were (1) daily self-monitoring of weight and BP each morning before breakfast and medications, (2) self-recording of HF symptoms, (3) recording of medication taking by replying (yes or no) to the push notifications, (4) gradual increase of physical activity to reach 20 to 30 minutes of moderate-to-vigorous physical activity (MVPA) per day most days of the week, and (5) following a low-sodium diet (2000-3000 mg of sodium/day).

Individually Tailored Text Messages (Text4HF)

Text4HF is a program of individually tailored text messages targeting patients' health beliefs (perceived barriers and benefits), self-efficacy, and knowledge about HF self-care. Patients in the intervention group received 4 text messages per week, at a day and time of their preference, via SMS. Tailoring of the text messages was guided by patients' responses to valid and reliable assessments of intervention target variables assessed at baseline and after 4 weeks . Items on the Health Belief scale are divided into benefit and barrier questions regarding adherence to prescribed medications, sodium-restricted diets, and self-monitoring of weight and HF symptoms. Each item on the scale received a 5-point score ranging from 1 (strongly disagree) to 5 (strongly agree). Participants who scored ≥3 on a barrier question or ≤3 on a benefit question received text messages tailored to that specific barrier or benefit item (Table 1). If a participant scored >3 on a benefit question or <3 on a barrier question, then a message in relation to those items was not sent because it was presumed that the patient already understood the barriers or benefits identified in that question. A similar approach was followed for the other 2 intervention target variables: self-efficacy and HF knowledge. For example, patients who gave an incorrect answer on an item of the Dutch Heart Failure Knowledge Scale received a patient education message in relation to that item.

XSL•FO
RenderX

Table 1. Sample tailored text messages based on responses to validated questions.

Intervention target	Question	Rating scale	Decision algorithm	Example text message
Medication adherence	Benefit question: if I take my water pills, I will lower my chance of being in the hospital.	5-point Likert (1 is strongly disagree and 5 is strongly agree)	If answer ≤3, then send text message	Taking water pills as prescribed can help remove extra water from the body and lessen the risk of getting hospitalized
Medication adherence	Barrier question: taking water pills makes it hard to go away from home.	5-point Likert (1 is strongly disagree and 5 is strongly agree)	If answer ≥3, then send text message	If taking water pills makes it hard to go away from home, one option is to take it several hours before you plan to go out or wait until after you return home to take it.
Diet adherence	Barrier question: food does not taste good on the low salt diet.	5-point Likert (1 is strongly disagree and 5 is strongly agree)	If answer ≥3, then send text message	You can flavor your food without using salt. You can use seasonings like pepper, lemon juice, garlic, onion powder, and basil.
Self-monitoring adherence	Barrier question: weighing myself is unpleasant.	5-point Likert (1 is strongly disagree and 5 is strongly agree)	If answer ≥3, then send text message	Although weighing yourself daily might be unpleasant, it is important to do so because it can help you identify fluid buildup in your body.
Self-care self-efficacy	How confident are you that you can keep yourself stable and free of symptoms	5-point Likert (1 is not confident and 5 is extremely confident)	If answer ≤3, then send text message	(Message 1) Following your doctor's advice and taking your medications as directed are important steps to managing your condition. (Message 2) Tell your doctor right away if you gain 3 or more pounds in a day or feel swelling in your feet, ankles, and other parts of your body or if it is hard to breathe.
Heart failure knowledge	What is the best thing to do in case of increased shortness of breath or swollen legs?	Multiple choice answer	If answer is other than "call the doctor or nurse," then send a text message	Call your health care provider if you feel any of the following: shortness of breath when lying flat or standing and swelling in your legs or stomach.

Control Group

Patients allocated to the control group received usual care provided through the outpatient HF clinic and primary care. Guideline-directed medical therapy, included initial and serial evaluation of HF (eg, physical examination, diagnostic tests, biomarkers, vital signs, symptoms, left ventricular EF [LVEF], volume status, weight, jugular venous pressure, and presence of edema); pharmacological treatment with diuretics, angiotensin-converting enzyme inhibitors, Angiotensin II receptor blockers, β blockers, and aldosterone receptor antagonists; nonpharmacological intervention (eg, patient self-care education and referral to cardiac rehabilitation); care coordination, and regular follow-up appointments with a cardiologist and Advanced Practice Registered Nurse at the Heart Failure Clinic 7 days postdischarge and every 2 to 3 months thereafter for further assessment and treatment.

Study Procedures

All study procedures were carried out in private examination rooms by certified key research personnel with training on human subjects research and HIPAA. After completion of baseline assessment and randomization, patients allocated to the intervention group received instructions and in-person training on how to use the mHealth apps and devices using the teach-back method. A research assistant downloaded the intervention apps on each participant's smartphone and then used a deidentified email address created specifically for this study to sign each patient into the intervention apps and pair the apps with their respective device via Bluetooth. Next, participants were shown how to use each app, sync the study devices with their personal smartphones, and view their data using the apps. Participants were introduced to the "position control" technology implemented in the Withings devices and were shown how to use the on-screen visual indicators to center their body on the scale and properly place the BP cuff on their

XSL•FO
RenderX

arm to ensure consistent and accurate measurements. As part of our study protocol and in accordance with clinical guidelines about HF self-care, patients were advised to use the mHealth devices and apps to record their weight, BP, and symptoms every morning after going to the bathroom and before eating breakfast and taking their medications. Daily reminders in the form of push notifications for medications, symptom tracking, and monitoring of weight and BP were programmed in each app according to patients' daily routines and preferences. To reduce complexity and participant burden, medication reminders were set up for 1 medication only (angiotensin-converting enzyme inhibitor, loop diuretic, or β-blocker) based on the documented regimen in the patient's electronic medical record and discussion with the patient at baseline. Patients were trained how to edit existing medications or add new ones and how to change the time of medication reminders if needed. At the end of the training session, participants were provided with an end user's manual that contained instructions on how to use each app and device and a copy of their study email and password for logging into the apps. Also, they were provided with a phone number to contact our team in case they experienced technical issues or had study-related questions. During training we emphasized to patients that the intervention was not a substitute for usual care and did not serve as a RPM system for identifying potential exacerbations or reporting medical emergencies.

The iCardia platform [39] was used to remotely collect all patient-generated health data captured by the mHealth apps and devices and to send the intervention text messages. A trained research assistant (interventionist) programmed the text messages in iCardia after completion of baseline and 4-week visits. iCardia is a secure, web-based system that is hosted on a HIPAA-compliant server at the University of Illinois Chicago and has been validated through multiple trials [47,49,50,68-71].

Masking of Outcome Assessors

By design, group assignments were identifiable to study participants, but outcome assessors and care providers treating patients were masked to group assignment. Outcome assessors worked in different office space than other study researchers who were aware of the group allocation. Before outcome assessment, patients were asked not to reveal to outcome assessors which group they were assigned to and were also asked to remove the Fitbit from their wrist to conceal their allocation. All outcome assessors were trained and continuously monitored.

Study Measures and Data Collection Schedule

Overview

Study participants were observed for 8 weeks. Table 2 lists all the measures and data collection schedule by outcome of interest. Once consent was obtained, participants provided basic demographic information (age, sex, race, ethnicity, employment status, marital status, living arrangement, education, and health insurance), and completed the Montreal Cognitive Assessment test [61] and Patient Health Questionnaire [72]. Clinical data, such as severity of HF (eg, LVEF and NYHA), primary cause of HF, comorbidities, BP, and anthropometrics (height, weight, and BMI), were retrieved from the electronic medical record at baseline. Study visits and assessments occurred in person at baseline, 4 weeks, and 8 weeks. Data from the mobile apps and devices were collected daily during the 8-week follow-up period.

XSL•FO

Outcomes	Measures	Baseline	4 weeks	8 weeks
Demographics	Age, sex, race, ethnicity, marital status, employment status, education, financial status, living arrangement, and health insurance	✓		
Clinical characteristics	LVEF[a], NYHA[b] class, BP[c], weight, height, and BMI.	✓		
Cognitive function	Montreal Cognitive Assessment test [61]	✓		
Feasibility (recruitment and retention)	Number of patients screened, number of eligible and ineligible patients, reasons for exclusion, recruitment rate, and retention rate	Monitored throughout the study	Monitored throughout the study	Monitored throughout the study
Acceptability	Technology acceptance questionnaire (perceived usefulness, ease of use, user satisfaction, confirmation of initial expectations, and intention to continue using the intervention apps and devices)			✓
HF[d] self-care (primary)	Self-Care Heart Failure Index (version 7.2)	✓	✓	✓
Self-efficacy	Self-Care Self-Efficacy scale	✓	✓	✓
Health beliefs	Beliefs about Medication Adherence Scale, Beliefs about Diet Adherence Scale, Beliefs about Self-Monitoring Adherence Scale	✓	✓	✓
HF-knowledge	Dutch Heart Failure Knowledge Scale	✓	✓	✓
Health status	Kansas City Cardiomyopathy Questionnaire	✓	✓	✓
Health care encounters	Hospitalizations and ER[e] visits were identified and recorded using the electronic medical record system and patient interviews.	✓	✓	✓
Mortality	Death certificate or other report in the electronic medical record system	✓	✓	✓
Self-monitoring adherence	Daily weighing and BP monitoring—timestamped data from the Withings Body Cardio Scale and BP cuff	Monitored throughout the study	Monitored throughout the study	Monitored throughout the study
Steps	Mean number of daily steps were measured with the Fitbit Charge 2 activity tracker.	Monitored throughout the study	Monitored throughout the study	Monitored throughout the study
MVPA[f] minutes	Mean number of MVPA minutes/day were measured with the Fitbit Charge 2.	Monitored throughout the study	Monitored throughout the study	Monitored throughout the study

[a]LVEF: left ventricular ejection fraction.

[b]NYHA: New York Heart Association.

[c]BP: blood pressure.

[d]HF: heart failure.

[e]ER: emergency room.

[f]MVPA: moderate-to-vigorous physical activity.

XSL•FO
RenderX

Feasibility Outcome Measures

Feasibility was assessed in the domains of patient recruitment and retention during the 8-week follow-up period. Feasibility measures assessed throughout the study included the following: (1) number of patients screened, (2) number of eligible patients, (3) reasons for ineligibility, (4) recruitment rate (mean number of patients recruited per month), and (5) retention rate (percentage of randomized participants who completed the study).

Primary Efficacy Outcome Measure

The primary efficacy outcome measure was self-reported HF self-care assessed with the Self-Care Heart Failure Index (SCHFI; version 7.2) [15] at baseline, 4 weeks, and 8 weeks (Table 2). SCHFI is a validated instrument that contains the following three subscales: (1) Self-care Maintenance (10-items), (2) Symptom Perception (9-items), and (3) Self-care management (10-items). Each subscale is scored separately. Response choices for all items in each subscale are summed and standardized to achieve a possible score of 0 to 100. Higher scores indicate better HF self-care. Scores <70 indicate insufficient self-care. The minimal clinically important change in SCHFI is one-half SD, or an 8-point difference in the standardized score of each subscale [73].

Secondary Outcome Measures

Secondary outcome measures (Table 2) included self-efficacy, health beliefs, HF-knowledge, health status, adherence to daily self-monitoring of weight and BP, physical activity, acceptance of the intervention, and adverse events.

Self-Efficacy

Confidence in performing routine HF self-care behaviors was assessed with the Self-Care Self-Efficacy questionnaire that has 10 items [15,74]. Similar to SCHFI, items in the Self-Care Self-Efficacy scale are summed and standardized to achieve a possible score of 0 to 100. Higher scores indicate greater confidence in HF self-care. Scores <70 indicate inadequate self-efficacy. The minimal clinically important change is one-half SD, or an 8-point difference in the standardized score [73].

Health Beliefs

Perceived benefits and barriers about HF self-care were assessed using three validated scales: (1) Beliefs about Medication Adherence Scale (12 items) [75], (2) Beliefs about Diet Adherence Scale (12 items) [75], and (3) Beliefs about Self-Monitoring Adherence Scale (12 items) [76].

HF Knowledge

The Dutch Heart Failure Knowledge Scale was used to measure general knowledge about HF, knowledge about HF treatment (including diet and fluid restriction) and symptoms, and symptom recognition [77]. The Dutch Heart Failure Knowledge Scale is a 15-item questionnaire that has a minimum score of 0 (no knowledge) and a maximum score of 15 points (optimal knowledge).

Health Status

The short version of the Kansas City Cardiomyopathy Questionnaire 12-item (KCCQ-12) was used to assess health status [78]. KCCQ-12 is a validated health status measure for patients with HF that contains 4 subscales: physical limitation, symptom frequency, quality of life, and social limitation. Each subscale provides an individual score from 0 to 100, with 0 denoting the worst and 100 the best possible health status. The mean of the 4 subdomain scores is presented as a summary score, with differences of ≥5 points considered clinically important [79].

Self-Monitoring Adherence

Daily adherence to self-monitoring of weight and BP was assessed using timestamped data automatically transmitted from the Withings devices and app to the iCardia server. Adherence was defined as the percentage of days patients used the Withings Body Composition scale and BP cuff along with the Health Mate app to measure their weight and BP over the 8-week follow-up period.

Physical Activity (Steps and MVPA)

Daily steps and MVPA were assessed with the Fitbit Charge 2 activity tracker that participants received as part of the intervention during 8 weeks. Participants were asked to wear the Fitbit daily for ≥10 hours (600 minutes) every day during waking hours and gradually increase their physical activity over time. A valid day consisted of 10 hours of wear time and a valid week consisted of at least 4 valid days. Daily Fitbit wear time was calculated by iCardia based on the collected heart rate data using a previously validated method [47,80].

Adverse Events

As part of our safety protocol and monitoring of adverse events, we recorded all hospitalizations, emergency room visits, and deaths that occurred during the follow-up period of our trial. At each study visit, a trained research assistant reviewed the electronic medical record of each patient (encounters and provider notes) and asked them for possible hospitalizations that occurred at UI Health or elsewhere, including adverse events. The study physicians adjudicated the encounters and events per our study safety protocol.

Intervention Acceptability

Exit interviews were conducted at 8 weeks (postintervention) with patients allocated to the iCardia4HF group to assess *acceptance* and elicit their feedback about the intervention. Measures of technology acceptance—adapted to the context of this study from the Technology Acceptance Model [81] and the Expectation-Confirmation Model of continued information technology use [82,83]—were assessed using a 3-point Likert scale and included the following: (1) perceived usefulness (7 items), (2) ease of use (5 items), (3) user satisfaction (3 items), (4) confirmation of initial expectations (3 items), and (5) intention to continue using the mobile apps and devices of the iCardia4HF intervention after the end of the study (3 items).

XSL•FO
RenderX

Statistical Analysis and Interpretation

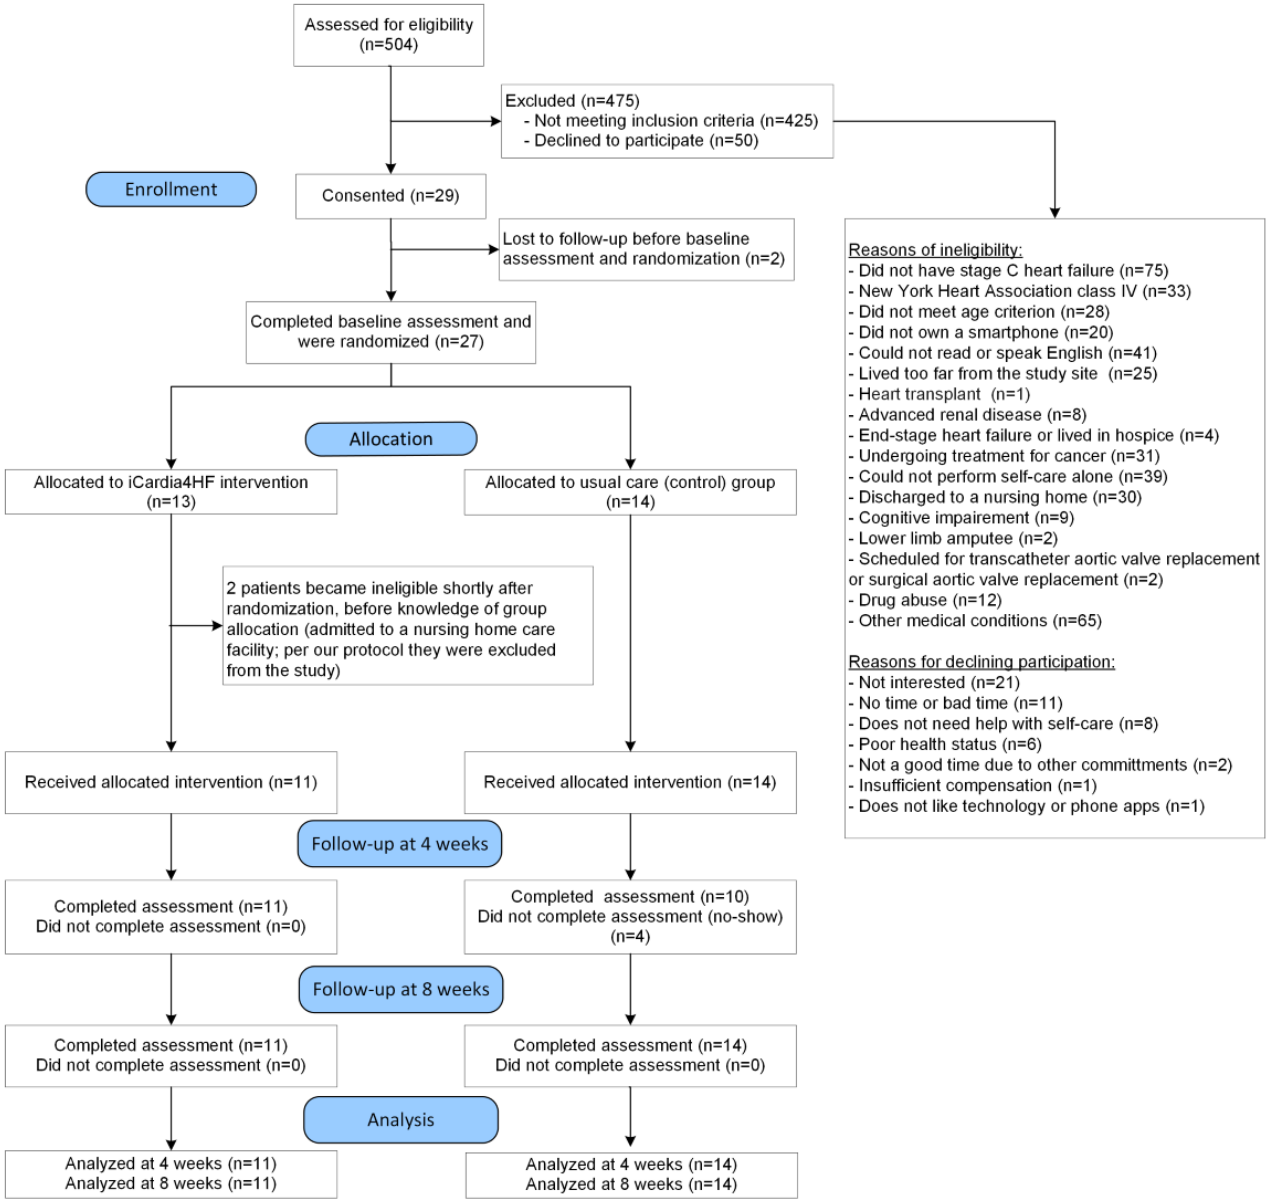
All analyses were conducted using an intent-to-treat approach (ie, participants were analyzed according to their assigned group) independent of the actual intervention dose received. All variables were checked for errant values. Descriptive statistics were computed for all items and scale scores. Distributions were examined for nonnormality and transformed if necessary. To deal with missing data, we used a multiple imputation approach [84]. Imputation of the missing values for each outcome was performed by treatment group, age, gender, BMI, NYHA, LVEF, Patient Health Questionnaire-9, and Montreal Cognitive Assessment to create 20 imputed datasets using the mice package [85] in R software (version 4.2.1; R Core Team) [86]. Analyses of between-treatment differences in primary and secondary outcomes were performed using a 2-sample *t* test to assess the intervention effect. Our approach to data reporting and interpretation regarding the intervention effects on HF self-care and secondary outcomes was focused on the direction and magnitude of treatment effect estimates, as well as the uncertainty behind each estimate (95% CI), and not on *P* values [87].

Daily weighing and BP self-monitoring adherence in the intervention group was measured by week (as the percentage of protocol-required measurements that were completed during the follow-up period), after adjusting for days outside of the hospital. For the Fitbit physical activity data, we first calculated the mean number of daily steps and daily MVPA minutes per week using all valid days for each participant. A valid day was one that had ≥600 minutes of wear time. We only included weeks that had ≥3 valid days. We also calculated the mean daily sedentary minutes and Fitbit wear time per day. To study the trajectories of the mean number of daily steps per week for the intervention group, we used linear mixed-effects models [88], where the continuous week variable was included as a fixed effects and a random intercept was included to account for the intrasubject correlations. We adopted the same analysis strategy to study the trajectories of the mean daily MVPA minutes, mean daily sedentary minutes, mean daily Fitbit wear-time, and mean daily weight and BP monitoring adherence for the intervention group. We used the Non-Linear Mixed Effects package [89] to fit the linear mixed-effects model in R.

Ethical Considerations

The study protocol was approved by the university's institutional review board, registered on ClinicalTrials.gov (NCT03642275), and reported in accordance with the CONSORT-eHEALTH checklist (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth; Multimedia Appendix 1). As compensation for their time and participation in the study, patients received US $25 for completing the baseline assessment, US $30 for completing the 4-week study visit, and US $30 for completing the 8-week study visit, which amounts to a total of US $85. They were also able to keep the apps and devices after completion of the study. In addition, they were provided with free parking and transportation reimbursement from and to University of Illinois Chicago and UI Health for study visits as needed.

Results



Description of the Population Sample

Figure 2 shows the numbers of patients who were screened for eligibility, enrolled in the trial, randomly assigned to one of the two groups, received intended treatment, completed follow-up assessments, and included in the final analysis. A total of 504 patients were assessed for eligibility through chart review and clinic recruitment. Of those, 84.3% (n=425) were ineligible, and 9.9% (n=50) patients declined to participate or be screened for participation in the study, yielding a recruitment fraction of 5.8% (29/504); proportion of potential participants who enrolled in the trial). On average, we enrolled 3 patients per month during the 10-month recruitment period (from January 2019 to November 2019). Of the 29 participants enrolled in the study, 7% (2/29) were lost to follow-up before baseline assessment and randomization. The 27 participants who completed baseline assessment were randomized to the intervention (n=13, 45%) or the control group (n=14, 52%). Two participants allocated to the intervention group were excluded from the study because they were admitted to a nursing home and became ineligible before allocation of the mHealth app and devices.

Table 3 presents the characteristics of the 25 eligible patients who enrolled in and completed the study. The mean age of patients was 56 (range 41-72) years, and 44% (11/25) were female. Regarding self-identified race, 92% (23/25) were Black and 8% (2/25) were White. Baseline demographic and clinical characteristics were similar between the intervention and control groups.

Effects on HF Self-Care Scores

At 4 weeks, there was a clinically important difference (>8 points) between the 2 groups in maintenance (Cohen *d*=0.57, 95% CI –0.32 to 1.46) and self-care management (Cohen *d*=0.91, 95% CI –0.01 to 1.82), favoring the iCardia4HF intervention (Table 4). Symptom perception improved in both groups from baseline to 4 weeks, but there was no clinically relevant difference between the 2 groups (Cohen *d*=0, 95% CI –0.84 to 0.85).

At 8 weeks, participants in the intervention group reported, on average, greater improvement in self-care maintenance (Cohen *d*=0.19, 95% CI –0.65 to 1.02), symptom perception (Cohen *d*=0.33, 95% CI –0.51 to 1.17), and self-care management (Cohen *d*=0.25, 95% CI –0.55 to 1.04) than the control group (Table 4).

Effects on Intervention Target Measures (Health Beliefs, Self-Efficacy, and HF Knowledge)

Assessment of health beliefs focused on perceived benefits and perceived barriers of adherence to 3 important HF self-care behaviors: medication taking, low-sodium diet, and self-monitoring.

With respect to medication adherence, there were no important differences between the intervention and control group at 4 weeks, but there was a meaningful difference (*d*=0.63) in perceived benefits at 8 weeks, favoring the iCardia4HF intervention (Table 5).

With respect to diet, there were meaningful treatment effects with the iCardia4HF intervention in perceived benefits both at 4 and 8 weeks (Cohen *d*=0.85 and 0.55, respectively), but no meaningful differences between the intervention and control group in perceived barriers (Table 5).

In terms of self-monitoring, there were positive treatment effects in perceived benefits with the iCardia4HF intervention at 4 and 8 weeks (Cohen *d*=0.47 and 0.94, respectively), compared with the control group (Table 5).

There were clinically meaningful differences in self-efficacy scores between the intervention and control group both at 4 and 8 weeks, favoring the iCardia4HF intervention (Table 5). Compared to baseline, patients in the intervention group had an improvement in self-efficacy scores at both time points, while patient scores in the control group declined.

The iCardia4HF intervention had no effect on HF knowledge at 4 weeks but trended to have a small positive effect at 8 weeks (Cohen *d*=0.21).

Effects on Health Status Scores

With respect to health status (Table 6), patients in the intervention group had moderate effect size improvements that were clinically meaningful (>5 points difference), both at 4 weeks (Cohen *d*=0.54) and 8 weeks (Cohen *d*=0.46). Improvements in the intervention arm were mainly driven by positive changes in the physical limitation, symptom frequency, and social limitation domains.

Self-Monitoring Adherence

Daily weighing and BP monitoring adherence over 8 weeks was 86.4% (SD 11.16%) and 86.22% (SD 10.35%), respectively, among patients allocated to the iCardia4HF intervention. Daily self-monitoring of weight and BP decreased by –0.2% (t_{78}=–0.32; *P*=.75) and –0.9% (t_{78}=–1.25; *P*=.21) each week during the intervention period, but the decline was not statistically significant (Table 7). From baseline to 4 weeks, mean daily weighing adherence was 85.5% (SD 20.8%), and mean daily BP monitoring adherence was 86.6% (SD 20.3%). From week 4 to week 8, mean daily weighing adherence was 87.2% (SD 10.8%), and daily BP monitoring adherence was 85.8% (SD 11.9%).

Table 7. Linear mixed-effects analyses of daily weighing and blood pressure (BP) monitoring adherence over time (intervention group).

Outcome	Variable	Mean (SE)	*t* test (*df*)	*P* value
BP	Intercept	92.08 (4.90)	18.76 (78)	<.001
BP	Slope	–0.95 (0.77)	–1.25 (78)	.21
Weight	Intercept	88.74 (5.19)	17.10 (78)	<.001
Weight	Slope	–0.26 (0.83)	–0.32 (78)	.75

Effects on Physical Activity

As shown in Table 8, the Fitbit activity tracker and Fitbit mobile app used for promotion and self-monitoring of physical activity did not have a clinically meaningful effect on the intervention participants' trajectory of daily steps, MVPA, or sedentary minutes over the 8-week intervention period. Overall, participants averaged 5480 (SD 3904) steps per day and 22.20 (SD 18.71) MPVA minutes per day during the 8-week intervention period. From baseline to 4 weeks, participants averaged 5341.49 (SD 3923.18) steps per day and 19.78 (SD 21.88) MVPA minutes per day. From 4 to 8 weeks, intervention participants averaged 5619.20 (SD 4015.03) steps per day and 24.62 (SD 20.45) MVPA minutes per day. On average, intervention participants wore their Fitbit for 1031 (SD 421.2) minutes per day during the 8-week intervention period. Mean

XSL•FO
RenderX

adherence to wearing the Fitbit for ≥600 minutes per day (as recommended at study orientation) was 85.3% (SD 23.12%). Wear-time slightly declined over the 8-week period by an average of 36 minutes per day (t_{76}=–4.46; *P*<.001).

Table 8. Linear mixed-effects analyses of physical activity and Fitbit wear-time over time (intervention group).

Outcome	Variable	Values, mean (SE)	*t* test (*df*)	*P* value
Daily steps	Intercept	5085.50 (1281.37)	3.97 (65)	<.001
Daily steps	Slope	25.70 (72.66)	0.35 (65)	.72

[a]MVPA: moderate-to-vigorous physical activity.

Acceptability of the Intervention

As shown in Table 9, most patients perceived the intervention to be useful in supporting HF self-care (mean 2.94 on a 3-point Likert scale, SD 0.07). During exit interviews, patients said that they found the intervention very engaging and that the mobile apps and devices empowered them to perform daily self-monitoring of weight, symptoms, and physical activity. Also, participants said that the text messages provided positive reinforcement and helped them become more informed about HF and self-care. Importantly, most patients reported that they felt more confident in managing their condition, and the data in the apps allowed them to have more informed discussions with their care providers during follow-up appointments. Most patients found the apps and devices easy to use (mean 2.97, SD 0.08) and positively commented on the ability of devices to automatically transfer data to the mobile apps on their phone via Bluetooth, thus eliminating any need for manual data entry. Overall, patients claimed to be very satisfied with the intervention components (mean 2.93, SD 0.14) and had a firm intention of continuing to use the apps and devices of the iCardia4HF intervention after the end of the study (mean 3, SD 0).

XSL•FO
RenderX

Table 9. Acceptance of the iCardia4HF intervention.

Subscales and measures	Scores, mean (SD)
Perceived usefulness (overall score)	2.94 (0.07)
I have maintained or improved my health by using the mobile app and smart devices of the iCardia4HF intervention	2.90 (.32)
I am more informed about my heart failure by using the mobile app and smart devices	3 (0)
My knowledge about self-managing my health has improved	3 (0)
I feel more confident taking care of my health	3 (0)
I am more autonomous in monitoring my vital signs and heart failure symptoms	3 (0)
I feel less anxious about my health	2.80 (0.42)
I have more informed discussions with my doctor about my heart failure based on the data I collect from the mobile app and smart devices	2.90 (0.32)
Ease of use (overall score)	2.97 (0.08)
I found it easy to use the mobile app and wearable device(s) for self-monitoring my heart failure	3 (0)
I found the mobile app and wearable/smart device(s) user-friendly	3 (0)
Learning how to use the mobile app and wearable/smart device(s) to self-manage my heart failure was easy for me	2.90 (0.32)
The information provided/stored in the mobile app(s) was easy to understand and interpret	3 (0)
Interacting with the mobile app and wearable/smart devices was clear and understandable	3 (0)
User satisfaction (overall score)	2.93 (0.14)
I am satisfied with the use of the mobile app and the wearable/smart devices for self-monitoring	3 (0)
I am pleased with the use of the wearable/smart devices	3 (0)
I am delighted with the use my wearable/smart devices	2.80 (0.42)
Confirmation of initial expectations (overall score)	2.90 (0.23)
My initial expectations concerning the use of the heart failure mobile app and wearable/smart devices have been confirmed so far	2.70 (0.68)
Using the heart failure mobile app and wearable/smart devices turned out to be easier that I first thought	3 (0)
There are more benefits to using the heart failure mobile app and wearable/smart devices than I first thought	3 (0)
Intention to continue using (overall score)	3 (0)
I have every intention of continuing to use the mobile app and wearable/smart devices in the future	3 (0)
I will continue to use the mobile app and wearable/smart devices to monitor different aspects of my health	3 (0)
I have no intention of stopping to use the heart failure mobile app and wearable/smart devices in the future	3 (0)

Adverse Events

During the study follow-up period of 8 weeks, there were 6 hospitalizations: 4 in the intervention group (1/11 patients, 9% experienced an event) and 2 in the control group (1/14 patients, 7% experienced an event). There were also 4 emergency room visits: 2 in the intervention group (2/11 patients, 18% experienced an event) and 2 in the control group (1/14 patients, 7% experienced an event). In terms of HF-related hospitalizations, there was 1 HF readmission in the intervention group (1/11 patients, 9% experienced an event) and none in the control group. There were no deaths during the follow-up period. There were no serious or other adverse events associated with the intervention or study procedures.

Discussion

Principal Findings and Interpretation

In this phase 1 randomized controlled trial, we examined the feasibility, acceptability, safety, and preliminary efficacy of a patient-centered mHealth intervention (iCardia4HF) on HF self-care and other health outcomes in a predominantly racial and ethnic minority population of middle-aged and older adult patients with HF. The iCardia4HF intervention integrates multiple consumer-grade mHealth apps and devices (MyApps) with a program of individually tailored text messages (Text4HF) targeting HF self-care and modifiable behavioral factors affecting HF self-care. Overall, our results demonstrated that iCardia4HF is a potentially feasible, acceptable, and safe intervention that warrants further exploration in a phase 2 clinical trial to determine its efficacy.

XSL•FO
RenderX

The results of our recruitment efforts provide important information that can be used in the planning of a phase 2 trial and other future mHealth intervention studies in midlife and older adult patients with HF. The numbers of patients eligible for the study were much lower than we originally anticipated and required a significantly larger pool of patients with HF to be screened during the recruitment period. The data show that approximately 16 patients needed to be screened for every patient enrolled (5.8% recruitment fraction). Although low, this rate is consistent with rates reported in other studies of patients with HF [90]. For example, the Better Effectiveness After Transition–Heart Failure study [91], one of the largest RCTs of remote patient telemonitoring in an HF population aged ≥50 years in the United States (n=1437 patients with HF, 664/1437, 46.2% female, and 316/1437, 22% African American), had a recruitment fraction of 4.7%. The study assessed 30,844 patients for eligibility and enrolled 1437 patients. Approximately 92.32% (28,476/30,844) of people screened did not meet the inclusion criteria. These numbers highlight the challenge of conducting RCTs in patients with serious chronic diseases, such as HF, who often have multiple comorbidities, functional disabilities, or other impairments that affect eligibility and may limit their ability to participate in research [90]. In our study, comorbidities (eg, cancer and severe or end-stage chronic kidney disease) and functional or cognitive impairments (eg, inability to walk, dementia, and Alzheimer disease) accounted for approximately 45% of exclusions. Future studies might consider modifying the eligibility criteria to enable testing of the iCardia4HF intervention in a larger and more diverse population with HF. Taken collectively, these results emphasize the need to carefully develop sound recruitment strategies before a study begins and devote sufficient financial and personnel resources to meet recruitment needs.

Despite the lower than anticipated recruitment rate, we achieved a high degree of participant retention and completion of study visits (85% at 4 weeks and 100% at 8 weeks). We also observed high rates of adherence (>80%) to wearing the Fitbit activity tracker and using the mHealth apps and devices daily for self-monitoring of vital signs and HF symptoms. Quantitative ratings from study participants allocated to the intervention (100% response rate) showed high levels of perceived usefulness, ease of use, and intention to continue using the technology for HF self-care. Patients were also satisfied with the text messages (Text4HF) and said that they provided them with positive reinforcement. These findings are consistent with previous studies and reviews on technology adoption, which report that older adults are more likely to adopt and consistently use a new technology if it is perceived as useful (ie, addresses an important need) and is easy to use [92-94]. The functional and cognitive changes that come with aging, such as poorer vision, cognitive decline, memory loss, decreased dexterity, and sensory impairments, make learning and using mHealth apps and wearable devices more challenging for older adults [94]. Hence, it is important for mHealth technologies to meet a series of end user requirements, such as user-friendly designs, limited manual data entry, easy-to-interpret visualizations, and appropriate user support [95,96]. Qualitative feedback during exit interviews illuminated that the salient features of our mHealth intervention supporting technology acceptance and satisfaction were (1) the automated capturing and syncing of the data, which eliminated the need for manual data entry into the mHealth apps; (2) the overall user-friendliness and ease of use of the intervention apps and devices; (3) the helpful content and positive reinforcement that the text messages provided; and (4) the feedback received from the intervention apps in the form of notifications and data visualizations. Another factor that most likely played a key role in the acceptance and use of the intervention technology, although not mentioned in the exit interviews, was the training and technical support participants received during the study. Participants received one-on-one instruction at baseline on how to use each mHealth app and device, including clear and simplified end user guides that our team developed for this study. They were also provided with a number they could call during office hours to receive technical support from study staff for individual problems with the devices. Previous research has consistently shown that with sufficient training and support, older adults are significantly more likely to learn and use new technologies, even if they have limited prior experience [97-100]; this is because they may need more time and tailored instruction to overcome potential barriers to adoption. Other factors that may have played a positive role in the acceptance and use of the intervention technology relate to the characteristics of our study sample. Specifically, the relatively younger mean age (56 years) of our HF population, which is reflective of the earlier age of HF onset in Black or African American people [62], and patient selection criteria of our study (eg, smartphone ownership, ability to independently perform self-care, and no major cognitive decline). Future studies and pragmatic trials are needed to determine whether older (aged ≥65 years) and more diverse populations with HF will be as willing to adopt and consistently use our intervention technologies over a longer period.

With respect to the preliminary efficacy of the intervention, iCardia4HF trended to improve HF self-care as indicated by the change in SCHFI scores from baseline. Even though the CIs were wide and included the null, there was a consistently positive effect on all 3 HF self-care domains (maintenance, symptom perception, and self-care management) in the intervention group. The between-group Cohen *d* effect sizes of 0.19, 0.33, and 0.25 for the 3 HF self-care subscales of *maintenance*, *symptom perception*, and *self-care management* at 8 weeks, respectively, qualify as a “probably positive” finding, according to the various scenarios prespecified in the study protocol about the possible intervention effect [68]. The SCHFI subscale scores observed in our study were higher at baseline compared with those reported in other studies in the literature [101-104], which means that, on average, many study participants were already performing adequate HF self-care when enrolled in our study based on self-report. This may have made it more difficult to demonstrate larger changes in HF self-care between the intervention and control groups. To address this issue, in the phase 2 trial of iCardia4HF [68], we are using SCHFI in the screening process to identify patients who are performing insufficient self-care and are more likely to benefit from the iCardia4HF intervention [105]. This approach has been used in other trials [106]. Given the small sample of our study, we found no significant correlations between HF self-care and patient demographic or clinical characteristics (eg,

XSL•FO
RenderX

age, sex, living alone, education, employment, LVEF, and NYHA). Future research should further explore the role of these factors as potential confounders or mediators of HF self-care [107].

Compared with usual care, the intervention trended toward improvement in self-reported health status (physical limitation, symptom frequency, and social limitation) as assessed with the KCCQ-12. The greatest improvements in terms of Cohen *d* values were observed in the intervention target variables of self-efficacy (0.68) and health beliefs about HF self-care, especially perceived benefits of medication adherence (0.63) and self-monitoring adherence (0.94). A possible explanation for this finding is that these measures, in addition to the mHealth apps and devices (MyApps), were directly targeted by the tailored text messaging component (Text4HF), which may have had an additive effect. However, this finding requires further exploration. In a new clinical trial that we are conducting with funding from the National Institute of Heart and Lung Blood Institute (1 R01 HL168376-01), we are using a 2×2 factorial randomized trial design to determine the independent and synergistic effects of the 2 iCardia4HF intervention components (MyApps and Text4HF).

Physical activity (steps and MVPA) measured with the Fitbit activity tracker in the intervention group only did not improve over time. A possible explanation for this finding, besides the short duration of the study, is the lack of specific physical activity goals pertaining to the 2 measures of interest: steps and MVPA. A recent systematic review and meta-analysis of Fitbit-based physical activity interventions showed that goal setting is more effective than Fitbit alone [51]. iCardia4HF could potentially be strengthened in this area by incorporating weekly physical activity goal setting for either steps or MVPA to gradually increase participants' physical activity as recommended by existing guidelines [1,108].

Comparison With Other Studies

In a recent systematic review and meta-analysis that we conducted and published [29], we identified 16 RCTs (n=4389 patients) of mHealth interventions for patients with HF. Most trials (12/16, 75%) evaluated the efficacy of RPM interventions (also known as telemonitoring) that included daily transmission of patient-generated health data to a clinical care team for review and delivery of actionable feedback based on the incoming data [29]. Fewer trials (n=4) tested the efficacy of stand-alone, patient-centered interventions (without RPM) targeting HF self-care through the use of mobile technologies. Of these 4 trials, 3 (75%) tested the efficacy of a single self-care support mobile app [102,109,110], while one trial [111] tested the efficacy of HF self-care text messages compared to usual care. Another RCT published after our systematic review tested a tablet-based mobile app designed to support HF patients' self-care at home [112]. Sample size in the 5 trials of mHealth interventions without RPM ranged from 18 patients to 767 patients, and follow-up duration ranged from 30 days to 6 months.

Daily adherence to using the app was reported to be high (>80%) among intervention participants in 2 studies [109,112], while in another study [102], patient engagement with the app and study completion were affected by challenges faced with using a chest-strap Bluetooth device (BioHarness-3) for vital signs and exercise monitoring. Only 72% (13/18) of participants completed the 30-day follow-up, and 43% (4/9) accessed the app daily.

HF self-care in the 5 RCTs was assessed using different instruments. A total of 2 studies used an older SCHFI version (version 6.2) [102,110], another 2 studies used different versions of the European Heart Failure Self-care Behavior Scale (EHFScB-12 and EHFScB-9) [109,112], and 1 study used generic items about self-care (not previously validated). Consequently, it is difficult to directly compare the results of these studies with our effect sizes and 95% CI. The 2 trials that used EHFScB found statistically significant improvements in the overall self-care score with the intervention, while results in the other 2 trials that used SCFHI were inconsistent. Athilingam et al [102] found significant improvements in the self-care management and self-care confidence subscales, while Dorsch et al [110] found no differences between the intervention and control groups in the SCHFI subscales.

Contrary to our intervention, the mobile apps used in these studies were not commercially available. They were developed internally by the research team and with input from health care providers (eg, cardiologists, HF nurses, and dieticians). In terms of HF self-care supported features, all 4 apps prompted active daily self-monitoring of weight and HF symptoms, included an education module on HF, and generated automated alerts of possible decompensated HF using an algorithm based on predetermined risk criteria or scores. The latter was a feature that our intervention did not have. Two apps [102,112] included a medication tracker feature and supported physical activity and exercise monitoring, and 1 app supported daily salt intake and dietary records [112]. Only 1 app supported wireless transfer of data from external devices (eg, weight scale) to the app. The other 3 apps required users to manually enter their vital signs recorded from external devices into the app (eg, weight, heart rate, BP, and steps). This is primarily due to the difficulty of integrating third-party devices with a custom-made app.

One of the 5 RCTs was a large trial (n=767) conducted in China [111] that investigated the efficacy of an SMS text messaging intervention on the composite end point of death- or readmission-free survival and the secondary outcome of self-care behavior compared with usual care over 180 days. Participants were recently discharged patients with ADHF (mean age 61, SD 15 years; 334/767, 43.5% female and 525/767, 68.4% NYHA class 3). Patients in the SMS group, as well as their caregivers, received educational and reminder text messages from a platform operated by research nurses. The educational text messages were condensed SMS about HF knowledge (eg, symptoms of HF decompensation), while the reminder text messages focused on self-care adherence (eg, taking medicine or weighing). Results showed that event-free survival was better in the SMS group when compared with the control group (odds ratio 0.819, 95% CI 0.677-0.991). In terms of self-care, patients in the SMS group reported better medication compliance (*P*=.03) and water restriction (*P*=.046) than the control group, but there were no significant differences in daily weighing adherence, restricted sodium diet, and physical activity. The latter finding

XSL•FO
RenderX

might be attributed to how self-care was assessed and to what extent the text messaging program targeted these self-care behaviors (daily weighing, low-sodium diet, and physical activity). Contrary to our study, self-care adherence was not assessed with digital devices or a validated instrument, and messages in this trial were not tailored to study participants. Text messages had a limited scope compared with our Text4HF program, which, in addition to HF knowledge and self-care adherence, focused on changing health beliefs (perceived benefits and barriers of HF self-care adherence) and increasing self-efficacy.

Previous research has shown that health communication interventions that succeed in targeting specific content areas and making information relevant to their intended audience are more effective than those that do not. In a pilot single-arm prospective study (n=15) of a text messaging intervention in a largely African American population with ADHF, Nundy et al [103] found that specific SCHFI items that improved over time were generally those directly targeted by the text messages [103]. Other self-care items, such as physical activity and exercise that were not targeted by the intervention did not improve. This is consistent with the findings of our study and highlights the importance of message tailoring and careful selection of intervention, target variables and behaviors. Despite differences in the content and structure of the messaging intervention compared with our study, the positive results observed in the Chen et al [111] trial highlight the potential contribution of text messaging as a stand-alone or adjunct intervention toward improving HF self-care adherence and event-free survival in patients with HF, especially when postdischarge follow-up may not be readily available due to geographical barriers and care provider shortages.

Study Strengths

This study has several strengths. First, we used a rigorous RCT design with allocation concealment and blinded outcome assessments at all time points to minimize selection bias and detection bias [113]. Second, we used an intention-to-treat analysis to minimize attrition bias [113]. Third, our intervention involved the use of mHealth apps and devices (eg, Fitbit and Withings) that are internationally known and widely available in different countries. This choice increases the potential for scalability and broader impact if the intervention is found to be effective in future studies. Fourth, we had a high representation of minority and female patients. African Americans and women are disproportionally studied in HF clinical trials compared with HF prevalence [5,114]. Fifth, we had a high rate of patient retention and compliance associated with the intervention. This allowed for optimal testing and delivery of our intervention. Sixth, the use of a previously validated digital health platform (iCardia) ensured reliable and consistent data collection from the mHealth apps and devices, including delivery of the text messaging intervention (intervention fidelity).

Study Limitations

Though several promising results were produced, this study is not without limitations. Two important limitations are the small sample size and short follow-up duration. This study was not powered to detect statistically significant differences between the 2 groups, and therefore, effect sizes should be interpreted with caution, taking into consideration the uncertainty of the estimates as reflected by the 95% CI. A larger and longer-duration study is needed, including a maintenance period to assess the sustainability effects of the intervention. Another limitation was that our primary efficacy outcome of HF self-care was a self-reported measure, which is known to be influenced by detection bias when patients are unblinded to treatment allocation. Although we used objective measures and data from the apps and devices to assess self-monitoring adherence, these behaviors do not cover the entire spectrum of HF self-care activities that patients need to perform to maintain physiological stability. In the phase 2 trial of the iCardia4HF intervention [68], we incorporate additional methods and tools to objectively assess other important self-care behaviors, such as medication adherence (eg, pill monitoring bottles), low-sodium diet (eg, urine sodium), and completion of follow-up appointments (eg, EMR). Our intervention was not designed for people who have end-stage renal disease (exclusion criterion in this study), and therefore, our results may not be generalizable to this population. Also, the compensation of enrolled patients for their participation in the study, along with the possibility of the Hawthorn effect (modification of behavior in response to awareness of being monitored), may have influenced the results. Finally, the health belief scales that guided the text messaging intervention were developed many years ago and have not been updated since. Therefore, many items focused on adherence to water pills, a low-sodium diet, and weight monitoring. In the future, we plan to include additional intervention target variables and expand our database of behavior change text messages to other healthy lifestyle behaviors, such as heart-healthy diet, guideline-directed medical therapy, smoking cessation, alcohol cessation, physical activity, and exercise. The methodological limitations described earlier (eg, sample size, short intervention, and follow-up duration) are reflective of a phase 1 feasibility trial.

Implications for Future Research and Practice

This study contributes importantly to the limited body of literature on stand-alone mHealth interventions for patients with HF. Furthermore, it directly responds to an American Heart Association scientific statement on the current science of consumer mHealth technologies for CVD prevention [33], which recommended that future intervention studies include commercially available mHealth apps and devices to determine their safety and efficacy on health outcomes and how to best incorporate these technologies (once proven) into a broader collaborative model of care.

To our knowledge, this is the first RCT of a patient-centered mHealth intervention (without RPM) that tested the feasibility, safety, and preliminary efficacy of multiple commercial mHealth apps and devices in patients with HF. Previous studies and efforts have mainly focused on developing a single mobile app that supports most, if not all, functions of HF self-care. This is not only difficult to achieve given the fragmented nature of the current mHealth ecosystem, but also fails to consider that people tend to use multiple “best of breed” mobile apps in short bursts to support their daily activities. iCardia4HF is a departure from previous models and studies. Rather than relying on a single

XSL•FO
RenderX

app, iCardia4HF provided patients with an integrated set of popular mHealth apps and devices (MyApps), each of which specialized in different preventative behaviors covering the main areas of HF self-care and supplemented these with a program of individually tailored text messages. The combination of smartphones and low-cost mHealth technologies that are commercially available makes the proposed intervention portable to other settings and creates exciting opportunities for scalability and broader impact. Text messaging is a proven, established technology that is both inexpensive and one of the most widely adopted mobile phone functions among adults. Unfortunately, text messaging for HF has been overlooked in favor of more advanced and "shiny" RPM technologies, including mobile apps and wearable sensor devices [115]. However, there is much to be learned from text message–delivered behavioral interventions. In our study, intervention patients indicated that text messages provided them with useful information, increased perceived support, enhanced motivation to engage in better HF self-care, and provided useful prompts for healthy behavior change. Additional trials are urgently needed to determine the efficacy of text messaging both as a stand-alone and as an adjunct intervention and to build a more robust evidence base for patients with HF.

Conclusions

The iCardia4HF intervention proved to be feasible, acceptable, and safe with no evidence of increased adverse effects on HF symptoms or acute health care use (hospital readmissions and emergency visits). These results, along with the positive effects observed in HF self-care behaviors and other health outcomes, provide good evidence that a full-scale RCT to more definitively examine the efficacy of the iCardia4HF intervention in patients with HF is warranted.

Acknowledgments

The authors are indebted to the following individuals for their instrumental contributions to the conduct of the study: Laura Nawrocki, Atreya Mishra, Antonio Nieto, Jonathan Leigh, and Ayomide Owoyemi. This work was supported by the National Institute on Aging of the National Institutes of Health (grant R24AG064191) and the Center for Clinical and Translational Science (grant UL1TR002003). The funder had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication.

Authors' Contributions

SK had full access to all the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis. SK conceived and designed the study with help from BSG, SJP, and SWB. SK designed and developed the MyApps intervention component and iCardia platform. SK, BSG, and SJP developed the Text4HF intervention component based on previous studies conducted by SJP. All the authors were responsible for the acquisition, analysis, or interpretation of the data and critical revision of the manuscript for important intellectual content. SK was responsible for drafting the manuscript and also obtained funding. JS and SK were responsible for the statistical analysis. SK, BSG, MMK, SWB, and SJP were responsible for the supervision of the study.

Conflicts of Interest

None declared.

Abstract

Background: Most adults and children in the United States fail to receive timely care for mental health symptoms, with even worse rates of care access for individuals who belong to racial and ethnic minority groups. Digital (ie, app-based) care has proven to be an efficacious and empirically supported treatment option with the potential to address low rates of care and reduce care disparities, yet little is known about the relative preference for such treatment. Furthermore, the rapid adoption of telehealth care during the COVID-19 pandemic may have shifted care preferences.

Objective: This study aimed to examine relative treatment preferences for 4 different types of mental health care: in-person psychological care, telehealth psychological care, digital treatment, or pharmacologic care. Care preferences were also examined relative to potential predictors of care use (ie, gender, race, age, stigma, discrimination, and level of shame).

Methods: In this cross-sectional online survey study of adults (N=237, mean age 35 years, range 19-68 years), we ranked 4 mental health care modalities based on care preference: (1) in-person care, (2) telehealth care, (3) digital care, and (4) pharmacologic care. Preference for treatment modality was assessed based on vignette presentation for generalized anxiety disorder and insomnia. In addition, participants completed self-report questionnaires for demographics, symptom severity, and psychological and stigma-related variables.

Results: We found no difference in overall preference for in-person versus both telehealth and digital care. For both generalized anxiety disorder and insomnia, participants preferred in-person care to telehealth care, although this finding was attenuated amongst older participants for insomnia treatment. Participants' depressed mood was associated with a greater relative preference for pharmacologic care. There was no evidence of differential preference for digital care according to demographics, symptom severity, or psychological and stigma-related variables.

Conclusions: These results indicate that digital care now competes well in terms of treatment preference with in-person, telehealth, and pharmacologic treatment options.

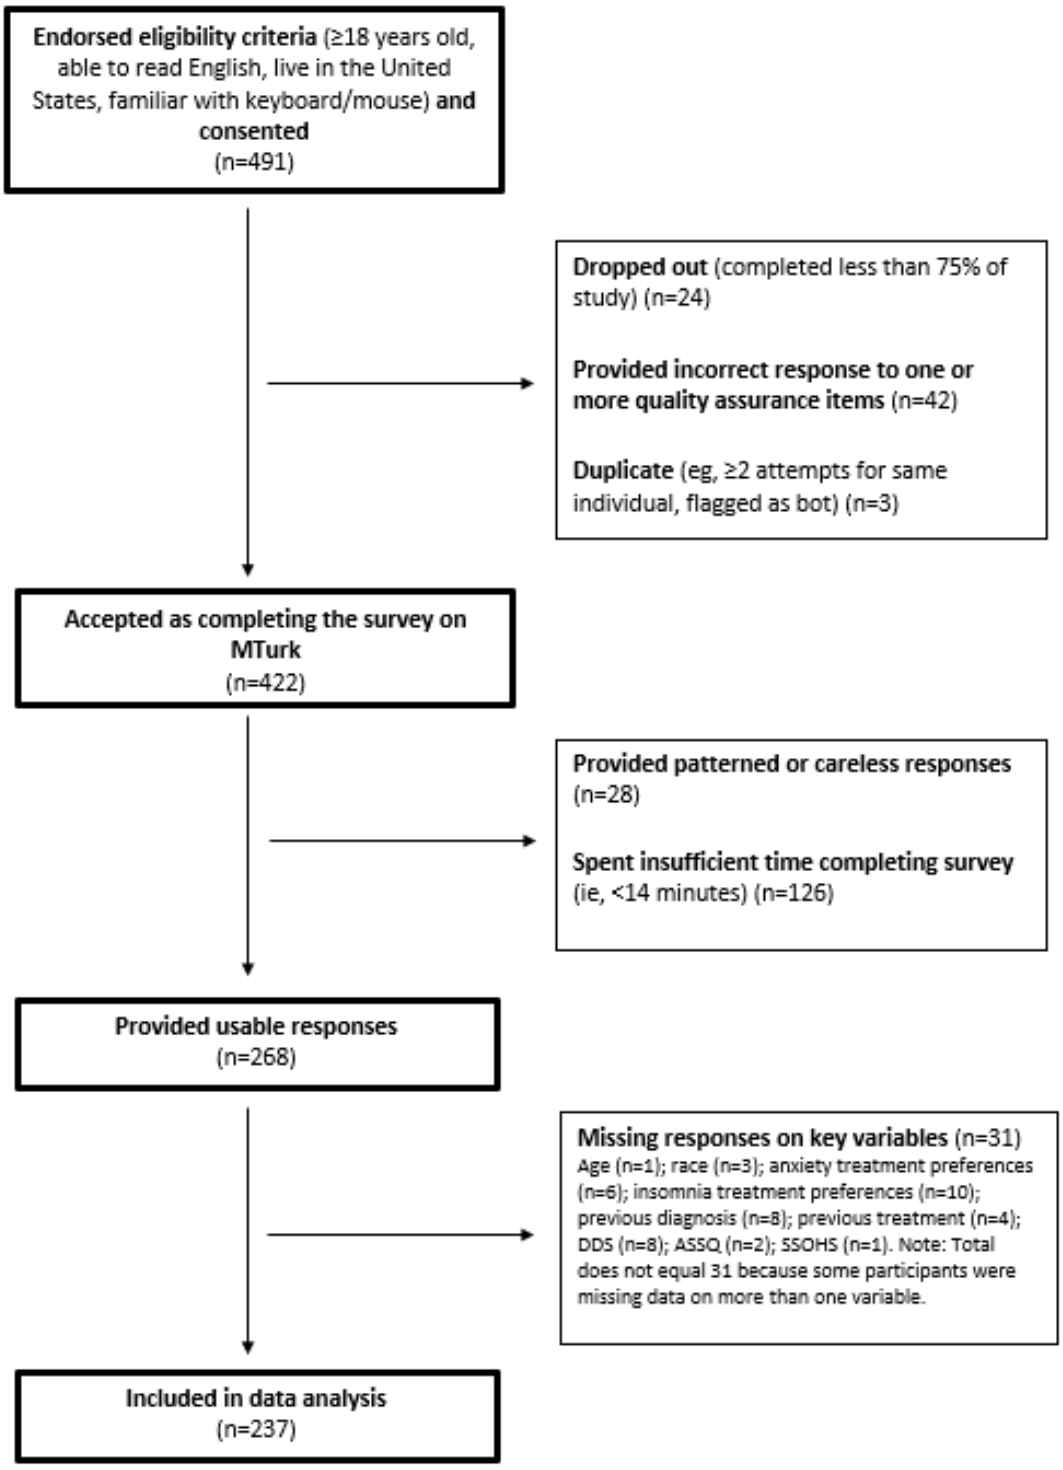
Introduction

The majority of adults and children in need of mental health services fail to receive care, with an intensification of this failure for individuals from racial and ethnic minority groups [1-4]. As a strategy to meet care needs, empirically supported digital treatment (treatments presented through a computer program or an app) has been recommended as a strategy to reduce stigma and cost and as an early modality in a stepped care model [5-8]. Meta-analyses of outcomes for digital care, and digital cognitive behavior therapy (dCBT), in particular, support this strategy as both an efficacious and cost-effective approach for addressing care needs [9-11]. Yet, little research has been done to evaluate whether dCBT addresses the attitudinal and structural barriers that prevent the initiation of mental health care. For example, data from respondents with *DSM-IV* disorders identified as part of the National Comorbidity Survey Replication revealed that the desire to manage symptoms on one's own, a facet of self-stigma, was the most common (72.6%) reason for not seeking treatment, and was followed by structural barriers such as cost, transportation, and care availability identified by 22.2% of respondents [12]. As such, there is a potential for fully autonomous dCBT to provide services for these individuals who are reluctant to seek in-person care [13] and those who face barriers to in-person care. In addition, because individuals from ethnic and racial minority groups have been found to perceive greater barriers and stigma for mental health treatment [2,14-16], there is a potential for digital treatments to help address these disparities in care by providing an alternative to specialty care clinics [17].

There is support for the hypothesis that digital treatment can indeed address some of the perceived barriers to treatment [18]. A previous study examined preference for digital or in-person treatment using 2 samples: undergraduate students and patients recruited from primary health care clinics. In both samples, there was a greater overall preference for in-person than digital treatment, but there was a significantly greater preference for digital treatment for those with higher levels of help-seeking self-stigma [18]. Greater preferences for digital treatment options have also been found for select groups, such as first-year college students [19]. Indeed, younger age and female sex, as well as treatment history and symptom levels, have been linked to a preference for digital treatment versus in-person treatment [20-22]. Yet, the care landscape appears to be changing rapidly. The COVID-19 pandemic hastened the acceptance of remote care options by both providers and consumers, with the rapid adoption of telehealth care across medical clinics [23,24], including mental health specialty clinics [25,26].

The purpose of this study was to examine relative treatment preferences for 4 different types of mental health care: in-person psychological care, telehealth psychological care (ie, provider and patient meeting online through a video conferencing platform), digital care (specifically, app-based treatment), or pharmacologic care. Care preferences were also examined relative to potential predictors of care use: gender, race, age, (self and public) stigma, discrimination, and level of shame. We conducted a large-scale online survey (through Amazon's Mechanical Turk [MTurk]) to assess preference for care based on the presentation of patient vignettes for generalized anxiety disorder (GAD) and insomnia, 2 common disorders with documented associations between self-stigma and care-seeking, for which each modality of care studied has documented efficacy [2,27-31]. We also examined whether treatment history [21] or degree of affective and insomnia symptoms influenced the care preference ratings for the vignettes.

Methods



Participants

In order to be eligible for enrollment, participants had to be 18 years of age or older and had to be able to understand English. To be included in the data analysis, participants also had to meet data quality standards appropriate for fully remote studies [32,33]. A total of 491 unique participants consented to the study, yet only 268 provided usable data, and 237 provided complete data on all variables and were included in the analysis (Figure 1 shows a diagram depicting the flow of data from consent to data analysis).

Participant ages ranged from 19 to 68 years, with a mean age of 35.41 (SD 10.53) years. In terms of the range of scores, the lowest quartile of ages reported ranged from 21 to 28 years, and the highest quartile ranged from 39 to 68 years. The majority of participants identified as male (141/237, 59.5%), 40.5% (96/237) as female, and none identified with other gender options. For race and ethnicity, 65.4% (155/237) of respondents identified as White, 20.7% (49/237) identified as Black or African American, 5.9% (14/237) identified as Asian or Asian American, 2.5% (6/237) identified as Latino/a/x or Spanish origin, 1.7% (4/237) identified as American Indian or Alaskan Native, 2.5% (6/237) selected other race or ethnicity, 0.8% (2/237) selected biracial or multiracial, 0.4% (1//237) selected Arab American/Middle Eastern or North African.

Figure 1. The flow of data from consent to analysis. ASSQ: Acculturative Stress Sensitivity Scale; DDS: Devaluation-Discrimination Scale; SSOHS; Self-Stigma of Seeking Help Scale.

Procedure

The survey was administered on Qualtrics between July 19, 2021, and July 26, 2021. Participants were recruited through Amazon's MTurk platform and received US $3 for study participation. Participants were asked to provide demographic information. Then, participants read 2 vignettes and ranked mental health treatment preference options pertaining to each diagnosis presented in the vignette, with the following question: "Imagine that you have symptoms of [anxiety/insomnia] like [name of the person in the vignette] and want to seek therapy for these symptoms, please rank order the following imagining that you will be interested in seeking treatment for anxiety/insomnia at a later point." The use of vignette-based questions is common in preference research [34] and has been shown to be effective in providing an environment to share

XSL•FO
RenderX

real-life experiences participants may otherwise be reluctant to offer [35]. In this study, 2 vignettes, one depicting GAD and the other, insomnia, were presented in a counterbalanced fashion to evaluate preference for in-person care, telehealth care, digital care, or pharmacologic care (more details in Multimedia Appendix 1). After completing vignette ratings, participants then completed questionnaires on their present levels of generalized anxiety and insomnia (GAD and Sleep Condition Indicator-8 [SCI-8]) and current interest in treatment for these concerns, presented in counterbalanced order. Participants then completed questionnaires about additional experiences that may impact treatment preferences (Patient Health Questionnaire-8 [PHQ-8], Structural Barriers, Shame Inventory [SI], Devaluation-Discrimination Scale [DDS], Self-Stigma of Seeking Help Scale [SSOSH], Brief Perceived Ethnic Discrimination Questionnaire-Community Version [Brief PEDQ-CV], and Acculturative Stress Sensitivity Scale [ASSQ]). Participants were subsequently asked to provide information on previous mental health diagnoses and whether they received treatment (8 participants indicated "declined to respond" regarding their previous mental health were coded as having no previous mental health treatment).

Measures

Anxiety Symptoms and Related Treatment Preferences

The GAD-7 is a self-report measure used to assess the severity of symptoms related to GAD from the past week [36]. It was shown to have good reliability and criterion and construct validity [36]. Participants indicate agreement with 7 statements using a 4-point Likert scale from 0 (Not at all) to 3 (Nearly every day), with responses on all items summed to create a total score ranging from 0 to 21. Higher scores indicate greater anxiety. The GAD-7 had excellent internal consistency in the current sample (α=.91). An additional item was added to assess participants' interest in treatment (yes or no), given their current level of anxiety.

Insomnia Symptoms and Related Treatment Preferences

The Sleep Condition Indicator-8 (SCI-8) is an 8-item scale used to screen for insomnia [37]. The scale can also be used to assist in diagnosis and for clinical and self-monitoring of changes in symptoms related to treatment [38]. It is considered reliable and valid. Participants respond using several 5-point Likert scales, all ranging from 0 to 4; all items are summed to create a total score ranging from 0 to 32. Higher scores indicate more mild symptoms, whereas scores of 16 or less reflect the recognized threshold criteria for insomnia disorder [37]. SCI-8 had good internal consistency in the current sample (α=.87). An additional item was added to assess participants' interest in treatment (yes or no), given their current level of sleep difficulties.

Depression Symptoms

PHQ-8 is a self-report scale providing a reliable and valid measure of the severity of depression [39,40]. Participants are asked to respond to 8 items using a 4-point scale from 0 (Not at all) to 3 (Nearly every day); all items are summed to create a composite score ranging from 0 to 24 [39]. Higher scores indicate stronger severity. In this study, this measure had excellent internal consistency in the current sample (α=.91).

Structural Barriers

A 6-item Structural Barriers scale that was developed for this study was used to assess the extent different structural barriers inhibit individuals from engaging in in-person mental health treatment (ie, lack of insurance coverage, cost, unsure about where to go or whom to see, the time required or inconvenience, being unable to get an appointment, problems with childcare, transportation, or scheduling). Items for this scale were adapted from a list of barriers to treatment identified in previous research [41]. Participants respond using a 4-point Likert scale ranging from 0 (Not at all) to 3 (To a great extent). Higher scores indicate greater hesitancy to engage due to structural barriers. This measure had acceptable internal consistency in the current sample (α=.79).

Shame

The SI is a 3-item self-report scale used to assess how individuals experience shame in relation to global and specific life events [42]. The Shame Inventory has been found to have high internal consistency, reliability, and construct validity [42]. There are 2 parts to this scale; part 1 asks about overall shame and was the only part used in this study. Participants responded on a 5-point Likert scale from 0 to 4. Items are summed, with higher scores indicating higher degrees of shame. The internal consistency of this measure in the current sample was acceptable (α=.77).

Mental Health Stigma

The DDS is a 12-item self-report measure used to assess the extent to which an individual believes others will discriminate or devalue someone with a mental illness [43]. It is one of the most frequently used measures to determine the perception of social stigma pertaining to mental illness and has high internal consistency and reliability [44]. Participants respond on a 6-point Likert scale from 1 (Strongly agree) to 6 (Strongly disagree), with higher scores indicating increased perception of public stigma. This measure has excellent internal consistency in the current sample (α=.9).

The SSOSH is a 10-item scale used to measure the self-stigma associated with seeking psychological help [45]. SSOSH has strong internal consistency reliability and test-retest reliability while also supporting its validity [45]. Participants are asked to evaluate the degree to which statements describe how they might react in situations related to seeking professional health (eg, My self-esteem would increase if I talked to a therapist, I would feel inadequate if I went to a therapist for psychological help) using a 5-point Likert scale from 1 (Strongly disagree) to 5 (Strongly agree). The internal consistency of this measure, the only measure with reverse-coded items in this study, was low (α=.53).

Racial and Ethnic Discrimination

The Brief PEDQ-CV is a 17-item measure used to assess perceptions of racial and ethnic discrimination [46]. Participants are asked to indicate how often various situations have happened to them, based specifically on their ethnicity, using a 5-point Likert scale from 1 (Never happened) to 5 (Happened very often). Higher scores indicate a higher perception of racial and

XSL•FO
RenderX

ethnic discrimination. The internal consistency of this measure in this study was excellent (α=.97).

The ASSQ is a 28-item scale used to measure an individual's sensitivity to discrimination and acculturative stress [47]. Participants respond on a 5-point Likert scale ranging from 1 (None) to 5 (Much or very much), with higher scores indicating greater acculturative stress. The internal consistency of this measure in the current sample was excellent (α=.98).

Data Analysis Strategy

Exploded logistic regression analyses with exact ties were estimated in SAS (version 9.4; SAS Institute) to examine systematic differences in treatment preferences (telehealth, digital, pharmacologic, and in-person therapy), with in-person therapy as the reference value. Data were structured such that each participant had 4 rows, 1 for each treatment option, and the outcome for each row was the assigned rank for that treatment option (1, 2, 3, or 4, with 1 being the most preferred and 4 being the least preferred). This was accomplished using PROC PHREG with exact ties and specifying participant ID numbers as strata to account for multiple observations.

After examining the main effects, interaction analyses were conducted to test whether participant characteristics were associated with rank choices by entering the multiplicative interaction term for each covariate separately with the nonreference choice values (ie, telehealth, app, and pharmacologic). Interactions were tested for significance using omnibus tests, such that a significant interaction indicated that this characteristic was associated with ranked choice broadly rather than examining only pairwise comparisons. However, individual *P* values for pairwise comparisons in interaction analyses are reported for completeness.

Ethical Considerations

All procedures were approved by the university Boston University Institutional Review Board (protocol #6064X). Electronic informed consent was obtained from all participants, who were informed of their right to withdraw from the study at any time. Participants received $3 for study completion. The data presented in this article have been deidentified.

Results

Symptom Severity and Treatment-Seeking

In terms of disorder status and treatment history, 34.2% (81/237) of participants self-reported 1 previous mental health diagnosis, 31.7% (75/237) of participants self-reported more than 1 previous mental health diagnosis, and 34.2% (81/237) self-reported no history of mental health diagnosis. Out of the full sample, 43.5% (103/237) reported previous mental health treatment, and 3% (7/237) of participants preferred not to answer. The mean score on the GAD-7 was 9.41 (SD 5.55), and 55.3% (131/237) of participants had scores in the clinical range (scores ≥10). Correspondingly, 61.2% (145/237) of the sample indicated a current interest in receiving treatment for GAD. The mean score on the SCI was 18.69 (SD 6.65), with 59.5% (141/237) scoring in the range for likely insomnia (scores ≤16). Finally, 57.4% (136/237) of the sample indicated a present interest in receiving treatment for their insomnia symptoms.

Treatment Preferences for Generalized Anxiety Disorder

Table 1 shows the mean treatment preference rankings for anxiety, as calculated using exploded logistic regression. There was no evidence that participants systematically preferred 1 type of treatment or tended to rank treatment options in a specific order (χ^2_3=4.25; *P*=.24). However, testing pairwise comparisons indicated that telehealth care was ranked as less preferable than in-person care (more details in Table 1).

There was no evidence that participant age (*P*=.41), gender (*P*=.51), or race or ethnicity (*P*=.74) were associated with anxiety treatment preference. Neither were previous mental health treatment (*P*=.61), previous mental health diagnosis (*P*=.4), baseline anxiety symptoms (*P*=.32), nor baseline sleep difficulties (*P*=.59) associated with overall treatment preferences for anxiety.

While baseline depression was not associated with treatment preference overall (χ^2_3=6.27, *P*=.10), pairwise comparisons found a significant increase in the odds of preferring pharmacologic versus in-person therapy for anxiety as depression symptoms increased (odds ratio [OR] 1.03, 95% CI 1.00-1.05; *P*=.02). Similarly, while the presence of structural barriers was not associated with treatment preference for anxiety overall, (χ^2_3=3.5; *P*=.32), pairwise comparisons found a marginally significant increase in the odds of preferring telehealth versus in-person therapy as structural barriers increased (OR 1.04, 95% CI 0.997-1.08; *P*=.07). None of the other psychological predictors were associated with treatment preference (shame: *P*=.81; devaluation discrimination: *P*=.53; self-stigma of seeking help: *P*=.54; acculturative stress sensitivity: *P*=.58; or racial and ethnic discrimination: *P*=.27).

Treatment Preferences for Insomnia

Table 1 shows the mean treatment preference ratings for insomnia. There was no evidence that participants systematically preferred one type of treatment or tended to rank treatment options in a specific order (χ^2_3=4.4; *P*=.22).

While participant age (*P*=.08) was not significantly associated with overall treatment preferences for insomnia, pairwise comparisons indicated a significant increase in the odds of preferring telehealth versus in-person treatment as age increased (OR 1.02, 95% CI 1.00-1.03; *P*=.02). Neither gender (*P*=.55), race or ethnicity (*P*=.73), previous mental health treatment (*P*=.47), previous mental health diagnosis (*P*=.49), baseline anxiety symptoms (*P*=.38), nor baseline sleep difficulties (*P*=.90) were associated with treatment preferences for insomnia.

While baseline depression was not associated with insomnia treatment preference in terms of overall ranking patterns (χ^2_3=5.06; *P*=.17), pairwise comparisons (ie, examining the impact of depression on only the preference of pharmacologic vs in-person therapy) found a significant increase in the odds of preferring pharmacologic versus in-person therapy as depression symptoms increased (OR 1.02, 95% CI 1.00-1.05; *P*=.05). Similarly, while shame was not associated with treatment preference overall (χ^2_3=4.69; *P*=.2), pairwise comparisons indicated that there was a marginally significant increase in the odds of preferring pharmacologic versus in-person therapy as shame increased (OR 1.05, 95% CI 0.998-1.11; *P*=.06). None of the other psychological variables were associated with treatment preference for insomnia (structural barriers: *P*=.57; devaluation discrimination: *P*=.89; self-stigma of seeking help: *P*=.09; acculturative stress sensitivity: *P*=.17; and racial and ethnic discrimination: *P*=.29).

Discussion

The purpose of this study was to examine relative treatment preferences for 4 different types of mental health care: in-person care, telehealth care, digital care, and pharmacologic care. Respondents reported familiarity with the mental health system, with almost 66% (156/237) reporting a previous mental health diagnosis and almost 44% (103/237) reporting previous mental health treatment; well over half the sample reported interest in future treatment for GAD or insomnia. For this sample, across these 2 referent disorders, there was consistent evidence that telehealth was less preferred than in-person psychological care. No significant difference in preference was found between in-person care and either digital care or pharmacologic care. Furthermore, of the range of demographic and psychological factors examined, moderation of preferences was evident only for depression and age. For rankings of both anxiety and insomnia care, the presence of greater depression was associated with a greater relative preference for pharmacologic than in-person care. Nonetheless, when all care options were considered, the degree to which pharmacologic care was selected as a first-choice option (approximately 22% (52/237) of the sample) was in strong accord with the 3-fold preference for psychosocial treatment options over pharmacologic treatment observed in a meta-analysis of this issue [34].

We did not replicate the common finding [20-22] of a greater preference for digital care among younger adults. Indeed, we found that telehealth care was relatively more preferred to in-person care among older rather than younger participants (within the age range evaluated: 19 to 68 years), although this association was found only for insomnia treatment. It is unclear whether this apparent loss of youth-based moderation of preferences for digital care is a result of the widespread adoption of more remote care options during the COVID-19 pandemic [23,24]. There are strong indications that the introduction of telehealth during the COVID-19 pandemic quickly led to a preference to continue this modality of care for mental health issues [48]. Likewise, a recent cross-sectional study reported that 73% of participants agreed or strongly agreed that the pandemic made them more open to telehealth in general [49]. A longitudinal examination of public discourse related to telehealth from March 2020 to April 2021 similarly suggests that continued widespread adoption and use of telehealth services is likely [50]. As such, one unexpected consequence

XSL•FO
RenderX

of the COVID-19 pandemic may be a more widespread acceptance of telehealth and digital treatments such that some of the traditional predictors of preferences for digital treatment (ie, younger adults) are no longer relevant.

Among psychological predictors, few appeared to have a discernible effect on treatment preferences. Greater barriers showed a nonsignificant trend toward predicting a greater preference for telehealth than in-person care for GAD. More consistent effects were evident for depression severity; for treatment selection for both generalized anxiety and insomnia, a greater preference for pharmacologic relative to in-person psychological treatment was found at greater levels of depression severity.

Empirically supported digital treatment has been recommended as a strategy to reduce stigma for care [5,7], yet we did not find a relationship between stigma and preference for digital care, although we did observe a trend level association between reported shame and a relatively greater preference for telehealth than in-person therapy for insomnia. What we documented instead was acceptance of digital care that rivaled that for in-person psychotherapy, telehealth psychotherapy, or pharmacotherapy, with approximately equal numbers of participants selecting each of these choices as a first preference option. An implication of this finding is that health systems and providers may need to be prepared to provide multiple strategies for care to enhance treatment acceptance among patients.

It is important to note a number of limitations to our study findings. First, our sample was recruited through an online survey, and accordingly, only those with access to the internet were able to partake in the study. As the purpose of this study was to examine preference for treatment options that included telehealth and digital care, the assessment of individuals willing to engage with a digital assessment may have biased the results. That is, those who are unable to attain easy access to the internet may have been less inclined to prefer a telehealth or digital treatment method compared with those who already have access. Second, our results were based on responses to vignettes depicting GAD or insomnia, so treatment preferences were derived only for these specific disorders. Different relative preferences may well be present for different disorders. Third, our findings were specific to the preference for treatment initiation and do not address how preferences may change as travel or cost burdens, side effects, or other adherence issues are experienced during treatment [12,21,51]. Fourth, our preference ratings presupposed that all modalities of treatment were equally available to participants and ignored the many settings or localities where specific empirically supported mental health treatment options may not be available. Finally, we recruited a few individuals in the oldest age ranges (eg, only 3% of the sample was 65 years and older), so our findings may not apply to the preferences of older adults in this age range.

Overall, our results are suggestive of an evening-out of care preferences, where digital care competes well with other modalities of care for mental health issues, specifically GAD and insomnia. Given the many individuals who fail to receive timely care for these and other disorders [1,52], our findings provide encouragement for further digital care development, validation, and dissemination to try to address these care needs for interested patients.

Acknowledgments

This study was supported by a subaward to the first author from the Columbia Roybal Center for Fearless Behavior Change NIA award P30AG064198. Work on this project was also supported by a Summer Research Project Award to the second author from Boston University's Institute for Health System Innovation and Policy. In addition, this work was supported by the National Institute on Aging of the National Institutes of Health (grant number R24AG064191). The funder had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; or decision to submit the manuscript for publication.

Conflicts of Interest

MWO receives compensation for his role on scientific and clinical advisory boards for Big Health, a digital mental health company. EMP and MWO have received grants from Big Health and NIH for the study of digital CBT outcomes. None of these entities provided support for this project and played no role in the decision to submit this paper or the content thereof.

Abstract

Background: Carbon emissions are a global concern due to their significant greenhouse effect. The health care sector's greenhouse gas (GHG) emissions must be controlled. Telemedicine in China continued to grow between 2020 and 2022, offering a promising solution for reducing carbon emissions in the country's health sector.

Objective: This study explores the potential of telemedicine for reducing GHG emissions and saving energy through a life cycle assessment.

Methods: This study used the Chinese Environmentally Extended Input-Output database, which is based on input-output models, to quantify the GHG emissions and energy consumption associated with care outpatient and telemedicine from a life cycle perspective. Data collected from the West China Second University Hospital of Sichuan University between 2020 and 2022 were incorporated into the analyses.

Results: The findings indicated that telemedicine could reduce GHG emissions by 36 tCO_2e. The GHG emissions per telemedicine session were only 19.14 $kgCO_2e$ and are expected to decrease from 2025 to 2030. Replacing in-person treatments with telemedicine can lead to an average reduction of 85.51 $kgCO_2e$ emissions.

Conclusions: In the future, the widespread adoption of telemedicine could help achieve carbon neutrality in the health care sector. Telemedicine is crucial for establishing the sustainable development of the health care sector.

KEYWORDS

telemedicine; carbon reduction potential; carbon emissions; energy consumption; sustainable development

Introduction

Background

Excessive greenhouse gas (GHG) emissions and energy usage have garnered global attention as the greenhouse impact intensifies. The Paris Agreement mandates a 43% reduction in GHG emissions by 2030 to achieve net zero by 2050 [1]. The health care sector's GHG emissions are 1.57 times higher than those of the worldwide air transport industry, estimated at 4.4% of total global net emissions, with the United States, China, and European Union countries responsible for 56% of the total global health care GHG emissions. China's health care sector is the third largest contributor to carbon emissions globally [2]. As one of the leading nations in global carbon emissions, China has been implementing measures to conserve energy and diminish carbon output. China is aiming to achieve net zero carbon emissions by promoting scientific and technological advancements and developing a comprehensive low-carbon technological innovation framework [3]. A correlation exists between expenditure in the industrial sector and GHG emissions. The total expenditure of China's health care sector as a proportion of the gross domestic product (GDP) increased from 6.43% in 2018 to 7.12% in 2020 [4]. A disparity persists

XSL•FO
RenderX

between China's health care expenditures and those of industrialized nations. As the health care industry continues to expand, its GHG emissions will also increase. The health care sector in China must use multiple strategies to mitigate GHG emissions and conserve energy.

Telemedicine refers to the use of network and information and communication technologies (ICTs) to provide remote access to health care services. It is widely used to deliver telehealth care and reduce medical expenses for patients [5,6]. The evolution of telemedicine in China has transpired via 3 phases. The initial phase, spanning from 2000 to 2015, was the early exploration period, giving rise to medical information and medical consultation businesses. The second phase, spanning from 2016 to 2019, was known as the policy development period, during which telemedicine-related policies were progressively implemented, enabling the integration of telemedicine into diagnostics. The third phase, from 2020 to 2022, was characterized by remarkable business expansion. In the context of the COVID-19 pandemic, in-person outpatient visits were halted, leading to an unprecedented surge in the demand for telemedicine. This shift altered public perceptions of health care, prompting numerous public medical institutions to adopt telemedicine, thereby enhancing its significance.

Literature Review

Telemedicine has cost-reduction benefits for patients who require time off from work, undergo alternative treatment, or face long-distance transportation challenges [7,8]. It can improve patients' access to health care by reducing the overall trip time and distance, making it more convenient for patients to receive in-person treatment [9]. The current clinical implementation of telemedicine in China primarily focuses on managing chronic diseases in internal medicine and providing home care services for postoperative patients. By enabling virtual communication, telemedicine can enhance patient care and satisfaction [10-12].

Previous research has demonstrated that telemedicine has beneficial environmental effects. It is acknowledged as a viable approach to reduce the carbon footprint by eliminating the need for patients to travel to health care facilities, potentially decreasing GHG emissions. Moreover, it can provide financial savings for patients in rural areas while promoting environmental sustainability [13,14]. Several studies have examined carbon emissions associated with telemedicine services in some regions. The findings suggest that teleconsultations delivered via telephone and video platforms are more environmentally sustainable than in-person consultations [15-17].

Telemedicine has grown significantly since the 21st century and gained widespread adoption, particularly during the COVID-19 pandemic in China. Research in telemedicine has primarily focused on system construction, remote consultation technology, and clinical application. While China's telemedicine policies are based on overarching regulations, they lack supportive measures such as financial assistance and proactive promotion [18]. To ensure the sustainable advancement of telemedicine, the government must increase its investment and construct a long-term operational framework [19]. Implementing telemedicine access policies will impact the construction and sustainable development of telemedicine platforms [20]. As a low-carbon development approach, telemedicine strategies should be tailored to local infrastructure conditions [21]. Artificial intelligence, blockchain, and robotics present new opportunities for the development of telemedicine, enabling direct interactions between doctors and remote patients through various platform models [22]. With advancements in medical service policies and telemedicine technology, China's ecological welfare performance and citizen-centered sustainable community services will continue to improve [23,24].

Prior studies have not conducted quantitative analyses on the ecological impacts and sustainable development of telemedicine in China. Given its extensive applicability, the steady development of telemedicine is important. This study aims to examine the benefits of telemedicine in reducing GHG emissions and conserving energy while also forecasting GHG emissions from outpatient visits and telemedicine utilization in China.

A model was developed using the Chinese Environmentally Extended Input-Output (CEEIO) database within the framework of life cycle assessment (LCA). LCA is an approach used to assess the environmental effects of products, processes, or activities through their life cycle, encompassing raw material acquisition, product manufacturing, transportation, distribution, utilization, potential reuse, maintenance, and ultimate disposal [25]. The LCA model has been applied to assess GHG emissions across various sectors in China, including energy, nuclear power, urban transportation systems, and biofuels [26-28]. As a comprehensive approach, LCA is also applicable for calculating energy conservation and emission reductions in telemedicine services within medical institutions. The CEEIO database has previously been used to conduct environmental assessments in China's building sector, quantify the environmental impact of resource extraction in China, and conduct input-output analyses of China's home water footprint [29-31].

Some studies have quantified the carbon emissions of telemedicine in medical institutions. In 2021, telemedicine services contributed to a 17,000 metric ton reduction in GHG emissions by Stanford Health Care [17]. An investigation of 17 research institutes in Italy indicated that a single telemedicine consultation might reduce carbon emissions by 13 kg [16]. Additionally, face-to-face outpatient clinics at the University Hospital of Northern Sweden generated 40 to 70 times more carbon emissions than telemedicine [15]. Thus, telemedicine has greater environmental advantages.

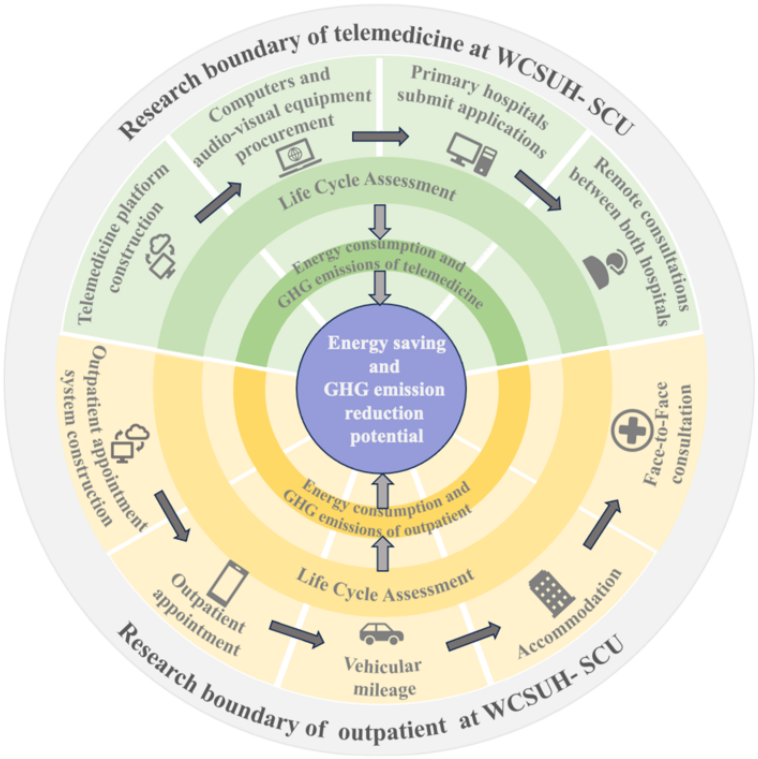
Despite extensive research on telemedicine policies and clinical applications, with some countries examining its low-carbon potential as an innovative technology, there is a lack of studies on telemedicine's contribution to sustainable development and its life cycle carbon emissions in China. As China pursues carbon neutrality and prioritizes a people-centric development strategy, enhancing the governmental recognition of the low-carbon characteristics of telemedicine is crucial for the sustainable advancement of China's health sector.

This study estimates the GHG emissions and energy consumption associated with telemedicine in China, evaluating its environmental advantages by developing a life cycle model based on patient-related data from teleconsultations at the West

XSL•FO
RenderX

China Second University Hospital of Sichuan University (WCSUH-SCU) from 2020 to 2022. WCSUH-SCU, directly supervised by the National Health Commission of China, is one of the top national tertiary hospitals and serves as a medical center for women and children in southwest China, playing a vital role in medical service, education, and research.

This study aims to reveal the level of telemedicine development and its associated ecological sustainability in southwest China. Consequently, it provides essential data to bolster the sustainable advancement of China's medical sector and offers policy recommendations for decision makers.



Methods

Research Boundaries

The research boundary of this study spans the entire process from beginning to end. At WCSUH-SCU, the telemedicine research boundary covers the development, establishment, and utilization of the telemedicine platform. Similarly, the research boundary on outpatient services at WCSUH-SCU extends from establishing the outpatient appointment platform to the in-person consultations.

The primary focus of this study is to explore the environmental benefits of telemedicine by estimating GHG emissions within both outpatient and telemedicine boundaries for the same patient. As shown in Figure 1, the outpatient appointment stage mainly includes developing the outpatient appointment system and scheduling outpatients. During the treatment stage, patients visit WCSUH-SCU for in-person consultations, with transportation assumed to be via passenger cars. Telemedicine life cycle management mainly includes the construction and usage of telemedicine platforms. The construction stage involves establishing an online telemedicine platform and purchasing computers and audiovisual equipment. During the utilizing stage, all processes are handled by the hospital administrators and doctors through computers and audiovisual equipment.

Figure 1. The research boundaries for telemedicine and outpatient of the West China Second University Hospital of Sichuan University (WCSUH-SCU). GHG: greenhouse gas.

Study Design

LCA summarizes and evaluates the energy and resource inputs and outputs of a product or activity throughout its life cycle, along with its potential environmental impact. In this study, we use LCA to evaluate the GHG emissions and energy consumption of telemedicine and outpatient services in China. Input-output models, commonly used in LCA, estimate embodied energy and carbon emissions based on industrial sector expenditures.

Previous health care environmental impact studies have used similar methods to estimate emissions from preoperative evaluation and cataract surgery [32,33]. In this study, the CEEIO database was used to quantify the GHG emissions from outpatient and telemedicine services. Additionally, Ecoinvent (version 3.9; Ecoinvent Association), a background database in LCA and other environmental assessments, was used to estimate the energy consumption per unit mileage of the car throughout its life cycle. A detailed calculation for the GHG emission reduction and energy-saving benefits of telemedicine is introduced as follows.

The CEEIO database is the result of extensive research based on the environmental extended input-output model tailored to the Chinese context. It consists of benchmark economic input-output tables published by China's government statistical agencies and statistical data from multiple sources, enabling an

XSL•FO
RenderX

extensive analysis of the environmental footprint of various industries in China. In this study, the GHG and energy intensities of China's industries were obtained from version 3.2 of the CEEIO database [34]. Detailed data on these GHG and energy intensities can be found in Table 1, where the energy consumption intensity of the software and health services is derived from the conversion of CO_2e emissions per unit standard carbon.

Table 1. GHG[a] intensities for outpatient and telemedicine industries.

Industry	GHG intensity (gCO_2e[b]/RMB[c])	Energy intensities (gce[d]/RMB)
Software services	2.66	1.08
Computer	0.72	2.05
Audiovisual equipment	0.72	2.05
Hotels	4.33	4.44
Health services	2.66	1.08

[a]GHG: greenhouse gas.

[b]The CO_2e emission per gram of standard coal is 2.46 g

[c]RMB: Renminbi (official Chinese currency).

[d]gce: grams of standard coal equivalent.

The GHG intensities due to transportation, calculated as the weighted average of passenger car emissions in China from 2020 to 2022, were 212.2, 236.07, and 247.77 g CO_2e/km, respectively [35-37]. According to the LCA from version 3.9 of Ecoinvent, the energy consumption per unit mileage of passenger cars was estimated to be 3.95 MJ/km. For electricity, the GHG intensities from 2020 to 2022 were 0.6101, 0.581, and 0.5703 $kgCO_2e$/kWh, respectively [38,39], while energy intensities were 0.305, 0.303, and 0.302 $kgCO_2e$/kWh, respectively [40].

This study used relevant data from patients who underwent telemedicine treatment over a specific period as samples, combined with economic data to calculate the GHG emissions of outpatient service and telemedicine under the same sample. This approach helped confirm the advantages of telemedicine for energy savings and GHG emission reduction.

A mathematical model was developed to estimate the GHG emission and energy consumption of both outpatient and telemedicine services, allowing for an assessment of telemedicine's GHG emission reduction and energy-saving benefits. The details of the method are described by the following 3 equations:

where $E_{outpatient}$ and $E_{telemedicine}$ represent the GHG emissions and energy consumption from outpatient and telemedicine services, respectively. $R_{outpatient}$ and $R_{telemedicine}$ represent the revenue mobilized by each industry involved in outpatient and telemedicine services, respectively. R represents the transportation distance and duration of telemedicine. Similarly, *f* not only represents the GHG and energy intensities of each industry involved in outpatient and telemedicine services, respectively, but also the GHG emissions and energy consumption per unit mileage of transportation, electric GHG emission factors, and energy consumption factors of electricity. E_{saved} represents the GHG emission reduction and energy saving of telemedicine.

Data Collection

The study sample comprised relevant data from 421 patients who completed telemedicine treatment between 2020 and 2022. The data set included the patient's primary hospital, telemedicine department, duration of telemedicine treatment, and telemedicine and outpatient service fees charged by participating doctors. Actual values are displayed in Tables S1 and S2 in Multimedia Appendix 1, taking the telemedicine data from WCSUH-SCU in 2020 as an example.

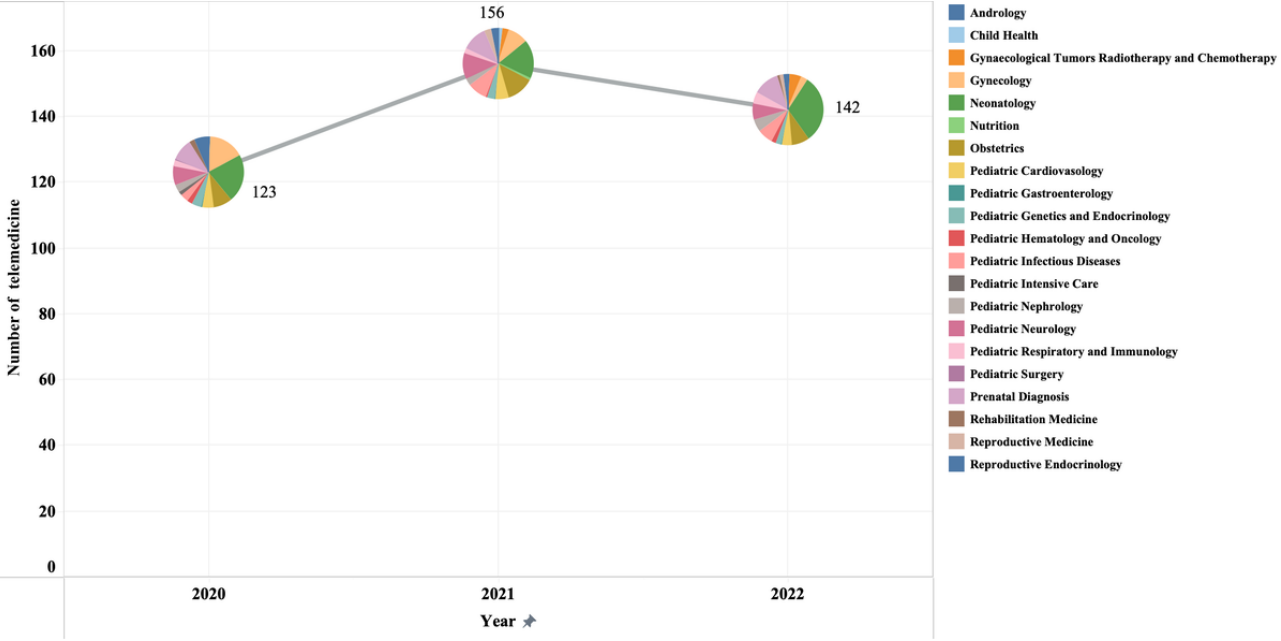
The round-trip distance for outpatient visits was calculated using the optimal driving route from the primary hospital to WCSUH-SCU, modeled through Python (version 3.7; Python Software Foundation) with Baidu Maps. Actual transportation distances for patients traveling to WCSUH-SCU for outpatient services are shown in Table S3 in Multimedia Appendix 1, using 2020 as a reference.

A hotel reservation was deemed necessary for trips exceeding 300 kilometers one way. Hotel prices were derived from the quarterly average prices of star-rated hotels in Chengdu from 2020 to 2022 [41]. The development costs of the telemedicine platform and outpatient appointment system were derived from the costs incurred by software companies collaborating with WCSUH-SCU. Outpatient and telemedicine service fees were determined according to the standards set by the Sichuan Provincial Development and Reform Commission and Sichuan Provincial Health Care Security Administration [42,43].

Data Analysis

A descriptive analysis was conducted on the distribution of telemedicine departments within WCSUH-SCU. Through modeling and data analysis, determinants influencing GHG emissions and energy consumption in outpatient and telemedicine were prioritized to reveal the principal causes impacting the GHG emissions and energy consumption in outpatient and telemedicine services.

XSL•FO
RenderX



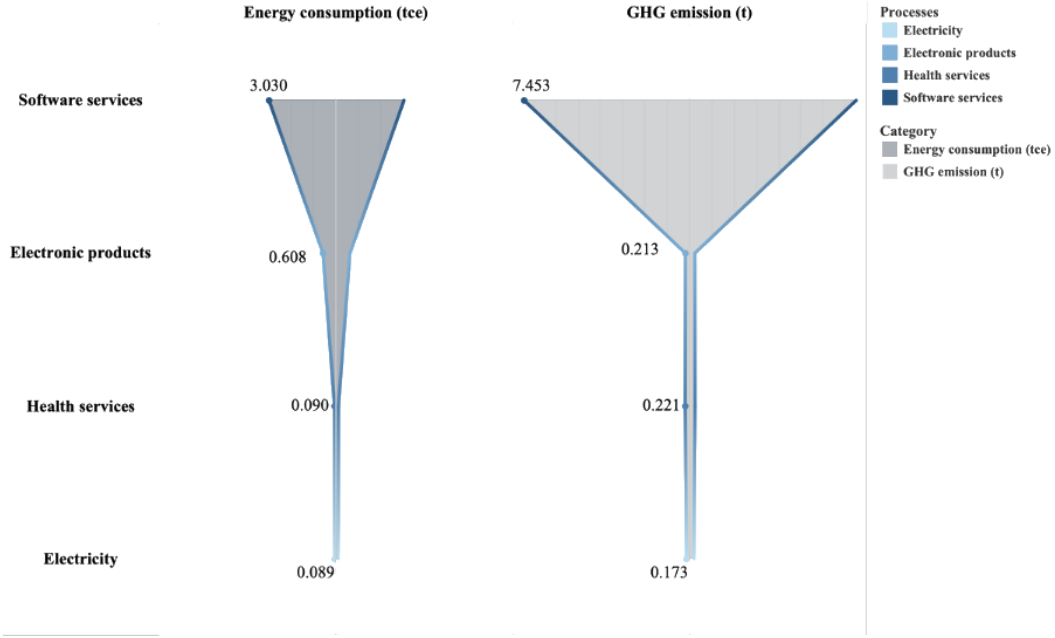
According to the existing literature, patient travel and electricity are the main factors affecting the sustainability of the health sector. This study constructed predictive models based on the average GHG emissions from transportation unit mileage, and electric GHG emission factors were established to reveal the future sustainable development of China's health care sector. The average GHG emissions related to transportation unit mileage from 2023 to 2030 were calculated by weighting the GHG emissions unit mileage of China's passenger cars from 2023 to 2030 with forecast data on vehicle ownership. Carbon emissions per unit mileage of China's passenger cars from 2023 to 2030 were based on forecast data obtained from the China Automobile Low Carbon Action Plan 2021 and 2022, including information on the carbon emissions of various energy vehicles in China. Additionally, forecast data on vehicle ownership with different energy sources in China from 2023 to 2030 were sourced from an automotive aftermarket white paper published by Roland Berger in 2022 [44]. Electric unit GHG emissions were calculated through variations in the proportion of nonfossil energy power generation combined with electricity intensities. The 14th Five-Year Plan for a Modern Energy System anticipates that the proportion of nonfossil energy in power generation will reach 39% by 2025. Simultaneously, the 2023 China Electric Power Industry Annual Development Report anticipates that the share of nonfossil energy power generation will reach 50% by 2030 [40].

Results

Descriptive Analyses

Between 2020 and 2022, a cumulative total of 421 telemedicine consultations were documented. The distribution of teleconsultation departments of WCSUH-SCU from 2020 to 2022 is shown in Figure 2. Over 3 years, telemedicine was implemented throughout 19 distinct clinical departments, encompassing reproductive medicine, pediatric subspecialties, obstetrics, and gynecology. The consultations predominantly comprised pediatric subspecialties, increasing from 55.3% (68/123) in 2020 to 65.5% (93/142) in 2022. The proportion of telemedicine in obstetrics and gynecology declined from 25.2% (31/123) in 2020 to 11.3% (16/142) in 2022. Since the onset of the COVID-19 pandemic in early 2020, the incidence of coronavirus infections among children in China has risen markedly. On the other hand, the volume of gynecological surgery patients has persistently declined due to the challenges associated with in-person medical care for epidemic control. By 2022, the prevalence of telemedicine in neonatology and prenatal diagnosis rose to 31% (44/142) and 12% (17/142), respectively, diverging from the declining trend of China's birth population from 2020 to 2022, primarily due to the Chinese government's enhancement of prenatal screening for expectant mothers and newborn disease assessments.

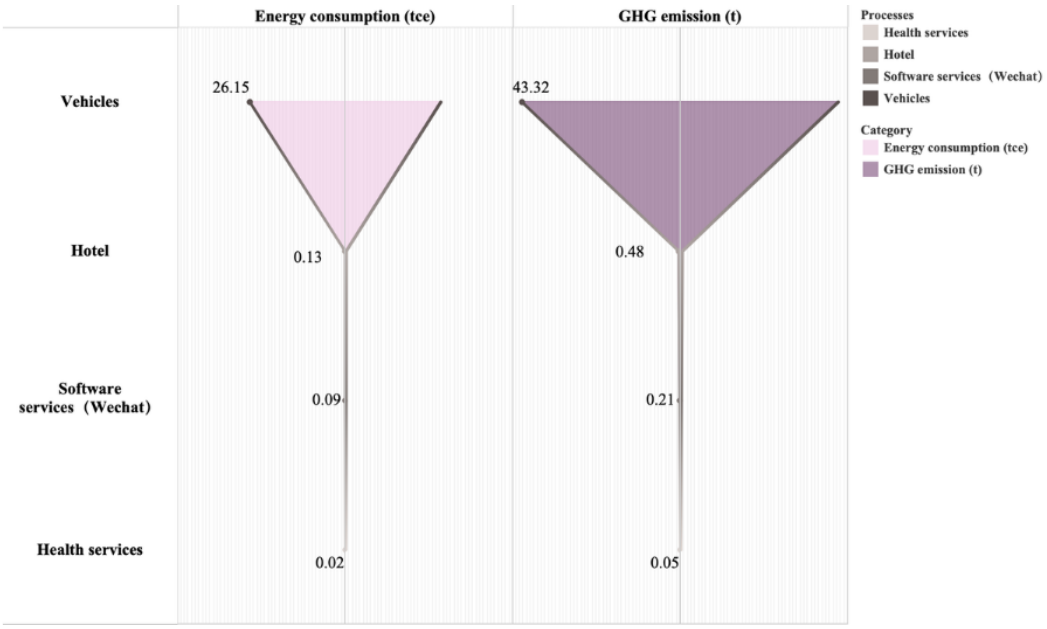
Figure 2. Distribution of telemedicine implementation departments in West China Second University Hospital of Sichuan University.



Reduction in GHG Emission and Energy Saving Through Telemedicine

Between 2020 and 2022, telemedicine services at WCSUH-SCU reduced GHG emissions by 36 tCO_2e, and their total life cycle emissions amounted to 8.06 tCO_2e, as shown in Figure 3. According to the life cycle management, the GHG emissions by telemedicine per patient amounted to 19.14 $kgCO_2e$. The software design and programming stage significantly contributed to telemedicine's GHG emissions, totaling 7.45 tCO_2e and representing 92.5% of the total. The amount of GHG emitted due to telemedicine use was 0.39 tCO_2e. Between 2020 and 2022, the energy-saving potential of telemedicine at WCSUH-SCU was 22.58 tce, while the total energy usage for telemedicine during this period was 3.82 tce. The energy consumption of software design and programming was measured at 3.03 tce, representing 79.4% of the energy consumed by telemedicine, thus remaining the largest contributor to energy consumption in this field. Furthermore, as energy consumption rose to 15.9%, electronic products, including computers and

XSL•FO
RenderX



video equipment, emerged as the second largest contributor, consuming 0.61 tce.

Figure 3. Energy consumption and greenhouse gas (GHG) emissions due to telemedicine services.

As illustrated in Figure 4, cumulative GHG emissions from outpatients between 2020 and 2022 totaled 44.06 tCO_2e, with per capita GHG emissions for outpatients reaching 104.66 $kgCO_2e$. Outpatient GHG emissions were higher than those of telemedicine services. Transportation-related GHG emissions significantly contributed to outpatient emissions, totaling 43.32 tCO_2e, which represented 98.3% of the overall emissions. Between 2020 and 2022, the total energy consumption due to outpatient services was 26.39 tce, 6.9 times greater than that of telemedicine. The energy consumption by vehicles remained the largest contributor at 26.15 tce, representing 99.1% of the overall energy consumption of outpatient services.

Figure 4. Energy consumption and greenhouse gas (GHG) emissions due to outpatient services.

Thus, telemedicine demonstrates a clear advantage in reducing emissions and conserving energy. This indicates that the effective implementation of telemedicine has the potential to improve health sector sustainability in China by enhancing energy conservation and reducing GHG emissions.

Regarding the transportation methods employed in this study, the development of clean energy and the increase in the market share of new energy vehicles are expected to help reduce GHG emissions related to transportation. In turn, this reduction is anticipated to have a positive impact on outpatient emissions. Moreover, optimizing China's energy-producing system, including enhancing hydropower and wind power, will lead to a simultaneous decrease in electric GHG emissions. Consequently, telemedicine will arise as a more environmentally friendly option for health care in China. An estimation of future

XSL•FO
RenderX

GHG emissions from transportation and electricity will then be projected based on the present policy.

Scenario Analysis

Key Factors of GHG emissions

To better demonstrate telemedicine's low-carbon characteristics and provide data to support its application and promotion, this study forecasted GHG emissions for both telemedicine and outpatient care from 2023 to 2030 based on key emission factors.

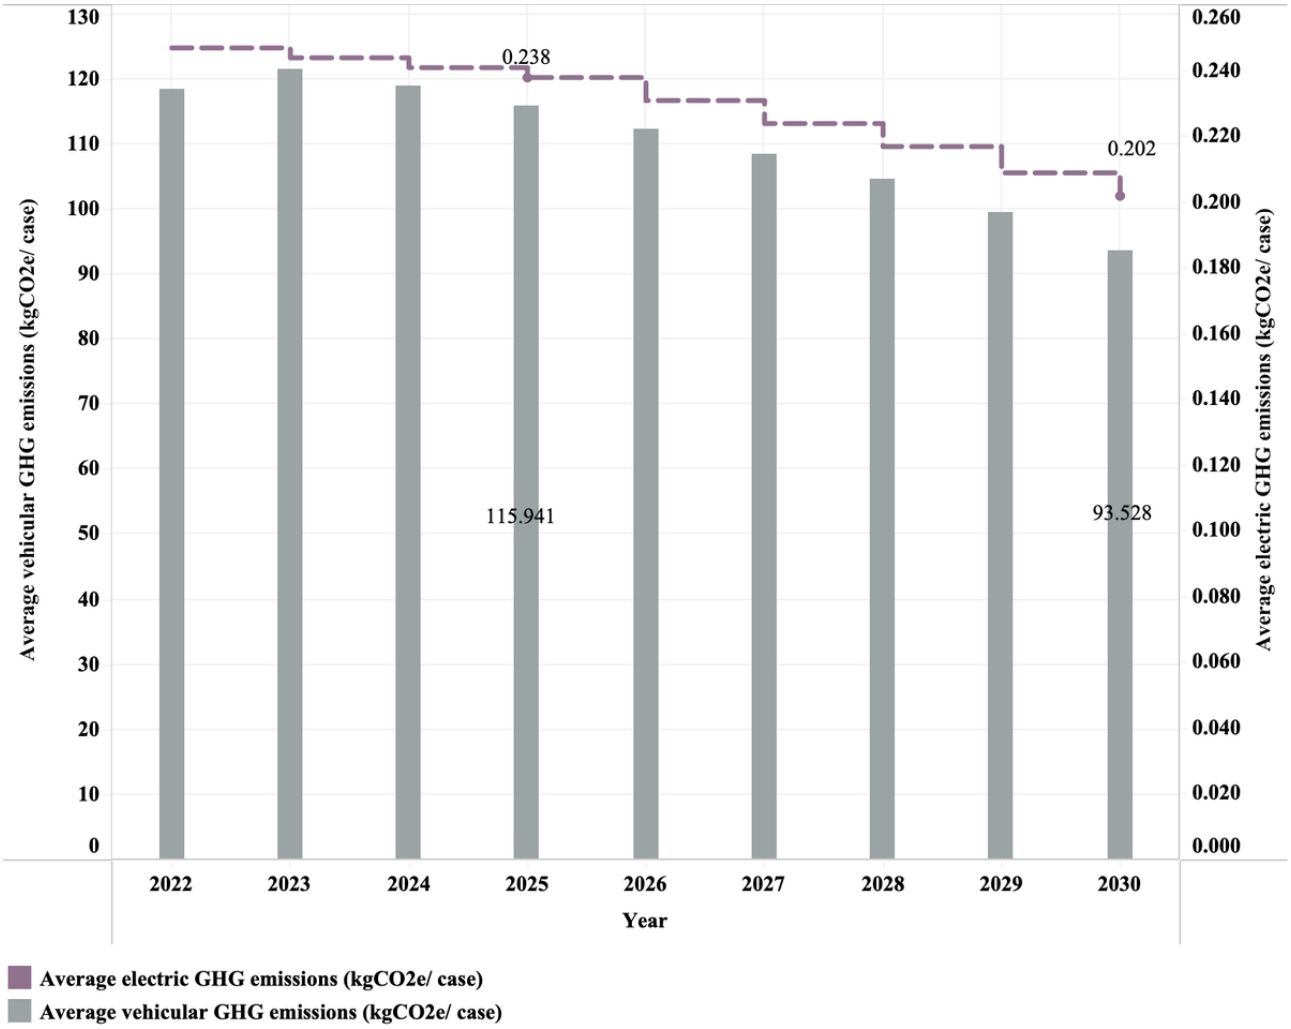
Between 2020 and 2022, transportation accounted for an average of 98.5% of GHG emissions during the patient treatment stage, making it the primary contributor to outpatient GHG emissions. Given that electricity is essential for telemedicine, it is commonly acknowledged as the main driver of telemedicine's GHG emissions.

In contrast, between 2020 and 2022, electricity was the main source of telemedicine-related emissions, averaging 75.2%. These findings highlight the significant role of electricity in contributing to GHG emissions. The primary determinants of outpatient and telemedicine GHG emissions in this study align with the findings of prior research. The GHG emissions of essential components significantly impact outpatient and telemedicine. Variations in GHG emissions from outpatient and telemedicine could be reflected in the variations in GHG emissions from transportation and electricity.

This study employed scenario analysis to forecast GHG emissions during medical treatment for patients, including telemedicine use. GHG emissions from transportation unit mileage and electricity from 2023 to 2030 were assessed according to existing national carbon emission policies. The projected GHG emissions for transportation unit mileage and electric unit GHG emissions from 2023 to 2030 are shown in Table 2.

Table 2. Projected average GHG[a] emissions for transportation per unit mileage and electricity.

Year	Transportation unit mileage GHG emissions (g CO_2e/km)	Electric unit GHG emissions (kgCO_2e/kWh)
2022	247.770	0.570
2023	254.419	0.563
2024	248.739	0.556
2025	242.776	0.549
2026	235.205	0.533
2027	227.208	0.516
2028	218.786	0.500
2029	208.402	0.483
2030	195.843	0.467



[a]GHG: greenhouse gas.

Predictive Results of GHG Emissions

Using the forecast results and 2022 teleconsultation data from WCSUH-SCU, the average transportation and electricity-related GHG emissions from 2023 to 2030 were estimated. As shown in Figure 5, there will be a brief increase in the average transportation-related GHG emissions from 2020 to 2024. The average transportation-related GHG emissions in 2025 were estimated to decrease by 2% compared to the corresponding emissions in 2022, reaching 115.94 kgCO_2e per case. This downward trend was expected to continue, with emissions expected to drop to 93.528 kgCO_2e per case in 2030. It is evident that with the increasing adoption of new energy vehicles, there will be a significant reduction in average transportation-related GHG emissions after 2025 compared to the preceding period.

XSL•FO
RenderX

Figure 5. The predictive results of greenhouse gas (GHG) emissions for transportation and electricity.

Regarding electricity-related GHG emissions, a 3.7% reduction was projected by 2025 compared to 2022, reaching 0.238 $kgCO_2e$ per case. Furthermore, the average electricity-related GHG emissions in 2030 will reduce by 15% compared to 2022. Implementing power generation structural reform has contributed to low-carbon development within the power generation industry.

Since GHG emissions from transportation account for a huge proportion of outpatient GHG emissions, GHG emissions from an average outpatient visit are expected to continue to decrease from 2025 to 2030. Depending on the effect of alterations in the average electricity-related GHG emissions from 2022 to 2030, it is anticipated that the GHG emissions of average telemedicine usage will also continue to decline from 2025 to 2030.

Discussion

Principal Results and Contributions

This study concludes that telemedicine may significantly decrease GHG emissions and energy consumption compared to in-person outpatient consultations, as determined by the LCA. Telemedicine usage leads to an average decrease of 85.51 $kgCO_2e$ emissions. In 2022, the total number of telemedicine consultations in China was 26.7 million, potentially reducing CO_2e emissions by a total of 2,283,117 metric tons. This corresponds to the yearly carbon emissions of 280,826 individuals in China [45]. According to the Mortality Cost of Carbon Model, the reduction in GHG emissions due to telemedicine could have saved 515 lives from climate change in 2022 [46]. The widespread implementation of telemedicine can markedly reduce GHG emissions and mortality rates. Telemedicine can serve as an excellent strategy for promoting environmental sustainability, reducing GHG emissions, and enhancing human health [47].

The health care sector safeguards both public health and environmental health. Expanding the accessibility and prevalence of telemedicine while minimizing carbon emissions from patient travel to hospitals is an efficient strategy to attain China's carbon neutrality objective in the health care sector [2]. Compared to the operational carbon emissions of medical institutions, telemedicine offers a clear advantage in reducing carbon emissions. This study, consistent with prior research, suggests that computers, audiovisual equipment, web servers, and electricity costs contribute to telemedicine-related GHG emissions [7]. As conventional manufacturing and technology companies globally implement low-carbon strategies to mitigate their energy consumption, there is a progressive decline in carbon emissions across the life cycle of technology-related

XSL•FO
RenderX

equipment, enhancing telemedicine's sustainability. Concurrently, sustainable energy serves as an additional impetus for the low carbonization in telemedicine. China's clean energy consumption is anticipated to rise from 25.9% in 2023 to 60% by 2030, making telemedicine a more environmentally sustainable technology [40]. As climate change intensifies, telemedicine's sustainable development of telemedicine is essential for the health care sector.

Transportation emissions remain the largest contributor to GHG emissions in outpatient care [48]. Telemedicine eliminates the need for patient travel, thereby reducing GHG emissions. China's major hospitals are predominantly concentrated in economically prosperous urban areas. However, mountainous regions in China account for 64.9% of the country's total land area, housing approximately 330 million permanent residents [49]. Patients living in mountainous regions emit large amounts of GHG when traveling to hospitals. Therefore, telemedicine can be a key solution for reducing travel-related GHG emissions.

This study confirms that in-person treatments generate more GHG than telemedicine. As 5G communication technologies and artificial intelligence continue to expand telemedicine's capabilities, more in-person treatments can be replaced. In 2022, the aggregate number of medical treatments in China was 8.42 billion, signifying a considerable potential for GHG emission reduction if telemedicine were to supplant in-person treatments.

To support the construction of a high-quality ecological environment, China has promulgated the Technology-Supported Carbon Peak Carbon Neutrality Implementation Plan (2022-2030), which proposes to achieve green development of hospital management based on green and low-carbon technological innovation. Telemedicine is innovative compared to traditional outpatient clinics. Furthermore, with the development of internet technology, more advantages and potential uses of telemedicine are coming to light. Large hospitals can make full use of telemedicine to help achieve hierarchical diagnosis and treatment. As China's medical industry shifts from a focus on medical insurance services to health services, telemedicine will expand beyond hospital diagnosis and treatment to include health monitoring and management of healthy individuals. As an innovative low-carbon technology, telemedicine will contribute significantly to the reduction of carbon emissions in China's health care industry.

Climate change is a global health crisis, and the health care sector—one of the fastest-growing sectors in terms of GDP—must take responsibility for reducing carbon emissions. Without effective intervention, global health care emissions could rise to 6 billion tons by 2050 [2]. The health care sector must promote decarbonization by developing sustainable solutions to reduce carbon emissions and improve human health. Telemedicine, as a win-win solution, should be taken seriously by the public. Despite the increased use of telemedicine during the COVID-19 epidemic, there is a lack of public awareness regarding its economic and environmental benefits. Government officials must enhance their comprehension of telemedicine's low emission advantages and implement effective procedures to facilitate its widespread adoption.

Limitations

This study uses an LCA to explore the potential of telemedicine to reduce GHG emissions and save energy. However, there are some limitations. First, transportation-related GHG emissions and energy consumption were estimated based on passenger cars. However, the diversity of transportation modes should be considered. Second, GHG emissions and energy consumption from other fixed assets, such as furniture, air conditioners in the consultation space, and network transmission during the consultation, were not included in this GHG emission reduction and energy-saving estimation. In future work, more factors affecting telemedicine carbon emissions should be included in the estimation. Third, in the carbon emission prediction section, we estimated future GHG emissions for outpatient and telemedicine services based on transportation and electricity usage without considering other factors. In future studies, more complex prediction models should be developed to predict telemedicine-related GHG emissions.

Conclusion

This study evaluates the environmental impact of telemedicine compared to traditional outpatient modes using a life cycle–based mathematical model. The findings confirm that telemedicine significantly reduces GHG emissions. From 2020 to 2022, 421 teleconsultations resulted in a total reduction of 36 tCO_2e in GHG emissions. Each telemedicine visit resulted in only 19.14 $kgCO_2e$ of GHG emissions, reducing emissions by 85.51 $kgCO_2e$ compared to in-person visits. Additionally, telemedicine use resulted in an average savings of 53.63 kg of standard coal. The primary contributors to life cycle GHG emissions in outpatient and telemedicine services were transportation and system programming design. Scenario analysis predicted that GHG emissions from telemedicine and outpatient services will continue to decline from 2025 to 2030, contributing to an overall decline in health care sector GHG emissions.

In 2022, China recorded 26.7 million telemedicine consultations, resulting in a potential reduction of 2,283,117 tons of CO_2e emissions. This reduction is equivalent to the annual carbon emissions of 280,826 individuals in China and could save 515 lives from climate change. Telemedicine serves as a dual-benefit measure by enhancing the efficiency of medical services and promoting the sustainable development of the health care sector. As the proportion of clean energy increases and ICT advances, telemedicine can be applied across more medical fields, thereby contributing more significantly to the health care sector's carbon neutrality efforts. Moreover, as the share of health services expands, telemedicine will extend beyond hospital diagnosis and treatment to encompass health monitoring and management for healthy individuals. Government decision-makers should deepen their comprehension of telemedicine's low-emission advantages and formulate effective legislation to facilitate its broad implementation.

In conclusion, this study quantifies telemedicine's role in reducing carbon emissions in China's health sector, emphasizing its significance in achieving carbon neutrality. It not only presents factual evidence to substantiate the sustainable

XSL•FO
RenderX

advancement of China's health sector but also offers a theoretical foundation for the future eco-friendly development of China's medical industry. While conducted within a Chinese context, the conclusions can extend to other nations pursuing similar sustainability goals.

Abstract

Background: With the increasing interest in the application of large language models (LLMs) in the medical field, the feasibility of its potential use as a standardized patient in medical assessment is rarely evaluated. Specifically, we delved into the potential of using ChatGPT, a representative LLM, in transforming medical education by serving as a cost-effective alternative to standardized patients, specifically for history-taking tasks.

Objective: The study aims to explore ChatGPT's viability and performance as a standardized patient, using prompt engineering to refine its accuracy and use in medical assessments.

Methods: A 2-phase experiment was conducted. The first phase assessed feasibility by simulating conversations about inflammatory bowel disease (IBD) across 3 quality groups (good, medium, and bad). Responses were categorized based on their relevance and accuracy. Each group consisted of 30 runs, with responses scored to determine whether they were related to the inquiries. For the second phase, we evaluated ChatGPT's performance against specific criteria, focusing on its anthropomorphism, clinical accuracy, and adaptability. Adjustments were made to prompts based on ChatGPT's response shortcomings, with a comparative analysis of ChatGPT's performance between original and revised prompts. A total of 300 runs were conducted and compared against standard reference scores. Finally, the generalizability of the revised prompt was tested using other scripts for another 60 runs, together with the exploration of the impact of the used language on the performance of the chatbot.

Results: The feasibility test confirmed ChatGPT's ability to simulate a standardized patient effectively, differentiating among poor, medium, and good medical inquiries with varying degrees of accuracy. Score differences between the poor (74.7, SD 5.44) and medium (82.67, SD 5.30) inquiry groups (P<.001), between the poor and good (85, SD 3.27) inquiry groups (P<.001) were significant at a significance level (α) of .05, while the score differences between the medium and good inquiry groups were not statistically significant (P=.16). The revised prompt significantly improved ChatGPT's realism, clinical accuracy, and adaptability, leading to a marked reduction in scoring discrepancies. The score accuracy of ChatGPT improved 4.926 times compared to unrevised prompts. The score difference percentage drops from 29.83% to 6.06%, with a drop in SD from 0.55 to 0.068. The

XSL•FO
RenderX

performance of the chatbot on a separate script is acceptable with an average score difference percentage of 3.21%. Moreover, the performance differences between test groups using various language combinations were found to be insignificant.

Conclusions: ChatGPT, as a representative LLM, is a viable tool for simulating standardized patients in medical assessments, with the potential to enhance medical training. By incorporating proper prompts, ChatGPT's scoring accuracy and response realism significantly improved, approaching the feasibility of actual clinical use. Also, the influence of the adopted language is nonsignificant on the outcome of the chatbot.

Introduction

Background

In recent decades, large language models (LLMs) have experienced significant advancements [1,2]. LLMs are artificial intelligence (AI) models designed to comprehend and process natural human language, as well as generate it [1,3]. Concurrent with the progression of AI, LLMs have exhibited substantial potential in executing tasks involving natural language processing [4]. LLM applications range from article synthesis to summarization to patient diagnosis, illustrating their flexibility in providing valuable assistance [5-9]. Among the various types of LLMs such as the generalist language model, Flamingo, and Minerva [10], ChatGPT stands out as one of the critical milestone models, which is the primary focus of this study.

ChatGPT, developed by OpenAI, a US-based company, represents a significant advancement in language models [11,12]. This model facilitates user interaction with follow-up questions and is fine-tuned for controlled output [13,14]. Additionally, it can be integrated into custom applications via an application programming interface, allowing developers to craft chatbots and virtual assistants with tailored behavior [13]. Built on GPT architecture, ChatGPT currently comprises 2 primary variants, GPT-3.5 and GPT-4. A key characteristic of ChatGPT is that its output is significantly influenced by the input prompt and can be fine-tuned by modifying this prompt. Consequently, prompt engineering is essential for optimizing ChatGPT's performance [15]. Despite ChatGPT and other LLMs, as well as the broader field of AI, being in developmental stages, they have demonstrated great potential in assisting human activities and may substitute human in certain tasks due to their low cost and high efficiency [16]. In the realm of medical education, traditional tests using standardized patients are no exception, involving substantial human labor and training costs [17-20].

The concept of a standardized patient, initially introduced by Barrows and Abrahamson [21], has become a widely recognized method in medical training and assessment [22,23]. In this context, "standardized" implies that the patient in a standardized patient scenario is trained to consistently portray a specific set of symptoms, medicine allergies, and medical history. Here, "patient" refers to an individual acting as if seeking medical care, unlike real patients, these are trained doctors or individuals simulating the diagnosis process to access medical professionals [23,24]. Consequently, a standardized patient is an individual trained to simulate a real patient, accurately portraying a set of symptoms or conditions. Medical students or doctors interact with standardized patients to practice and evaluate their clinical skills [22]. A critical aspect of this procedure is conversing with the standardized patient to obtain essential information for diagnosis, which is known as history-taking tasks. As the entire training process for an SP is both time-consuming and expensive, rural hospitals may even fail to provide such medical training due to poor access to high-quality health care services [25-27]. Our research aims to fill this research gap by applying LLMs, such as ChatGPT, in the assessment process involving standardized patients to tackle these problems. A critical factor influencing ChatGPT's response is the prompt input given to the model [28,29]. Nevertheless, ChatGPT's accuracy and precision require enhancement for medical applications [30,31]. Therefore, this study explored a novel approach to standardized patients in medical training evaluation by substituting human standardized patients with ChatGPT, as well as maintaining relatively high accuracy and precision. The study is conducted along 2 distinct dimensions. Initially, the capability and feasibility of ChatGPT functioning as a standardized patient are investigated. Subsequently, this study explores prompt engineering and revisions to enhance ChatGPT's performance. Finally, this study examines the differences in scores and wording between original and revised prompt (RP) results generated by ChatGPT.

Objectives

This study applied an exploratory approach to standardized patients in medical training evaluation by substituting human standardized patients with ChatGPT, as well as maintaining relatively reasonable accuracy and precision. The main objective can be divided into 2 stages of experiment. Initially, the capability and feasibility of ChatGPT functioning as a standardized patient are investigated. Subsequently, exploring prompt engineering and revisions to enhance ChatGPT's performance, and also examining the differences in scores and wording between the original prompt (OP) and RP results generated by ChatGPT.

Methods

Standardized Patient Resource

The West China Medical Simulation Center of West China Hospital of Sichuan University has released a comprehensive

XSL•FO
RenderX

standardized patient training script, encompassing a scenario-based conversational analysis and a specific performance criterion for participants, detailed in Table 1. This criterion emphasizes a procedure-oriented approach, where interactions with the standardized patient are critically evaluated and graded. The criterion comprises 2 principal aspects for evaluation: inquiry skills and humanistic care. The inquiry skills evaluation encompasses 4 dimensions, conversation arrangement, type of question, verifications, and use of professional jargon. In the domain of humanistic care, 2 dimensions are considered: speech and amiable behavior. Each dimension has 5 tiers, from tier 1 to tier 5, with ascending levels of performance. Comprehensive judgment criteria are illustrated in Table 1. ChatGPT exhibits limitations concerning criteria based on subjective judgment, as it lacks emotional response and is not fully adaptable to subjective grading. Therefore, this study focuses solely on the objective grading criteria. For example, an evaluation point could be whether the user inquired about the medicine history or not. Such criteria can be objectively assessed based on the conversation.

Table 1. Standardized patient consultation skills grading and scoring criteria. This scoring sheet can be used in standardized patient assessments to quantitatively evaluate the performance of candidates, where 5= best performance.

Skills	Ranking tiers				
	5-tier	4-tier	3-tier	2-tier	1-tier
Inquiry skills					
Conversation arrangement	The beginning, middle, and end of the consultation are clear and precise, with questions asked in an orderly manner.	Between 5-point and 3-point	Most of the consultation is conducted in an orderly fashion, but the beginning and ending are not clearly defined.	Between 3-point and 1-point	The consultation lacks coherence and organization.
Question types	Reasonable use of open-ended or closed-ended questions.	Between 5-point and 3-point	No open-ended questions, directly asking with closed-ended questions.	Between 3-point and 1-point	Frequently uses sequential and leading questions.
Verifications	Conduct a comprehensive and thorough verification and reference.	Between 5-point and 3-point	The verification and reference are incomplete and not sufficient.	Between 3-point and 1-point	Did not conduct verification and reference.
Professional jargon	The explanation is clear and easy to understand, not using complicated medical terminology.	Between 5-point and 3-point	The explanation is understandable, with minimal use of complex medical terminology.	Between 3-point and 1-point	Frequently uses complicate medical terminology.
Humanistic care					
Speech	Appropriate speech speed and tone.	Between 5-point and 3-point	The speech speed and tone are mildly uncomfortable.	Between 3-point and 1-point	The speech speed and tone are noticeably uncomfortable.
Amiable behavior	Appropriate response and comfort.	Between 5-point and 3-point	Provides responses and comfort.	Between 3-point and 1-point	No response or comfort.

Study Design

To date, ChatGPT has introduced 2 versions of its language model: GPT-3.5 and GPT-4. OpenAI reports that GPT-4 exhibits improved word processing and memory retention capabilities. These advancements make GPT-4 particularly suitable for the aims of our research [32]. The preliminary step involves ascertaining the feasibility of ChatGPT functioning as a standardized patient in medical training evaluations. To gain preliminary insights, we conduct a preliminary, exploratory conversation with ChatGPT-4. We chose inflammatory bowel disease (IBD), a relatively rare condition with multiple symptoms that can be easily confused with other diseases [33,34]. In this experiment, the chatbot was given only the name of the disease, without detailed criteria, and was asked to perform as a standardized patient to assess users' performance as if taking a standardized patient examination.

We asked a series of questions regarding IBD's symptoms to determine if ChatGPT could respond appropriately like a real standardized patient. Subsequently, ChatGPT was requested to provide a score for our inquiry process, along with its criteria for assessment. The chatbot was evaluated using 3 different approaches: using poor, medium, and good inquiries. The criteria were as follows: in the poor inquiry approach, no questions pertinent to IBD were posed, and the language was unprofessional and overly casual. The medium inquiry approach exhibited a combination of relevant and irrelevant questions, with varying degrees of accuracy. Conversely, the good inquiry approach demonstrated both linguistic precision and a consistently accurate focus on relevant topics. Each level

XSL•FO
RenderX

underwent 3 consecutive tests, and in each test, the chatbot generated the answer 10 times, from which an average score out of 30 (5 scores each × 6 groups) was calculated for each level.

For further exploration, a second phase of the experiment was designed. In this subsequent experiment, we used a detailed script accompanied by clear criteria provided by our clinical skill training center. An example from the script, featuring a perfect, full-score conversation between a standardized patient and a medical student, was used to test the chatbot. By modifying the dialog, including additions and deletions, the final score could vary. To initiate the conversation, the chatbot was provided with a patient's medical record, along with a prompt outlined in Table 2. During the subsequent conversation, the questions on the script list were asked respectively to assess if the chatbot can extract information from the medical record precisely. Each answer was checked and compared to identify the flaws in responses, which were considered as key points for future improvement. At last, a score based on the given criteria was assigned by ChatGPT, along with a detailed analysis of the score. Repeated experiments (OP-1 to OP-5) were conducted 5 times, for each experiment, ChatGPT was asked to generate the score 30 times to obtain an average error rate for this overall preliminary experiment. From OP-1 to OP-5, the questions asked differed; therefore, the total standard score also varied. The questions asked and the total score were different, but the criterion was the same. From OP-1 to OP-5, the total score was in increasing order: 20/100, 60/100, 75/100, 85/100, and 90/100, respectively. A score of 20/100 is classified as "poor inquiry," while scores of 60/100 and 75/100 are classified as "medium inquiry," and 85/100 and 90/100 are classified as "good inquiry." Given that the total score varied across each trial, we used a metric known as the score difference percentage (SDP) to quantify ChatGPT's performance. This metric represents the error rate in terms of the percentage difference between expected and actual scores. The formula used is as follows.

After the preliminary experiment was done, a full inspection of the entire conversation was given. ChatGPT's performance on the following key points is focused on: the degree of anthropomorphism, clinical accuracy, and adaptability. Considering the degree of anthropomorphism, ensuring ChatGPT mimics a real patient accurately is crucial for its validity as a standardized patient, the chatbot should emulate the tone, behavior, and emotional responses typical of a real patient. In an authentic standardized patient assessment, to simulate a real-life patient, standardized patients may pose questions driven by anxiety, for instance, "Doctor, why does my stomach ailment keep recurring? Will it eventually lead to cancer?" [35]. It is acknowledged that ChatGPT may not initiate such inquiries due to its inherent limitations; however, we will investigate whether integrating a predesigned prompt enables the chatbot to generate these types of questions [36]. Moreover, the chatbot needs to communicate the symptoms effectively, maintaining a balance between being too vague and excessively detailed. It should provide information that is similar to what a real patient may disclose. For clinical accuracy, it is essential that the chatbot delivers precise information aligned with the provided medical record, which is a critical aspect of using ChatGPT in standardized patient assessments. The response from the chatbot must align with the corresponding description in the medical record. ChatGPT is expected to recall previous responses and consistently adhere to the documented medical history. For adaptability, in actual standardized patient tests, medical students may request information from the standardized patient that is not provided in the script or medical history; therefore, ChatGPT must be capable of inferring unspecified information. Following each evaluation, ChatGPT's performance would be evaluated based on the earlier criteria, subsequently generating a list of issues. Based on the identified issues, the prompt was modified. Subsequently, a new series of experiments began, using RP. The final version of the prompt is determined when ChatGPT demonstrates satisfactory performance in terms of anthropomorphism, clinical accuracy, consistency in responses, and adaptability, among other factors. Additionally, the scores provided were closely inspected. We designed a comparative experiment involving the OP group. RP-1 to RP-5 were crafted correlating with OP-1 to OP-5. For each paired experiment, the questions posed and the total score were identical. The only difference between the OP and RP groups was the variation in the prompts provided. For each group, 30 runs were conducted to minimize the potential bias. Ultimately, the error rates will be compared with results from OPs to assess the efficacy of RP. A sample dialogue with ChatGPT is included in Multimedia Appendix 1.

Finally, the performance of the RPs was evaluated using a different standardized patient script to verify generalizability. In preliminary experiments, the dialogues with the chatbot were conducted in Chinese to minimize potential errors introduced by translation and the prompt provided was in English. However, according to a previous study on Chinese National Medical Licensing Examination questions, the translation of Chinese questions into English resulted in only a minor improvement (P=.16) [37]. To validate this research, the test group would be divided into 4 subgroups, representing all possible combinations of 2 languages used in prompts and dialogues, which were prompts in English (PE) + dialogue in English (DE); prompts in Chinese (PC) + dialogue in English (DE); prompts in English (PE) + dialogue in Chinese (DC); and prompts in Chinese + dialogue in Chinese (DC). All the tests in each group would be conducted 15 times to minimize the deviation caused by the inconsistency of the chatbot responses.

Table 2. Initial prompt given to ChatGPT[a].

Prompt	Consideration
I'm a first-year medical student. Please help me with an interactive test case. Are you familiar with the procedure of a standardized patient assessment? Now, I want you to play the role of a standardized patient, while I play the role of the student. Follow these steps.	Initialization
Your basic situation: [The detailed medical history is provided to ChatGPT based the script]	Set up specific scenario
You need to answer the questions I'm asking you based on the facts.	Restrict the free response of ChatGPT
At the end of my consultation, you need to rate my consultation process, based on following criteria: [The specific scoring rules are provided]	Grade with detailed criteria

[a]This is the initial, unrevised prompt used for interactions with ChatGPT in the phase 2 study design, prior to prompt engineering.

Data Analysis

The analysis software used in this research is R (version 4.3.3; R Foundation for Statistical Computing). For the first phase of the experiment, a 2-tailed *t* test is performed on the results to ascertain whether ChatGPT can differentiate between varying levels of problem relevance. In the second phase, the Shapiro-Wilk normality test was conducted to examine whether the data collected were normally distributed. For data not normally distributed, the Mann-Whitney *U* test was used to evaluate the significance of the differences in ChatGPT scores and standard scores, as well as between the OP and RP groups, thereby ascertaining the enhancements postprompt engineering. The data were collected during November 2023, December 2023, and August 2024.

Results

Feasibility Test

In the feasibility test, upon receiving the keyword “IBD,” ChatGPT automatically generated a virtual medical record, in subsequent interactions, it adhered to the information within the record, simulating a real patient’s behavior. For each inquiry quality group, 30 runs were conducted. Subsequently, ChatGPT provided an average score of 74.7/100 (SD 5.44) for a poor inquiry, an average score of 82.7 (SD 5.30) for a medium inquiry, and an average score of 85.0 (SD 3.27) for a good inquiry. These statistical data are presented in Table 3.

To demonstrate ChatGPT’s ability to distinguish the results, 2 inquiry model groups were established. The score differences between the poor and medium inquiry groups, between the medium and good inquiry groups, and between the poor and good groups were respectively examined. Both the score differences between the poor and medium inquiry groups ($P<.001$), between the poor and good groups ($P<.001$) were significant at a significance level of $\alpha=.05$, while the score differences between the medium and good inquiry groups were not statistically significant ($P=.16$).

The density diagram of the scores is illustrated in Figure 1. Along with each score, the chatbot provided a detailed rating scale. Across various trials, ChatGPT’s criteria varied slightly, yet the core remained consistent: it consisted of 5 components: relativeness, inquiry into medical history, clinical reasoning, professionalism, and problem-solving.

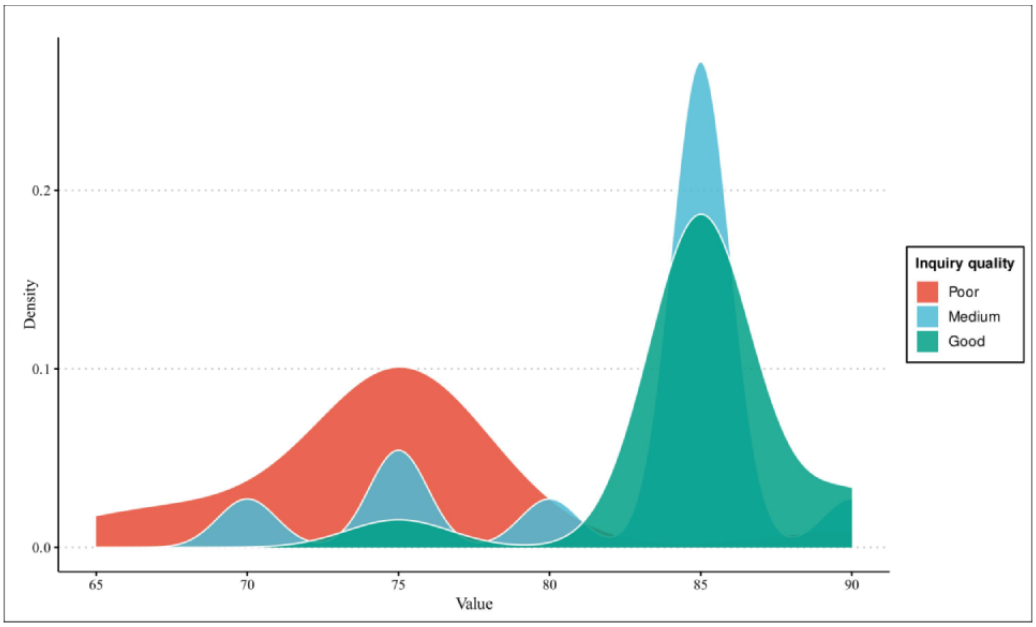

Table 3. Scores given by ChatGPT in feasibility test[a].

Inquiry quality	Mean (SD)
Poor	74.7 (5.44)
Medium	82.67 (5.30)
Good	85.00 (3.27)

[a]The table displays the mean (SD) scores provided by ChatGPT for different inquiry qualities related to inflammatory bowel disease symptom questions. The test involved three levels: “poor” (irrelevant questions and casual language), “medium” (mixed relevance), and “good” (precise and relevant). For each level, 30 interactions were conducted, and ChatGPT adhered to a virtual medical record generated for inflammatory bowel disease throughout the conversation, simulating a standardized patient.

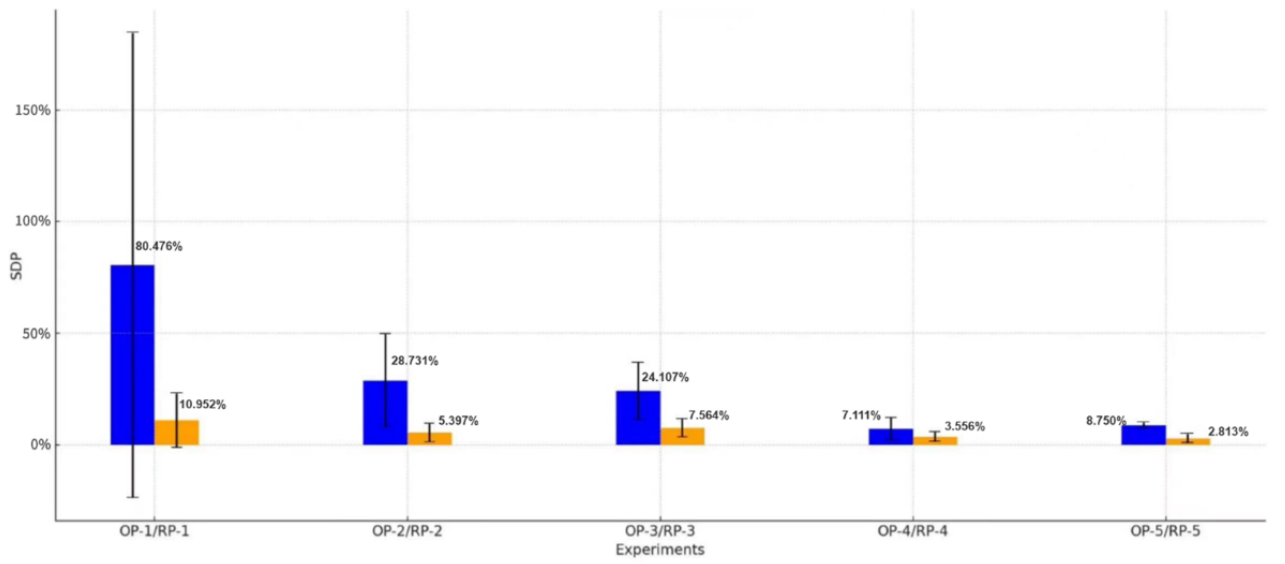
XSL•FO
RenderX

Figure 1. Scores given by ChatGPT in feasibility test. This figure illustrates the density distribution of scores given by ChatGPT when evaluating different levels of inquiry quality (poor, medium, and good) regarding IBD symptoms. Each quality level reflects varying degrees of relevance in questioning, with ChatGPT adhering to an IBD standardized patient scenario. The distribution shows how ChatGPT assessed each inquiry type. IBD: inflammatory bowel disease.

Performance Enhancement

The results from the preliminary experiment of the second phase demonstrated that ChatGPT can accurately replicate the clinical symptoms recorded in medical records; however, the scores it provided showed significant divergences compared to the standard scores. The results are presented in Figure 2. The upper band of each bar indicates the mean value of the SDP for each dataset, while the vertical line denotes SD. The data collected from the OP experiments are compared with the RP group subsequently.

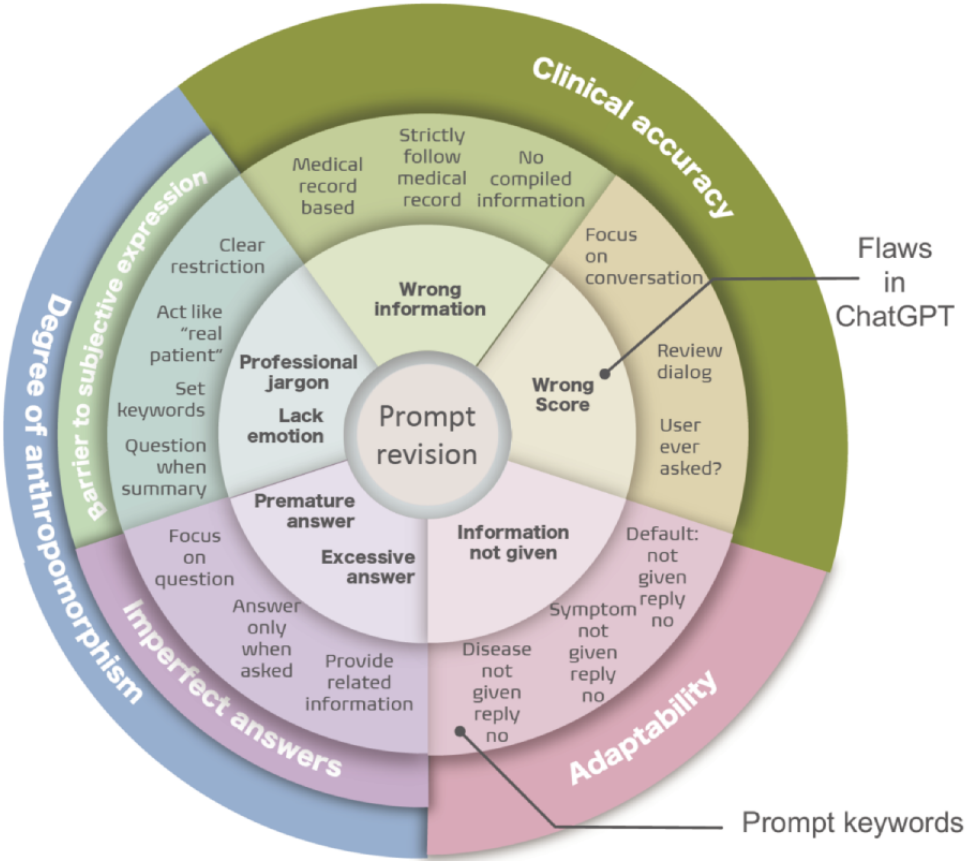
To enhance performance, we focused on the following key aspects: degree of anthropomorphism, clinical accuracy, and adaptability. Regarding the degree of anthropomorphism, some responses provided by ChatGPT were notably overly professional with medical jargon. For instance, when inquired "Where do you feel unwell?" ChatGPT responded with "Processus xiphoideus." This term is rarely used in everyday language, typically, one might say "My chest hurts." Consequently, the chatbot was instructed to "Please perform like an ordinary person that does not have much professional knowledge in the medical field and avoid using professional jargons" to adjust its behavior. Moreover, without prompts, ChatGPT cannot replicate real-life standardized patients who may ask certain questions due to anxiety. To address this, the OP was enhanced with "When I present a summary of symptoms and seek your confirmation, please first respond to my inquiry." Subsequently, simulate a patient tone characterized by anxiety, posing questions like "Can my illness be treated?" or "Is this a serious or minor illness?" Concerning clinical accuracy, several issues were identified. When queried, "Do you have any vomiting symptoms?" ChatGPT responded "Yes, basically undigested food. And my stools are normal, no black stools appeared" (this response originated from the provided medical history). The chatbot specifically inquired about the vomit habits; however, it responded with details on vomit habits and additionally mentioned the stool condition, which was documented in the medical record subsequent to the vomiting information. This indicates that ChatGPT may provide premature and overly comprehensive responses. A prompt can be introduced to address this issue: "Just answer the question each time I gave you, do not provide information that is not related to my question." Furthermore, ChatGPT provided responses not aligning with the medical records. This issue, although infrequent, emerged several times during our experiment, when asked "Where are you feeling discomfort," ChatGPT replied "head" instead of "stomach." Although the chatbot can follow the content in medical records strictly in most situations, clinical accuracy is greatly favored, the chatbot must not make mistakes in this part. Additional prompts like "Please follow strictly with the information in medical record I provided you, do not compile information already provided in the medical record" can be added. When grading, ChatGPT sometimes did not focus on the conversation about standardized patients. After providing the criteria, the chatbot would just assume the conversation has happened. This could result in a high-scoring error rate. However, when initially adding the prompt "When scoring, please concentrate solely on the dialogue that took place during the standardized patient simulation. For each criterion listed, review our conversation history to determine whether I asked the specified question. If I did not, please assign a zero for that criterion." Regarding adaptability, when ChatGPT was asked about diseases or symptoms not provided in the medical record, the chatbot was unable to answer these questions accurately, while the correct response should be "No." For instance, when being asked "Have you experienced a heart attack," ChatGPT responded with "Sorry, I cannot confirm this, as it is not indicated in the medical record." As a medical record serves as a checklist for the patients' disease history and symptoms experienced to date, it should be a



XSL•FO
RenderX

complete reflection of the patients' medical situation. Therefore, when asked about the symptoms or disease that is not provided in the medical record, ChatGPT's answer should be "No, I do not have this symptom or disease." Additional prompt can be added to ascertain the adaptability: "The patient's all disease history and symptoms are as described in the medical record. The patient does not have any disease or symptoms not mentioned." Our results are shown in the circular diagram in Figure 3. Combining all the revisional prompts, new prompts are listed in Table 4.

The results of the RP group are shown in Figure 2. We first used the Shapiro-Wilk normality test to determine whether the data in each experiment were normally distributed. The results show that all the data we got, both in OP and RP groups, were not normally distributed (all P<.001). Then Mann-Whitney U test was used to determine the significance between the mean of each dataset and the standard score. For instance, considering the OP-1 group, the standard score is 20/100, we used the Mann-Whitney U test to test if the difference between the mean of real scores ChatGPT provided in OP-1 and number of 60 has significance. Then, Mann-Whitney U tests were conducted between each paired OP and RP groups, respectively, to determine if RP indeed improved the performance of ChatGPT. The detailed result is shown in Table 5.



Using another new patient script, a total of 60 experiments were conducted on 4 test groups. The results are shown in Figure 4. The PE+DC group exhibited the highest performance, achieving an average SDP value of 3.21%. The PC+DE group demonstrated the lowest performance, recording an average SDP value of 4.2%. The average SDP values achieved by the PC+DC and PE+DE groups were generally identical (SDP=3.46%). However, the PE+DE group showed superior performance over the PC+DC group, as evidenced by a smaller deviation in results. Meanwhile, the results from the Mann-Whitney U tests, conducted across all groups, indicated no significant differences (P=.65, between PC+DC and PE+DC; P=.46, between PC+DC and PC+DE; P=.98, between PC+DC and PE+DE; P=.29, between PE+DC and PC+DE; P=.51 between PE+DC and PE+DE; and P=.37, between PC+DE and PE+DE).

Figure 2. Error bar histogram of RP and OP experiments. This figure displays SDP across 5 experiments (OP-1 to OP-5 and RP-1 to RP-5) comparing OP and RP used for ChatGPT's evaluation as a standardized patient. Each experiment involved 30 interactions, measuring the deviation of ChatGPT's provided scores from the standard scores. The blue bars represent the mean SDP for each OP group, and the orange bars indicate the corresponding RP group. Error bars denote the SD of SDP, highlighting variations in accuracy across prompt types. OP: original prompt; RP: revised prompt; SDP: score difference percentage.

Figure 3. Prompt revision for ChatGPT in standardized patient assessment. This diagram summarizes key areas for prompt revision aimed at improving ChatGPT's performance as a standardized patient. Focus areas include clinical accuracy, degree of anthropomorphism, and adaptability. Each segment outlines specific issues identified during initial tests—such as premature answers, use of professional jargon, and deviation from medical records—and corresponding prompt modifications. These adjustments were designed to enhance ChatGPT's ability to simulate realistic patient behavior, adhere to medical records, and respond consistently during medical interactions.

Table 4. The revised prompt given to ChatGPT[a].

Prompt	Consideration
I'm a first-year medical student. Please help me with an interactive test case. Are you familiar with the procedure of a standardized patient assessment? Now, I want you to play the role of a standardized patient, while I play the role of the student. Follow these steps:	Initialization
Your basic situation: [The detailed medical history is provided to ChatGPT based the script]	Set up specific scenario
You need to answer the questions I'm asking you based on the facts.	Restrict the free response of ChatGPT
Please perform like an ordinary person that does not have much professional knowledge in medical field. Avoid using professional jargons.	Avoid professional jargon
When I present a summary of symptoms and seek your confirmation, please first respond to my inquiry. Subsequently, simulate a patient tone characterized by anxiety, posing questions like 'Can my illness be cured?' or 'Is this a serious or minor illness?'	Set up question due to anxiety
Just answer the question each time I gave you, do not provide information that is not related to my questions.	Avoid premature and excessive answer
Please follow strictly with the information in medical record I provided you, do not compile information that is already provided in medical record.	Avoid wrong information
When giving score, please only focus on the conversation happened in standardized patient simulation, for each list in criteria, review our conversation history to check if I have ever asked this question, if not, then you give me a zero for this list.	Improve grading accuracy
The patient's all disease history and symptoms are as described in medical record. The patient does not have any disease or symptoms not mentioned.	Improve adaptability
At the end of my consultation, you need to rate my consultation process, the specific scoring rules are as follows: [The specific scoring rules are provided]	Grade with detailed criteria

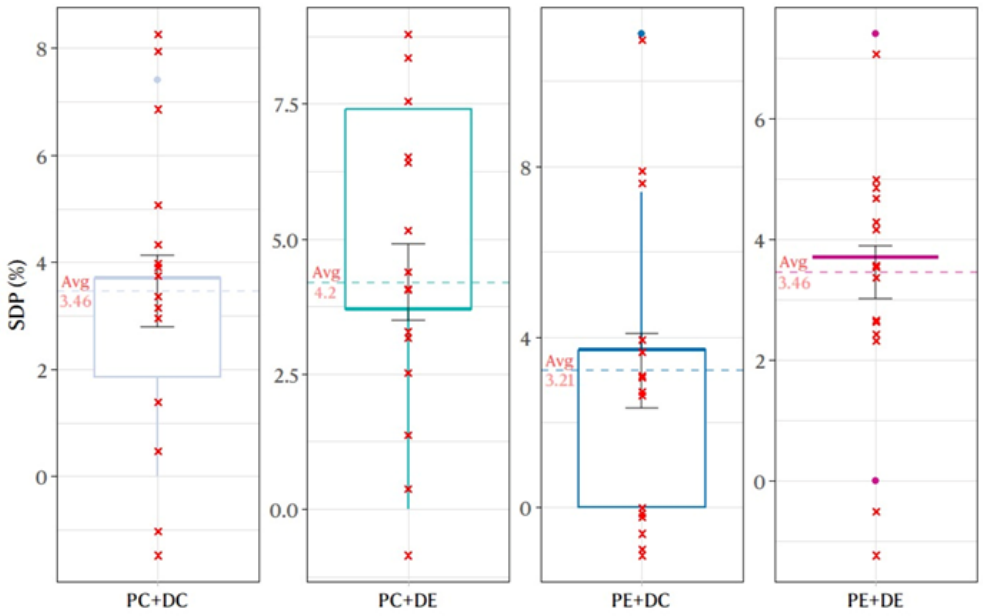
[a]This is the revised prompt used for interactions with ChatGPT in the phase 2 study design, after prompt engineering.

Table 5. Statistical data for experiment, using SDP[a,b].

Experiment order	Real score			
	Mean (SD), %	Mean ChatGPT score	Accurate score	*P* value
OP[c]-1	80.476 (1.058)	12.633	7	<.001
RP[d]-1	10.952 (0.123)	7.033	7	.28
OP-2	28.731 (0.212)	26.567	21	<.001
RP-2	5.397 (0.041)	20.333	21	<.001
OP-3	24.103 (0.131)	32	26	<.001
RP-3	7.564 (0.039)	24.033	26	<.001
OP-4	7.111 (0.051)	32.134	30	<.001
RP-4	3.556 (0.021)	29.8	30	.81
OP-5	8.750 (0.013)	34.8	32	<.001
RP-5	2.813 (0.021)	32.833	32	<.001
OP-overall	29.834 (0.550)	__[e]	—	—
RP-overall	6.056 (0.068)	—	—	—

[a]SDP: score difference percentage.

[b]The table presents the accuracy of ChatGPT's scoring during standardized patient assessments, comparing the OPs and RPs. The scoring measures how well ChatGPT's responses align with predefined standard scores for each scenario. Metrics include the mean and SD of the SDP, indicating the deviation between ChatGPT's scores and the expected standards. The table also provides accurate scores and *P* values from Mann-Whitney *U* tests, evaluating the significance of differences between ChatGPT's scoring and the expected results.



[c]OP: original prompt.

[d]RP: revised prompt.

[e]No data.

XSL•FO
RenderX

Figure 4. Experiment results using new script. This figure displays the performance of ChatGPT using revised prompts on another script across 4 language combinations: PC+DC, PC+DE, PE+DC, and PE+DE. Each group underwent 15 trials, and the results were analyzed based on the SDP metric, which measures the accuracy of ChatGPT's scoring. The Mann-Whitney U tests indicated no significant differences between any group pairs, suggesting similar performance across language combinations. PC: prompts in Chinese; PE: prompts in English, DC: dialogue in Chinese; DE: dialogue in English. SDP: score difference percentage.

Discussion

Principal Findings

Phase 1: Preliminary Experiment

In this study, we conducted an exploratory study to examine the potential of using ChatGPT as standardized patients in medical education. Also, the performance enhancement after RP was evaluated. The knowledge of ChatGPT is not updated every day, therefore the precision and accuracy of the chatbot may decrease when it comes to new diseases and medicine [30,38]. All the papers designed in this study for ChatGPT evaluation do not include diseases newly found, as all the analyses and questions provided to ChatGPT were conducted between November 2023 to December 2023. We found that with refined prompts, ChatGPT could simulate patient interactions effectively, demonstrating improvements in realism, clinical accuracy, and adaptability. The use of ChatGPT as a standardized patient offers a cost-effective alternative to traditional human standardized patients, potentially enhancing access to medical training, especially in resource-limited settings.

Our results suggest that, in the preliminary experiment, poor inquiry is most dense in a relatively high score of around 75, this score seems to be higher than expected as all 4 questions inputted to ChatGPT are basically irrelevant to the standardized patient test. However, ChatGPT is an LLM that is finetuned by humans, it is finetuned to minimize offense to humans [39,40] It is understandable that ChatGPT tends to give the user a higher score even if all the questions are wrong. As to the chatbot, it may seem to be offensive if providing a low score to human users while not having a detailed criterion. This problem disappeared in the later experiments where detailed criterion was provided. As for the medium inquiry way, ChatGPT provided an average score higher than that of a poor inquiry model. Our results suggest that the score of the medium inquiry group is the most spread, as well as the largest data range among the 3 models. This reflects that in the field of standardized patient assessment, ChatGPT can distinguish between a relevant question and an irrelevant one, but its performance is not stable and easily affected without proper definition and restriction.

Even though the average score difference between medium and good inquiries is not significant, good inquiry has the smallest variance with the highest data density. As our results suggest, the difference between poor and medium groups is significant, while the difference between medium and good is not statistically significant. Considering other trends, however, the increase in the average score, along with other data features, with respect to the increase and difference in inquiry question relevance, indicate that ChatGPT is aware of which question does not belong to a standardized patient assessment process and which question belongs to it. Although it cannot distinguish clearly without a concrete prompt, the chatbot is familiar with the process of standardized patient assessment. However, its criterion is different from the criterion provided by experts, and the scores it provides are erroneous. This is sufficient to provide evidence for the feasibility of using ChatGPT to perform standardized patient training.

Phase 2: Prompt Engineering

The preliminary experiment of the performance enhancement set up a blueprint of the whole experiment. As illustrated in Figure 2, in the first few experiments, the improvement of RP is quite significant. For instance, in the OP-1 experiment, the mean score has the SDP around 0.8 which means that the score

XSL•FO
RenderX

provided by ChatGPT is 1.8 times higher than the accurate score. With an overall average SDP of 29.834%, this shows that ChatGPT's behavior is highly unpredictable and unreasonable, and thus not feasible for application based on the current method. One noticeable trend from Figure 2 is that, when the experiment continues, the SD and average score become more accurate. This is not because of the fact that the performance of ChatGPT improves as the experiment is conducted, rather, literature suggests ChatGPT falls short when handling similar tasks. Without prompt limitation, the chatbot tends to include the content of the whole conversation into grading, beyond the user's query. For example, if the user asked 1 question that addressed 1 key point in the criteria, but ChatGPT's reply went beyond the scope of this question, its answer may cover two or more key points in the criteria. Therefore, even though the user did not explicitly inquire about certain key points, ChatGPT's expansive response might still count these unasked points during grading. Consequently, this feature will let ChatGPT tend to provide a higher overall score.

To ensure a stable, accurate performance in standardized patient assessment, prompt engineering plays a critical role. ChatGPT's output can be generally modified and controlled by changing prompts, thus a good prompt with many restrictions can constrain ChatGPT to guide the chatbot to our ideal output. The enhancement and revision of prompts become pivotal, which is the most significant and pivotal contribution of this study. The reasons why choosing the degree of anthropomorphism, clinical accuracy, and adaptability as our evaluation key point is based on ChatGPT's prompt optimizing key features [41,42]. In the context of standardized patient training, the chatbot is required to perform like a real person, moreover, it must adhere more closely to the behaviors of a real-life patient, which is the essence of the test. In achieving so, the fundamental requirement for the chatbot is to have a high level of anthropomorphism which consists of 2 major problems discovered in this research: barrier to subjective expression and imperfect answers. For the former aspect, ChatGPT tends to use professional medical jargon to illustrate symptoms in medical reports which do not accurately reflect its role as a real patient. Also, in only 1 of 5 experiments, ChatGPT responded to a question as if it were experiencing anxiety. In OP-3, when asked "Have you ever been to the hospital before for this disease?" ChatGPT first answered the question objectively, then subjectively added, "I fear that this disease has lasted for too long, so I came here to consult you." Although the case that ChatGPT has an anxiety tone is rare, this demonstrates that the chatbot can imitate this tone, requiring only some constraints in the prompt. Future studies may explore the possible prompts engineering to improve its performance in simulating human emotions. In essence, the performance of ChatGPT in the preliminary experiment is unstable and poor; however, it possesses the capability for preliminary testing yet lacks guidance, thereby necessitating optimization via prompt engineering [43], underscoring the significance and necessity of the second-phase experiment.

Ultimate Performance Enhancement

After applying RP, ChatGPT used descriptive words to answer questions like "Where is your discomfort," instead of detailed medical jargon, and the chatbot asked questions like "Why my symptoms persist?" "Can my disease be cured?" After the user has summarized the conversation. Though the chatbot's tone may seem "mechanical," it indicates that RP indeed works. For the latter aspect, the imperfect answers here refer to the chatbot's premature and excessive answers, which significantly influence grading. This part has a great influence on grading. For instance, when asked "Have you ever had other diseases in stomach?" the chatbot first answered yes, and explained when diagnosed and with what diseases. After providing sufficient information for the question, ChatGPT added "I have been to the hospital for the first time for this 2 months ago." The answer may seem reasonable. Yet, during grading, ChatGPT automatically awarded full marks for "Asking about information on previous hospital visits," justifying that the user had inquired about it. However, no question related to this was asked in that conversation. When asked for more detailed information, ChatGPT responded that since the content of the conversation mentioned the patient had gone to the hospital 2 months ago, it should count; even though this information was provided by the chatbot subjectively, not in response to the user's question. Therefore, premature and excessive questions not only influence degrees of anthropomorphism but also contribute dramatically to grading errors. Subsequently, clinical accuracy is also a concern [44]. When restrictive prompts such as "Focus on my question" and "Answer only what is asked" are used, ChatGPT began to use plain, short answers to respond, from one extreme to another, but the answer contains the essence without premature questions, making these responses preferable. During the preliminary experiments, ChatGPT can strictly follow the medical record, only once mistaking a stomachache for a headache. Additionally, in 1 conversation, the chatbot provided compiled information on the medical history. Therefore, to assure accuracy, a restrictive prompt asking ChatGPT to base answers only on the record is crucial. Also, the chatbot must be accurate when giving the score, as this is the only quantitative reflection of ChatGPT's performance in correctly evaluating medical students' performance who are taking the standardized patient examination.

With RP, the chatbot now focuses on the content that appears in the standardized patient training conversation, before that, it sometimes mistook the content of the criteria as part of the judgment, resulting in full mark. Adaptability is also important, RP made a ChatGPT response with "No" for the symptoms asked but not in medical history in the following experiment. After applying RP, ChatGPT's performance improves dramatically. One of the most serious problems in using ChatGPT is that the answer it provides has a high level of randomness and this is hard to avoid. The average SDP improved to 20 times higher than OP results. Considering the high randomness in answers provided by the chatbot, this result is quite acceptable. Also, the score deviation for each experiment is quite small, the average SD decreased to 0.068 from 0.55 in the original group results. By adding these prompts, we reduce SD to nearly one-fifteenth of its original value. Massive differences in average value and SD indicate that by giving our extra, RP, the performance of ChatGPT as a standardized patient improves significantly. The significant difference between the OP and RP results indicates that RP improved ChatGPT's performance significantly. RP-2, RP-3, and RP-5 generally have

XSL•FO
RenderX

lower SD with a lower mean SDP, which represents a higher accuracy and precision than their corresponding OP groups. To fully use ChatGPT in a standardized patient training process, good accuracy and consistency in responses are required. After applying our RP, ChatGPT has an overall SDP of 6.056%. This score is closer to 0% and improves a lot compared to the un-RP group (29.834%), even though there still remains space to improve. The results also indicate that ChatGPT's performance can be fine-tuned through the revision of prompts provided to it. Future studies may conduct a more comprehensive examination to reduce the SDP further.

The efficacy of RP was confirmed through its universal applicability when tested on another script, achieving a similar average SDP to our preliminary script. Furthermore, validation tests conducted on the new script also indicated that the impact of language on chatbot performance is insignificant ($P>.05$, for all groups). The observed performance deviation is within acceptable limits. However, the highest accuracy rate was observed in the test group that used English prompts and Chinese dialogues.

Limitations

There are several limitations in this study. First, to minimize errors associated with word translation, we conducted the simulated standardized patient test dialog with ChatGPT in standard simplified Chinese [45]. Nevertheless, the prompt provided to ChatGPT was in English to ensure accuracy. Although a separate experiment was conducted to confirm the minor impact of language used on the performance of ChatGPT, future studies may test the performance of ChatGPT on standardized patients in other languages and corresponding prompt engineering to improve its performance. Secondly, the criteria provided to ChatGPT involved only objective key points. In real standardized patient tests, some subjective judgments may also be made accordingly. Finally, the prompt revision we provided represents the optimal approach. Further research is necessary to use ChatGPT more effectively in standardized patient training.

Conclusions

ChatGPT, as a representative LLM, has much potential application in medical assessment. Our study suggests that it is feasible to use ChatGPT as a simulated patient for standardized patient evaluation and scoring. The output performance concerns introduced by the randomness of ChatGPT could be improved by adding detailed, restrictive prompts. By using prompts revised in this study, the accuracy of ChatGPT's scoring significantly improved to an acceptable level that could be used in actual standardized patients involved in medical training. Additionally, ChatGPT's responses during the conversation became more accurate and lifelike. It is worth noting that, in this application scenario, the influence of the adopted language on the chatbot's outcome is nonsignificant. Overall, ChatGPT's accuracy and performance in standardized patient assessment are acceptable, but they highlight the need for continuing improvement before it can be used as a fully trustworthy clinical assessment method.

Acknowledgments

The authors used the generative artificial intelligence tool ChatGPT by OpenAI to examine the potential use of LLMs in replacing the role of standardized patients, mainly focusing on their feasibility and accuracy. A sample dialogue with ChatGPT is made available in Multimedia Appendix 1. This study was funded by the Aier Eye Hospital-Sichuan University Research Grant (23JZH043). This study was supported by Training Programs for Innovation and Entrepreneurship of Sichuan University (project 20241039L); the Interdisciplinary Crossing and Integration of Medicine and Engineering for Talent Training Fund, West China Hospital, Sichuan University; and the 1·3·5 project for disciplines of excellence, West China Hospital, Sichuan University (ZYYC21004). Abstract

Background: Prevention of suicide is a global health priority. Approximately 800,000 individuals die by suicide yearly, and for every suicide death, there are another 20 estimated suicide attempts. Large language models (LLMs) hold the potential to enhance scalable, accessible, and affordable digital services for suicide prevention and self-harm interventions. However, their use also raises clinical and ethical questions that require careful consideration.

Objective: This scoping review aims to identify emergent trends in LLM applications in the field of suicide prevention and self-harm research. In addition, it summarizes key clinical and ethical considerations relevant to this nascent area of research.

Methods: Searches were conducted in 4 databases (PsycINFO, Embase, PubMed, and IEEE Xplore) in February 2024. Eligible studies described the application of LLMs for suicide or self-harm prevention, detection, or management. English-language peer-reviewed articles and conference proceedings were included, without date restrictions. Narrative synthesis was used to synthesize study characteristics, objectives, models, data sources, proposed clinical applications, and ethical considerations. This review adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) standards.

Results: Of the 533 studies identified, 36 (6.8%) met the inclusion criteria. An additional 7 studies were identified through citation chaining, resulting in 43 studies for review. The studies showed a bifurcation of publication fields, with varying publication norms between computer science and mental health. While most of the studies (33/43, 77%) focused on identifying suicide risk, newer applications leveraging generative functions (eg, support, education, and training) are emerging. Social media was the most common source of LLM training data. Bidirectional Encoder Representations from Transformers (BERT) was the predominant model used, although generative pretrained transformers (GPTs) featured prominently in generative applications. Clinical LLM applications were reported in 60% (26/43) of the studies, often for suicide risk detection or as clinical assistance tools. Ethical considerations were reported in 33% (14/43) of the studies, with privacy, confidentiality, and consent strongly represented.

Conclusions: This evolving research area, bridging computer science and mental health, demands a multidisciplinary approach. While open access models and datasets will likely shape the field of suicide prevention, documenting their limitations and potential biases is crucial. High-quality training data are essential for refining these models and mitigating unwanted biases. Policies that address ethical concerns—particularly those related to privacy and security when using social media data—are imperative. Limitations include high variability across disciplines in how LLMs and study methodology are reported. The emergence of generative artificial intelligence signals a shift in approach, particularly in applications related to care, support, and education, such as improved crisis care and gatekeeper training methods, clinician copilot models, and improved educational practices. Ongoing human oversight—through human-in-the-loop testing or expert external validation—is essential for responsible development and use.

KEYWORDS

suicide; suicide prevention; large language model; self-harm; artificial intelligence; AI; PRISMA

Introduction

Background

Prevention of suicide is a global health priority [1]. Approximately 800,000 individuals die by suicide yearly, and for every suicide death, there are another 20 estimated suicide attempts [1]. Despite the largely preventable nature of suicide, factors such as limited service capacity, variable service quality, and barriers to service access significantly impact the progress being made toward reducing suicide rates [2]. Recent advances in transformer-based artificial intelligence (AI)—the technology that has accelerated the development of powerful large language models (LLMs) that human clinicians and consumers can converse with—have been suggested as a potential solution to enhancing the scalability, accessibility, and personalization of health care interventions [3]. In the context of suicide research and care, LLMs can generate novel insights into suicide risk by parsing language, classifying or scoring text, and comprehending and generating human-like language, with the potential to enhance treatments by improving user engagement with digital interventions. Such improvements can also expand the capacity of crisis support services by providing real-time crisis clinician copilots, automated risk assessments, or expedited triage, enabling the optimized use of human resources. In addition, LLMs can improve the quality of training programs for those who may intervene by mentoring trainees through clinical scenarios and flexibly adopting a variety of crisis-seeking personas for clinical role-play scenarios. Hence, LLM technology might be a critical catalyst for advancement in the field. However, the relatively unexplored nature of the field means that we are only just beginning to understand how LLMs can be harnessed safely and effectively for suicide prevention. In parallel, there is a pressing need to explore how emerging trends in LLM-based research, such as the nature of training data, model types, the contexts of application, and methodological norms from relevant research fields, may shape the trajectory and direction of suicide prevention research (either positively or negatively), now and into the future.

AI refers broadly to machine and computational processes used to execute tasks usually thought of as requiring human intelligence. Natural language processing, a language-focused subfield of AI, has advanced significantly with the advent of transformer-based LLMs [4]. LLMs are the current state-of-the-art technology in computational linguistics, comprising attention-based language encoders trained using massive text datasets, generally with billions of parameters [5]. In addition to language comprehension, LLMs have recently shown their utility in generative language applications, such as generative AI interfaces (chatbots) [6]. The availability of LLMs, such as OpenAI's generative pretrained transformer (GPT) models, Google's Bard, and Meta's Llama, has created unprecedented opportunities for language generation and analysis at scale [7], with LLM applications already becoming widespread across fields such as business analytics, commerce, administration, and education [8].

Under the right conditions, LLMs can demonstrate contextual understanding and content generation that closely mimics human interaction. Accordingly, research into LLM applications in health care settings, where human interaction forms the basis of much of service delivery, is accelerating at a rapid pace; for example, LLMs have been investigated as a potential aid in preconsultation, diagnosis, and the management of disease (eg, infectious diseases and cancer [9-11]), as well as in recommending specialist appointments via SMS text messaging–based self-assessment tools for remote populations [12] and generating patient education materials [13].

Given that language is the primary basis upon which symptoms are reported and assessed in mental health, LLMs represent a significant technological advancement in mental health research. LLMs are currently under investigation for their utility in cognitive behavioral therapy facilitation [14], for emotion identification during psychotherapy sessions [15], and for the detection of positive therapeutic behaviors during motivational interviewing [16]. LLMs have also shown potential benefits in helping individuals understand personal coping styles and in facilitating stress reappraisal [7]. The application of LLMs in the field of suicide prevention is particularly promising, given that traditional methodologies, which have struggled to provide actionable insights into complex constructs such as suicide risk, are complemented by the analytic and generative capabilities of LLMs [17].

In evaluating the promising aspects of LLMs, it is also important to consider that these models present a number of challenges to researchers and end users alike. LLMs are often criticized for the inaccuracy of generated information, reducing trust and credibility [5], a failing that is compounded by the lack of interpretability of LLM functioning resulting from their "black box" architecture. Challenges also exist around data security and privacy; for example, LLMs have been demonstrated to identify individuals from deidentified digital data (eg, location data, medical billing information, or a collection of social media posts and metadata) [17]. When considering application contexts, the generalizability of LLMs is restricted to the degree of representativeness of the training data with respect to age, ethnicity, or even those who use social media versus those who do not [18]. Nevertheless, LLMs hold promise for improving models of suicide risk (eg, via digital phenotyping) [17]; for creating synthetic data [19] to increase sample sizes and statistical power for research on low base-rate events such as suicide; for powering conversational agents that support early triage, crisis support, and help seeking; and for clinician assistance tools, such as automated patient assessment systems, and simulation of crisis scenarios to improve training outcomes. Despite these potentialities, the integration of LLMs into suicide prevention currently trails other fields. Critically, significant gaps must be addressed for the field to move forward in a

XSL•FO
RenderX

manner that is safe and acceptable, including understanding the interpretability of LLM outputs, addressing biases within training data, and ensuring ethical deployment within prospective crisis settings.

To date, there have been no reviews examining the integration of LLMs into research on suicide prevention and self-harm. Prior reviews have focused predominantly on research undertaken in adjacent fields, such as applications of machine learning or chatbots to mental health more broadly [20-23]. Although several reviews have explored the use of machine learning [24-27] or AI-based strategies [28-31] in suicide prevention contexts, these have not focused on applications of LLMs specifically. Furthermore, although 1 commentary [32] and a review [25] focused on the integration of computational linguistics or natural language processing more broadly in suicide prevention, these articles did not focus on LLMs specifically, nor have any explored applications of LLMs to self-harm.

Objectives

The aim of this scoping review was to provide an understanding of current applications of LLMs in the field of suicide prevention, including applications to self-harm. The research questions guiding this review were as follows:

1. What trends are present in the literature with regard to the models used, data sources, and LLM objectives?
2. What are the clinical applications reported in the literature?
3. What ethical considerations are noted in the literature?

Specifically, we aimed to identify emerging trends in the literature related to the types of training data, models used, and intended objectives.

Our secondary aim was to explore reported potential clinical applications of LLMs (eg, as clinical copilots or to augment suicide prevention training programs) and identify ethical considerations that are crucial as the field progresses. Reported potential clinical applications were sought to better understand the future trajectory of practical LLM use in the field, with ethical considerations identified to understand the important considerations for practical deployment.

A *scoping* review was selected to map the breadth of evidence across the varied fields from which LLM-based research originates to identify key characteristics of studies, reveal knowledge gaps, and inform future research [33]. In doing so, we aim to highlight emergent trends in the research and address critical clinical and ethical considerations to ensure safe, effective, and equitable research outcomes in this key field.

Methods

This review is presented in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Multimedia Appendix 1) and was developed and carried out with reference to the JBI best practice methodological standards [34,35]. In accordance with the JBI recommendations [36], the protocol was preregistered on the Open Science Framework and is publicly available [37].

Inclusion and Exclusion Criteria

To meet the eligibility criteria, studies needed to describe the application of an LLM to the area of suicide or self-harm. Although various natural language processing models using machine learning methods exist (eg, support vector machines, Bayesian networks, and random forest algorithms), for this review, we focused on contemporary LLMs, defined as computer-engineered language models that use transformer-based neural network architecture [4]. Although LLM training parameters generally exceed 10 billion, there is no formal consensus on parameter scale [6]. In this review, smaller models (<10 billion parameters) such as early incarnations of the Bidirectional Encoder Representations from Transformers (BERT) and Text-to-Text Transfer Transformer (T5) were eligible for inclusion as they represent language models capable of contextual understanding. Studies describing the use of AI, machine learning, or big data approaches in the absence of LLM methodology were ineligible.

The domain of suicide prevention included, but was not restricted to, areas such as ideation, planning, attempts, prediction, intervention, support, means restriction, gatekeeper training, and public awareness campaigns, as well as self-harm. Studies focusing on LLM applications to mental health or psychiatry that did not specifically mention suicide or self-harm were ineligible. Studies describing quantitative, qualitative, or mixed methods designs were eligible. All studies involving human participants were required to report ethics approval. Source documents were peer-reviewed journal articles or conference proceedings. Conference proceedings were included as they have become the dominant form of published research in computer science (encompassing LLMs) in recent years [38]. Conference proceedings were required to have a comprehensive methodology and results sufficient for replication. Conference abstracts were excluded, as were other reviews and meta-analyses.

Studies using electronic health records (EHRs) were not included in this review. EHRs represent a specific type of corpus representative of individuals who are in contact with the health system. Given that a significant proportion of individuals experiencing suicidal ideation are not in contact with formal health services [39], models that draw primarily on EHR data may generate insights that do not generalize to the broader population of individuals who experience suicidality or self-harm. In addition, substantial work has focused on the use of EHRs for the prediction of suicide risk in recent years [20], with the potential for these studies to populate a stand-alone systematic review. This review sought to elicit an understanding of novel deployments of LLMs, particularly in the individual use context, and to propose future use possibilities or potentialities for support, treatment, or prevention. Studies not published in English were also excluded from this review. There was no limitation on country of origin or publication date; however, the advent of transformer architecture in 2017 naturally limited publications from prior years.

Search Strategy

Searches were conducted in 4 databases: PsycINFO, Embase, PubMed, and IEEE Xplore. An initial search was conducted on

XSL•FO
RenderX

December 6, 2023. Following abstract and full-text screening, the search was updated on February 16, 2024, to ensure recency of the search prior to final text extraction. Additional studies identified via citation chaining were also included at this point.

The search strategy used index terms and free-text terms to cover two core themes: (1) LLMs and (2) suicide or self-harm. Individual database search strings are provided in Table S1 in Multimedia Appendix 2. Search results were imported into Covidence review management software (Veritas Health Innovation Ltd) [40], which was used for abstract and full-text screening as well as data extraction.

Study Selection and Screening Process

Reflecting prior systematic research [41], title and abstract screening were conducted by 1 author (GH), with a sample of studies reviewed by multiple authors during screening and extraction. In line with recommendations for ensuring reliability and bias mitigation [33], 20.2% (77/381) of the studies identified in the initial search were randomly selected and reviewed by a second author (BT). Agreement was achieved for 71 (92%) of the 77 studies. Conflicts were discussed and resolved with input from a third author (AW).

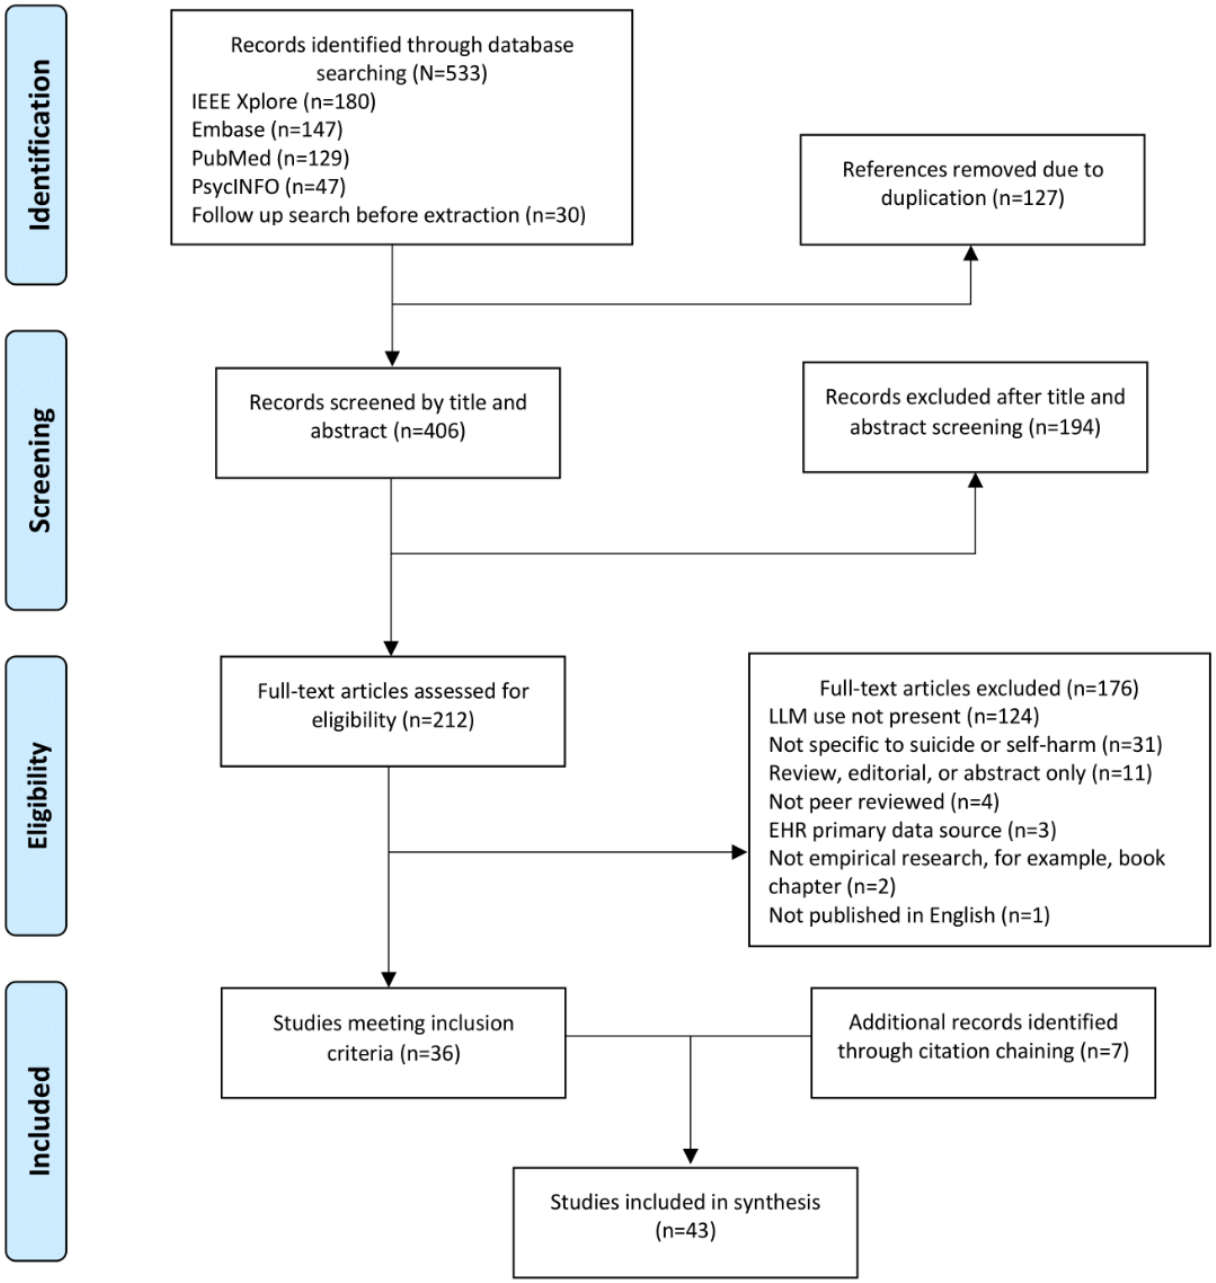
A similar process was adopted for full-text screening, which was conducted by 1 author (GH), with 20.3% (38/187) of the full texts randomly selected for review by a second author (BT). There was 92% (35/38) agreement between the authors. Conflicts were discussed and resolved with input from a third author (AW).

Data Extraction

The data extraction template was piloted with 9% (4/43) of the included studies by 2 authors (GH and BT) in line with prior research [41,42], resulting in >90% agreement. Minor refinements were made to the template to assist later synthesis. Data extraction from the 43 included articles was performed by 1 author (GH), with 19% (8/43) of the studies randomly selected and data independently extracted by a second author (BT). The comparison of extracted data showed >90% agreement. The data extraction template included items under the headings of study characteristics, methods, outcomes, and reproducibility and is available in Table S2 in Multimedia Appendix 2.

Analysis

Studies were classified across deductively derived categories, with categories based on previous research [42] and with scope for adjustments during the review process if required (eg, the aggregation of specific data sources to report on social media more generally as a source of data). Descriptive statistics were computed and presented in textual, tabular, or graphical format, as appropriate. A narrative synthesis of the included studies was conducted to answer the key research questions.



Results

Selection of Sources of Evidence

The search results are presented in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart (Figure 1). The search yielded 533 studies; after removing 127 (23.8%) duplicates, 406 (76.2%) studies were retained for title and abstract screening. Of these 406 studies, 194 (47.8%) were excluded, leaving 212 (52.2%) for full-text review. After full-text screening, 176 (83%) of the 212 studies were excluded (the reasons for exclusion are shown in Figure 1), and 36 (17%) studies met the inclusion criteria. An additional 7 studies were identified through citation chaining, resulting in 43 studies included for synthesis.

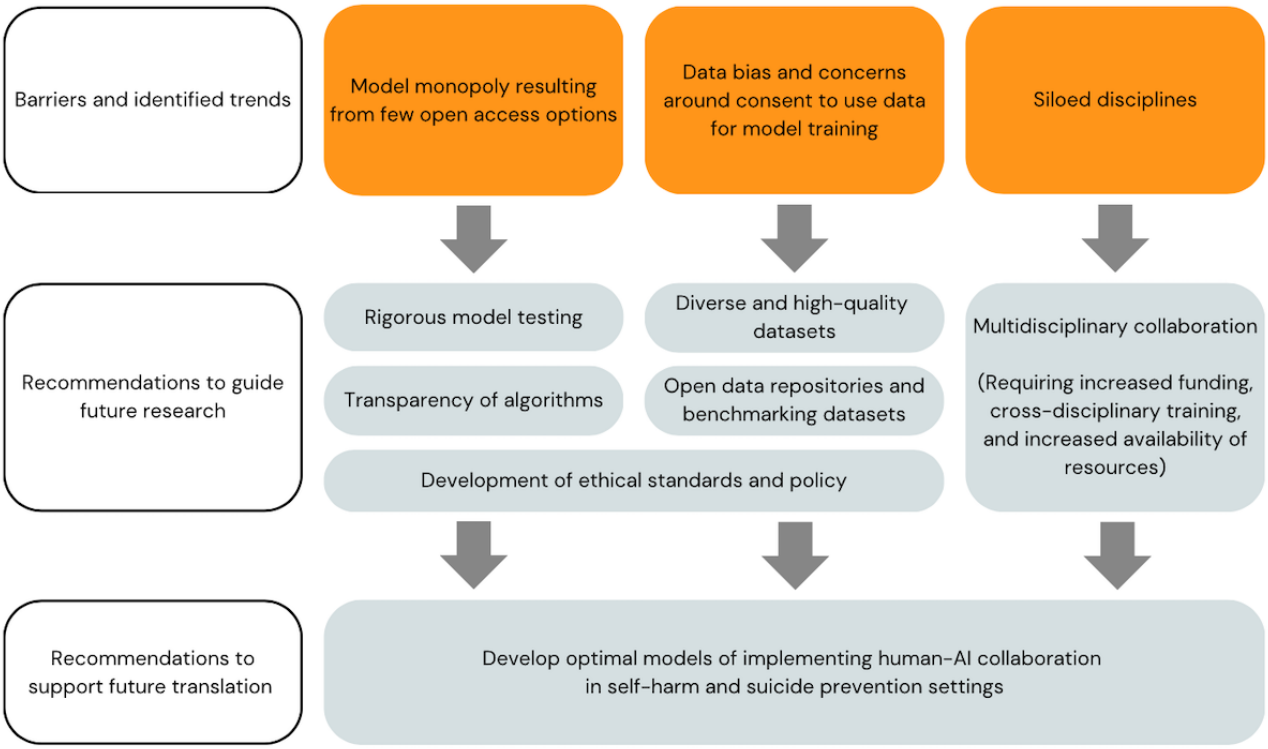
Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. EHR: electronic health record; LLM: large language model.

Characteristics of Included Studies

A full list of included publications and associated results data is presented in Multimedia Appendix 3 [43-85]. The number of publications by year demonstrated a compounding pattern, with the first publications emerging in 2019 after the development of the transformer architecture [4] in 2017 and then increasing sharply in 2023 after the release of ChatGPT to the public in November 2022.

The articles identified for this review came from 20 different sources that predominantly came from 2 fields (determined by reviewing individual journal aims and scope): computer engineering (23/43, 53%) and health (18/43, 42%). The bifurcated nature of the publication field of origin demonstrates the cross-disciplinary nature of LLM research. Approximately a third of the studies (16/43, 37%) were published as conference proceedings via IEEE Xplore, reflecting publication norms in computer engineering [38]. The largest proportion of studies came from the United States (10/43, 23%). Study funding was predominantly sourced through grants (23/43, 53%). Of the 43 studies, 4 (9%) indicated no funding, and 16 (37%) did not provide funding information.

Synthesis of Results



Base LLMs Used

A synthesis of identified trends with associated recommendations is presented in Figure 2. Most of the studies (35/43, 81%) applied some derivation of Google's BERT.

XSL•FO
RenderX

OpenAI's GPT family of LLMs were used in 9 (21%) of the 43 studies. Other models included XLNet (3/43, 7%); Google's Fine-Tuned Language Net (FLAN; 2/43, 5%); and Alpaca, Alexa, DeepMoji, and contrastive language-image pretraining (1/43, 2% each). Some studies applied >1 model type. The widespread adoption of BERT can be attributed in part to its status as one of the earliest open-source models (accessible since its inception in 2018), allowing users to freely download and use the model for research purposes. FLAN [86] is also open source, though more recently released, in 2022. Contrastive language-image pretraining, DeepMoji, Alexa, and GPT-3.5 are accessible via an application programming interface but are not open-source models, limiting data transparency and the reliability of availability required for most research applications.

Figure 2. Trends and associated recommendations for ensuring safe and effective integration of large language models into suicide prevention and self-harm research. AI: artificial intelligence.

In 33 (77%) of the 43 studies, the primary purpose of LLMs was contextual understanding of language, while 9 (21%) studies extended upon this by using the capacity of LLMs to generate natural language responses to prompts (all these studies were published in 2023). The study by Badian et al [47] also used an LLM for image interpretation. Applications that focused on contextual language understanding were predominantly used for the identification, detection, or prediction of suicide risk. Generative applications also focused on prediction-based tasks [43,44,83] but extended to the evaluation of suicide risk [58,61,66], the identification of circumstances preceding suicide [85], information retrieval or question-answering systems [46], and the creation of mental health nursing care plans [81]. Of the 9 generative applications, 7 (78%) used the text-based ChatGPT user interface, while the remaining 2 (22%) used text-based interfaces for an educational BERT model [46] and a data-secure FLAN model [85]. The prevalence of GPT use in generative applications stands in contrast to the dominance of the use of the BERT model across LLM-based research to date more generally. This hints at a potential shift away from studies primarily focused on BERT. Whether this trend reflects a broader shift in model preference or was influenced by factors such as availability, the ease of use, or specific application requirements was not clear from the included studies.

Data Sources

The majority of the included studies (31/43, 72%) used data from user posts on social media platforms for LLM training, validation, testing, and deployment to answer a research question. Reddit was the most commonly used platform from which data were derived (18/43, 42% studies), followed by X (formerly Twitter; 13/43, 30% studies). User posts from other platforms were also used [51,52,82,84]. Meta's Facebook was used only in the study by Badian et al [47], in which only images, not text data from users, were used. Of the 31 studies using social media data, only the study by Badian et al [47] sought user or poster consent for the use of their data. Of the 12 studies that did not use social media data, 3 (25%) used data from crisis counseling apps or services [48,59,73]; 6 (50%) used a heterogeneous collection of data from the National Violent Death Report System [80,85], educational or academic documents [46,64], or participant vignettes [66,81]; 1 (8%) used research participant data gathered during the course of the study [70]; 1 (8%) did not use collected data but applied prompt inputs to ChatGPT to evaluate responses [61]; and 1 (8%) proposed an LLM-moderated train safety device, designed to initiate braking and deploy an inflatable safety cell in front of the train after voice activation by the train driver [77].

XSL•FO
RenderX

Identified Objectives

Studies were grouped by 4 main objectives: prediction, identification or classification, support, and education or training. The majority of the studies (33/43, 77%) identified in this review applied LLM models to identification or classification tasks, with prediction applications the next most common (6/43, 14%). Studies that focused on the problems of identification or classification sought to identify content indicative of suicidal distress from text-based data, such as in Reddit posts [49,56-58,60,63,68,71,76], in X (formerly Twitter) posts [45,53,69,72,78], or in crisis or helpline conversations [48]. Additional uses included identifying precipitating events to suicide from death investigation narratives [80] and identifying self-harm from social media posts [54]. Prediction-focused studies predominantly used LLMs with data from Reddit [50,65,83], other social media [84], images posted on social media [47], crisis counselling data [59], or clinical data [50] to predict suicide risk.

The remaining model applications (4/43, 9%) assessed support [61], education [46], and "other" (ie, the generation of mental health care plans and means restriction) [77,81]. Of these 4 studies, 3 (75%) involved the use of generative AI. Regarding education, a question-and-answer interface was developed to generate specific information requested by individuals at risk and their families. The model underlying this interface drew on a corpus of >300 suicide-specific documents curated by clinicians [46]. Of the 2 studies that involved ChatGPT, 1 (50%) aimed to assess the safety of publicly available conversational agents by prompting them with sequential Patient Health Questionnaire-9 items to examine chatbot responses to a patient simulation indicating escalating suicide risk [61], while 1 (50%) asked ChatGPT to generate mental health nurse care plans based on vignettes about a fictitious person self-harming [81]. Overall, study objectives focused on suicide and self-harm detection, while the development of generative LLM technologies has facilitated more recent LLM use in care, support, and education.

Clinical Applications

We examined trends in proposed clinical applications of LLMs to suicide or self-harm prevention. Studies were expected to have provided sufficient depth of discussion regarding ways in which the research could be translated into real-world settings. Brief general statements or single-sentence phrases about clinical applications were not considered sufficient for inclusion in addressing this research question.

Clinical applications were discussed in 26 (60%) of the 43 studies. Of the 17 publications that did not discuss clinical applications, 13 (76%) were from the field of computer science. The identified applications included improved detection of suicidality (13/26, 50%), use as a clinical assistance tool (10/26, 38%), improved accessibility of services (3/26, 12%), improved services (3/26, 12%), assisting the development of policy (3/26, 12%), and use as a training tool (2/26, 8%). Specifically, studies discussing the ability of LLMs to improve the detection of suicidality mentioned the creation of automated systems that could be applied to language data (eg, social media posts) to detect suicidal ideation for early intervention [48,55,57]. Studies focusing on the potential applications of LLMs as clinical assistance tools discussed possible use cases where LLMs could aid clinicians in evaluating a client's level of suicide risk [48,57], supporting diagnosis and treatment [50,67], providing a second opinion [66], or predicting a score on a mental health scale [83]. Future-oriented clinical assistance tool applications included AI-enabled avatars that could be accessed remotely, could deliver therapeutic services, could conduct simple examinations, provide advice, or recommend referrals for additional care [66]. Applications related to service improvement included LLM integration to improve crisis counseling services [48,73] and improving existing mental health chatbots [54]. Applications to training included enhancing training, clinical procedures, and best practices among mental health and medical professionals [73,79]. Improved policy was noted as of clinical relevance [73,79] because there may be a lack of policy safeguarding people considered vulnerable and the use of LLMs [81]. Cost-effectiveness and increasing the quality of data annotation were also noted [58], as was use in public health surveillance, potentially allowing practitioners to track the prevalence of infrequent conditions [85].

Ethical Considerations

We also explored trends in the nature and type of ethical considerations reported. To be considered as having meaningfully reported on ethical issues, studies needed to include discussion of the ethical considerations and their possible implications. Cursory mention of potential ethical issues without discussion of their implications was not considered sufficient (eg, mention of LLMs as being a "black box" without any further discussion of the implications [47,59] was not considered sufficient).

Ethical considerations were discussed in 14 (33%) of the 43 studies. Of the 29 studies not presenting ethical perspectives, 18 (62%) were published in computer engineering journals, where greater emphasis was given to the technical aspects of model development, training, and validation. Privacy (9/14, 64%) was the most common ethical consideration discussed, followed by bias (5/14, 36%), hallucinations (the tendency of LLMs to sometimes generate false responses; 3/14, 21%), the "black box" nature of LLMs (3/14, 21%), possible threats to the client-clinician relationship (eg, clinicians replaced with digital agents; 2/14, 14%), and false positives or negatives in classification or identification (2/14, 14%).

Specifically, studies that discussed ethical issues regarding privacy touched on concerns about confidentiality and consent to use publicly available data [55,75,82,83], with researchers highlighting the need to value the privacy, security, and anonymity of the original posters and end users [57,66]. Some researchers presented ethical concerns related to publicly traded companies inferring or collecting sensitive health information about their users and acting on it or sharing it without explicit consent [50,58]. Nontransparent data collection and inference processes currently used by social media platforms were highlighted as a growing area of concern [74]. Hallucinations were identified as impacting the safety and reliability of LLM applications [58,85]. Some of the studies (2/14, 14%) raised concerns that models trained on vast amounts of data containing social biases or prejudices may perpetuate stigma toward suicide

XSL•FO
RenderX

or self-harm [58,83]. Related concerns were raised regarding the generalizability of LLMs to populations whose racial, ethnic, or cultural demographics differ from those present in training data [48,75]. The study by Levkovich and Elyoseph [66] noted that these data biases or the lack of diversity could lead to erroneous predictions that may exacerbate existing disparities in suicide prevention strategies. Furthermore, 3 (21%) of the 14 studies noted a lack of transparency, resulting from the opaque functioning of the underlying algorithms (termed "black box") [59,66], with the study by Woodnutt et al [81] noting a lack of governance in this regard.

Of the 14 studies, 2 (14%) raised concerns about LLMs threatening the client-clinician relationship, potentially leading to human-centered clinical interactions being replaced by digital alternatives. Karapetian et al [64] discussed the issue of LLM agents lacking human attributes, such as empathy for suicidal distress, and Malhotra et al [67] noted that the integration of LLMs into clinical care may lead to a sense of distancing of the clinician from the individual, potentially fostering feelings of invalidation or insignificance and exacerbating suicidal thoughts or self-harm behaviors. False negatives (when suicidality goes undetected) and false positives (when suicidality is incorrectly flagged as being present) were noted as concerns [74,75] as psychological harm can result (eg, resulting in missed opportunities to intervene with someone at risk or in unnecessary mental health evaluations for someone who is not at risk) [74]. Safety was also noted as a concern because conversational AI may advance at a pace that outstrips associated safety measures [61]. Relatedly, issues of clinical responsibility were highlighted, particularly regarding the use of LLMs in aiding the generation of mental health care plans, as some authors believed that this could leave mental health practitioners legally vulnerable [81]. More generally, studies emphasized that guidelines for safe development, auditing, and regulation are very much needed to address ethical risks in this area of research [83].

Discussion

The primary aim of this scoping review was to summarize and characterize emerging trends in the application of LLMs in the field of suicide prevention and self-harm research. This review maps the study characteristics and key methodological components of the included studies (n=43) and further addresses the secondary aims of examining the clinical applications and ethical considerations proposed in the included studies.

Study Characteristics

The studies included in this analysis exhibited a notable divergence in disciplinary focus, with approximately equal representation from computer engineering (23/43, 53%) and health-related (18/43, 42%) fields. The bifurcation of domain expertise in this emerging field has important implications for the safety, effectiveness, and real-world impact of the research outputs, particularly considering the differences in technical training, publication norms, and approach to validation and evaluation used across the different fields; for example, only recently has there been a call to integrate education in the technicalities and ethics of AI into mental health training programs, and many mental health researchers may not yet receive technical training in AI to be able to develop and apply LLMs for clinical research purposes. In parallel, while computer science researchers have significant technical training to enable the development of innovative AI models and access to industry partnerships that can support the scalability of new AI-based tools, the real-world usefulness of these innovations hinges on a deep understanding of the ethical and clinical context in which they are to be applied, the facilitators and barriers to their use, and the needs and priorities of end users—areas of expertise where clinical training is often paramount. Recognizing and addressing the complementary strengths and gaps in these divergent disciplines will be crucial for ensuring that LLM innovations in suicide prevention are grounded in technical excellence and clinical acumen.

Similarly, the dissemination of research from computer science often outpaces the dissemination of research from the field of mental health owing to the stronger focus on conference proceedings with expeditious publication timelines. The accelerated dissemination of LLM-based suicide prevention research originating from computer science fields may mean that practices focused on innovation—a crucial benchmark of research impact in computer science (eg, via patents) [87]—come to dominate early research advancements in this area [88]. Although innovation is crucial for achieving technological advancements, this innovation often comes at the expense of comprehensive clinical validation [89], and there has been growing emphasis on the need for frameworks for validating new AI tools in health research [90].

Recognizing and navigating these disciplinary disparities is essential. Encouraging multidisciplinary collaboration among experts from diverse backgrounds is likely to be critical for bolstering the quality, safety, and impact of research on LLMs for suicide prevention. This could be done by fostering the development of agile methods for disseminating validation research (such as through cross-disciplinary repositories and benchmarking datasets), establishing sound ethical and safety frameworks that cut across key disciplines (such as living guidelines), and facilitating ongoing education and cross-disciplinary training for researchers across both fields. Crucially, prioritizing and supporting studies led by multidisciplinary teams that rigorously assess safety and effectiveness is imperative for ensuring that research efforts lead to broader societal benefits.

Base LLMs Used

There was minimal variation in the base LLM model applied in the identified studies. Most of the studies (35/43, 81%) used either the base BERT model or some variation of a trained or fine-tuned BERT model [91]. The relatively early release date (2018), open-source availability, compact size of this model compared to subsequent models such as GPT, and its adaptability through fine-tuning for diverse applications are all factors assisting the widespread use of BERT in this research area. While open access is critical for facilitating replication and democratizing access to this modern technology, an important consideration is that open-access LLMs trained on generalized datasets might inadvertently perpetuate unwanted biases; for example, BERT has been shown to exhibit

XSL•FO
RenderX

stereotypical biases in areas such as gender, profession, race, and religion, with this bias not related to the size of pretraining corpora but likely due to the nature of the training data [92]. In the same study, GPT-2 was found to have less bias, hypothesized in part to be due to antistereotypical associations present in the training data. LLMs are "stochastic parrots" [93] in their generative responses, their outcomes dependent on the quality of the input training data. Therefore, the testing, application, and comparison of multiple models is important to detect and mitigate model biases permeating an entire discipline. Promoting the use of a diverse range of models to assess performance variability [58,83] and uncover potential biases [92] could enhance the strength of research outcomes in suicide prevention. In addition, there is a pressing need to develop specialized open-access models (such as those being developed in medicine) [94,95] for mental health and suicide prevention. These models should draw upon the expertise of mental health professionals, cross-disciplinary researchers, ethicists, and individuals with lived experience. Establishing standards and policies that ensure the transparent reporting of model training data and inherent potential biases is also imperative to enable the critical evaluation and validation of model suitability [7], particularly for self-harm and suicide prevention contexts.

Data Sources

Most of the studies (31/43, 72%) used data from social media platforms such as X (formerly Twitter) and Reddit to train LLMs. Although these are rich data sources, a reliance on social media data as a form of training data may lead to limitations in the usefulness of LLMs. To protect their users, social media platforms often implement policies to detect, suppress, or remove content related to suicide or self-harm. Therefore, using social media data for LLM training may result in an underrepresentation of critical data that would enable LLMs to effectively recognize and respond to expressions of suicidal distress. In addition, algorithms embedded within social media platforms are designed to promote engaging content. As a result, these algorithms often promote user posts that are biased toward certain viewpoints and controversial or sensational topics, while simultaneously minimizing diversity of perspective. Accordingly, the algorithms in social media platforms may drive artificial patterns in the nature and frequency of certain types of user post data that do not reflect real-world interpersonal interactions.

It is also crucial to evaluate whether the profiles and behavior of individuals who post on social media platforms align well with those of the potential end users of LLM-based suicide prevention interventions; for example, while Reddit's user anonymity may constitute a perceived benefit to users, evidence indicates that users engage in differing behavior when posting anonymously compared to when their identity is known [96]. To mitigate this, it is imperative to curate training datasets that are diverse and balanced [97], as well as representative of the population that the LLM is intended to serve [7]. The inclusion of input from those with lived experience is important during the development of these datasets because these experiences can provide valid human-generated data for model training. Furthermore, lived experience can provide a valuable perspective in reviewing LLM-generated data, enabling key human-in-the-loop validation of otherwise unavailable data for model training (eg, crisis care transcripts). In addition, actively seeking out content, including positive interactions, supportive conversations, and safe discussions around self-harm and suicide prevention, may help enhance the effectiveness of LLM-based suicide prevention interventions.

Identified Objectives

The studies included in this review predominantly deployed LLMs for the identification, detection, classification, and prediction of suicide or self-harm risk. These areas represent a narrow band of potential use, and despite research focused in this area, there remains a lack of solutions that implement these models in clinical settings [55]. One reason for this is that computer scientists, who are at the forefront of technological innovation in this area, do not generally have in-depth knowledge of clinical processes and workflows used in the mental health field. This limits their ability to envision the broader applicability of LLMs in mental health settings and results in a tendency to gravitate toward more familiar applications, such as classification and regression. Similarly, suicide prevention researchers often do not possess the technical expertise required to adapt LLMs for their specific needs. Consequently, multidisciplinary collaborations are critical to the development of sound research programs that combine the clinical and technical expertise necessary for high-caliber research. As this research advances and models continue to improve, those focused on clinical areas may be deployed in various contexts. However, it has been noted that this may be insufficient and may not reduce suicide attempts or deaths unless the treatment needs of people identified as being at risk are met [98]. Hence, it is imperative to explore innovative solutions in clinical care, consultation, and therapy.

This review highlighted a small number of recent applications that move beyond identification and prediction by leveraging the generative features of LLMs. These applications included assessing whether LLMs could provide access to suicide-related educational information [46], whether they could detect escalating suicide risk and the need for human intervention [61], and whether they could assist in generating mental health nurse care plans for individuals who self-harm [81]. These studies showed that, at present, LLMs can perform well on specific elements of these roles, including providing immediate access to accurate information relevant to suicide prevention [46], using health theory frameworks to construct detailed care plans with tangible goals for clients [81], and generating training aids for mental health providers [81]. However, these studies also highlighted areas where LLMs currently fall short. Specifically, they showed that LLMs did not effectively detect and respond to signs of escalating clinical risk by referring into care [61]. Moreover, concerns were noted regarding how the accountability of health care providers may be impacted by the use of AI-generated mental health care plans [81]. These examples highlight the critical role of human expertise in the deployment of LLMs in suicide prevention contexts, and an important area for future research will be to determine optimal approaches to implementing human-AI collaboration in suicide prevention settings, including through the use of copilot or

XSL•FO
RenderX

human-in-the-loop systems that are beginning to be explored in other areas [89,99].

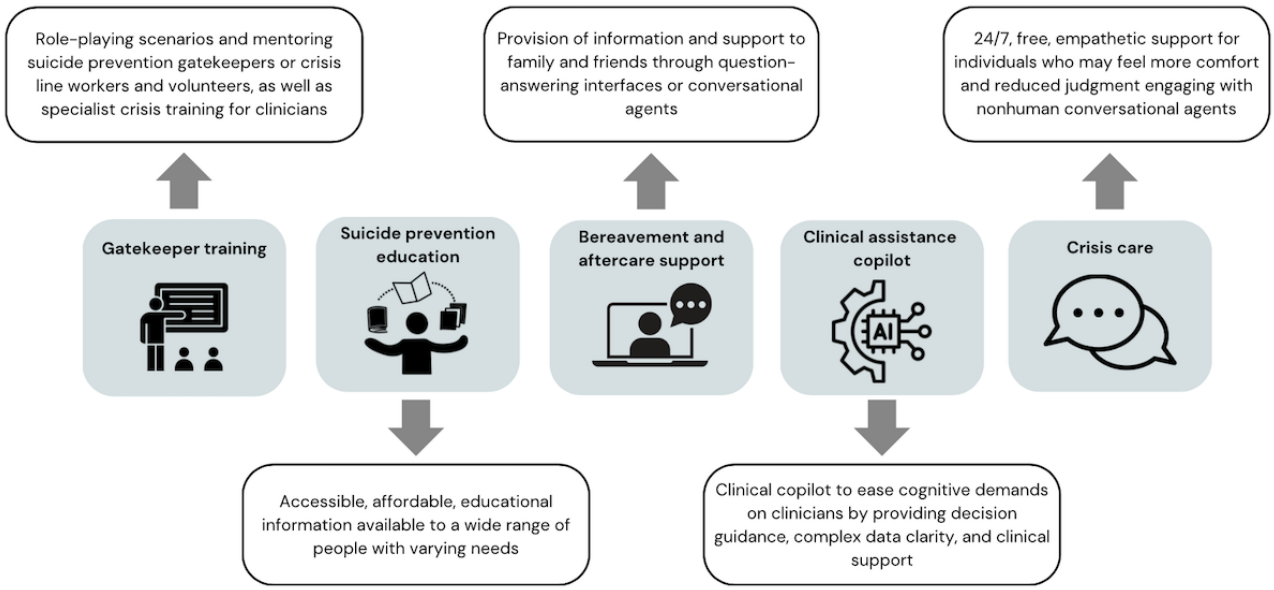
Clinical Applications

The secondary aim of this scoping review was to consider the clinical applications and ethical considerations of LLMs in suicide prevention practice. Among the studies describing clinical applications of LLMs, "enhanced detection of suicidality" and use as a "clinical assistance tool" were the most commonly presented clinical applications. The ability to identify and predict suicide has remained at near-chance levels for many years [24], and improvement upon this with the help of novel technologies such as LLMs can provide a valuable contribution to the field. However, accurate risk detection alone is insufficient and must be paired with effective and scalable interventions [24]. The use of LLMs as clinical assistance tools can support clinical professionals by aiding with a myriad of tasks [48,57,66,70]. The conception and design of these applications should start with the end point in mind to best plan for the translation of research results into implementation in a clinical setting. Critically, researchers should engage clinicians, health professionals, lived experience representatives, and other relevant stakeholders early in the research project development to ensure that the research can meet the needs of end users. In the case of lived experience representatives, it is imperative to understand how they, as representatives of end users, interact with the various potential applications of LLMs to ensure safety and effectiveness. Clinical applications described in the studies include assisting clinical decision-making by providing a second opinion [66], functioning as a clinician copilot [48], serving as a mental health triage tool [57], and supporting therapy delivery [70]. However, these applications were limited to hypothesized future uses [48,57,66] or pilot studies [70]. More investment is required to develop implementable clinical assistance tools, particularly in supporting the integration of multidisciplinary teams to collaborate on areas such as clinical training and support as well as identifying novel use cases with the potential to positively impact suicide prevention practice. Importantly, LLMs should not replace clinical judgment but rather supplement it, aiding clinicians and health professionals to make more informed decisions [66] by enhancing access to information (eg, suggesting differential diagnoses, proposing alternate hypotheses, or collating scattered information into more coherent forms to facilitate human interpretation). LLM applications should not exceed this human-in-the-loop support-based role until their safety and effectiveness can be clearly demonstrated.

It is also important to consider the context in which an LLM-based application will be implemented, acknowledging that its success may be limited by existing clinical workflows [100] and the overall capacity of the health system to integrate new tools and provide relevant training [101]. As with all new technological advancements in care, LLM integration into health care practices requires strategic integration into existing—often outdated and practically constrained—care models if we are to realize their full benefit. Forward thinking and responsive policy is required, led by governments that engage with stakeholders to map policy and standards to provide for the harmonious integration of LLM clinical support tools, given the accelerating use and potential of AI.

Research indicates that a majority of individuals do not engage with formal mental health services before suicide, potentially due to stigma or fear of judgment [39]. While none of the identified studies deployed LLMs to directly support or intervene with individuals in distress, the ease of access that a language-based user interface offers may help some overcome stigma-related barriers to engaging with formal mental health services. Indeed, preliminary evidence for the acceptability of generative LLMs in support contexts has been demonstrated; for example, evidence shows that a large majority of individuals (78%) would be willing to use ChatGPT for self-diagnosis or to aid in self-managing their symptoms [102]. Some individuals also indicate a willingness to disclose information to nonhuman agents citing reduced fear, less need for impression management, and greater ease in expressing the severity of their emotions [103].

This review found evidence that LLMs can deliver accurate information relevant to suicide prevention [46] and support clinical needs in related contexts such as mental health evaluations, therapeutic consultations, and patient education [104]. Therefore, LLMs hold the potential to offer individuals quick, empathic responses to mental health queries [105], while avoiding potential or perceived judgment and stigma, at little to no cost, available 24/7. Nevertheless, the efficacy of LLMs in providing precise, evidence-based support to individuals in suicidal distress has not been empirically validated. Furthermore, LLMs currently lack the ability to collect information vital for diagnosing and managing a patient's health condition [106]; for example, ChatGPT's performance has been found to deteriorate as the complexity of clinical cases increases [105], and research identified in this review demonstrates that GPT-powered conversational agents and chatbots can be dangerously slow to escalate high-risk mental health situations for human clinical intervention [61]. While there may be a safe use threshold at which LLMs are beneficial for information and psychoeducational purposes, they are not advanced enough to be used as stand-alone therapeutic devices. Looking forward, models of LLM use in crisis support contexts are most likely to be those that are driven by clinical oversight, with sufficient guardrails in place to trigger referrals when clinically indicated.



The incorporation of LLMs into training and educational contexts presents a promising opportunity for research and development under clinical oversight. Educational resources, such as the question-answering system in an included study that was aimed at providing suicide prevention information [46], provide an illustrative example. This mode of education is highly scalable and may provide a cost-effective means for deploying training programs. Such educational tools would be particularly useful in large-scale, multifaceted, community-wide interventions such as the European Alliance Against Depression [107] and Lifespan [108] models, both of which have community awareness and training as key components. Another study identified in this review [81] suggests that LLMs such as ChatGPT could support training by assisting less experienced mental health practitioners in creating care plans, brainstorming ideas, or pinpointing relevant aspects of patient presentation.

XSL•FO
RenderX

However, it was noted that these generated plans, while appearing credible to laypersons, have been found to contain significant errors and ethical issues upon professional evaluation, highlighting the indispensable role of clinical oversight [81]. LLMs could also facilitate the creation of diverse case scenarios for health care providers to hone their risk assessment and communication skills. By role-playing case scenarios, LLMs can offer real-time, interactive training experiences for crisis call center staff, counselors, and suicide prevention gatekeepers, enhancing their confidence in discussing suicide and building clinical competencies. In addition, the use of LLMs to converse in a role-play scenario has the potential to improve initial training outcomes [109]. Critically, suicide prevention gatekeeper training outcomes are shown to diminish over time [110]; however, engagement with a role-playing LLM could result in improved retention of training outcomes and more individuals at risk identified, approached, and referred for help.

These training and education use cases should be moderated by human oversight and iterated with human feedback for continuous and rapid improvement. Future research should aim to develop models trained in this domain that can demonstrate reliability and effectiveness in providing training or educational outputs. The development of the underlying model in this use case has the potential to translate to alternative clinical applications while providing researchers with a greater understanding of the guardrails and parameters of operation that are required for safe deployment across suicide prevention applications (Figure 3).

Figure 3. Potential future applications of large language models in the field of self-harm and suicide prevention. AI: artificial intelligence.

Ethical Considerations

Growing emphasis has been placed on the need for a clear and comprehensive ethical framework for integrating LLMs into mental health research and practice [111]. Hence, another aim of this review was to understand the ethical issues involved in the integration of LLMs into suicide prevention and self-harm research. Ethical considerations raised in the included studies focused on privacy and autonomy, bias, transparency and trust, and potential adverse impacts on the therapeutic relationship.

The integration of LLMs and social media data was noted as presenting a double-edged sword in terms of balancing privacy and confidentiality concerning the use of publicly available data with opportunities for suicide detection [55,75,82,83]. On the one hand, the vast repository of publicly available language-based data on social media platforms provides the potential for real time identification of individuals at risk. On the other hand, while such methods can be lifesaving, they bypass the consent traditionally required in research and clinical practice. User or poster consent was sought in only 1 (3%) of the 31 identified studies that used social media data for training their models. Users of social media sites are often not afforded the opportunity to opt out of such surveillance or analysis, nor are they made aware of the potential adverse consequences associated with having their data used in this manner (eg, the risk of data privacy breaches, as has happened with some LLMs) [112]. This contravenes the fundamental human right to privacy, recently underscored by European legislation prohibiting certain data-gathering practices related to health information by the algorithms of Facebook and other large social media companies [74,113]. This legislative approach is aligned with suggested practices to mitigate ethical concerns around privacy and confidentiality through the establishment of legal boundaries [82]. The use of social media and other data to train LLMs requires deep discussion to discern the regional, social, cultural, and temporal factors (among others) that influence ethical decisions around safe use of this data. An important ethical concern for the field of LLM-based suicide prevention research is how to balance the potential safety of users with their fundamental right to privacy. Inclusion of the lived experience perspective in this discussion is crucial if we are to arrive at a workable solution. Real-world clinical application of LLMs focused on detecting individuals at heightened suicide risk also raises critical ethical issues regarding the implications of false positives, if acted on by authorities, and the potential threats this poses to personal autonomy.

XSL•FO
RenderX

Bias is another important ethical consideration that was noted in the identified studies. In a recent review of AI algorithms applied to mental health, Straw Callison-Burch [114] found that significant biases exist with respect to religion, race, gender, nationality, sexuality, and age. These biases result from the expression of data (the manner in which the original data are presented) [115], the analysis of data (influenced by the contextual prelearnings of the model), and the interpretation of results (human annotation influenced by unconscious bias may produce model bias after training on that annotated data set) [114]. The presence of bias at any stage of model development risks creating tools that disadvantage certain groups of individuals [114]. Rigorous multimodel testing, comparison, and validation are required to isolate and mitigate inherent biases and thereby ensure unbiased performance across diverse populations. Understanding the specific factors that contribute to the effectiveness or limitations of a model also allows researchers to make informed decisions about how to optimize future training processes. This may involve collecting more diverse and representative data, implementing better preprocessing techniques, or fine-tuning model parameters.

Ethical issues of transparency and trust were also discussed in several of the included studies. In contrast to traditional machine learning algorithms, LLMs are opaque "black box" architectures with complex internal structures, which makes it difficult to understand and explain their decisions [67]. This is particularly challenging when hallucinations occur, with little recourse for discovering the source of the error. LLMs do not offer their "reasoning" unless prompted, and when prompted, they often fail to articulate how the provided information was retrieved, vetted, curated, or prepared. This lack of transparency is a fundamental flaw that hinders our ability to understand how these models operate, undermining their trustworthiness in health care applications [67]. Efforts are being made to distill this unknown "thinking" with the application of explainable AI methods. Of the 43 included studies, 2 (5%) [63,67] applied such methods in the form of Shapley additive explanations [116], local interpretable model-agnostic explanations [117], and Topic BERT [118]. The results indicate that these techniques can provide reasonable explainability for both short and long user-generated text and provide insights about data quality issues in training datasets [67]. However, current methods in this area fall somewhat short of delivering the transparency needed to establish total trust, limiting LLM deployment to contexts that restrict or protect against the potential for model hallucinations. Ongoing research into explainable AI techniques is critical in bridging this transparency gap to facilitate trust and enable real-world implementation.

Of the 43 included studies, 2 (5%) noted the client-clinician relationship as an ethical consideration: one in relation to LLM agents lacking human attributes [61] and the other noting a sense of distancing of the clinician from the individual, potentially fostering feelings of invalidation or insignificance [81]. At present, LLMs lack the authenticity and relational aspects required for modern mental health care [81]. Although LLMs can simulate empathy, it is important to consider the specific care needs of individuals experiencing suicidal ideation. If deployed incorrectly, LLM technologies have the potential to incite harm [119], requiring careful implementation to maintain safe practices. When consideration is given to the development of LLMs for use in suicide prevention, sound policy needs to be written to safeguard care recipients, reflecting the complexity of the relationships they have with traditional care providers [81]. In addition, stringent testing and oversight are required during the development and subsequent application of LLMs in the mental health domain [61]. While acknowledging the important ongoing role of human-led therapies, there is a clear need for further research into developing AI systems that can effectively integrate professionals into the loop. This would allow LLMs to serve as an aid in clinical settings, complementing rather than supplanting human practitioners.

Limitations

Some limitations must be kept in mind when interpreting the findings of this scoping review. First, the categorization of machine learning technologies in the existing literature was not always clear, sometimes rendering it challenging to discern whether a study used an LLM or other machine learning model. It is possible that some relevant articles may have been excluded from the review. Second, due to the cross-disciplinary nature of the field and resulting publications, reporting detail varied between disciplines. Health-related publications provided more clinical and ethics-related information, whereas computer engineering publications were more likely to provide in-depth detail about the LLM model and training process. This made the synthesis and comparison of certain study attributes challenging; for example, data preparation and input methods were not sufficiently covered in the studies published in health-related journals to allow meaningful synthesis. Third, all data were extracted by a single author. Although data extraction was piloted by 2 authors to ensure consistency of approach at the outset, some data that were extracted were qualitative, potentially resulting in researcher bias; for example, data extraction related to ethical considerations such as privacy could be subject to bias due to researcher beliefs. Fourth, this review was conducted in an area of research that is currently experiencing significant growth and development; therefore, it only provides a time-stamped representation of the field. Finally, this review excluded studies using EHR data, given that EHR data may not be representative of individuals at risk of suicide because a large proportion of individuals experiencing suicidality are not in contact with formal mental health services [120]. However, excluding EHR studies reduced the number of included studies that focused on predicting suicide risk.

Conclusions

LLMs represent a promising avenue for enhancing the scalability, accessibility, affordability, and personalization of tools in the field of suicide prevention and self-harm research; however, collaboration between computer science and mental health experts is essential to leverage the strengths of both disciplines effectively. This review identified a strong bias toward the use of BERT, with the potential for inherent biases indicating a pressing need for rigorous model comparison and testing, alongside the curation of diverse training datasets to mitigate model bias effectively. The growing use of generative

XSL•FO
RenderX

LLM applications indicates promise for transformative applications in care, support, training, and education, such as improved crisis care and gatekeeper training methods, clinician copilot models, and improved educational practices. However, clinical accountability remains crucial to ensure the responsible use of LLMs in applications targeting suicide prevention. The identified ethical considerations underscore the need for clear governance via the establishment of policies and standards to guide the integration of LLMs into clinical use. LLMs have significant implications for self-harm and suicide prevention, underscoring the need to support continued research and development in this domain.

Abstract

Background: Cervical cancer remains the fourth leading cause of death among women globally, with a particularly severe burden in low-resource settings. A comprehensive approach—from screening to diagnosis and treatment—is essential for effective prevention and management. Large language models (LLMs) have emerged as potential tools to support health care, though their specific role in cervical cancer management remains underexplored.

Objective: This study aims to systematically evaluate the performance and interpretability of LLMs in cervical cancer management.

Methods: Models were selected from the AlpacaEval leaderboard version 2.0 and based on the capabilities of our computer. The questions inputted into the models cover aspects of general knowledge, screening, diagnosis, and treatment, according to guidelines. The prompt was developed using the Context, Objective, Style, Tone, Audience, and Response (CO-STAR) framework. Responses were evaluated for accuracy, guideline compliance, clarity, and practicality, graded as A, B, C, and D with corresponding scores of 3, 2, 1, and 0. The effective rate was calculated as the ratio of A and B responses to the total number of designed questions. Local Interpretable Model-Agnostic Explanations (LIME) was used to explain and enhance physicians' trust in model outputs within the medical context.

Results: Nine models were included in this study, and a set of 100 standardized questions covering general information, screening, diagnosis, and treatment was designed based on international and national guidelines. Seven models (ChatGPT-4.0 Turbo, Claude 2, Gemini Pro, Mistral-7B-v0.2, Starling-LM-7B alpha, HuatuoGPT, and BioMedLM 2.7B) provided stable responses. Among all the models included, ChatGPT-4.0 Turbo ranked first with a mean score of 2.67 (95% CI 2.54-2.80; effective rate 94.00%) with a prompt and 2.52 (95% CI 2.37-2.67; effective rate 87.00%) without a prompt, outperforming the other 8 models (P<.001). Regardless of prompts, QiZhenGPT consistently ranked among the lowest-performing models, with P<.01 in comparisons against all models except BioMedLM. Interpretability analysis showed that prompts improved alignment with human annotations for proprietary models (median intersection over union 0.43), while medical-specialized models exhibited limited improvement.

Conclusions: Proprietary LLMs, particularly ChatGPT-4.0 Turbo and Claude 2, show promise in clinical decision-making involving logical analysis. The use of prompts can enhance the accuracy of some models in cervical cancer management to varying degrees. Medical-specialized models, such as HuatuoGPT and BioMedLM, did not perform as well as expected in this study. By contrast, proprietary models, particularly those augmented with prompts, demonstrated notable accuracy and interpretability in medical tasks, such as cervical cancer management. However, this study underscores the need for further research to explore the practical application of LLMs in medical practice.

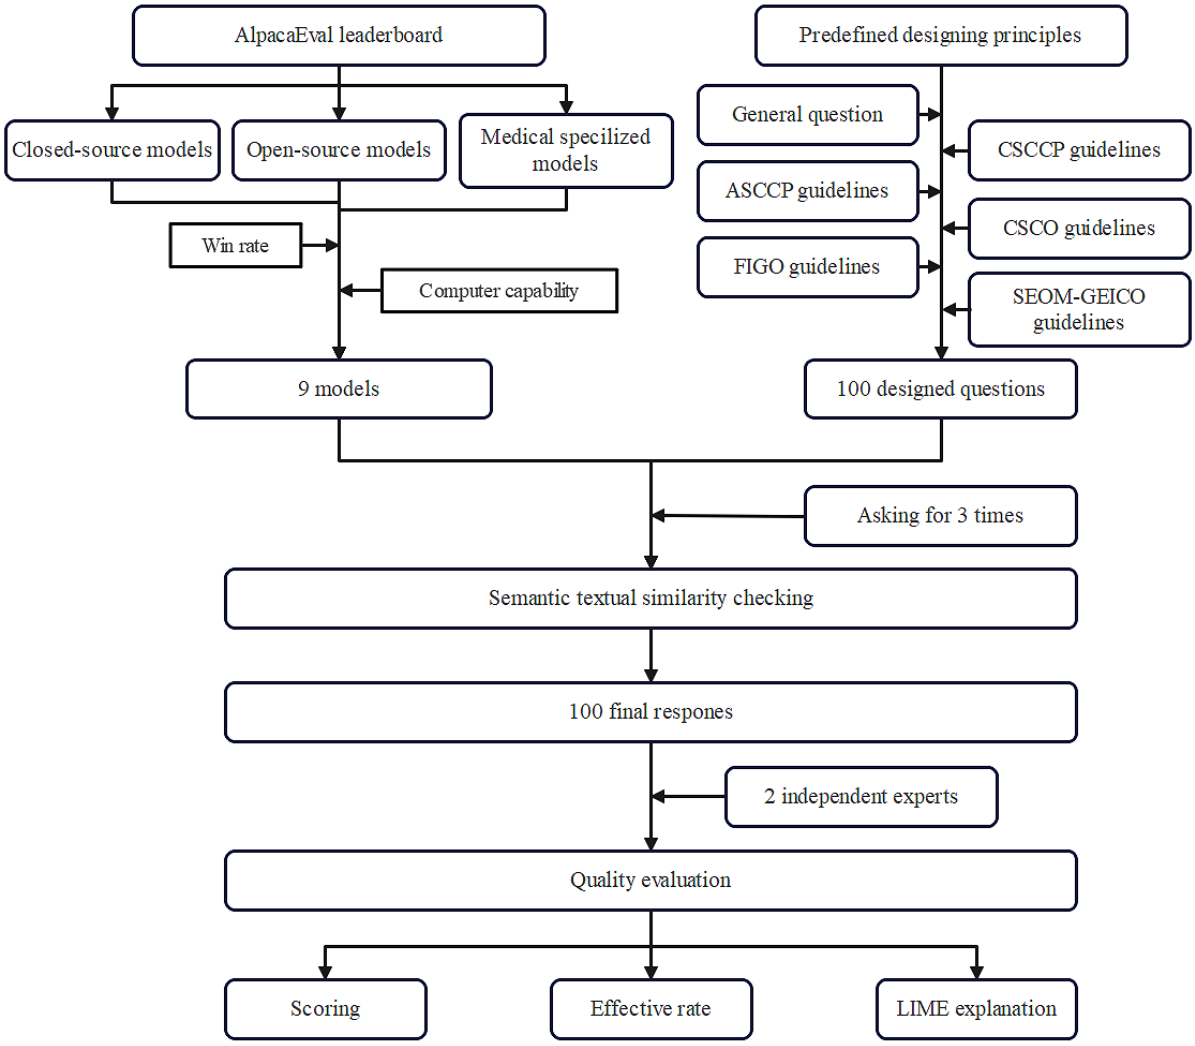
large language model; cervical cancer; screening; artificial intelligence; model interpretability

Introduction

Cervical cancer is a significant global public health challenge, ranking fourth among all female cancers and remaining the leading cause of death in many low-income countries [1]. In 2020, approximately 604,127 new cases and 341,831 deaths from cervical cancer were reported worldwide [1]. Effective cervical cancer control necessitates an integrated approach that combines screening, accurate diagnosis, and personalized treatment to reduce morbidity and mortality. Despite a substantial decline in cervical cancer incidence in the United States since the introduction of screening [2], up to 25% of women remain inadequately treated [3], with even higher rates observed in resource-limited and developing countries [1]. Moreover, precise diagnosis and appropriate treatment are essential for addressing abnormalities detected through screening, particularly to prevent disease progression and improve survival outcomes [4]. Hence, strengthening these efforts is essential for reducing the global burden of cervical cancer and improving patient outcomes across diverse health care contexts.



Large language models (LLMs), as cutting-edge technologies in artificial intelligence, are trained on vast data sets and enable a wide range of applications, from text polishing to complex problem-solving, thanks to their unprecedented natural language understanding capabilities. In the health care domain, LLMs hold the potential to revolutionize medical practices, including decision-making, patient management, and clinical data interpretation [5,6]. Notably, OpenAI's proprietary LLMs, ChatGPT-3.5 and ChatGPT-4.0, have demonstrated high performance on the United States Medical Licensing Examination (USMLE), with ChatGPT-4.0 achieving particularly impressive results [7,8]. Additionally, ChatGPT has shown competence across various medical fields, including surgery [9], cardiology [10], and plastic surgery [11]. Compared with generic language models, medical-specialized models—fine-tuned on domain-specific data sets and subjected to specialized adjustments—have achieved equivalent or superior performance [12].

To date, only a limited number of studies [13] have applied LLMs to questions related to cervical cancer, as well as explainability analyses on either closed- or open-source LLMs to assess transparency and interpretability. The management of abnormal cervical cancer screening results, diagnosis, and treatment is a complex task that requires careful interpretation and follow-up [14]. When deploying LLMs in cervical cancer management, it is crucial to evaluate their performance in managing abnormalities and to identify their strengths and limitations, particularly regarding model transparency and interpretability.

In this study, we aim to compare the performance of current prevalent LLMs in cervical cancer management by evaluating their responses to a set of specifically designed questions (Figure 1). This research may provide valuable evidence to help clinicians manage screening results more effectively and accurately, particularly in regions with limited health care infrastructure.

XSL•FO
RenderX

Figure 1. The flowchart of evaluation of LLMs' performance in cervical cancer management. Nine LLMs, including closed-source, open-source, and medical-specialized types, selected from AlpacaEval leaderboard were evaluated with 100 predefined questions derived from general inquiries and guidelines from ASCCP, CSCCP, FIGO, SEOM-GEICO, and CSCO guidelines. Responses were collected 3 times for each question, analyzed for semantic similarity, and reviewed by 2 experts for accuracy, effectiveness, and interpretability using LIME. ASCCP: American Society for Colposcopy and Cervical Pathology; CSCCP: Chinese Society for Colposcopy and Cervical Pathology of the China Healthy Birth Science Association; CSCO: Chinese Society of Clinical Oncology; FIGO: International Federation of Gynecology and Obstetrics; GEICO: Grupo Español de Investigación en Cáncer de Ovario; LIME: Local Interpretable Model-agnostic Explanations; LLM: large language model; SEOM: Sociedad Española de Oncología Médica.

Methods

Model Selection

The AlpacaEval leaderboard is an automated system designed to evaluate language models based on their adherence to instructions, ranking them by comparing their responses to reference answers from top-performing models such as GPT-4. It aims to reduce biases, such as those related to output length. Unlike other leaderboards that may focus on a single type, this leaderboard includes both open- and closed-source models. The selection of potential models—whether closed-source, open-source, or medically specialized—is determined by their win rates on version 2.0 of the leaderboard, updated on March 3, 2024.

For closed-source models, both free and paid versions are included, excluding those that are not publicly available or are in private beta. Open-source models are required to perform effectively on consumer-grade computers with standard configurations, given their potential use in resource-limited applications such as cervical cancer screening. The computer specifications for deploying these models are detailed in Multimedia Appendix 1, with a maximum model size capacity of approximately 7 billion trainable parameters. The selection of medical-specialized models, which are limited in number on leaderboards, is informed by a study [15] summarizing existing medical LLMs and their respective GitHub star counts. The performance of these medical LLMs is assessed based on the benchmark scores of their underlying models.

Criteria for Question and Prompt Designing

Questions Designing

A comprehensive question set was developed to evaluate model performance, including general questions and those specifically focused on cervical cancer screening, diagnosis, and treatment. General questions were designed by our gynecological experts

XSL•FO
RenderX

to address the most common queries about cervical cancer, covering essential, foundational information frequently encountered in clinical practice. Screening-related questions were crafted with reference to the Chinese Society for Colposcopy and Cervical Pathology of the China Healthy Birth Science Association (CSCCP) Consensus on cervical cancer screening and abnormal management in China [16]. To ensure relevance and keep our questions up to date, we also incorporate the 2019 American Society for Colposcopy and Cervical Pathology (ASCCP) Risk-Based Management Consensus Guidelines for Abnormal Cervical Cancer Screening Tests and Cancer Precursors [17]. The questions comprehensively address each clinical decision outlined in the CSCCP guideline flowcharts, as detailed in Multimedia Appendix 2. Additional screening questions were developed based on the Chinese Society of Clinical Oncology (CSCO) Guidelines for the Diagnosis and Treatment of Cervical Cancer (2023) [18]. The diagnosis and treatment questions were developed with reference to the Sociedad Española de Oncología Médica-Grupo Español de Investigación en Cáncer de Ovario (SEOM-GEICO) Clinical Guidelines on Cervical Cancer (2023) [19], the CSCO Guidelines for the Diagnosis and Treatment of Cervical Cancer [18], and The International Federation of Gynecology and Obstetrics (FIGO) 2018 Gynecologic Cancer Report – Interpretation of the Cervical Cancer Guidelines [20]. The design was guided by the principles outlined in Textbox 1.

Textbox 1. Principles guiding design.

1. Diverse complexity levels

- A combination of basic and advanced questions was included to evaluate the model's ability to address both routine and complex clinical scenarios.

2. Strict guideline adherence

- Questions were structured to prioritize guideline-based knowledge, minimizing reliance on outdated or nonevidence-based practices.

3. Primarily closed-ended format

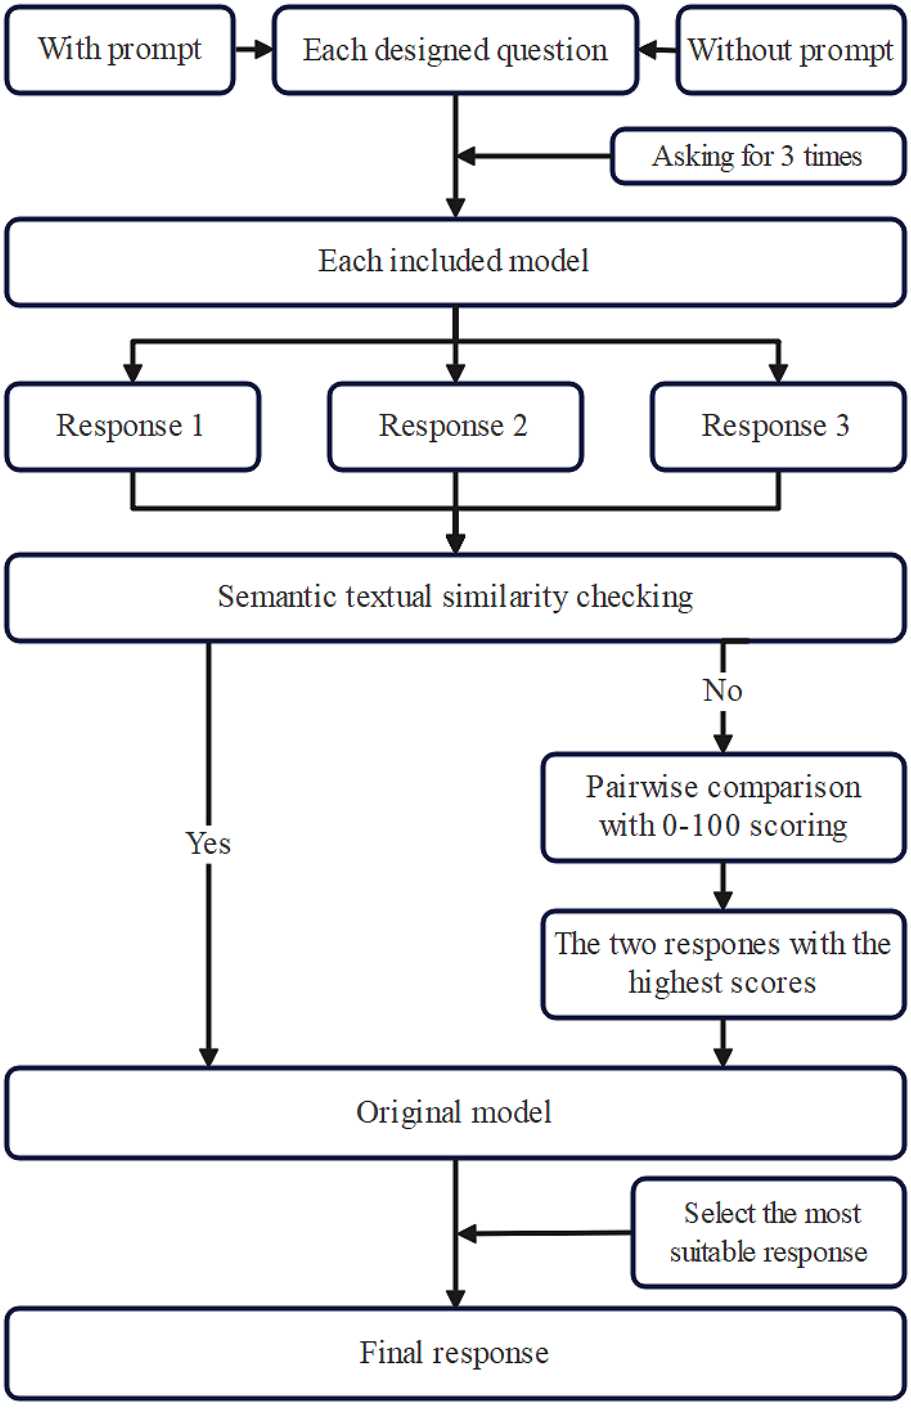
- Predominantly closed-ended questions were used to reduce subjective bias, with a few open-ended questions included to assess the model's capacity for divergent medical problem-solving.

4. Definitive answers

- Each question was designed to have a clear, definitive answer.

These questions aim to evaluate the models' understanding of clinical guidelines, their decision-making processes, and their ability to provide clear, actionable advice.

Prompt Designing



The prompt was designed using the Context, Objective, Style, Tone, Audience, and Response (CO-STAR) framework, which was ranked as the top prompt in the inaugural GPT-4 Prompt Engineering Competition. This framework was applied to guide the LLM in generating expert-level responses in gynecology, with a clear focus on defining the context, objective, style, tone, audience, and response format.

Questioning Method

Each designed question was sequentially input 3 times for each model, both with and without the designed prompt, to test consistency. The coherence of the responses was evaluated using semantic textual similarity [21] by ChatGPT-3.5, the top-performing model on AlpacaEval, which was not used as a test model. If the semantics of all 3 responses are identical, they are sent back to the originating model to select the most suitable answer. In cases of discrepancies, a pairwise comparison is performed with scores ranging from 0 (not typical at all) to 100 (extremely typical) [22]. The 2 responses with the highest similarity scores are returned to their model, which then selects the most appropriate answer (Figure 2).

XSL•FO
RenderX

Figure 2. The flowchart of final response determination for LLMs. Each question was tested 3 times per model, with and without prompts, to assess consistency. Responses were analyzed using STS by ChatGPT-3.5 (not included as a test model). If all 3 responses were semantically identical, the model selected the most suitable answer. For discrepancies, a pairwise comparison scored responses from 0 (Not typical at all) to 100 (Extremely typical), and the 2 highest-scoring responses were returned to the model to determine the final response. LLM: large language model; STS: semantic textual similarity.

Scoring Process and Criteria

Two gynecological experts independently and anonymously reviewed the responses to each question. If both experts agreed on a score, it was directly accepted; otherwise, they discussed it to determine the final score. Responses were evaluated based on accuracy, adherence to clinical guidelines, clarity of communication, and practicality. A scoring system, modified from a previous study [23], was used to categorize responses into 4 grades: A, B, C, and D, to minimize subjective bias. Grades A and B were considered effective, and the model's effective rate was calculated as follows:

$$\text{Effective rate} = (N_A+N_B)/(N_A+N_B+N_C+N_D) \times 100\%$$

where N represents the number of each grade. Scores are weighted at 3, 2, 1, and 0 points for statistical analysis (Table 1).

XSL•FO
RenderX

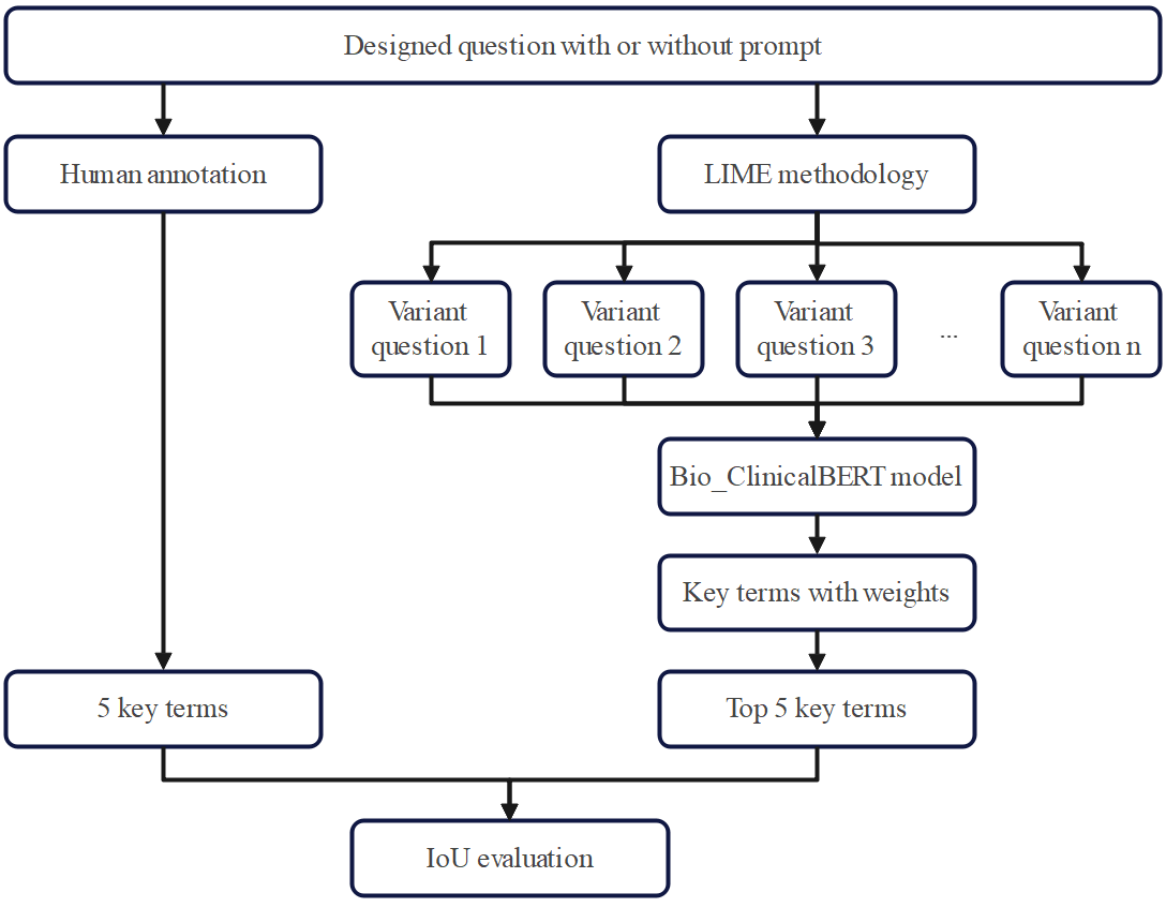


Table 1. Criteria of scoring for response.

Grade	Description	Scores
A	Completely correct with comprehensive information	3
B	Mostly correct, but with missing information or minor errors	2
C	Contains major errors but with some correct content	1
D	Completely wrong or off-topic	0

Model Explainability Analysis

Local Interpretable Model-Agnostic Explanations (LIME) is widely recognized for generating locally interpretable explanations of machine learning model predictions, including natural language processing models [24,25]. In this study, LIME was used to interpret LLM outputs by adapting methods previously successful in natural language processing. The primary LIME parameter, the number of samples, was set to 10 times the input sentence's token count, based on preliminary experiments and prior applications of LIME to LLMs [26]. Each input question was analyzed to identify key terms with assigned weights, and the top 5 key terms by weight were selected. Our experts manually annotated 5 key terms per question for comparison. An intersection-over-union (IoU) analysis was performed between the LIME-selected key terms and the expert-annotated key terms to evaluate their alignment (Figure 3).

Figure 3. The flowchart of model explainability analysis by the Local Interpretable Model-agnostic Explanations (LIME) methodology. LIME was used to interpret large language model (LLM) outputs by analyzing each input question and generating variant questions with or without prompt. The number of samples was set to 10 times the token count of the input sentence. Key terms were extracted using the Bio_ClinicalBERT model, and the top 5 terms by weight were selected. Experts manually annotated 5 key terms per question for comparison. An intersection over union (IoU) analysis was conducted to evaluate the alignment between LIME-selected and expert-annotated key terms. BERT: Bidirectional Encoder Representations from Transformers.

$$IoU(x1, x2) = (|x1 \cap x2|)/(|x1 \cup x2|)$$

Ethical Considerations

This study did not involve human participants, identifiable patient data, or protected health information. The data utilized

XSL•FO
RenderX

in this study comprised publicly available sources, including leaderboards, clinical guidelines, and secondary analyses of model-generated outputs. Therefore, an ethical review was not required under Zhongnan Hospital of Wuhan University's secondary research policies. The study complied with the Declaration of Helsinki and institutional guidelines for secondary data use.

Statistical Methods

Analyses were conducted using R version 4.3.1 (R Foundation) and RStudio 2023.12.1+402 (R Foundation). Differences across models were assessed using the chi-square test for categorical variables. For paired comparisons, data were first tested for normality. If normally distributed, a paired *t* test was applied, with results reported as mean and SD; otherwise, a paired Wilcoxon rank sum test was used, with outcomes presented as median and IQR. Effective rates were reported as mean values with 95% CIs. A *P* value of less than .05 was considered indicative of a significant difference.

Results

Model Selection

After screening for win rates and conducting tests on our computers, our study included 9 models. The proprietary models are ChatGPT-4.0 Turbo, Claude 2, and Gemini Pro, which are accessible through their official websites. The open-source LLMs include Mistral-7B-v0.2, Starling-LM-7B Alpha, and Microsoft Phi-2. The medical-specialized models are the Chinese models HuatuoGPT and QiZhenGPT, along with the English model BioMedLM 2.7B. The expected performance ranking of the selected models is as follows: ChatGPT-4.0 Turbo > Gemini Pro > Claude 2 > Mistral-7B-v0.2 > Starling-LM-7B Alpha > ChatGLM 6B (QiZhenGPT) > Phi-2 > Baichuan2-7B-Chat (HuatuoGPT). BioMedLM 2.7B is excluded from this ranking because it is not listed on the AlpacaEval Leaderboard. The characteristics of the included models are presented in Table 2.

Table 2. The characteristics of included models.

Model and access reference	AlpacaEval win rate	Description
ChatGPT-4.0 Turbo [27]	50%	Developed by OpenAI, ChatGPT-4.0 Turbo is an LLM[a] that is currently the most powerful in terms of performance.
Claude 2 [28]	17.19%	Developed by Anthropic, it is built on the GPT-3 architecture. This model features a context window of 100,000 ultra-long tokens, enabling it to handle longer context inputs efficiently.
Mistral-7B-v0.2 [29]	14.72%	Mistral-7B-v0.2 is the strongest open-source model on the list that can be deployed on consumer computers. Furthermore, the popularity of this model is high, as it received more than 700,000 downloads in January 2024.
Starling-LM-7B alpha [30]	14.25%	A fine-tuned model that outperforms all models to date on MT-Bench except for OpenAI's GPT-4 and GPT-4 Turbo.
Gemini Pro [31]	18.18%	Developed by Google DeepMind, the more advanced Gemini Ultra is not yet available to the public, so we used the Pro version.
HuatuoGPT 2-7B [32]	1.99% (base model)	Developed by the Shenzhen Institute of Big Data and The Chinese University of Hong Kong, this Chinese medical LLM is fine-tuned based on Baichuan2-7B. Uses deploying method. The online demo is available at [33].
QiZhenGPT [34]	3.01% (base model)	Released by Zhejiang University, the project includes 3 versions, each fine-tuned from the base models of ChatGLM-6B, Chinese-LLaMA-7B, and CaMA-13B.
Phi-2 [35]	2.34%	Released by Microsoft, this small language model has a data size of only 2.7 billion. Easy to deploy, even on consumer-grade computers, where it exhibits exceptionally fast response times.
BioMedLM 2.7B [36]	N/A[b]	Previously known as PubMedGPT 2.7B, this model was developed through pretraining.

[a]LLM: large language model.

[b]N/A: not applicable.

Questions and Prompts for LLMs

The question set consisted of 100 questions designed to encompass a broad range of clinical scenarios commonly encountered in cervical cancer management. The first 22 questions focused on general knowledge, emphasizing foundational aspects frequently encountered in clinical gynecology. The next 40 questions addressed cervical cancer screening, aligning with the latest consensus guidelines and decision-making protocols. Subsequently, 6 and 32 questions covered diagnosis and treatment, respectively, offering a comprehensive evaluation of the models' ability to interpret diagnostic criteria and recommend evidence-based treatment options. By including both routine and complex queries, the question set serves as a robust benchmark for assessing model performance, accuracy, and adherence to evidence-based medical practices. The complete list of questions is provided in Table 3.

Table 3. The 100 designed questions based on cervical cancer guidelines.

Category	Questions
Questions related to general knowledge	• What are the risk factors that may necessitate cervical cancer screening? • At what age or under what conditions is cervical cancer screening typically deemed unnecessary? • What strategies are effective in reducing the risk of developing cervical cancer? • What are the common clinical symptoms of cervical cancer? • For individuals who have been vaccinated against HPV[a], is it still necessary for them to undergo cervical cancer screening? • Is cervical cancer screening still recommended for individuals who have had only 1 sexual partner or are not currently sexually active? • What are the recommended intervals for cervical cancer screening, and do these intervals vary among different age groups? • Is cervical cancer screening universally recommended for all age groups? If not, what are the reasons for excluding certain age groups from undergoing cervical cancer screening? • How necessary is cervical cancer screening for women who have undergone total hysterectomy? • What is the significance of cervical cancer screening? • Why is the combined use of cytological screening (Papanicolaou test) and HPV testing not recommended for women aged 21-29 years? • Is there an invariable link between HPV infection and the onset of cervical cancer? • How should one interpret an abnormal result from a cervical cancer screening test? Does such a result definitively indicate the presence of cervical cancer? • Why is yearly cervical cancer screening not recommended? • What are the objectives of cervical cancer screening protocols? • Is cervical cancer hereditary? If so, should individuals with a familial history of cervical cancer be subject to more frequent screening protocols? • What's the difference between a pelvic examination and a Pap test? • Can individuals independently administer HPV tests, and if so, how accurate are these self-administered tests? • Is it possible for cervical cancer to manifest within the interscreening interval, particularly between 2 consecutive cervical screening tests? • Is cervical screening necessary for individuals who have reached menopause? • Is it recommended to undergo cervical screening during pregnancy? • What procedures are typically involved in cervical cancer screening?

Category	Questions
Questions related to screening	• What is the examination process for HPV-positive high-risk types? • When the initial screening shows positive HPV with high-risk HPV types, emphasizing that HPV is not typed, what is the next step in the examination? • When the initial screening shows positive HPV with high-risk HPV types, and the cytological examination result is negative, what does it indicate? Should regular check-ups follow? And if so, what should be the frequency? • When the initial screening shows positive HPV with high-risk HPV types, and the cytological examination result is ≥ASC-US[b], should the next step be a colposcopy? • When the initial screening shows positive HPV with high-risk HPV types, typing identifies HPV16/18 positivity, should the next step be a colposcopy? • When the initial screening shows positive HPV with high-risk HPV types, and upon typing, it shows neither HPV16/18 positive but 1 of the other 12 types, what is the most likely subsequent examination? • When cytological examination indicates ASC-US as an abnormal initial screening result, what is the next step in the examination? • When cytological examination indicates ASC-US as an abnormal initial screening result, and HPV is used for triage, if HPV is positive, should a colposcopy follow? • When cytological examination indicates ASC-US as an abnormal initial screening result, and HPV is used for triage, if HPV is negative, what should be the subsequent examination? • When cytological examination results show ASC-H[c], LSIL[d], HSIL[e], is a colposcopy needed next? • When cytological examination results show AGC[f], what is the next examination required? • If both cytological and high-risk HPV joint tests show negative results, what other examination should follow? • If joint testing of cytology and high-risk HPV shows HPV negative and the cytological result is ASC-US, what should be done next? • If joint testing of cytology and high-risk HPV shows HPV negative, and the cytological result is >ASC-US, what should be done next? Is a colposcopy required? • In cervical cancer detection, if joint testing of cytology and high-risk HPV shows HPV positive and the cytological result is ≥ASC-US, what specific examinations should follow? • In cervical cancer detection, if joint testing of cytology and high-risk HPV shows HPV positive and the cytological result is negative, what specific examinations should follow? • In cervical cancer detection, if joint testing of cytology and high-risk HPV shows HPV positive and the cytological result is negative, and the HPV typing is HPV16/18 positive, what specific examinations should follow? • In cervical cancer detection, if a patient has joint testing of cytology and high-risk HPV, with the results showing HPV positivity, a negative cytological result, and no typing for HPV16 or HPV18, are additional tests needed? • In cervical cancer screening, if a patient has a histopathological confirmation (biopsy) of LSIL, cytology findings of LSIL or higher, and a TZ3[g] classification, what follow-up steps should be conducted? • In cervical cancer screening, if a patient has a histopathological confirmation (biopsy) of LSIL, cytology findings of LSIL or higher, and a TZ1/2 classification, what follow-up steps should be conducted? • In cervical cancer screening, if a patient has a histopathological confirmation (biopsy) of LSIL and cytology findings of ASC-H or higher, what follow-up steps should be conducted? • In cervical cancer screening, if a patient aged 21-24 years has a histopathological confirmation (biopsy) of LSIL and cytology findings of ASC-H or higher, what follow-up steps should be conducted? • In cervical cancer screening, if a patient aged 21-24 years has a histopathological confirmation (biopsy) of LSIL, cytology findings of ASC-H or higher, and a TZ3 classification for colposcopy, what follow-up steps should be conducted? • In cervical cancer screening, if a patient aged 21-24 years has a histopathological confirmation (biopsy) of LSIL, cytology findings of ASC-H or higher, and a TZ1/2 classification for colposcopy, what follow-up steps should be conducted? • In cervical cancer screening, if a pregnant patient has a histopathological confirmation (biopsy) of LSIL and cytology findings of ASC-H or higher, what follow-up steps should be conducted? • In cervical cancer screening, if a patient has a histopathological confirmation (biopsy) of HSIL and a TZ1/2 classification, what follow-up steps should be conducted? • In cervical cancer screening, if a patient has a histopathological confirmation (biopsy) of HSIL and a TZ3 classification, what follow-up steps should be conducted? • In cervical cancer screening, if a patient aged 21-24 years has a histopathological confirmation (biopsy) of CIN[h] III/HSIL, what follow-up steps should be conducted? • In cervical cancer screening, if a patient aged 21-24 years has a histopathological confirmation (biopsy) of HSIL and a TZ3 classification for colposcopy, what follow-up steps should be conducted? • In cervical cancer screening, if a patient aged 21-24 years has a histopathological confirmation (biopsy) of CIN II/III/HSIL or CIN II/HSIL and a TZ1/2 classification for colposcopy, what follow-up steps should be conducted? • In cervical cancer screening, if a pregnant patient has a histopathological confirmation (biopsy) of HSIL, what follow-up steps should be conducted? • After diagnostic/therapeutic cervical conization for cervical cancer, what follow-up steps should be conducted? • In cervical cancer screening, if a pregnant patient has a histopathological confirmation (biopsy) of HSIL without invasive cancer during pregnancy, what follow-up steps should be conducted after childbearing? • What are the strategies for HPV vaccine use? What are the recommended vaccination programs for different age groups? • Is HPV primary screening applicable in low-income countries? If so, why? • Which cervical cancer screening methods are widely used in low-income countries, particularly in sub-Saharan Africa? • What are the key indicators included in the expert consensus for quality control management of HPV testing? • What is the difference in clinical management between ASC-US and ASC-H? • Is 4-quadrant sampling still necessary for patients with no abnormalities on colposcopy? • What are the differences in cervical cancer screening and management strategies for women during pregnancy?

[g]TZ3: Type 3 transformation zone.

[h]CIN: cervical intraepithelial neoplasia.

[i]FIGO: International Federation of Gynecology and Obstetrics.

Using the CO-STAR framework, the prompt was designed to guide the model in providing clinically relevant and detailed responses, meeting the standards necessary for accurate interpretation in cervical cancer management. The specific details of the prompt are presented in Table 4.

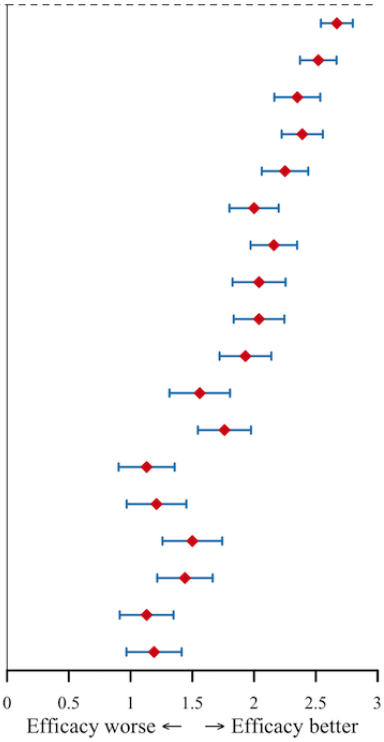
Table 4. Prompt designing based on the CO-STAR[a] framework.

Prompt element	Content
# Context #	Now you are a gynecologist with over 20 years of experience in medicine and you are answering questions about the medical specialty of cervical cancer treatment, diagnosis, and screening.
# Objective #	Please answer the following questions correctly and in strict accordance with the latest guidelines for the screening, treatment, and diagnosis of cervical cancer.
# Style #	The information should be clear, concise, and medically accurate, using terminology appropriate for both health care professionals and patients.
# Tone #	The tone should be formal and professional, recognizing the sensitive nature of cancer-related discussions.
# Audience #	The primary audience includes health care professionals, researchers, and patients seeking information about cervical cancer management.
# Response #	Generate detailed responses to specific queries regarding cervical cancer. Assess the accuracy and relevance of the information provided.

[a]CO-STAR: Context, Objective, Style, Tone, Audience, and Response.

Model Stability

Among the 9 models evaluated, 7 demonstrated good reproducibility with stable responses. However, the repeatability of Phi-2 and QiZhenGPT was unsatisfactory, as posing the same question 3 times often resulted in varying answers. For Phi-2, 61 out of 100 responses with the prompt and 68 responses without the prompt exhibited semantic differences across repetitions. Similarly, for QiZhenGPT, 60 responses with the prompt and 55 without the prompt varied. In both cases, pairwise comparisons were necessary to determine the final output (see Multimedia Appendix 2).



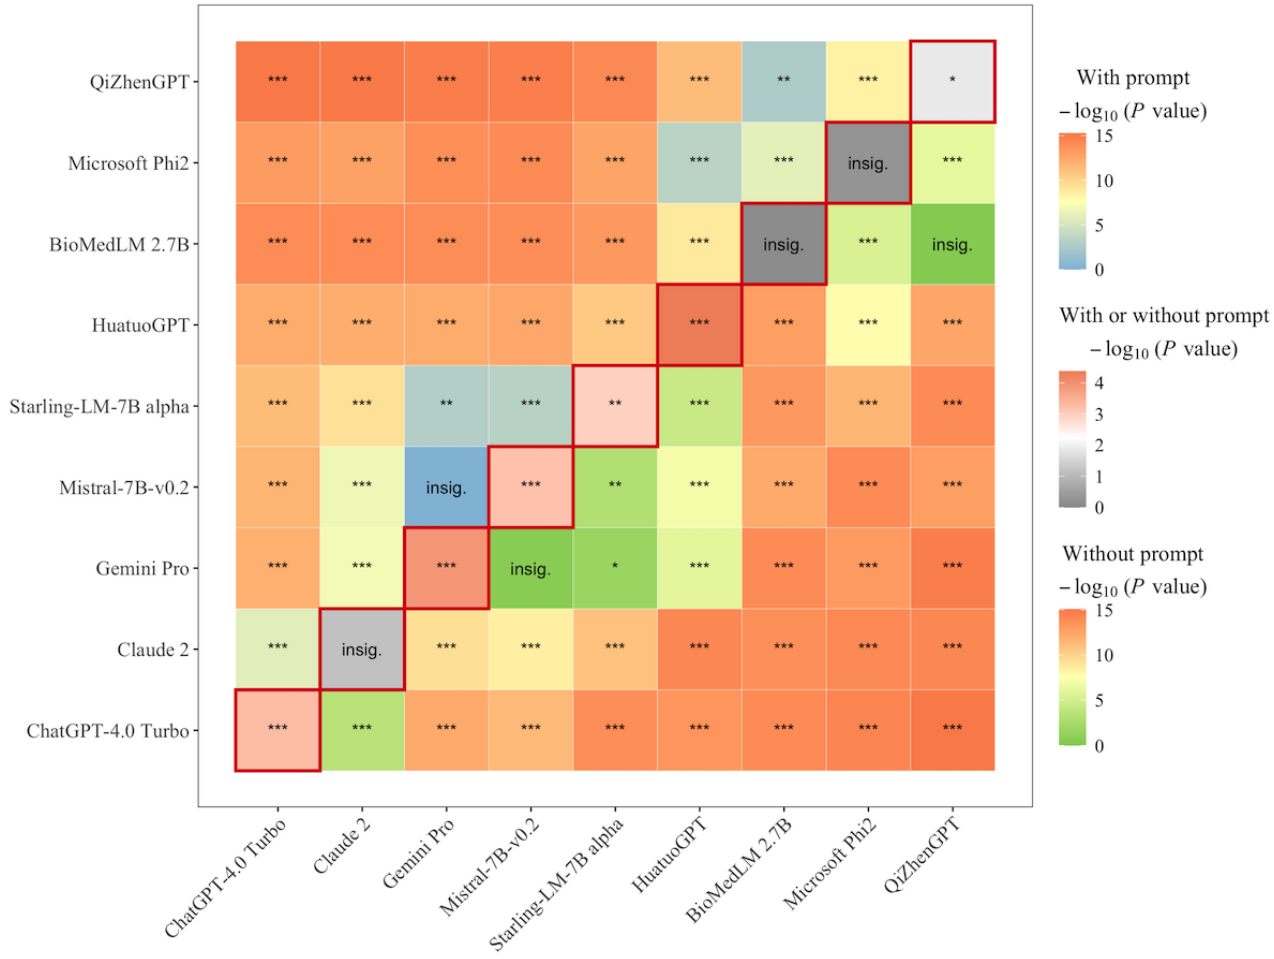
Model Efficacy

The evaluation results for each model, with and without the prompt, are presented in Figure 4. The top 3 performers were all proprietary models. ChatGPT-4.0 Turbo achieved the highest effective rate, at 94% (mean score 2.67, 95% CI 2.54-2.80) with the prompt and 87% (mean score 2.52, 95% CI 2.37-2.67) without it, highlighting the positive impact of the prompt on its performance. Claude 2 maintained an effective rate of 85% both with and without the prompt, with similar mean scores of 2.35 (95% CI 2.16-2.54) and 2.39 (95% CI 2.22-2.56), respectively. Gemini Pro showed moderate improvement, with its effective rate increasing from 66% (mean score 2.00, 95% CI 1.80-2.20) without the prompt to 77% (mean score 2.25, 95% CI 2.06-2.44) with the prompt.

XSL•FO
RenderX

Figure 4. The efficacy assessment of each model with and without the prompt. The number in A, B, C and D represents the distribution of response quality in each grade. ChatGPT-4.0 Turbo achieved the highest effective rate (94% with a mean score of 2.67, 87% without at 2.52), while Claude 2 remained consistent at 85%. Gemini Pro improved from 66% to 77% with prompts. Among medically specialized models, HuatuoGPT slightly increased from 53% to 57% without prompts, BioMedLM stayed low (39% vs 38%), and QiZhenGPT had the lowest rates (33% vs 32%), showing minimal impact from prompts.

Models	Prompt	A	B	C	D	Mean [95%CI]	Effective rate
ChatGPT-4.0 Turbo	With	74	20	4	2	2.67 [2.54, 2.80]	94%
	Without	66	21	12	1	2.52 [2.37, 2.67]	87%
Claude 2	With	61	25	10	4	2.35 [2.16, 2.54]	85%
	Without	58	27	11	4	2.39 [2.22, 2.56]	85%
Gemini Pro	With	47	27	20	6	2.25 [2.06, 2.44]	77%
	Without	42	24	26	8	2.00 [1.80, 2.20]	66%
Mistral-7B-v0.2	With	48	26	20	6	2.16 [1.97, 2.35]	74%
	Without	47	23	17	13	2.04 [1.83, 2.25]	70%
Starling-LM-7B alpha	With	44	27	18	11	2.04 [1.83, 2.25]	71%
	Without	39	28	20	13	1.93 [1.72, 2.14]	67%
HuatuoGPT	With	33	21	18	28	1.56 [1.32, 1.80]	53%
	Without	34	23	28	15	1.76 [1.54, 1.98]	57%
BioMedLM 2.7B	With	22	17	22	39	1.13 [0.90, 1.36]	39%
	Without	24	14	21	41	1.21 [0.97, 1.45]	38%
Microsoft Phi2	With	28	21	20	31	1.50 [1.26, 1.74]	49%
	Without	23	26	23	28	1.44 [1.22, 1.66]	49%
QiZhenGPT	With	16	17	29	38	1.13 [0.91, 1.35]	33%
	Without	21	11	34	34	1.19 [0.97, 1.41]	32%

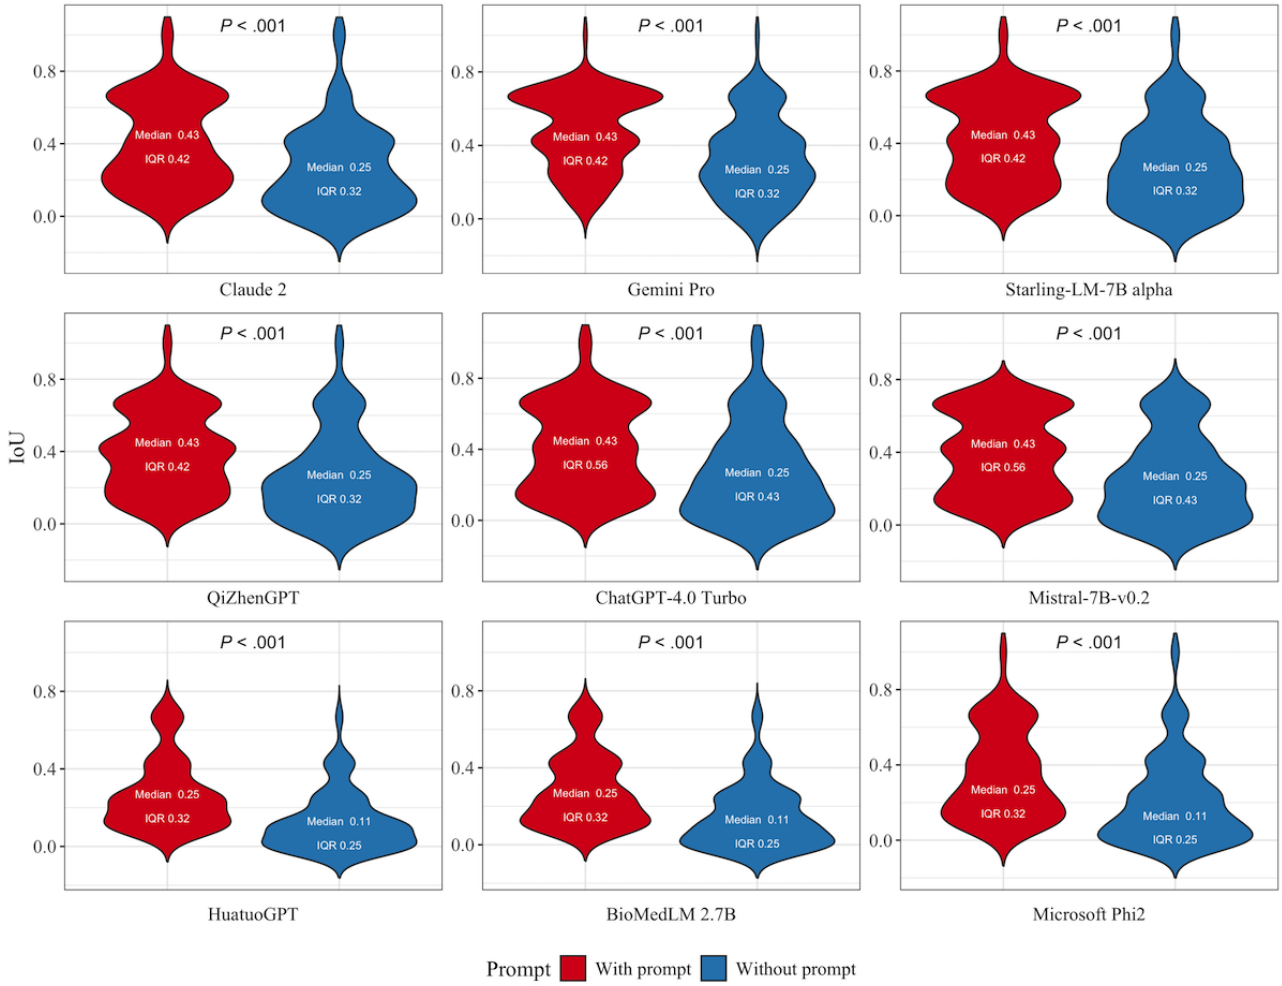


By contrast, the 3 medically specialized models exhibited lower effective rates. HuatuoGPT achieved an effective rate of 53% (mean score 2.00, 95% CI 1.80-2.20) with the prompt, which unexpectedly increased to 57% (mean score 1.76, 95% CI 1.54-1.98) without it. BioMedLM showed minimal improvement, with an effective rate of 39% (mean score 1.13, 95% CI 0.90-1.36) with the prompt and 38% (mean score 1.76, 95% CI 1.54-1.98) without it. QiZhenGPT had the lowest performance, with an effective rate of 33% (mean score 1.13, 95% CI 0.91-1.35) with the prompt and 32% (mean score 1.19, 95% CI 0.97-1.41) without it, showing limited impact from the prompt on enhancing its responses. The STS testing results are provided in Multimedia Appendix 3. Detailed responses and original scoring are provided in Multimedia Appendix 4.

The chi-square test revealed significant differences across models (P=.001). As the data for each model did not follow a normal distribution (P<.01), the Wilcoxon rank sum test was applied. With the prompt, ChatGPT-4.0 Turbo and Claude 2 exhibited highly significant differences (P<.001) compared with most other models, indicating substantial performance enhancement when the prompt was used. This pattern remained consistent in comparisons with lower-performing models, such as HuatuoGPT, BioMedLM, and QiZhenGPT. Without the prompt, significant differences were still observed, particularly between high-performing models such as ChatGPT-4.0 Turbo (P<.001) and Claude 2 (P<.001) and lower-performing models. However, the absence of the prompt reduced significance in certain comparisons, such as between Mistral-7B and Gemini Pro (P=.30) or BioMedLM and QiZhenGPT (P=.64). When comparing performance with and without the prompt, ChatGPT-4.0 Turbo and Gemini Pro demonstrated statistically significant improvements with the prompt (P<.001), whereas Claude 2 showed no significant difference (P=.07). By contrast, models such as BioMedLM (P=.77), Phi-2 (P=.53), and QiZhenGPT (P=.01) exhibited minimal or insignificant changes (Figure 5).

XSL•FO
RenderX

Figure 5. Pairwise significance comparison between models with and without the prompt. The upper triangle represents significance levels between models with the prompt, while the lower triangle displays significance levels without the prompt. The diagonal section shows significance of performance differences within each model between the prompted and unprompted conditions. The Wilcoxon rank sum test was performed as the data for each model did not follow a normal distribution. ChatGPT-4.0 Turbo and Claude 2 showed significant improvements (P<.001) with prompts, outperforming HuatuoGPT, BioMedLM, and QiZhenGPT. Without prompts, differences persisted but were less pronounced, especially between models such as Mistral-7B and Gemini Pro. insig.: insignificant; *P<.05; **P<.01; ***P<.001.



Model Explainability

Given the nonnormal distribution of IoU values for each model, the Wilcoxon rank sum test was used to assess differences. As shown in Figure 6, the inclusion of prompts significantly improved the alignment between model-generated explanations and human annotations, with all models exhibiting statistically significant differences between prompted and unprompted conditions (P<.001). Specifically, Claude 2, Gemini Pro, Starling-LM-7B Alpha, ChatGPT-4.0 Turbo, and Mistral-7B-v0.2 demonstrated a consistent median IoU of 0.43 with prompts. Among these, ChatGPT-4.0 Turbo had the widest IoU range (IQR 0.56). Without prompts, the median IoU for these models dropped to 0.25, with narrower IQRs ranging from 0.32 to 0.43, indicating reduced interpretability consistency. Among the medically specialized models, QiZhenGPT showed the most substantial improvement with prompts, achieving a median IoU of 0.43 (IQR 0.42), aligning it with the performance of proprietary models under similar conditions. By contrast, BioMedLM 2.7B and HuatuoGPT exhibited lower interpretability, with median IoUs of 0.29 and 0.25, respectively, and smaller IQRs in nonprompted conditions (median IoU of 0.11 and IQR of 0.25 for both).

XSL•FO
RenderX

Figure 6. Model explainability analysis by intersection over union (IoU) for included models with or without the prompt. Data are expressed as median and IQR and the Wilcoxon rank sum test was applied due to nonnormal distribution within each model's data. Claude 2, Gemini Pro, Starling-LM-7B alpha, ChatGPT-4.0 Turbo, and Mistral-7B-v0.2 achieved a median IoU of 0.43 with prompts, dropping to 0.25 without prompt, with ChatGPT-4.0 Turbo showing the widest range (IQR 0.56). QiZhenGPT showed the most improvement among medical models with a median IoU of 0.43 with prompt. BioMedLM 2.7B and HuatuoGPT showed lower interpretability, with nonprompted IoUs of 0.11 (IQR 0.25).

Discussion

Principal Findings

This study systematically evaluated 9 LLMs for their performance, stability, and interpretability in cervical cancer management. The results revealed that proprietary models, such as ChatGPT-4.0 Turbo, Claude 2, and Gemini Pro, achieved superior response accuracy and interpretability, particularly with prompt guidance. By contrast, medically specialized models such as HuatuoGPT, QiZhenGPT, and BioMedLM demonstrated comparatively lower effectiveness, with limited improvement from prompt use. Notably, while proprietary models exhibited consistent reproducibility, certain open-source and specialized models, such as Phi-2 and QiZhenGPT, showed variable responses upon repeated questioning. Furthermore, the use of prompts significantly enhanced interpretability in models such as Claude 2, Gemini Pro, and Starling-LM-7B Alpha, highlighting the potential of structured input to improve alignment with clinical expectations.

Comparison to Prior Work

In terms of average score ranking, proprietary models such as ChatGPT-4.0 Turbo, Claude 2, and Gemini Pro outperformed open-source models. This result aligns with traditional views on the superiority of proprietary systems [37]. However, without the prompt, Mistral-7B outperformed Gemini Pro. Among the open-source models, Mistral-7B-v0.2 and Starling-LM-7B Alpha outperformed HuatuoGPT and BioMedLM 2.7B. However, the repeatability of answers from Microsoft Phi-2 was poor, making it unsuitable for medical applications, while ChatGPT-4.0 Turbo and Claude 2 provided accurate and consistent responses. Our results indicated that the performance of the 3 medical models was average, challenging the prevailing belief that medical-specific models are superior for medical queries [38]. Previous studies [21,39] have shown that larger models, characterized by increased parameter counts, tend to perform better. Additionally, as the model scale increases, its generalization ability improves [40]. This may explain the relative underperformance of medical models compared with proprietary models, given the substantial disparity in parameter magnitude between them.

XSL•FO
RenderX

Recent advancements in algorithms have been shown to improve the performance of LLMs in the medical field [23,39], with research [41] indicating significant accuracy improvements using specific prompts. The integration of prompts has had a notable impact on the performance of several LLMs, emphasizing the value of structured input in guiding model responses within clinical contexts. Proprietary models, such as ChatGPT-4.0 Turbo and Gemini Pro, showed marked improvements in effective rate and response accuracy when guided by the CO-STAR prompt framework, suggesting that structured prompts help enhance focus on relevant clinical information and reduce ambiguity [42]. Conversely, models with specialized but limited training, such as BioMedLM, exhibited minimal sensitivity to prompts, likely due to architectural limitations in processing complex prompt structures [43]. Interestingly, HuatuoGPT experienced a decline in performance with the addition of prompts. This unexpected outcome suggests that the structured prompt for HuatuoGPT may have interfered with its response generation by introducing constraints that conflicted with its training data or underlying language patterns, potentially limiting its ability to accurately interpret open-ended clinical scenarios [44]. Additionally, smaller models often become confused when handling longer prompts [45]. The variation in prompt effectiveness across models underscores that, while structured prompts generally improve response precision, their impact is influenced by the model design and data scope.

The IoU serves as a robust indicator of alignment between model-generated explanations and human annotations, providing insights into the interpretability of LLMs in clinical contexts [46]. A higher IoU reflects greater consistency with human-provided explanations, suggesting enhanced model transparency and reliability in decision-making support. Our results demonstrate that a higher IoU corresponds to better alignment between model-generated explanations and human annotations, indicating improved interpretability. Proprietary models, particularly ChatGPT-4.0 Turbo and Claude-2, performed well in aligning with human explanations when prompts were used, highlighting their potential for generating clinically relevant interpretations. Interestingly, the rankings for model explainability based on IoU scores do not directly correlate with those based on effective rates. This discrepancy likely arises because improvements in model performance do not necessarily enhance explainability [47]. According to previous studies [48], as models become more accurate, their alignment with human-annotated explanations does not necessarily improve. This misalignment suggests that the factors driving a model's effectiveness in task accuracy differ from those contributing to explainability. Higher-performing models may rely on complex, implicit patterns that are not fully captured by metrics such as IoU, which primarily assess agreement with human logic rather than the model's actual reasoning process [49]. However, IoU alone may not fully capture explanation quality, as it can overlook aspects such as coherence and clinical relevance. Therefore, incorporating qualitative assessments alongside IoU could provide a more comprehensive measure of model explainability in clinical contexts.

Ethical Issues

LLMs have performed well in the cervical cancer question-and-answer task, but ethical considerations, such as transparency, data privacy, and algorithmic bias, remain [50]. Tools such as LIME enhance transparency and simplify the explanation of AI decisions, with further progress expected [51]. Deployments adhere to strict data laws to ensure ongoing improvements in privacy, and technological advancements are anticipated to further safeguard patient privacy [52]. Bias issues are managed through explainable AI and methods such as training with multiple multiinstitutional or population data sets, as well as using generative adversarial networks to obtain more representative data [53]. While practical challenges remain in technology integration and staff training, LLMs are more easily adopted due to their application programming interfaces and their ability to act as personalized learning assistants, reducing the reliance on extensive medical staff training [54,55].

Limitations

Our study also has limitations: (1) Because of the limited capabilities of our computers, we were unable to test all existing LLMs. It is possible that there are models with better performance than ChatGPT-4.0 Turbo in handling abnormal cervical screening results. (2) Our study did not include augmented algorithms or corpora that have been shown to improve LLM performance in other studies, as not all patients or physicians are familiar with these tools. The lack of these enhancements may limit the ability of LLMs to demonstrate their full potential in answering medical questions. This absence could have restricted the models from showcasing their full capabilities in medical query resolution, potentially affecting the generalizability of our results in more advanced settings. (3) The study conducted assessments under controlled, structured questions, which may not fully reflect the model's performance in dynamic, real-world clinical settings. This controlled environment may limit our ability to assess the adaptability of LLMs in unpredictable or complex patient interactions.

Conclusions

This study highlights the pivotal role of LLMs, particularly proprietary ones such as ChatGPT-4.0 Turbo, in enhancing clinical decision-making in cervical cancer screening. ChatGPT-4.0 Turbo outperforms both open-source and medical-specialized models in interpreting clinical guidelines and handling medical queries. Such findings are essential for improving the accuracy and efficiency of medical screenings and diagnoses, ultimately enhancing health care delivery and patient care. Further research is needed to assess the effectiveness of LLMs in medical applications, potentially leading to the development of models more tailored for medical practice and advancing overall health care.

Abstract

Background: Recent advancements in artificial intelligence, such as GPT-3.5 Turbo (OpenAI) and GPT-4, have demonstrated significant potential by achieving good scores on text-only United States Medical Licensing Examination (USMLE) exams and effectively answering questions from physicians. However, the ability of these models to interpret medical images remains underexplored.

Objective: This study aimed to comprehensively evaluate the performance, interpretability, and limitations of GPT-3.5 Turbo, GPT-4, and its successor, GPT-4 Vision (GPT-4V), specifically focusing on GPT-4V's newly introduced image-understanding feature. By assessing the models on medical licensing examination questions that require image interpretation, we sought to highlight the strengths and weaknesses of GPT-4V in handling complex multimodal clinical information, thereby exposing hidden flaws and providing insights into its readiness for integration into clinical settings.

Methods: This cross-sectional study tested GPT-4V, GPT-4, and ChatGPT-3.5 Turbo on a total of 227 multiple-choice questions with images from USMLE Step 1 (n=19), Step 2 clinical knowledge (n=14), Step 3 (n=18), the Diagnostic Radiology Qualifying Core Exam (DRQCE) (n=26), and AMBOSS question banks (n=150). AMBOSS provided expert-written hints and question difficulty levels. GPT-4V's accuracy was compared with 2 state-of-the-art large language models, GPT-3.5 Turbo and GPT-4. The quality of the explanations was evaluated by choosing human preference between an explanation by GPT-4V (without hint), an explanation by an expert, or a tie, using 3 qualitative metrics: comprehensive explanation, question information, and image interpretation. To better understand GPT-4V's explanation ability, we modified a patient case report to resemble a typical "curbside consultation" between physicians.

Results: For questions with images, GPT-4V achieved an accuracy of 84.2%, 85.7%, 88.9%, and 73.1% in Step 1, Step 2 clinical knowledge, Step 3 of USMLE, and DRQCE, respectively. It outperformed GPT-3.5 Turbo (42.1%, 50%, 50%, 19.2%) and GPT-4 (63.2%, 64.3%, 66.7%, 26.9%). When GPT-4V answered correctly, its explanations were nearly as good as those provided by domain experts from AMBOSS. However, incorrect answers often had poor explanation quality: 18.2% (10/55) contained inaccurate text, 45.5% (25/55) had inference errors, and 76.3% (42/55) demonstrated image misunderstandings. With human expert assistance, GPT-4V reduced errors by an average of 40% (22/55). GPT-4V accuracy improved with hints, maintaining

XSL•FO
RenderX

stable performance across difficulty levels, while medical student performance declined as difficulty increased. In a simulated curbside consultation scenario, GPT-4V required multiple specific prompts to interpret complex case data accurately.

Conclusions: GPT-4V achieved high accuracy on multiple-choice questions with images, highlighting its potential in medical assessments. However, significant shortcomings were observed in the quality of explanations when questions were answered incorrectly, particularly in the interpretation of images, which could not be efficiently resolved through expert interaction. These findings reveal hidden flaws in the image interpretation capabilities of GPT-4V, underscoring the need for more comprehensive evaluations beyond multiple-choice questions before integrating GPT-4V into clinical settings.

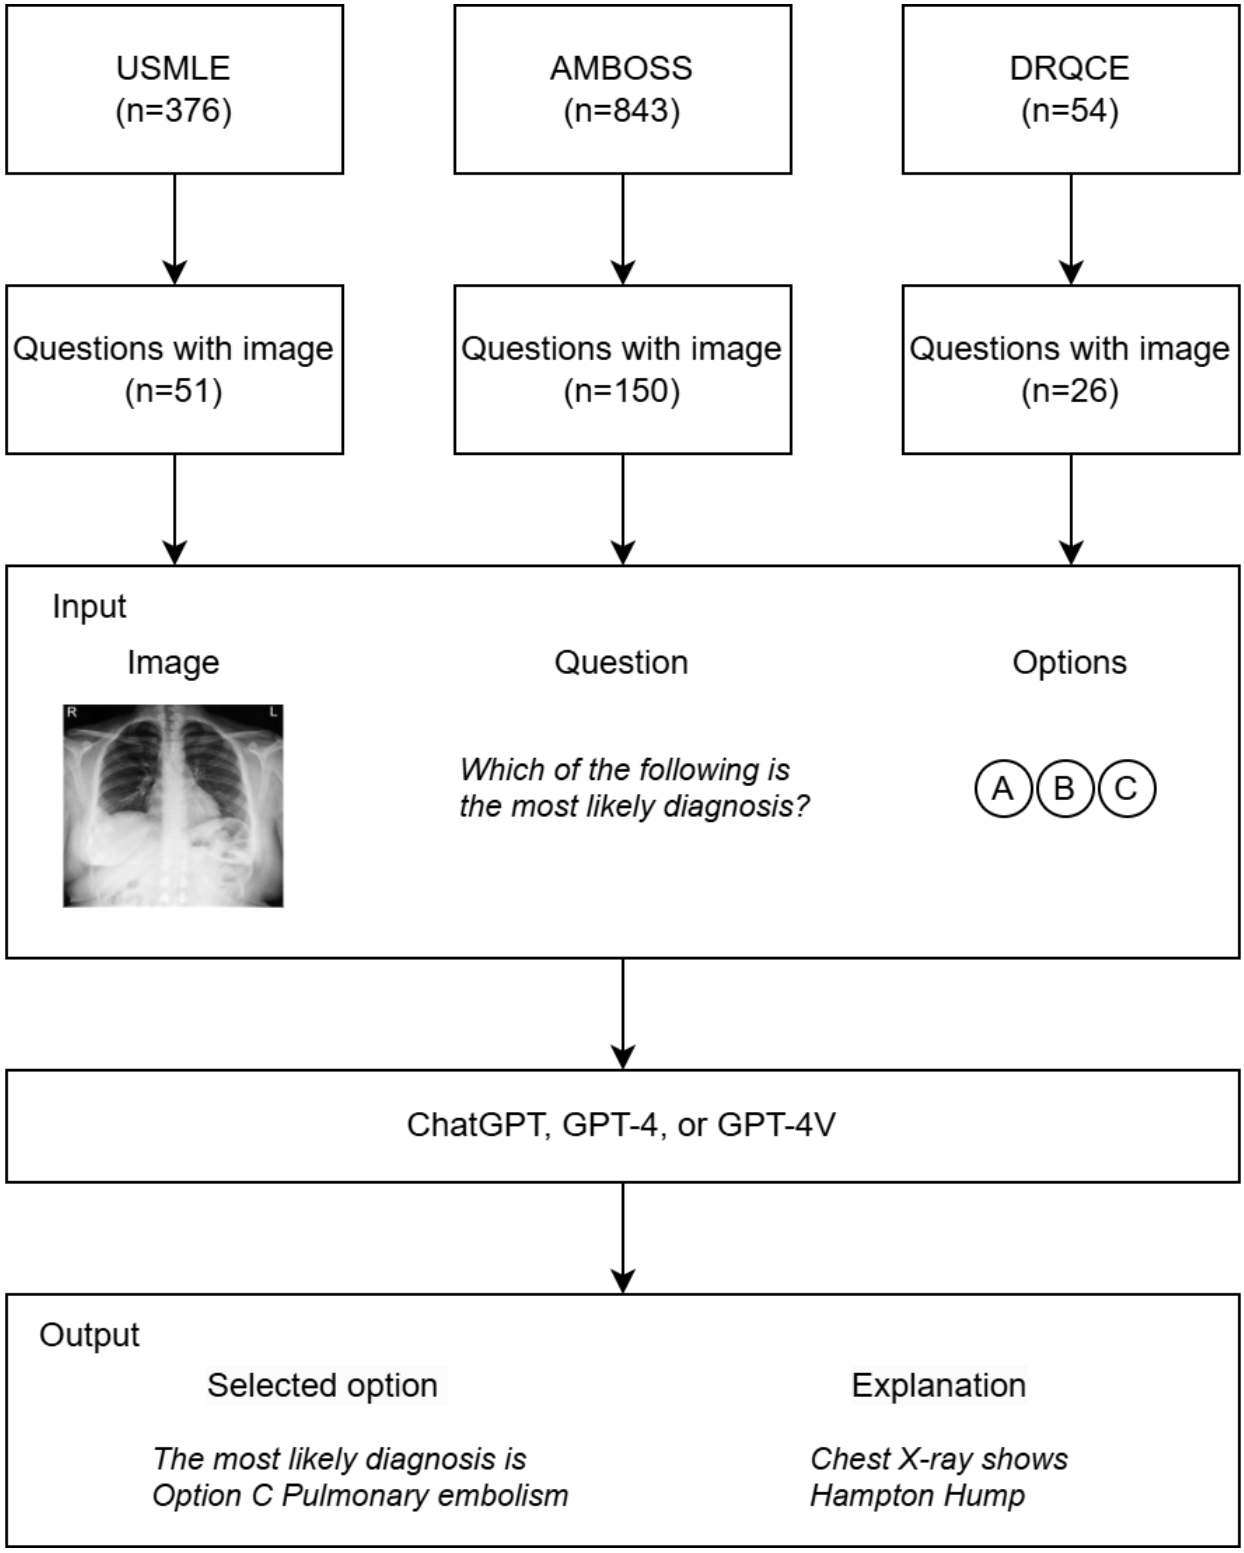
Introduction

Using computers to help make clinical diagnoses and guide treatments has been a goal of artificial intelligence (AI) since its inception [1]. The adoption of electronic health record systems by hospitals in the United States has resulted in an unprecedented amount of digital data associated with patient encounters. Computer-assisted clinical diagnostic support systems (CDSSs) endeavor to enhance clinicians' decisions with patient information and clinical knowledge [2]. There is burgeoning interest in CDSS for enhanced imaging [3] in various disciplines such as breast cancer detection [4], COVID detection [5], diagnosing congenital cataracts [6], and hidden fracture location [7]. For a decision to be trustworthy for clinicians, CDSS should not only make the prediction but also provide accurate explanations [8-10]. However, most previous imaging CDSSs only highlight areas deemed significant by AI [11-14], providing limited insight into the explanation of the diagnosis [15].

Recent advances in large language models (LLMs) have encouraged much discussion in health care. State-of-the-art LLMs include GPT-3.5 Turbo, a chatbot released by OpenAI in October 2022, and its successor, GPT-4, released in March 2023. The success of GPT-3.5 Turbo and GPT-4 is attributed to their conversational ability and their performance, which have approached or matched human-level competence in cognitive tasks, spanning various domains including medicine [16]. Both GPT-3.5 Turbo and GPT-4 have achieved commendable results in the United States Medical Licensing Examination (USMLE), leading to discussions about the readiness of LLM applications for integration into clinical [17-19] and educational [20-22] environments.

One limitation of GPT-3.5 Turbo and GPT-4 is that they can only read and generate text and are unable to process other data modalities, such as images. This limitation, known as "single modality," is a common issue among many LLMs [23]. Advancements in multimodal LLMs promise enhanced capabilities and integration with diverse data sources [24-26]. OpenAI's GPT-4V is a state-of-the-art multimodal LLM equipped with image processing and understanding ability [27]. However, the ability of GPT-4V to answer medical questions with images with explanations has not been comprehensively evaluated. In this study, we aimed to expose hidden flaws in GPT-4V's ability to interpret clinical images by thoroughly evaluating its performance on medical licensing examination questions involving image interpretation. For GPT-4V to be useful to medical professionals, it should not only provide correct responses but also offer accurate explanations for its reasoning, especially in complex multimodal clinical scenarios [28].



Methods

Overview

This cross-sectional study aimed to expose the hidden flaws of GPT-4V in clinical image interpretation by comparing the performance between GPT-4V, GPT-4, and GPT-3.5 Turbo in answering medical licensing examination questions. This study also investigates the quality of GPT-4V explanation in answering these questions. The overview of the study is shown in Figure 1. This study was conducted in October 2023.

Figure 1. A summary of the image question selection process and prompt to large language models.

Ethical Considerations

The requirement for ethical approval and informed consent was waived by the institutional review board at the VA Bedford Health Care System because no patient data were used. The experiments were performed in accordance with the Declaration of Helsinki.

Medical Exams and a Patient Case Report Collection

We obtained study questions from 3 sources. USMLE consists of 3 steps required to obtain a medical license in the United States. USMLE assesses a physician's ability to apply knowledge, concepts, and principles, which is critical to both health and disease management and is the foundation for safe, efficient patient care. Step 1 assesses foundational scientific concepts essential for medical practice, Step 2 clinical knowledge (CK) evaluates the application of clinical science

XSL•FO
RenderX

for supervised patient care, and Step 3 tests the medical knowledge required for unsupervised practice. Step 1, Step 2 CK, and Step 3 of the USMLE sample exam released from the National Board of Medical Examiners consist of 119, 120, and 137 questions respectively. We accessed these questions from publicly available links [29]. Each question contained multiple options to choose from. We then selected all questions with images, resulting in 19, 14, and 18 questions from Step 1, Step 2 CK, and Step 3. Medical subdomains include but are not limited to radiology, dermatology, orthopedics, ophthalmology, cardiology, and general surgery.

The sample exam only included limited questions with images. Thus, we further collected similar questions from AMBOSS, a widely used question bank for medical students, which provides students' performance on the exam. The performance enabled us to assess the comparative effectiveness of the model. For each question, AMBOSS associated an expert-written hint to tip the student to answer the question and a difficulty level that ranges from 1-5. Levels 1, 2, 3, 4, and 5 represent the easiest 20%, 20%-50%, 50%-80%, 80%-95%, and 95%-100% of questions respectively [30]. Hints are designed to guide students to the correct answer. They are typically formatted as a short paragraph that describes the image. We manually checked that no hint had disclosed the answer directly. In addition to the gold standard choice, each answer is associated with a detailed explanation by AMBOSS. They were developed through an internal peer-review process involving more than 50 physicians who achieved high scores in the exam. We used a commercial license to access the questions. Since AMBOSS is not publicly available and its licensing terms restrict the automatic website scraping of its proprietary content, they are not in the CommonCrawl data set used to train GPTs [31]. We randomly selected and manually downloaded 10 questions from each of the 5 difficulty levels. We repeated this process for Step 1, Step 2 CK, and Step 3. This resulted in a total number of 150 questions.

In addition, we collected questions from the Diagnostic Radiology Qualifying Core Exam (DRQCE) [32], which is an image-rich exam to evaluate a candidate's foundational knowledge and clinical judgment across practice domains of diagnostic radiology, which is offered after 36 months of residency training. Since DRQCE is proprietary, we used a commercial license to access the 26 questions with images of 54 questions in the preparation exam offered by the American Board of Radiology. In total, we had 227 questions with images from the 3 aforementioned sources.

To illustrate GPT-4V's potential as an imaging diagnostic support tool and further expose its limitations, we used part of a patient case report [33] to resemble a typical "curbside consultation" between medical professionals [34]. In this case, the patient's admission info, such as history of present illness, labs, and images of the case report will be presented to both a physician and GPT-4V. The physician can then work with GPT-4V through question answering, for example, by asking GPT-4V to help interpret images, for the final clinical diagnosis.

How to Answer Image Questions Using GPT-4V Prompts

GPT-4V took image and text data as inputs to generate textual outputs. Given that input format (prompt) played a key role in optimizing model performance, we followed the standard prompting guidelines of the visual question-answering task [35]. Specifically, we prompted GPT-4V by first adding the image, then appending context (ie, patient information) and questions, and finally providing multiple-choice options, each separated by a new line. An example user prompt and GPT-4V response are shown in Figure S1 in Multimedia Appendix 1. When multiple subimages existed in the image, we uploaded multiple subimages to GPT-4V. We did not append a hint to the end of the question, unless other specified. The response consists of the selected option as an answer, supported by a textual explanation to substantiate the selected decision. When using GPT-3.5 Turbo and GPT-4 models that cannot handle image data, images were omitted from the prompt. These models were accessed through OpenAI application programming interfaces. Responses were collected from the September 25, 2023, version of models.

Evaluation Metrics

For answer accuracy, we evaluated the model's performance by comparing the model's choice with the correct choice provided by the exam board or question bank website. We defined accuracy as the ratio of the number of correct choices to the total number of questions.

We also evaluated the quality of the explanation by preference from 3 health care professionals (1 medical doctor with 35 years of experience in internal medicine, 1 registered ward nurse with 2 years of experience, and 1 third-year medical school student). For each question from the AMBOSS data set (n=150), we first asked the health care professionals to choose their preference between an explanation by GPT-4V (without hint), an explanation by an expert, or a tie without knowing the correctness of GPT-4V's answers. The exclusion of correctness is to avoid bias in their preference of explanations. In addition, the source of the explanations was blinded to the health care professionals, ensuring that their judgments were not influenced by knowing whether an explanation came from GPT-4V or an expert.

In addition, we also asked health care professionals to evaluate the GPT-4V explanation from a sufficient and comprehensive perspective [36,37]. They determined if the information exists in the explanation, that consists of (1) image interpretation: GPT-4V tried to interpret the image in the explanation, and such interpretation is sufficient to support its choice; (2) question information: explanations contained information related to the textual context (ie, patient information) of the question, and such information was essential for GPT-4V's choice; (3) comprehensive explanation: the explanation included comprehensive reasoning for all possible evidence (eg, symptoms, lab results) that leads to the final answer.

Finally, for each question answered incorrectly, we asked health care professionals to check if the explanation contained any errors that consisted of (1) image misunderstanding (if the

XSL•FO
RenderX

sentence in the explanation showed an incorrect interpretation of the image; eg, GPT-4V said that a bone in the image was for the hand, but it was in fact the foot); (2) text hallucination (if the sentence in the explanation contained made-up information [38]; eg, claiming Saxenda was insulin); (3) reasoning error (if the sentence did not properly infer knowledge in either image or text to an answer; eg, GPT-4V reasoned that a patient took a trip within the last 3 months and therefore diagnosed the patient as having Chagas disease, despite the clinical knowledge that Chagas disease usually develops 10-20 years after infection); or (4) nonmedical error (GPT is known to struggle with tasks requiring precise spatial localization, such as identifying chess positions on the board [27]).

In this study, we asked an internal medicine doctor with 35 years of experience to articulate a detailed rating guideline above. Our study has shown that the medical student and nurse, both of whom participated independently, agreed with the doctor's ratings of 95% and 86%, respectively. This high agreement ratio underscores the effectiveness of the standardized guidelines in ensuring consistent evaluation across varying levels of expertise.

Statistical Analysis

Chi-square tests and pairwise comparisons with Bonferroni corrections were used for the performance metrics of GPT-3.5 Turbo, GPT-4, and GPT-4V on visual question answering exams. GPT-4V's accuracies on the AMBOSS data set were compared between different difficulties using unpaired chi-square tests with a significance level of 0.05. All analysis was conducted in Python software (version 3.10.11; Python Software Foundation).

Results

Overall Answer Accuracy

For all questions in the USMLE sample exam (including ones without images), GPT-4V achieved an accuracy of 88.2%, 90.8%, and 92.7% among Step 1, Step 2 CK, and Step 3 of USMLE questions, respectively. In comparison, GPT-3.5 Turbo and GPT-4 achieved an accuracy of 55.1% and 81.5% in Step 1, 59.1% and 80.8% in Step 2 CK, and 60.9% and 88.3% in Step 3, respectively (Table 1). GPT-4V outperformed GPT-4 and GPT-3.5 Turbo by 11.3% (95% CI 11.5%-11.1%; $P<.001$) and 32% (95% CI 32.3%-31.7%; $P<.001$). The score of GPT-4V passes the standard for the USMLE (about 60%). The performance of GPT-4V across different subdomains is shown in Table S1 in Multimedia Appendix 1.

XSL•FO
RenderX

Table 1. Performance of GPT-3.5 Turbo, GPT-4, and GPT-4V on a USMLE sample exam from the National Board of Medical Examiners without hints.

Exam name and agents	Performance	
	Questions with image, n (%)	All questions, n (%)
USMLE[a] sample exam-Step 1[b]		
Sample size	19	119
GPT-3.5 Turbo	8 (42.1)	66 (55.1)
GPT-4	12 (63.2)	97 (81.5)
GPT-4V	16 (84.2)	105 (88.2)
USMLE sample exam-Step 2 clinical knowledge[c]		
Sample size	14	120
GPT-3.5 Turbo	7 (50)	71 (59.1)
GPT-4	9 (64.3)	97 (80.8)
GPT-4V	12 (85.7)	109 (90.8)
USMLE sample exam-Step 3[d]		
Sample size	18	137
GPT-3.5 Turbo	9 (50)	73 (60.9)
GPT-4	12 (66.7)	121 (88.3)
GPT-4V	16 (88.9)	127 (92.7)
DRQCE[e] sample exam[f]		
Sample size	26	54
GPT-3.5 Turbo	5 (19.2)	31 (57.4)
GPT-4	7 (26.9)	35 (64.8)
GPT-4V	19 (73.1)	48 (88.9)

[a]USMLE: United States Medical Licensing Examination.

[b]19 questions with images and 119 questions in total in Step 1.

[c]14 questions with images and 120 questions in total in Step 2 CK.

[d]There were 18 questions with images and 137 questions in total in Step 3.

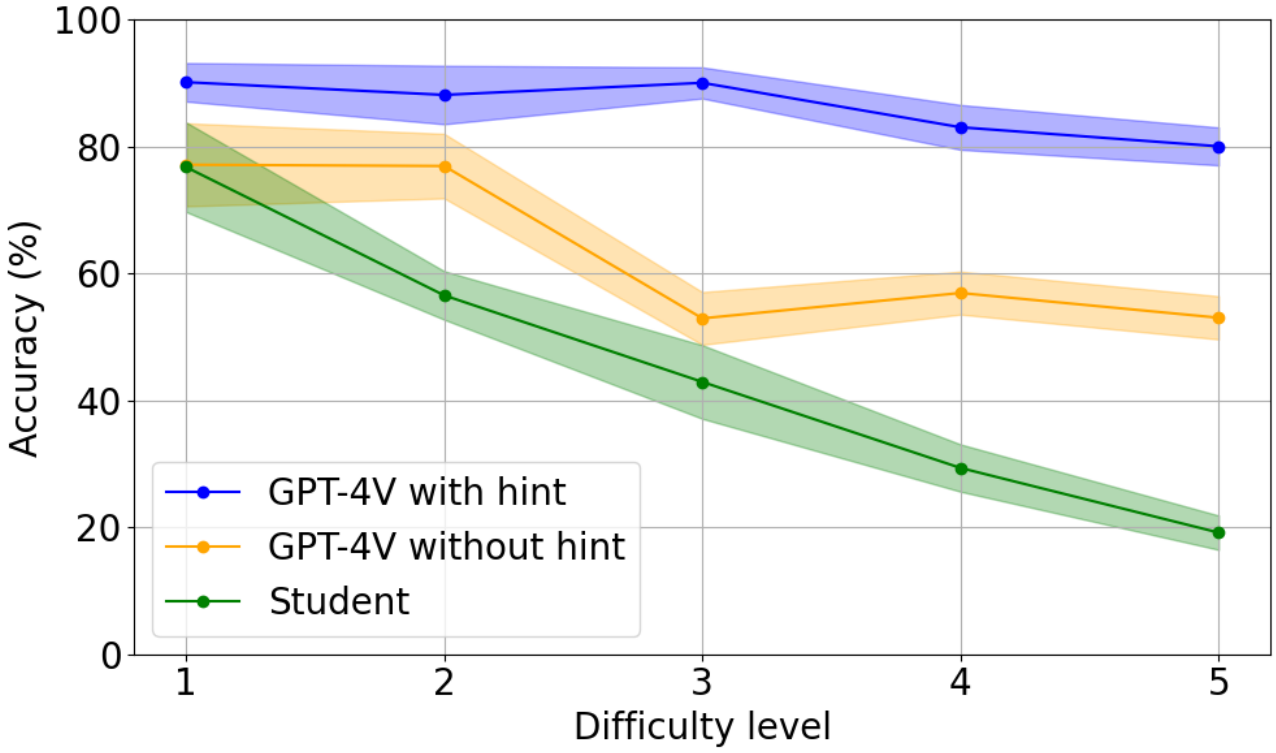
[e]DRQCE: Diagnostic Radiology Qualifying Core Exam.

[f]There were 26 questions with images and 54 questions in total in DRQCE.

For questions with images, GPT-4V achieved an accuracy of 84.2%, 85.7%, and 88.9% in Step 1, Step 2 CK, and Step 3 of USMLE questions, respectively. It outperformed GPT-3.5 Turbo and GPT-4 by 42.1% (8/19; 95% CI 36.8%-47.4%; *P*<.001) and 21.1% (4/19; 95% CI 7.8-34.2%; *P*=0.01) in Step 1, 35.7% (5/14; 95% CI 3.1%-39.7%; *P*=.03) and 21.4% (3/14; 95% CI 4.7%-38.1%; *P*=.02) in Step 2 CK, 38.9% (7/18; 95% CI 32.2%-45.7%; *P*<.001) and 22.2% (4/18; 95% CI 5.5%-38.9%; *P*=.02) in Step 3, respectively. Similarly, GPT-4V achieved an accuracy of 73.1%, outperforming GPT-3.5 Turbo by 53.9% (14/26; 95% CI 41.6%-66.2%; *P*<.001) and GPT-4 by 46.2% (12/26; 95% CI 29.8%-62.5%; *P*<.001) in DRQCE (Table 1). This highlights the superior ability of GPT-4V to interpret clinical images compared with earlier versions.

Impact of Difficulty Level and Use of Hints

When asking GPT-4V questions without a hint, it achieved an accuracy of 60%, 64%, and 66% for AMBOSS Step 1, Step 2 CK, and Step 3, respectively (Table 2). GPT-4V was in the 72nd, 76th, and 80th percentile with AMBOSS users who were preparing for Step 1, Step 2 CK, and Step 3, respectively. When asking GPT-4V questions with a hint, it achieved an accuracy of 84%, 86%, and 88% for AMBOSS Step 1, Step 2 CK, and Step 3, respectively. Figure S2 in Multimedia Appendix 1 is an example where GPT-4V switched the answer from incorrect to correct when a hint was provided. GPT-4V predictions on the entire AMBOSS data set with images are reported in Table S2 in Multimedia Appendix 1 (n=646). Conclusions drawn from automatic evaluation align with our findings presented in Table 2 (n=150).



XSL•FO
RenderX

Table 2. Performance of GPT-4V on AMBOSS.

AMBOSS steps and hint availability	GPT-4V accuracy on AMBOSS, %					
	Overall (n=50)	1 (n=10)	2 (n=10)	3 (n=10)	4 (n=10)	5 (n=10)
Step 1						
Without hint	60	70	70	30	70	60
Expert hint	84	80	80	80	90	90
Step 2 clinical knowledge						
Without hint	64	80	70	70	50	50
Expert hint	86	100	90	100	70	70
Step 3						
Without hint	66	80	90	60	50	50
Expert hint	88	90	90	90	90	80

Figure 2 shows a decreasing trend in GPT-4V's performance in the AMBOSS data set when the difficulty of questions increased (P=.04) without a hint. However, with the hint, the performance of GPT-4V plateaued across 5 difficulty levels. Importantly, the accuracies of both GPT-4V, with or without a hint, in general, outperformed the accuracies of medical students, and the gap between the performance of GPT-4V and medical students increased when the difficulty increased. On the most difficult questions, GPT-4V with hint outperformed medical students by 60% (18/30, 95% CI 56.8%-63.1%; P<.001), and GPT-4V without hint outperformed medical students by 26.7% (8/30, 95% CI 24.2%-29.3%; P<.001). The findings show that while GPT-4V outperforms medical students in accuracy, its performance is largely dependent on context-based hints, reflecting a fundamental flaw in image reasoning.

Figure 2. Performance of GPT-4V and students on 150 AMBOSS questions with different difficulty levels.

Quality of Explanation

We evaluated the user's preference among GPT-4V-generated explanations and expert-generated explanations. When GPT-4V answered incorrectly, our results show that health care professionals overwhelmingly preferred expert explanations as shown in Table 3. In total, 47 preferred experts and 0 preferred GPT-4V. When GPT-4V answered correctly, the quality of GPT-4V-generated explanations was close to expert-generated explanations: out of 95 votes, 19 preferred experts, 15 preferred GPT-4V, and 61 preferred either. The preference for expert explanations in incorrect answers highlights key weaknesses in GPT-4V's ability to interpret clinical images accurately and offer dependable reasoning.

XSL•FO
RenderX

Table 3. Health care professionals preferred explanations for 150 AMBOSS questions.

AMBOSS steps and correctness of GPT-4V (without hint) responses	Health care professionals' preference		
	Prefer expert	Ties	Prefer GPT-4V
Step 1			
Correct	4	23	3
Incorrect	16	4	0
Step 2 clinical knowledge			
Correct	10	15	7
Incorrect	18	0	0
Step 3			
Correct	5	23	5
Incorrect	13	4	0

We further evaluated the quality of the GPT-4V generated explanation by verifying if the explanation includes image and question text interpretation in Table S3 in Multimedia Appendix 1. When examining the 95 correct answers, 84.2% (n=80) of the responses contained an interpretation of the image, while 96.8% (n=92) aptly captured the information presented in the question. On the other hand, for the 55 incorrect answers, 92.8% (n=51) interpreted the image, and 89.1% (n=49) depicted the question's details. In terms of comprehensiveness, GPT-4V offered a comprehensive explanation in 79% (n=75) of correct responses. In contrast, only 7.2% (n=4) of the wrong responses had a comprehensive explanation that led to the GPT-4V's choice.

We also evaluated the explanations of incorrect responses by GPT-4V image and grouped them into 4 categories, that are image misunderstanding, text hallucination, reasoning error, and nonmedical error. Among GPT-4V responses with wrong answers (n=55), we found that 76.3% (n=42) of responses included misunderstanding of the image, 45.5% (n=25) of responses included logic error, 18.2% (n=10) of responses included text hallucination, and no responses included nonmedical errors.

A Case Study of Curbside Consultation

We present a clinical case study involving a 45-year-old woman with hypertension and altered mental status. As shown in Figure S3 in Multimedia Appendix 1, a collaborative design of GPT-4V allows communication between GPT-4V and physicians. In this scenario, when asked to interpret a CT scan, GPT-4V initially provided an irrelevant answer. GPT-4V needed 5 additional physician-guided prompts to list potential diagnoses, including primary aldosteronism, hypertension, and Cushing's syndrome. For instance, when the physician specifically prompted, "If I suspect Cushing's syndrome due to ectopic ACTH secretion, what would be the next steps to evaluate this patient to determine the source of the hormonal abnormality?" and pointed to a specific area on the CT scan, GPT-4V was then able to respond correctly. This interaction indicates that GPT-4V struggles to autonomously interpret medical images, requiring continuous and specific prompts for accurate interpretation, which underscores its flaws in independent image reasoning.

Discussion

Principal Findings

Recent advancements in medical question-answering systems have leveraged domain-specific transformer models. Early models such as PubMedBERT [39] with 100 million parameters score around 38.3% in USMLE. The introduction of larger models marked a substantial improvement. JMLR [40] with 13 billion parameters, Med-Palm [41] with 540 billion parameters, and GPT-4 achieves 62.5%, 86.2%, and 90.2% respectively. However, previous works only tested these models on text-only questions without images [20,42-44] or questions in non-English languages [45,46]. Unlike previous works that focus primarily on accuracy [47,48], we emphasize explanation quality as a crucial metric for assessing the model's clinical applicability. In particular, we evaluated GPT-4V's ability to interpret medical images (a new feature) to highlight hidden flaws in clinical image interpretation.

We found that GPT-4V outperformed both GPT-3.5 Turbo and GPT-4 (Table 1). When evaluating all questions in the USMLE sample exam, GPT-4V achieved an accuracy of 90.7% outperforming GPT-3.5 Turbo (58.5%) and GPT-4 (83.8%). In comparison, medical students can pass the USMLE exam with more than 60% accuracy, indicating that the GPT-4V performed at a level similar to or above a medical student in the final year of study. The accuracy of GPT-4V highlights its grasp over biomedical and clinical sciences, essential for medical practice, and showcases its ability in patient management and problem-solving skills [49]. Other studies further demonstrated the potential for clinical routines, such as summarizing radiology reports [50] and differential diagnosis [51,52].

For medical exam questions with images, we found that GPT-4V achieved an accuracy of 62%, which was equivalent to the 70th-80th percentile with AMBOSS medical students. This finding indicates that GPT-4V has the capability to integrate information from both text and images to answer questions, making it a promising tool for answering clinical questions based on images. However, our evaluation also reveals hidden flaws in its image interpretation, particularly in its inconsistency and the need for extensive context to provide accurate answers.

XSL•FO
RenderX

Another important finding is that GPT-4V significantly outperformed medical students for questions considered difficult for the students. Specifically, our results, as shown in Figure 2, show that while medical students' performance linearly decreased when the difficulty of questions increased, GPT-4V's performance stayed relatively stable. When expert hints were provided, GPT-4V's performance stayed plateau among questions in all difficult levels. This consistent performance indicates that GPT-4V effectively addresses questions that medical students find challenging. Its advanced capabilities suggest potential as an educational assistant, particularly for complex topics. Under the supervision of teachers' hints, medical students could benefit from its advanced capabilities to understand and analyze complex medical questions.

There may be multiple factors that contribute to GPT-4V's performance on difficult questions. Instrument methods (eg, item response theory [53]) have been typically used for the construction and evaluation of measurement scales and tests. For example, item response theory uses a statistical model that links an individual person's responses to individual test items (questions on a test) to the person's ability to correctly respond to the items and the items' features. Therefore, medical examination test sets have been specifically selected and tailored to medical students' performance with the intended distribution where the performance decreases when the difficulty level increases. Although more evaluation is needed to draw the conclusion that GPT-4V substantially outperformed medical students in difficult questions, our results at least show that GPT-4V performed differently.

On the other hand, we found that GPT-4V's performance was inconsistent among different medical subdomains. As shown in Table S1 in Multimedia Appendix 1, GPT-4V achieved high accuracy on subdomains such as immunology (5/5, 100%), otolaryngology (6/6, 100%), and pulmonology (6/8, 75%), and low accuracy on others such as anatomy (1/4, 25%), emergency medicine (1/4, 25%), and pathology (5/10, 50%). This suggests that while GPT-4V shows potential in some specialties or subdomains, it may require further development to be reliable across the board. The uneven performance highlights the need for tailored approaches to enhancing the model's capabilities where it falls short.

Another advantage of GPT-4V is its ability to explain its image content. Previous studies have shown limited use of current CDSS as most of them offered limited decision explanations and thus gained limited trust among physicians (unlike their colleagues) [54-57]. In contrast, GPT-4V has the potential to improve the effectiveness and credibility of CDSS by providing explanations preferred by experts. As our results indicate, the quality of explanations generated by GPT-4V, when answering correctly, is close to that of expert-generated explanations. Although in more complex scenarios (such as in our curbside consult setting), GPT-4V currently requires continuous highly specialized guidance, which temporarily prevents it from enhancing physician work efficiency, this feature still has the potential to encourage physicians to adopt and use GPT-4V more confidently and broadly.

In terms of explanation quality, we found that more than 80% of responses from GPT-4V provided an interpretation of the image, regardless of whether the responses were correct or not. This suggests that GPT-4V consistently takes into account the image while generating responses. Figure S1 in Multimedia Appendix 1 illustrates an example of a high-quality explanation that uses images to answer a hard question. In this example, more than 70% of students answered incorrectly on the first try, because both bacterial pneumonia and pulmonary embolism may involve symptoms such as cough. To differentiate them, GPT-4V correctly interpreted the x-ray with a radiologic sign of Hampton hump, which further increased the suspicion of pulmonary infarction rather than pneumonia [58]. To show the need for an x-ray as mentioned in the explanation, we removed the image from the input, and GPT-4V switched the answer to bacterial pneumonia while also acknowledging the possibility of pulmonary infarction. This change in response demonstrated the high quality of the GPT-4V explanation, as its explanation about x-rays was not fictional and it truly needed the x-ray to answer this question.

On the other hand, we found that the quality of generated explanations was poor when GPT-4V answered incorrectly. Manual analyses by health care professionals concluded that image misunderstanding was the primary reason why GPT-4V answered incorrectly. Out of 55 wrong responses, 42 (76.3%) were due to misunderstanding of the image. In comparison, only 18.2% (10/55) of the mistakes were attributed to text misinterpretation. Clearly, GPT-4V's proficiency in processing images was considerably lagging behind its text-handling capability. This gap in capability suggests that GPT-4V's advancements in image understanding remain nascent and require significant refinement to align with its text analysis capabilities. To circumvent its image interpretation issue, we additionally prompted GPT-4V with a short hint that described the image. We found that 40% (22/55) of responses switched to the correct answer. One potential future direction involves strengthening GPT-4V's domain-specific knowledge by integrating extensive clinical datasets into its training. For example, employing domain-adaptive pretraining methods—such as those used in MEDITRON [59], which leverages medical guidelines and specialized clinical corpora—could significantly improve the model's understanding of medical concepts, leading to more precise and contextually relevant explanations. In addition, incorporating retrieval-augmented generation based on domain-specific corpora [40] would enable the model to access and retrieve pertinent clinical information during inference, grounding its explanations in verified data. This could improve factual accuracy and reduce the likelihood of incorrect or unsupported responses. Together, these strategies aim to bolster the model's capacity to provide high-quality, accurate explanations, thereby enhancing its overall reliability and usefulness in clinical applications.

Creating these image-related hints requires clinical expertise, limiting the use of GPT-4V as a CDSS. In our case study, when GPT-4V delivered an irrelevant response, the physician needed to come up with correct hints for GPT-4V. These findings reveal a key limitation: GPT-4V's reliance on external guidance from

XSL•FO
RenderX

experts to interpret complex image content effectively, thereby exposing its inability to operate independently in clinical scenarios. Efforts improving GPT-4V on images include multimodal LLMs with reinforcement learning from human feedback to align the outputs of LLMs with physicians' intentions and expectations. This alignment is critical not only for enhancing the accuracy and relevance of the responses but also for integrating GPT-4V seamlessly into clinical environments where time is of the essence [60].

Another significant drawback of GPT-4V involved its tendency to produce factually inaccurate responses, a problem often referred to as the hallucination effect, which is prevalent among many LLMs such as GPT-4V [38]. We found that more than 18% of GPT-4V explanations contain hallucinations, potentially misleading or distracting physicians, particularly the less experienced medical students and residents. This finding emphasizes the need for robust evaluation and correction mechanisms to minimize hallucinations, which are critical to ensure GPT-4V's reliability and safety in clinical practice. One future direction is to integrate GPT-4V and a probabilistic model with CI and citations from credible sources to show the reliability of the response [40,61,62]. The confidence score could also help prioritize the list of differential diagnoses, making it clearer to the physician which conditions are more probable. Thereby reducing the risk of confusion and enhancing the reliability of the CDSS response when additional physician review is warranted [15].

Limitations

This study has several limitations. First, our findings are constrained in their applicability due to the modest sample size. We gathered 227 questions from a total of 28 subdomains or specialties that included images, which might not comprehensively represent all medical disciplines. The small number of questions in each subdomain may not be sufficient to conclude that GPT-4V's performance is inconsistent between medical subdomains. Second, the exams used to test GPT-4V are written in English. Future work could explore other languages. Third, the models used for evaluation were from September 2023, and frontier models may have evolved since then, potentially impacting the results. Fourth, we cannot guarantee that OpenAI strictly adhered to licensing terms when determining which content was included or excluded from their training sets; therefore, even though AMBOSS is not publicly available and its licensing terms restrict the automatic website scraping of its proprietary content, GPT may have already seen the data during training, potentially impacting the results. Finally, while GPT-4V has demonstrated proficiency in medical license examination, its CDSS ability remains untested. Future work could explore continued training GPT-4V in the medical domain for better CDSS integration. Medical exams provide options, but such options would rarely be provided by physicians during CDSS. Our study highlights the inherent limitations in GPT-4V's image interpretation abilities, particularly without expert guidance. We showed that GPT-4V can reduce errors with expert hints, but in more realistic clinical environments, it required continuous highly specialized guidance to make partially correct diagnoses and subsequent examination recommendations, revealing limitations in its autonomous decision-making capabilities. Therefore, more cases with clinician questions should be explored to confirm our findings before clinical integration. Extrapolating the efficacy of GPT-4V to broader clinical applications requires appropriate benchmarks and further research.

Regarding ethical considerations, deploying AI systems for medical advice poses significant ethical implications, especially in medical education and clinical decision-making. Incorrect AI-generated explanations risk disseminating misinformation that could misguide medical professionals, impacting patient safety and treatment outcomes. This is particularly concerning when AI is used in training settings, as it could shape the decision-making abilities of future healthcare providers in potentially harmful ways. Integrating AI into clinical workflows also raises broader societal concerns. While AI has the potential to enhance healthcare efficiency, it could alter patient care dynamics and physician roles. Overreliance on AI may reduce direct physician-patient communication, eroding trust and undermining the relationship-building essential for effective care. Physicians might also become too dependent on AI, potentially compromising their clinical judgment and their ability to critically assess AI-generated insights. Thus, integrating AI in a manner that complements human expertise (supporting rather than replacing health care providers) is vital. Moreover, current benchmarks, including the one in our study, do not fully assess an AI's capabilities for real-world clinical decision-making. Although some LLMs perform well on benchmarks, they lack the comprehensive clinical skills and nuanced understanding required to navigate complex medical scenarios effectively. Viewing these AI models as tools that assist rather than replace clinicians is crucial to ensuring their safe and beneficial use in health care. A responsible approach is needed when deploying AI for medical advice, one that ensures ethical standards are maintained. Issues such as privacy, bias, and the broader implications of AI in society must guide the development and implementation of these systems. By enhancing data diversity, ensuring privacy, and fostering a transparent understanding of AI's role, we can work toward ethical advancements in health care that enhance outcomes without compromising human oversight or patient trust. Future work should focus on developing AI technologies that are fully aligned with health care professionals, maintaining a collaborative and ethically sound approach to their integration.

Conclusion

In this study, GPT-4V demonstrated remarkable overall accuracy on the medical licensing examination and provided high-quality explanations when correct. The evaluation of questions with images (a relatively novel feature for GPT models) allowed us to expose hidden flaws in GPT-4V's image interpretation abilities, offering a unique insight into its strengths and weaknesses. Its performance on image-related questions ranged from 60% to 88%, while physician misdiagnosis rates can be as high as 40% [63,64]. GPT-4V substantially outperformed medical students on difficult questions, but we observed severe issues in its explanations and reasoning, including hallucinations, errors, and misinterpretations. These findings reveal significant challenges in GPT-4V's ability to independently interpret and reason through complex image-based questions, which is crucial

XSL•FO
RenderX

for clinical applications. Despite its strong performance on multiple-choice questions, GPT-4V may still encounter comprehension or explanation errors. When assisted by human experts, GPT-4V reduced some errors with image-related hints. However, in realistic curbside consult settings, continuous and highly specialized prompting was still required, making it time-consuming and limiting its utility as a clinical decision support system in real-world clinical practice. Table 4 lists the summary of key findings.

Table 4. Summary of key findings.

Metric	Findings
Accuracy of image-based questions	GPT-4V achieved 84.2% in Step 1, 85.7% in Step 2 CK[a], 88.9% in Step 3, and 73.1% in DRQCE[b], outperforming GPT-3.5 Turbo (42.1%, 50%, 50%, 19.2%) and GPT-4 (63.2%, 64.3%, 66.7%, 26.9%).
Explanation quality	When GPT-4V provided correct answers, its explanations were almost on par with those given by domain experts. However, for incorrect responses, the explanation quality was often lacking: 18.2% included inaccurate information, 45.5% involved inferencing mistakes, and 76.3% reflected misinterpretations of images.
The impact of human expert hints	There is a decreasing trend in GPT-4V's performance in the AMBOSS dataset when the difficulty of questions increased) without hint. However, with the hint, the performance of GPT-4V plateaued.
Performance of GPT-4V on most difficult questions	GPT-4V with hints outperformed medical students by 60%, and GPT-4V without hints outperformed medical students by 26.7%.

[a]CK: clinical knowledge.

[b]DRQCE: Diagnostic Radiology Qualifying Core Exam.

Overall, our findings emphasize the need for a more comprehensive evaluation of GPT-4V's multimodal capabilities, especially in clinical image interpretation, before considering its integration into clinical decision support systems. Future randomized clinical trials will help further verify the actual utility of GPT-4V and promote more extensive and profound integration of AI in the medical domain.

Acknowledgments

This work was funded by the grant R01MH125027 from the National Institute of Mental Health of the National Institutes of Health. The funding source had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication. Abstract

Background: Molecular tumor boards (MTBs) require intensive manual investigation to generate optimal treatment recommendations for patients. Large language models (LLMs) can catalyze MTB recommendations, decrease human error, improve accessibility to care, and enhance the efficiency of precision oncology.

Objective: In this study, we aimed to investigate the efficacy of LLM-generated treatments for MTB patients. We specifically investigate the LLMs' ability to generate evidence-based treatment recommendations using PubMed references.

Methods: We built a retrieval augmented generation pipeline using PubMed data. We prompted the resulting LLM to generate treatment recommendations with PubMed references using a test set of patients from an MTB conference at a large comprehensive cancer center at a tertiary care institution. Members of the MTB manually assessed the relevancy and correctness of the generated responses.

Results: A total of 75% of the referenced articles were properly cited from PubMed, while 17% of the referenced articles were hallucinations, and the remaining were not properly cited from PubMed. Clinician-generated LLM queries achieved higher accuracy through clinician evaluation than automated queries, with clinicians labeling 25% of LLM responses as equal to their recommendations and 37.5% as alternative plausible treatments.

Conclusions: This study demonstrates how retrieval augmented generation–enhanced LLMs can be a powerful tool in accelerating MTB conferences, as LLMs are sometimes capable of achieving clinician-equal treatment recommendations. However, further investigation is required to achieve stable results with zero hallucinations. LLMs signify a scalable solution to the time-intensive process of MTB investigations. However, LLM performance demonstrates that they must be used with heavy clinician supervision, and cannot yet fully automate the MTB pipeline.

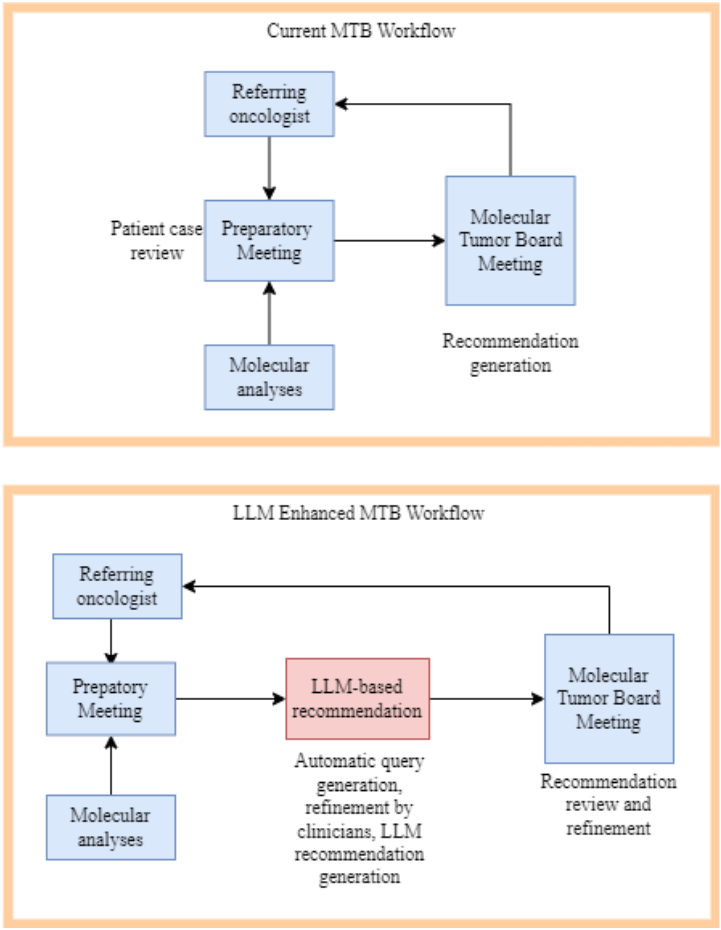
Introduction



Background

Precision oncology is a rapidly evolving field in which patient treatment is determined by the DNA signature of the tumor. Advancements in genome-sequencing techniques, molecular analysis, and a growing body of clinical trials, have all allowed for the field to integrate more easily into oncology research [1]. Using these techniques to optimize treatment has been shown to be associated with favored clinical outcomes [1]. As a mechanism to facilitate precision oncology, the molecular tumor board (MTB) serves as an approach in which a panel of expert

XSL•FO
RenderX

health care providers use their collective knowledge to interpret the genomic profile of an oncology patient and jointly develop an optimal treatment plan given available therapies. Access to MTBs is likely to correlate to improved patient care [1]. The workflow of an MTB is usually as follows: traditionally, before the conference meeting, members of the panel review a list of patients and their corresponding history and characteristics. During the meeting, members propose targeted therapies and generate a consensus recommendation, which is then received by the treating physician [1]. We propose using large language models (LLMs) to enhance this workflow. The current and proposed LLM-enhanced MTB workflows are shown in Figure 1.

Figure 1. On the top is the current MTB workflow. On the bottom is the LLM-enhanced MTB workflow, in which patient characteristics from the preparatory meeting are used to automatically generate queries. These queries are refined by clinicians and then fed into the LLM for recommendation generation. This recommendation is then reviewed and refined by the MTB panel. LLM: large language model; MTB: molecular tumor board.

One standing challenge to MTBs is the amount of required resources. Currently, the interpretation of a patient's molecular profile is a manual process, consisting of searching through various databases, such as OncoKB by Memorial Sloan Kettering Cancer Cancer [2], COSMIC by Wellcome Sanger Institute [3], and PubMed [4]. The process of generating the optimal treatment plan is laborious, and scales poorly, potentially limiting the number of patients that can be reviewed in a given conference. The median MTB experience time, which is the time needed to conduct molecular analysis and hold discussion, was reported in a global analysis published in 2020 to be 38.4 days, with a large range from 12.4 to 86 days [5].

LLMs are models trained on large amounts of textual data that are capable of generating language similar to that of humans. LLMs' capabilities span a diverse array of tasks, including question-answering, summarization, translation, and conversing. The development and integration of LLMs is advancing rapidly across different sectors. In particular, LLMs demonstrate impressive performance in automated analyses and syntheses of data [6]. As the written text is used heavily in the medical domain for communication between health care providers, between health care providers and patients, and reports on diagnoses, procedures, and patient results, it is an opportune moment for LLM application [7-10]. LLMs have a high potential to improve patient care and the scalability of patient care by increasing medical reasoning, medical knowledge competency, and access to scientific knowledge [11].

The use of MTBs, as stated above, is aided by the advancements in several adjacent fields within oncology, yet its connection to artificial intelligence remains understudied. LLMs have the potential to drastically increase the scalability of MTBs, ease access to information, and prevent human error [12]. LLMs, when used in the proper context with proper understanding, can be a catalyst for precision oncology integration.

Previous Works

Previous works have demonstrated the feasibility of using natural language processing (NLP) in the field of precision

XSL•FO
RenderX

medicine for a plethora of applications, from treatment plans to predictive diagnoses and prognoses. Within precision oncology, researchers have already conducted a study evaluating LLMs for the role they can play in clinical decision-making in the MTB space, although this evaluation does not include experimentation on using different information retrieval (IR), or retrieval augmented generation (RAG) techniques in conjunction with a pretrained LLM [13]. As a result, this study found that LLMs are not suitable to be used in automating the MTB process [14].

Outside the context of MTBs, there has been a substantial amount of research on creating LLMs for the clinical domain. This can be done through different approaches such as generative data augmentation [15], pretraining on medical domain literature [16,17], and fine-tuning on clinical domain data [17-20]. Additionally, these investigations explore different LLMs such as LLaMA, which is open-source, as opposed to GPT, which is proprietary. The result of this difference is that LLaMA can be run locally and therefore offers inherent data security advantages.

Additionally, there are several related works in the field of IR. Such studies investigate how to use NLP and named entity recognition (NER) to analyze medical databases. Through NER, literature can be obtained for a given keyword search, such as a gene, by filtering articles by term presence [21]. One study published the RetriLite framework, in which IR combines with NLP and LLMs in powerful ways to create a functional pipeline in which NLP is used for context analysis and NER, and IR is used for query expansion and relevancy-based ranking [22,23]. RetriLite is an IR framework that capitalizes on NLP to identify relevant articles from domain-specific knowledge bases and extract these sources [22]. This approach focuses on retrieving the highest quality of results, but does not explore the presentation of that output via LLM-produced textual responses.

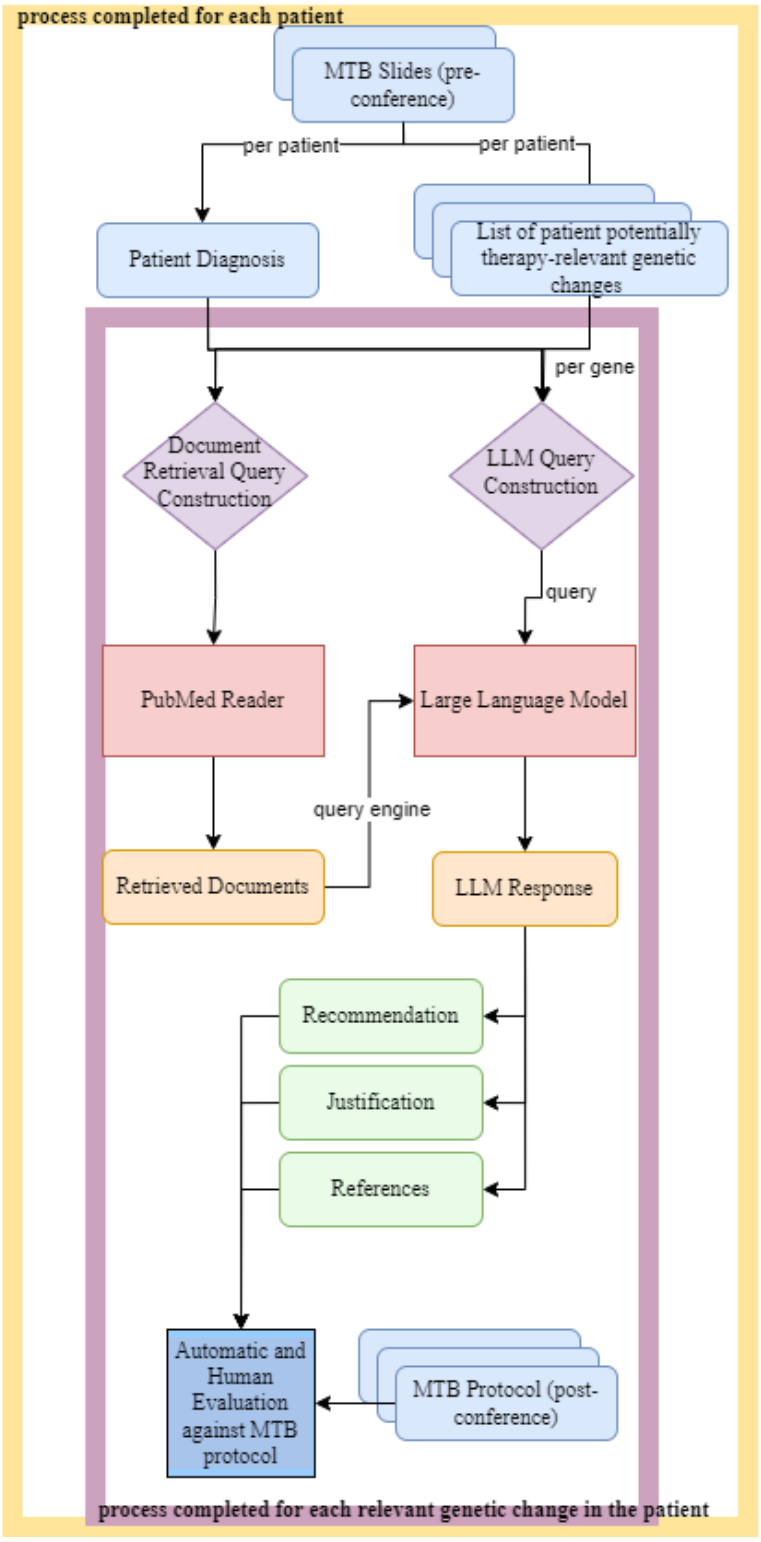
To summarize, previous works have focused on IR in the medical domain and fine-tuning LLMs for medical domain-specific tasks. Some models that have focused specifically on the interaction and integration of IR and NLP retrieve high-relevancy results. However, the use of LLMs within precision oncology to produce meaningful, evidence-based recommendations remains undetermined. Applying LLMs to MTBs has clear promise in terms of saving time and money, improving accessibility, and increasing the feasibility and scale of MTBs.

Objectives

This article (1) presents a framework for using LLMs with medical domain knowledge to generate treatment plans for sample cases from MTB conferences, (2) explores the effects of different prompt and query techniques on the LLM, and (3) conducts an evaluation against ground truth historical cases from an MTB annotated by members of the MTB panel.

Methods

Ethical Considerations



This study was exempted by the University of Tübingen's ethics review board due to the exclusive use of nonidentifiable data (Article 2(1) GDPR).

Constructing the LLM Framework

To construct the framework that would be used to obtain treatment recommendations for sample MTB cases, we first selected a baseline model to use. This decision was driven by experimenting with various open-source LLMs and selecting the LLM that had the best performance on treatment recommendations without any downstream fine-tuning. Prompt experimentation on different LLMs is shown in Table S1 in Multimedia Appendix 1. The selected model was Llama-2-7b-chat [24]. In addition to its baseline performance prior to fine-tuning, as mentioned in Previous Works, LLaMA also offers inherent security advantages over other non-open-source models such as GPT-4.0. We also experimented with various hyperparameters for this model. The optimal hyperparameters are shown in Table S2 in Multimedia Appendix 1. A full workflow is shown in Figure 2.

XSL•FO
RenderX

Figure 2. Given the input documents to an MTB conference, we parse the data into actionable queries for each pair of cancer type and genetic mutation. For each patient, we identify the diagnosis and the relevant genetic mutations by filtering the genes that are oncoKB level 1, 2, or 3, as scraped and listed in Table S4, Multimedia Appendix 1. We construct a query for document retrieval and a query for LLM inference. The LLM uses RAG, incorporating documents retrieved by querying the PubMed Data Loader using LlamaIndex, as detailed in the Methods. For each LLM response, we isolate the treatment recommendation, justification, and references and evaluate them against the MTB protocol, which we consider the ground truth. LLM: large language model; MTB: molecular tumor board; RAG: retrieval augmented generation.

To interface with the LLM as a search engine and to integrate PubMed data, we used LlamaIndex [25]. LlamaIndex is an orchestration framework for incorporating custom data into an LLM. It injects data from custom sources into the LLM, embeds the data as vectors, and allows the data to be queried by storing it in a vectorized database. Using LlamaIndex allows us to use RAG to harness the capabilities of an LLM for domain-specific tasks. We then feed the PubMed papers from LlamaIndex into the LLM to be used for RAG [25]. This is highlighted in red and orange in Figure 2. A full workflow of the LLamaIndex

XSL•FO
RenderX

orchestration, detailing data selection and literature retrieval is shown in Figure S1 in Multimedia Appendix 1.

To determine the ideal query for the PubMed-adjusted LLM, we experimented with different query types both for document retrieval and for text generation. We determined the optimal document retrieval query from the PubMed data loader would be the name of the broader cancer type, and the genetic mutation to be investigated. This is shown in Table 1, and further discussed in the discussion. Experimentation of various queries with the same LLM pipeline is shown in Table S3 in Multimedia Appendix 1. The genetic mutations to be further queried were determined as follows: for a given patient's list of genetic mutations that are included in the briefing document sent out to MTB panelists before the meeting, any genetic mutation from that list that is flagged on OncoKB as "level of evidence one, two, or three" (under their original name or alternate name) is further queried. These 3 levels distinguish varying degrees of available clinical evidence. Level 1 drugs are Food and Drug Administration (FDA) recognized biomarkers that are predictive of response to an FDA-approved drug in a specific indication. Level 2 drugs are standard care biomarkers recommended by the National Comprehensive Cancer Network (NCCN) or other professional guidelines predictive of response to an FDA-approved drug. Level 3 drugs have compelling clinical evidence supporting the biomarker as being predictive of response to a drug. Other drugs exist on OncoKB with evidence categorized as biological rather than clinical, with hypothetical therapeutic implications based on preliminary data, or without a determined level of evidence [2]. The resulting full list of genes is shown in Table S4 in Multimedia Appendix 1. For example, "Occult metastatic melanoma NRAS" would be a query for document retrieval. NRAS is listed on OncoKB as a level 1 gene. We define "broader cancer type" as the cancer diagnosis excluding the stage of the cancer, the location of the tumor, or other additional information that may have been included in the diagnosis. This is because when the query exceeds a certain length, the results are too noisy for meaningful articles to be retrieved. Then, a Vector Store Index is constructed from the retrieved documents, which then serves as a query engine. The Vector Store Index stores each document node and corresponding embedding in a Vector Store, allowing a query to fetch the most similar nodes. The optimal query for the LLM uses the full name of the cancer, provided by the MTB. The query is shown in Table 1.

Table 1. Input illustration for document retrieval and large language model (LLM) querying. For the Cancer Type Short, we input the type of cancer without further specifications such as stage or tumor location. For Cancer Type Long, we input the exact diagnosis listed in the molecular tumor board (MTB). The gene mutation is inputted as it is listed on OncoKB.

Task	Query
Document retrieval	Cancer Type Short + " " + Gene Mutation
LLM response	*A patient has* + Cancer Type Long +, *and the* + Gene Mutation +*gene mutation. What is thebest therapy treatment for this patient? Cite the PubMed sources you used to inform your response.*

The results from these queries are in the form of text paragraphs. Each paragraph states the recommendation, provides justification, and cites sources. Including justification in the recommendation allows for chain-of-thought reasoning, which has been shown to improve LLM performance [26]. The number of sources to cite is unspecified in the response. Asking the LLM to cite sources has many shown benefits including allowing the reader to fact-check the LLM response and improving faithfulness and decreasing hallucinations by forcing LLMs to justify their recommendations [27].

Evaluation Set Construction From Historical MTB Cases

To evaluate LLM recommendations, we created a dataset by retrieving previous cases presented at MTB conferences at the Center for Personalized Medicine at the Universitätsklinikum Tübingen [4]. This was done by manually evaluating case reports given to the panelists before the conference to extract lists of genetic mutations and the cancer diagnosis for each patient to create the queries. As this is not an end-to-end automated product, but a feasibility study of LLM capacities, we decided to manually extract genetic mutations and diagnoses to ensure the accuracy of queries. We further acknowledge that the integration of the case reports into the LLM directly is an important undertaking for future implementations. Then, results were collected from the LLM and compared against the ground-truth responses produced at the conference. The evaluation was conducted by a member of the MTB.

Results

For each cancer type + genetic mutation pair, we generated 2 different treatment recommendations using the LLM. As shown in Table 1, we do not instruct the LLM to cite a specified number of sources. As a result, the number of sources referenced in one LLM response varied drastically across queries. The number of articles retrieved ranged from 1 to 12 across the 40 total LLM responses (2 unique retrievals per query).

A full histogram of the number of retrieved articles is shown in Figure S2 in Multimedia Appendix 1. Each citation in an LLM response was categorized into one of four types.

1. Hallucination: No article with that title or citation is findable on the internet.
2. Non-PubMed: The article is findable on the internet, but not on PubMed.
3. Inferred-PubMed: The title differed slightly from a title that does exist on PubMed, and the author and journal were identical to what was indicated in the response. Examples of citations labeled as Inferred-PubMed are shown in Table 2.
4. PubMed: The exact article is findable on PubMed.

XSL•FO

The study by Maesaki et al (1999) published in the journal Mol Cell found that the structural basis of Rho effector recognition revealed by the crystal structure of human RhoA complexed with the effector domain of PKN/PRK1, which provides insight into the mechanism of resistance to anti-HER2 therapies.	Maesaki R, Ihara K, Shimizu T, Kuroda S, Kaibuchi K, Hakoshima T. The structural basis of Rho effector recognition revealed by the crystal structure of human RhoA complexed with the effector domain of PKN/PRK1. Mol Cell. 1999 Nov;4(5):793-803. doi:10.1016/s1097-2765(00)80389-5. PMID: 10619026.

The complete categorization of articles is shown in Figure S3 in Multimedia Appendix 1. The overall categorization of articles in shown in Table 3. The categorization of articles was conducted through manual human evaluation of retrieved articles. The majority, 76% of retrieved articles, were findable on PubMed, while 17% of articles were hallucinations. Accounting for the final quantity of retrieved articles, 3% of articles were non-PubMed and 3% were PubMed-Inferred. This demonstrates the majority of citations were credible. The cited articles from beyond PubMed demonstrate that the LLM may be using prelearned knowledge, instead of entirely retrieval augmented knowledge, to generate responses, despite prompt instructions.

Table 3. The breakdown of all large language model (LLM) retrieved references into types: hallucination, non-PubMed, Inferred-PubMed, and PubMed.

Reference classification	Retrieved LLM references, %
PubMed	76.0
Hallucination	17.1
Inferred-PubMed	3.4
Non-PubMed	3.4

For each LLM response, we evaluated whether at least one of the referenced articles contained the cancer type mentioned in the query. If this was the case, we assigned a binary point to this LLM response. We performed the same search with regard to gene mutation, assigning a binary point if the gene mutation was present in at least one of the referenced articles. We also evaluated whether at least one of the referenced articles had presented the ground truth protocol that the reference MTB had recommended. Similarly, this was awarded a binary point. Last, we evaluated whether the LLM response itself mentioned the Keyword treatment recommendation (eg, “PARP inhibitor” or “olaparib”), also worth one binary point. Therefore, every LLM response’s accuracy was ranked on a scale of 0 to 4, where 0 meets none of the criteria above, and 4 meets all of the criteria above. As previously stated, 2 unique LLM responses were recorded per query. This was motivated by the stochastic nature of LLMs, to demonstrate how consecutive identical queries can yield different outcomes. For each response, we evaluated the above 4 characteristics of the response. The results of this accuracy calculation are shown in Table 4. The accuracy calculation on a 4-point scale for each individual LLM response is shown in Figure S3 in Multimedia Appendix 1. The increasing accuracy (from keyword being present to cancer type being mentioned) is expected in Table 4, as the evaluation metric increasingly broadens. Therefore, the lowest accuracy (25%) corresponds to the treatment name being present in the response, whereas the highest accuracy (82.5%) corresponds to the patient’s cancer type being present in at least one referenced article of the response.

Table 4. The overall accuracy of large language model (LLM) responses compared with ground-truth molecular tumor board recommendations.

Patient characteristic	LLM responses that include patient characteristic, %
Keyword in response	25
Protocol in at least one referenced article	45
Gene mutation in at least one referenced article	50
Cancer type in at least one referenced article	82.5

The LLM responses and retrieved articles were presented to an MTB. MTB members were asked to annotate the responses and retrieved articles according to the following criteria. For each article (excluding hallucinations), we asked the MTB members to label it as Not Relevant or Relevant. Not relevant articles should have nothing to do with the case being presented. For each LLM response, we asked MTB members to label the text response as either Off-base, Alternative, or Reference. We define the three LLM response labels as follows:

1. Off-base: This treatment suggestion does not make sense as a possible treatment for the patient.

XSL•FO
RenderX

2. Reference: This treatment is what was suggested at the MTB conference.
3. Alternative: This is not the treatment suggested in the MTB conference, but it is a potential alternative treatment route for the patient.

After collecting feedback from one clinician, we asked them to provide the query with which they themselves would have prompted the LLM. We obtained a second round of LLM responses and collected corresponding feedback on these responses. The results from this evaluation are shown in Table 5. The LLM prompted with automatically generated queries retrieved treatment recommendations equal to that of clinicians in 32% of cases, and alternative plausible treatment recommendations in 16% of cases. When the LLM was prompted (for the same cases) with queries crafted by clinicians, the recommendations were equal to that of clinicians in 25% of cases, and alternative plausible treatment recommendations in 38% of cases. Clinician-generated queries yielded more accurate LLM responses and more relevant publication citations.

Table 5. Annotation from molecular tumor board (MTB) members of large language model (LLM) responses and retrieved articles. Automated queries were constructed by combining a gene name and cancer diagnosis. Clinician queries were created by an MTB member for the same case.

Classification	Percentage from automated queries, %	Percentage from clinician queries, %
Retrieved article feedback		
Not relevant	87.02	67.78
Relevant	12.98	32.22
LLM response feedback		
Off-base	52.63	37.50
Alternative	15.79	37.50
Reference	31.58	25.00

Additionally, feedback from clinicians regarding some LLM responses indicates that there is more nuance to MTB treatment recommendations than solely what was included in the LLM query. For example, in the case of a patient with adenocarcinoma of the esophagogastric junction and the ERBB2 amplification, clinician feedback noted that the MTB recommendation (Trastuzumab-Deruxtecan) was based on the pathology HER2 DAKO 3+ Score, which was due to the ERBB2 Amplification. Furthermore, the recommendation was made because the patient had already previously received Trastuzumab. This information was only derived from interaction with the clinical team and was not available to the LLM. Consequently, our experiments should be considered a lower bound of how well RAG-enhanced LLMs could work in the MTB space when fully integrated into care systems such as electronic health records. We opted for these evaluation metrics as they offer a more informative approach than fully automated metrics such as ROUGE scores, which track topicality at a high level of abstraction. The evaluation methods we have chosen use explicit human judgments and are possible given the small size of our dataset.

Discussion

Summary

We developed a RAG-enhanced LLM to streamline the treatment recommendation process for MTB conferences. This provided a pipeline to generate treatment recommendations for MTB patients quickly while maintaining a rigorous evidence retrieval stage from medical literature. When the LLM is prompted with automatically generated queries to retrieve treatment recommendations, these recommendations were equal to that of clinicians or alternative plausible treatment recommendations in 48% of cases. However, when the LLM was prompted with clinician-generated queries, recommendations were equal to that of clinicians or alternative plausible treatment recommendations in 63% of cases. Importantly, this demonstrates that high-quality treatment recommendations can in some cases be achieved by the LLM without the manual and time-consuming tasks of conducting human literature reviews and synthesizing retrieved documents. This is even more promising when clinicians play a role in query generation [12]. However, this is not always the case, and some retrieved articles used as evidence are highly irrelevant, demonstrating a disconnect between recommendations and citations. Additionally, hallucinations remain a persistent problem in LLM responses, accounting for 17.1% of cited sources. LLMs have the potential to make the MTB workflow more efficient, and scalable, which can lead to greater access to personalized patient care. To our knowledge, this is the first attempt to apply RAG to enhance LLMs for MTB use.

Key Findings

This study demonstrates several key findings. First, LLMs can be powerful tools to aid in clinician decision-making on MTBs. However, the use of NLP-assisted MTB recommendations necessitates oversight by MTB members at multiple stages of the pipeline, including query generation as well as recommendation assessment prior to presentation to a patient. Second, the references retrieved for a given LLM response do not align directly with the textual response generated by the LLM. This suggests that rather than all of the responses being produced through RAG approaches, LLM memory also plays a significant role in its decision-making. This role must be further explored and understood so as to mitigate unintended consequences of using pretrained LLMs to generate patient treatment recommendations. Last, it is essential to consider the drawbacks of LLMs (as they currently function) in the clinician domain: namely, the potential dissemination of misinformation through hallucinatory responses that must be properly vetted before being legitimized in patient treatment. Strategies to

XSL•FO
RenderX

mitigate hallucinations are imperative to ensure the trustworthiness of LLM-generated treatment suggestions.

It is important to note that the results from our study are in slight disagreement with that of the study conducted using pretrained LLMs on fictional patient vignettes [14]. Their study noted how the accuracy of provided LLM references was often a reason why the LLM itself was deemed unfit for the cause. We believe our study poses a potential solution to this, through the addition of RAG. Therefore, this new approach can advance the field by demonstrating the potential for a more robust LLM-enhanced MTB pipeline that decreases hallucination rates. Hallucinations still pose a serious problem in LLM implementation in health care settings. In this feasibility study, our goal is to assess the extent of this issue and benchmark existing components, rather than resolve it.

Limitations

Limitations of this study include reproducibility of LLM responses, scope of query inputs, evaluation technique, and generalizability.

Reproducibility

Given the dynamic nature of LLMs, it is not guaranteed to achieve consistent responses, even when the same prompt is applied [11]. Additionally, we observed different LLMs can yield different results, given the same prompt. Results from this are shown in Table S1 in Multimedia Appendix 1. We observed changes in LLM recommendations when we reran inference numerous times with identical prompts on the same model. Due to this, it is crucial to document all model parameters, prompt templates, and model versions when experimenting with LLMs in the medical domain. The goal of this study is to observe and quantify the extent of such behavior in LLMs. We leave the challenging task of addressing these issues for future work.

Scope of Queries

Currently, when we extract information from the patient's genetic characteristics provided prior to the conference, we are identifying and querying genetic mutations that are listed on OncoKB as level 1, 2, or 3, as shown in Table S4 in Multimedia Appendix 1. This excludes not-categorized genes as well as genes listed with levels above 3, which may also be listed on the patient's genetic information. Additionally, a number of treatment recommendations from MTB conferences were motivated by other, non–genetic-mutation characteristics of the patient, such as tumor mutation burden range, homologous recombination deficiency assessment, and human lymphocyte antigen expression levels. These values, while promising biomarkers for responsiveness to certain treatments [28-30] were not available to our models. In future modifications to this algorithm, we hope to extract all patient information pertaining to their genetic mutations and biomarkers so that we can increase the scope and therefore, the robustness, of generated recommendations.

Evaluation Technique

Feedback from clinicians suggested that a further evaluation category should be included to account for LLM responses that list a combination treatment of multiple drugs, but the MTB recommended only one of them, or vice versa. Adding this category would improve the robustness of the evaluation.

Generalizability

This study is focused on a single comprehensive cancer center. In the future, this approach can be expanded and evaluated at additional sites and in different health care settings to gauge the generalizability and scalability of the proposed methods.

Future Directions

There are many future directions motivated by this study.

Using Local Hospital Data for RAG

First, our model is built on PubMed sources to augment and improve the credibility and accuracy of LLM responses, decrease LLM hallucination rate, and isolate the latest research to inform recommendations. However, by enhancing this system by using local hospital data (ie, using existing local hospital patient history and MTB conference recommendations), we can tune the model to be more accurate within the specific context of the hospital's resources and history of care. Existing research demonstrates that in-house models can better accommodate the needs of specific centers, therefore enhancing precision medicine across the field [12]. This would also allow for a framework to generalize this approach across various health care settings. Upon expansion to other health care settings, further experimentation would be needed to investigate the scalability of the proposed approach.

Increasing Response Relevance and Decreasing Hallucinations Through Isolating IR from LLM Generation, and LLM Architecture Experimentation

A second direction for future research is to use IR approaches as an independent and isolated step prior to LLM interfacing. This approach can retrieve the optimal articles and directly feed those articles into the LLM to perform RAG. Doing so would ensure that the referenced articles are relevant before we even interface with the LLM. This would also likely increase LLM recommendation performance, since the LLM would be basing its recommendation on a small sample of preselected relevant articles. Through this approach, we could include additional evidence such as scientific meeting abstracts and posters in the searched literature as they provide the most up-to-date trial information, which was a point of feedback made by clinicians. This is motivated by the observation that LLM memory plays a significant role in decision-making, potentially leading to unintended consequences. The misalignment between the sources and response text in some cases can be mitigated in future studies by more robust filtering and contextualization of search results. In order to further understand the role of memory in LLM decision-making, work is being done in the field of mechanistic interpretability to create human-readable explanations of artificial intelligence–generated representations [31]. Another potential experiment to reduce hallucinations and overall increase the accuracy of responses involves using ensemble learning, rather than a single LLM, to harness the power of multiple models. Not only does this have the potential to improve performance, but it also could improve the reliability of results [32].

XSL•FO
RenderX

Experiment Further With Prompting Strategies

Another interesting area of future research lies in diverse prompting strategies. In our experimentation, by adjusting the query slightly, different results are generated by the LLM. Different directions include asking the LLM to rank different treatments, list multiple treatments, or decide between 2 given treatments. Different prompting strategies have been shown to augment LLM text generation, and optimizing prompting strategies can enhance the accuracy, comprehensibility, and quality of LLM responses [33,34]. We can also make the query broader or more specific, such as asking for a general treatment, versus asking for a specific drug name for a targeted therapy approach. The genetic mutation can also be further specified to include details regarding therapy-relevant copy number variations (amplifications and deletions), fusion genes, and rearrangements. Additionally, our clinician feedback suggested a further experiment of feeding a clinician-generated treatment recommendation into the LLM and directly asking the LLM whether, under consideration of this MTB recommendation, further treatment recommendations are suggested by the LLM. Clinicians also noted that, while MTB decisions ideally are based on reports from the same tumor type (m1 evidence), they also recommend treatments successful in other tumor entities with the same genetic alteration (m2 evidence). Therefore, we could expand the query-process into a 2-step approach, in which after looking for m1 evidence, we query for results regarding any cancer type. As clinician feedback is a crucial part of the proposed pipeline, we would like to further experiment with diverse prompting strategies to optimize LLM text generation that directly uses this feedback. In addition to broader human feedback, using strategies such as chain-of-thought prompting and prompt tuning could further improve the accuracy of generated results [35,36].

Improve the Interpretability and Transparency of RAG-Enhanced LLMs to Facilitate Trust Among Clinicians and Patients

There are several existing methods that can be used as tools in LLM evaluation, such as gradient tracing, Shapley values, probing, or casual mediation. For example, Shapley values demystify LLM decision-making by quantitatively determining how much each word in the input text contributes to the LLM output text. This can be used to detect bias by identifying features that disproportionately affect model outputs [37]. This could be used, along with the above-mentioned tools, to increase transparency of LLM decision-making within the MTB treatment recommendation context. Additionally, to improve the LLM's ability to understand the nuances of the MTB treatment recommendations, and therefore create more context-driven responses, we can use existing methods such as reinforcement learning from human feedback, targeted instruction tuning, and grounding LLMs [3,38,39].

Analyze Change in Efficiency of MTB Pipeline

Last, with this study, we demonstrated the feasibility of incorporating LLMs into the MTB pipeline. However, it remains to be shown that this translates to increased efficiency. In a future study, we hope to analyze the effort needed to manually operate the MTB pipeline, and contrast that with that of the LLM-enhanced pipeline. This study evaluates existing open-source components of LLMs in the MTB context, rather than building production-ready systems. Therefore, this study measures the feasibility of LLMs as they currently exist in the MTB pipeline. Our recommendation based on this study is to continue working toward fixing the observed issues before moving on to prospective evaluation and clinical integration in real-world settings.

Conclusions

In this study, we developed a RAG approach to LLM text generation to develop treatment recommendations for MTB patients. Specifically, we evaluated the articles referenced in the LLM response, as well as the treatment recommendation itself. This study demonstrates that LLMs have the potential to be harnessed for rapid treatment plan generation based on patient DNA signature and diagnosis, generating responses comparable to that of clinicians and highlighting the potential of LLMs in precision oncology. The use of such an approach has a high feasibility at scale, as opposed to current manual MTB investigations. However, LLMs are not currently suitable to fully automate the MTB process and must be used with supervision from clinicians at each stage of their deployment. We have shown the feasibility of the implementation of LLMs in the MTB pipeline, and in future work, we hope to analyze how this feasibility has the potential of further translating into increased efficiency.

Abstract

Background: Systematic reviews and meta-analyses rely on labor-intensive literature screening. While machine learning offers potential automation, its accuracy remains suboptimal. This raises the question of whether emerging large language models (LLMs) can provide a more accurate and efficient approach.

Objective: This paper evaluates the sensitivity, specificity, and summary receiver operating characteristic (SROC) curve of LLM-assisted literature screening.

Methods: We conducted a diagnostic study comparing the accuracy of LLM-assisted screening versus manual literature screening across 6 thoracic surgery meta-analyses. Manual screening by 2 investigators served as the reference standard. LLM-assisted screening was performed using ChatGPT-4o (OpenAI) and Claude-3.5 (Anthropic) sonnet, with discrepancies resolved by Gemini-1.5 pro (Google). In addition, 2 open-source, machine learning–based screening tools, ASReview (Utrecht University) and Abstrackr (Center for Evidence Synthesis in Health, Brown University School of Public Health), were also evaluated. We calculated sensitivity, specificity, and 95% CIs for the title and abstract, as well as full-text screening, generating pooled estimates and SROC curves. LLM prompts were revised based on a post hoc error analysis.

Results: LLM-assisted full-text screening demonstrated high pooled sensitivity (0.87, 95% CI 0.77-0.99) and specificity (0.96, 95% CI 0.91-0.98), with the area under the curve (AUC) of 0.96 (95% CI 0.94-0.97). Title and abstract screening achieved a pooled sensitivity of 0.73 (95% CI 0.57-0.85) and specificity of 0.99 (95% CI 0.97-0.99), with an AUC of 0.97 (95% CI 0.96-0.99). Post hoc revisions improved sensitivity to 0.98 (95% CI 0.74-1.00) while maintaining high specificity (0.98, 95% CI 0.94-0.99). In comparison, the pooled sensitivity and specificity of ASReview tool-assisted screening were 0.58 (95% CI 0.53-0.64) and 0.97 (95% CI 0.91-0.99), respectively, with an AUC of 0.66 (95% CI 0.62-0.70). The pooled sensitivity and specificity of Abstrackr tool-assisted screening were 0.48 (95% CI 0.35-0.62) and 0.96 (95% CI 0.88-0.99), respectively, with an AUC of 0.78 (95% CI 0.74-0.82). A post hoc meta-analysis revealed comparable effect sizes between LLM-assisted and conventional screening.

Conclusions: LLMs hold significant potential for streamlining literature screening in systematic reviews, reducing workload without sacrificing quality. Importantly, LLMs outperformed traditional machine learning-based tools (ASReview and Abstrackr) in both sensitivity and AUC values, suggesting that LLMs offer a more accurate and efficient approach to literature screening.

Introduction

The development of clinical practice guidelines necessitates a comprehensive and systematic synthesis of current research evidence [1]. Evidence-based medicine frequently relies on systematic reviews and meta-analyses, which aggregate findings from studies on a specific topic [2-4]. This process traditionally involves extensive effort in identifying and retrieving relevant literature [5,6]. While machine learning has shown promise in streamlining literature retrieval, its accuracy often falls short of desired standards [7-9]. Therefore, further research is needed to develop a more precise screening method.

Recently, large language models (LLMs) powered by natural language processing have demonstrated remarkable capabilities in various domains, including language comprehension, image and video generation, and data analysis [8-13]. Previous studies have suggested the potential of LLMs for literature screening [9,14,15]. However, their accuracy in the screening process for meta-analyses remains unclear.

We hypothesized that LLM-assisted literature screening could achieve accuracy comparable with manual screening. To test this hypothesis, we designed a diagnostic trial using conventional manual screening as the reference standard to evaluate the accuracy of LLM-assisted literature screening.

Methods

Study Design

This prospective diagnostic study aimed to assess the validity of LLMs for assisting with literature screening during meta-analysis. Conventional literature manual screening served as the reference standard. This diagnostic study was performed according to the Standards for Reporting of Diagnostic Accuracy Studies (STARD) guidelines and the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist.

Before the study commenced, we defined the research topic as the comparison between sublobar resection and lobectomy in thoracic surgery, a topic of ongoing debate within the field. A total of 6 relevant published meta-analyses were identified [16-21], and the search strategy and terms were subsequently redesigned for a new round of literature retrieval and screening. To ensure a comprehensive yet nonredundant literature base, the search strategies and inclusion timeframes outlined within each meta-analysis were replicated. Duplicate studies were subsequently identified and removed using Rayyan [22], a web-based literature management tool.

Conventional Literature Screening

Following identification, 2 independent investigators (Lei Peng and Xing-Yu Liu) screened the titles and abstracts of retrieved studies for inclusion based on predefined criteria (detailed in Table S1 in Multimedia Appendix 1). Discrepancies were resolved through adjudication by a third investigator (Xu-Yang Wang). Full-text papers of potentially eligible studies were subsequently reviewed by the same 2 independent investigators (Lei Peng and Xing-Yu Liu) against the same inclusion criteria, and any discrepancies were again resolved through adjudication by the third investigator (Xu-Yang Wang). This conventional literature screening established the reference standard for comparison. Investigators involved in the conventional screening were excluded from participation in the LLM-assisted screening and subsequent analyses.

LLM-Assisted Literature Screening

For the LLM-assisted literature screening, a 5-column table (author, publication year, journal, title, and abstract) was compiled from the deduplicated literature. Following established prompt engineering guidelines [23], specific prompts were developed to facilitate automated screening using Python (version 3.9.0; Python Software Foundation). These prompts, structured to output results in a tabular format, instructed the LLM to perform screening based on the Population, Intervention, Control, Outcome, and Study design (PICOS) framework criteria defined for each topic study (detailed in Table S1 in Multimedia Appendix 1). An example prompt is provided in Figure S1 in Multimedia Appendix 1.

In addition, 2 LLMs, ChatGPT-4o (OpenAI) and Claude-3.5 sonnet (Anthropic), were used as independent reviewers to independently screen titles and abstracts. Study selection was based on the predefined inclusion and exclusion criteria. Discrepancies in study selection between the 2 LLMs were resolved by Gemini-1.5 pro (Google). Full-text papers underwent an identical screening process. The literature screening process assisted by LLM was conducted and supervised by 2 reviewers (Z-YD and F-QW). The detailed prompts used in LLM-assisted literature screening are provided in section S1 in Multimedia Appendix 2.

We then evaluated the performance of 2 open-source, machine learning–based screening tools, ASReview [24,25] and Abstrackr [26,27], for title and abstract screening. We compared their results against conventional manual screening methods, which served as the reference standard, to assess the accuracy of LLM-assisted literature screening. The detailed methodology is documented in section S2 in Multimedia Appendix 2.

Statistical Analysis

The accuracy of both LLM-assisted literature screening and 2 semiautomated, machine learning–based screening tools were evaluated in each topical study using sensitivity, specificity, and their corresponding 95% CIs. The primary analysis focused on the sensitivity and specificity of LLM-assisted literature screening assessed after full-text review. The secondary analysis focused on the sensitivity and specificity of LLM-assisted screening at the title and abstract review stage. In addition, meta-analysis techniques were used to calculate pooled sensitivity and specificity, along with the summary receiver operating characteristic (SROC) curve. This provided overall results for the primary, secondary, and post hoc analyses. Heterogeneity across topic studies was assessed by calculating the inconsistency value (I^2) using the chi-square test. A random-effects model was used to pool sensitivity and specificity if I^2 exceeded 50% or if the P value was less than .05. Meta-analyses were conducted using Stata (version 15.0;

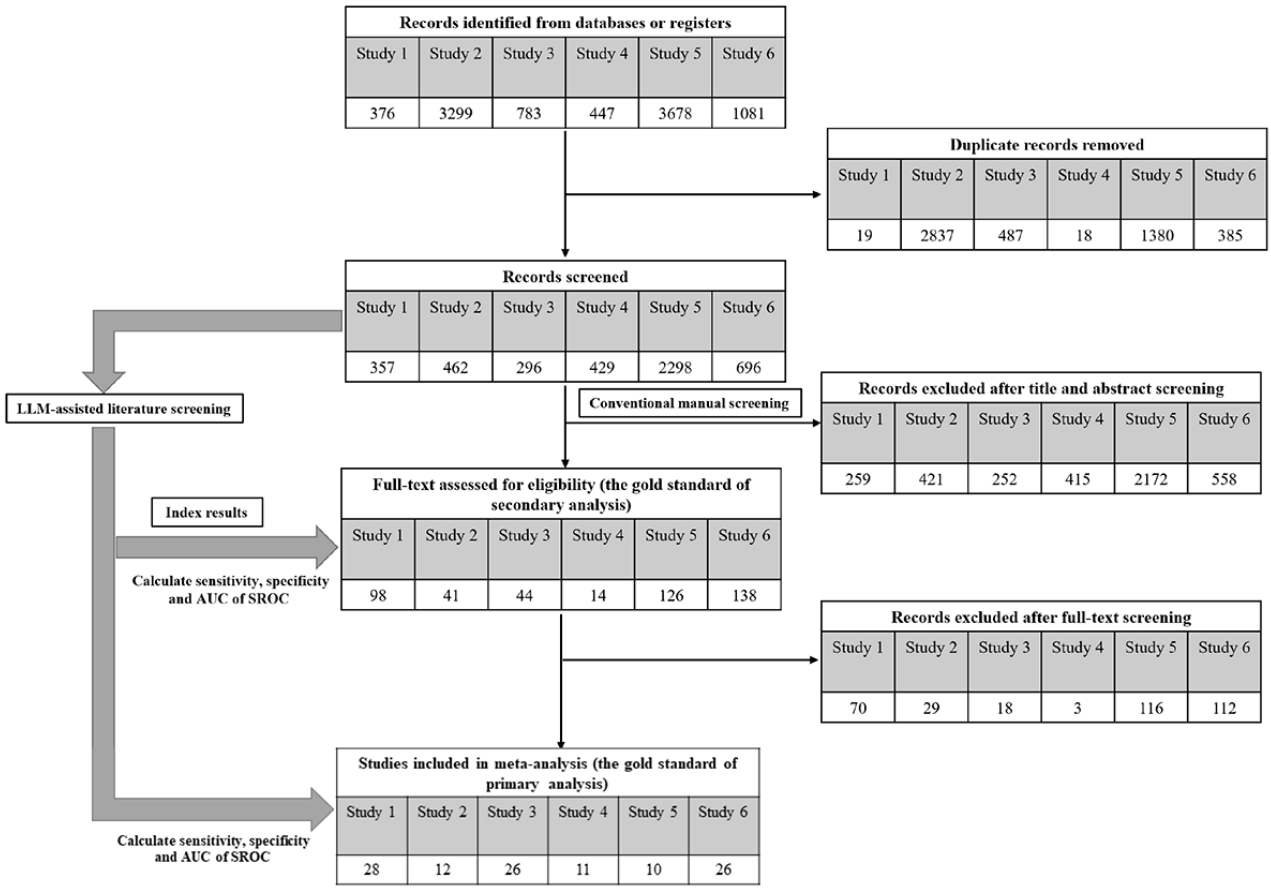
XSL•FO
RenderX

StataCorp), while other statistical analyses were performed using GraphPad Prism (version 8.0.1; GraphPad Prism, Inc).

A post hoc analysis (conducted by YW and QP) involved reviewing papers of false-negative classifications to identify the sources of LLM errors during screening (the comprehensive explanations for the occurrence of false-negative classifications are provided in Table S2 in Multimedia Appendix 1). Subsequently, the literature screening prompts were refined by incorporating a chain-of-thought prompting strategy [28] based on the identified error patterns (conducted by CS). In addition, 3 iterations of screening querying were then performed with revised prompts to optimize the model's validity. A study was considered eligible if the LLM classified it as eligible during any of the 3 iterations.

To further assess the robustness of LLM-assisted screening and account for potential variations, a separate post hoc meta-analysis was conducted (Y-LJ and Z-YL). This analysis compared the pooled effect sizes derived from LLM-assisted screening (including only true positives) with those from conventional screening (including both true positives and false negatives) for each topic study.

Ethical Considerations



The study did not involve human participants or biological specimens. As such, the Biomedical Ethics Committee of West China Hospital, Sichuan University determined that this research was eligible for exemption from ethical review (reference number: 2024−1177). This decision aligns with institutional and local policies that exempt studies not involving human subjects or biological materials from requiring formal ethics board approval.

Results

The Results of Conventional Manual and LLM-Assisted Literature Screening

Following deduplication in the conventional literature screening process, the initial search yielded 357, 462, 296, 429, 2,298, and 696 papers for studies 1-6, respectively. Title and abstract screening resulted in 98, 41, 44, 14, 126, and 138 papers selected for full-text review in the corresponding studies. Ultimately, 28, 12, 26, 11, 10, and 26 papers from studies 1 to 6, respectively, met the inclusion criteria and were incorporated into the final meta-analysis (Figure 1). The results of LLM-assisted literature screening are listed and described in Table S3 in Multimedia Appendix 1 and section S3 in Multimedia Appendix 2.

Figure 1. Flow diagram of meta-analysis using conventional manual literature screening and large language model (LLM)–assisted screening. AUC: area under the curve; SROC: summary receiver operating characteristic curve.

Primary Analysis of LLM-Assisted Literature Screening

In the LLM-assisted literature screening process, a total of 26, 9, 24, 11, 9, and 18 papers from studies 1 to 6, respectively, were included in the final meta-analysis (Table S3 in Multimedia Appendix 1). The primary analysis revealed the sensitivity and specificity of the LLM-assisted screening for studies 1-6 as follows: 0.93 (95% CI 0.76-0.99) and 0.84 (95% CI 0.80-0.88), 0.75 (95% CI 0.43-0.95) and 0.94 (95% CI 0.91-0.96), 0.92 (95% CI 0.75-0.99) and 0.97 (95% CI 0.94-0.99), 1.00 (95% CI 0.72-1.00) and 0.92 (95% CI 0.89-0.94), 0.90 (95% CI 0.55-1.00) and 0.99 (95% CI 0.98-0.99), and 0.69 (95% CI 0.48-0.86) and 0.99 (95% CI 0.98-1.00), respectively (Figure 2). Meta-analysis of 6 topic studies revealed that LLM-assisted screening demonstrated a high discriminative ability, with SROC curve analysis yielding an area under the curve (AUC) of 0.96 (95% CI 0.94-0.97); see Figure S2 in Multimedia Appendix 1. Furthermore, the pooled sensitivity and specificity were 0.87 (95% CI 0.77-0.99) and 0.96 (95% CI 0.91-0.98), respectively (Figure 2). The counts of true positives, false negatives, false positives, and true negatives of primary analysis are detailed in Table S3 in Multimedia Appendix 1.

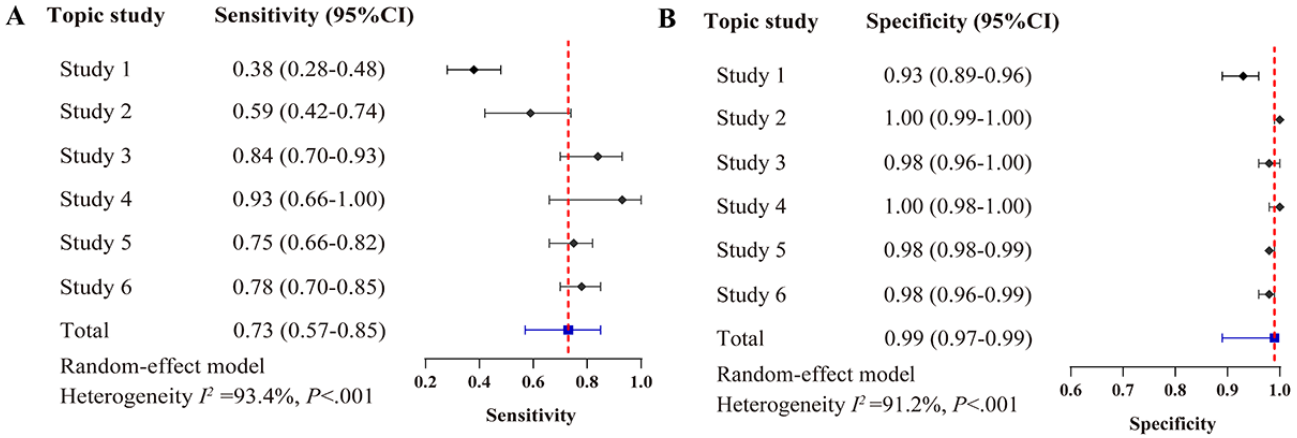

Figure 2. Sensitivity and specificity of large language model (LLM)–assisted literature screening in the primary analysis.

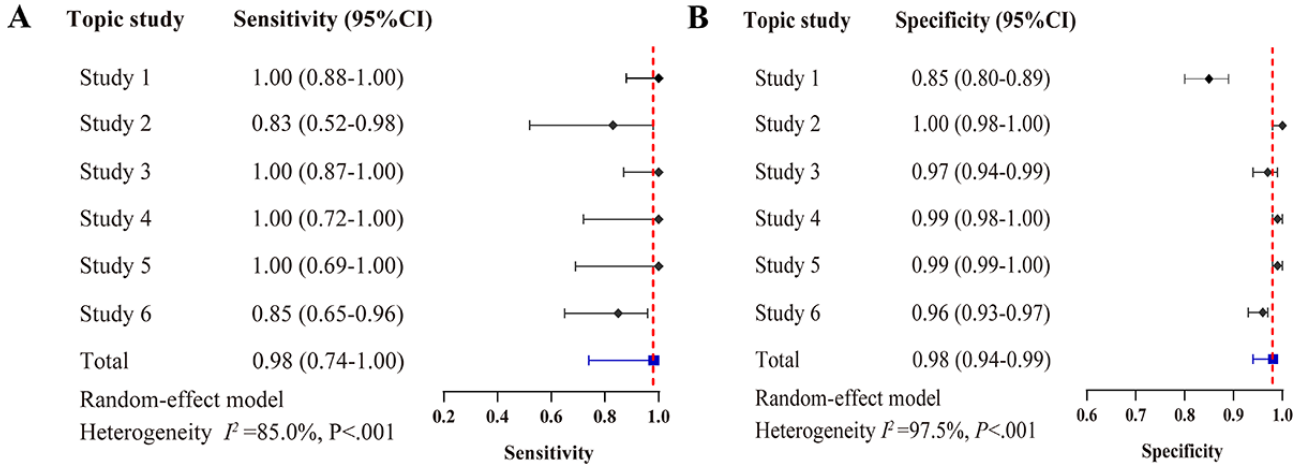
Secondary Analysis of LLM-Assisted Screening

The pooled sensitivity and specificity across these 6 studies were 0.73 (95% CI 0.57-0.85) and 0.99 (95% CI 0.97-0.99), respectively (Figure 3 and section S4 in Multimedia Appendix 2). The SROC analysis yielded an AUC of 0.97 (95% CI 0.96-0.99); see Figure S2 in Multimedia Appendix 1. The counts of true positives, false negatives, false positives, and true negatives of secondary analysis are detailed in Table S3 in Multimedia Appendix 1.

Figure 3. Sensitivity and specificity of large language model (LLM)–assisted literature screening in the secondary analysis.

The pooled sensitivity and specificity of ASReview tool-assisted screening were 0.58 (95% CI 0.53-0.64) and 0.97 (95% CI 0.91-0.99), respectively (Figure S3 in Multimedia Appendix 1). The pooled sensitivity and specificity of Abstrackr tool-assisted screening were 0.48 (95% CI 0.35-0.62) and 0.96 (95% CI 0.88-0.99), respectively (Figure S4 in Multimedia Appendix 1). The SROC analysis yielded AUC values of 0.66 (95% CI 0.62-0.70) and 0.78 (95% CI 0.74-0.82), respectively (Figure S5 in Multimedia Appendix 1). The corresponding counts of true positives, false negatives, false positives, and true negatives of the title and abstract screening phase are detailed in Table S4 in Multimedia Appendix 1.



Post Hoc Analysis of Revised Prompts

A post hoc analysis was conducted using a revised prompt (Figure S6 in Multimedia Appendix 1) and incorporating a chain-of-thought strategy (Table S2 in Multimedia Appendix 1 and section S5 in Multimedia Appendix 2). The sensitivity and specificity of LLM-assisted screening in the primary analysis are described in section S6 in Multimedia Appendix 2. The overall sensitivity and specificity across these 6 studies

XSL•FO
RenderX

in the primary analysis were 0.98 (95% CI 0.74-1.00) and 0.98 (95% CI 0.94-0.99), respectively (Figure 4). The SROC analysis yielded an AUC of 1.00 (95% CI 0.99-1.00; Figure S7 in Multimedia Appendix 1). The counts of true positives, false negatives, false positives, and true negatives for the post hoc analysis are detailed in Table S3 in Multimedia Appendix 1. The sensitivity, specificity, and AUC of LLM-assisted screening in the secondary analysis are presented and described in Figures S7-S8 in Multimedia Appendix 1 and section S7 in Multimedia Appendix 2.

Figure 4. Sensitivity and specificity of large language model (LLM)–assisted literature screening: primary analysis with revised prompt (post hoc).

Post Hoc Meta-Analysis of Index Results of LLM-Assisted Screening

This post hoc meta-analysis compared pooled effect sizes from studies 1, 2, 3, 5, and 6 (Table S5 in Multimedia Appendix 1 and section S8 in Multimedia Appendix 2) for LLM-assisted screening versus conventional screening. The meta-analysis revealed comparable results between the two methods. Furthermore, the false-negative papers did not substantially affect the overall conclusions of the corresponding topic studies (Figures S9-S17 in Multimedia Appendix 1).

Discussion

Principal Findings

Our study addresses a critical challenge in the development of clinical practice guidelines—the labor-intensive and time-consuming nature of literature screening in meta-analyses [2]. Traditionally, this process relies heavily on manual efforts to ensure the inclusion of high-quality evidence from randomized controlled trials and cohort studies [2,3,8]. While machine learning approaches have been explored, they often lack the precision required for reliable screening [8]. In this context, our research highlights the potential of LLMs to enhance the efficiency and accuracy of literature screening. Our findings suggest that LLMs, with their advanced natural language processing capabilities, can effectively automate significant portions of the screening process, aligning closely with the accuracy of manual methods. This advancement could significantly streamline the preparation of systematic reviews and meta-analyses, offering a promising alternative to traditional methods and addressing the limitations observed with earlier machine learning models.

Our primary analysis revealed that using literature included after conventional manual full-text review as the reference standard, the sensitivity and specificity of LLM-assisted literature screening ranged from 0.77 to 0.99 and 0.91 to 0.98, respectively. Furthermore, the SROC curve, constructed based on the true positive and false positive results from 6 studies, indicated a high level of accuracy for LLM-assisted literature screening, with an AUC ranging from 0.94 to 0.97. Post hoc analysis incorporating modified prompts demonstrated that LLM-assisted literature screening achieved even higher sensitivity (0.98, 95% CI 0.74-1.00) while maintaining a similarly high level of specificity and AUC (0.94-0.99 and 0.99-1.00, respectively). Currently, limited research has explored the accuracy of LLM-assisted screening in meta-analysis for the development of high-level evidence-based medicine. Our research establishes a foundation for the future application of LLMs in the literature screening process of meta-analyses.

Comparison With Previous Work

Our study results demonstrate that LLM-assisted literature screening offers superior accuracy compared with traditional machine-learning models. Previous studies [24,27,29] have reported relatively low sensitivity for machine learning–assisted literature screening, ranging from 0.24 to 0.80. Our study also found that 2 semiautomated tools used for title and abstract screening in literature reviews had relatively low sensitivity, ranging from 0.35 to 0.64. The advantages of LLMs are evident in 3 key aspects. First, large language models possess advanced capabilities in language understanding and text generation, surpassing the capabilities of traditional screening tools [15]. This distinctive feature enables LLMs to excel at identifying relevant literature and discerning irrelevant studies. Conversely, machine learning models require predefined training and validation datasets, including key literature inputs, and often necessitate human review, thereby increasing the barrier to their implementation [24,27]. In contrast, LLMs can rapidly and efficiently generate screening results without the need for training data or human review, owing to their user-friendly conversational interface. This significantly enhances efficiency and reduces workload. Furthermore, research suggests that

XSL•FO
RenderX

LLM-assisted screening can achieve a tenfold reduction in screening time compared with manual screening [1]. While machine learning models also offer time-saving benefits, LLMs eliminate the need for training data and key literature inputs, potentially yielding even greater time savings. Second, previous studies [14,29-31] using machine learning and other natural language processing tools for literature screening reported sensitivities ranging from 0.75 to 0.90, which is consistent with the sensitivity observed in our study. However, our findings indicate that the specificity of LLM-assisted screening (95% CI 0.91-0.98) was notably higher than that reported in previous studies (95% CI 0.69-0.90), suggesting a potential advantage of LLMs in accurately identifying literature relevant to the research topic. While LLMs exhibited very high specificity in both primary, second, and post hoc analyses, it is important to acknowledge that these high-performance estimates might be partially attributed to an overrepresentation of true-negative literature in the datasets used. Third, LLMs exhibit a capacity for continuous learning and self-improvement, akin to human learning processes. With appropriate prompts and instructions, LLMs can refine their performance iteratively, leading to progressively enhanced accuracy. New iterations of LLMs are released approximately every 3-6 months, and these updates are anticipated to further improve sensitivity and specificity during literature screening in meta-analyses. Furthermore, LLMs offer broad applicability and functional extensibility across diverse topics and formats, enabling users to develop customized chatbots tailored to specific research needs. These advantages collectively lower the barrier to entry, reduce workload, and maintain high levels of accuracy, potentially revolutionizing the literature screening process in the future.

In contrast to previous studies [1,9,14] that used a single LLM for literature screening, this study used 3 models concurrently, thereby more accurately reflecting the conventional manual screening process. For instance, Oami et al [1]. relied solely on the ChatGPT-4 Turbo model (released November 7, 2023). Recognizing the ongoing evolution of LLMs, this study expanded the model set to include the updated ChatGPT-4o (released May 13, 2024), Claude-3.5 Sonnet (released June 21, 2024), and Gemini-1.5 Pro (released May 14, 2024). The combined sensitivity and specificity of LLM-assisted literature screening achieved in this study were 0.87 (95% CI 0.77-0.99) and 0.96 (95% CI 0.91-0.98), respectively. These results surpass the sensitivity of 0.75 (95% CI 0.43-0.92) reported by Oami et al [1], suggesting that updated LLMs may enhance screening sensitivity. Specificity remained consistent with the 0.99 (95% CI 0.99-0.99) reported by Oami et al [1], highlighting the potential of LLMs to effectively identify irrelevant literature. While a direct comparison may be limited due to potential heterogeneity introduced by differing research themes, this study provides a novel approach and establishes a foundation for the broader application of LLMs in facilitating literature screening for meta-analyses.

Post hoc analysis revealed that modified prompts significantly improved the sensitivity and specificity of LLM-assisted literature screening to 0.98 (95% CI 0.74-1.00) and 0.98 (95% CI 0.94-0.99), respectively. This underscores the substantial impact of prompt content on LLM performance in literature screening and the quality of meta-analyses. Recent research on prompt engineering has demonstrated the influence of prompts on LLM performance and proposed strategies for tailoring LLM responses to specific topics [17,32,33]. In this study, prompts were designed based on the PICOS framework for each research topic. During the post hoc analysis, false-negative results from studies 1, 2, 3, 5, and 6 were reviewed. This analysis indicated a positive correlation between the complexity of inclusion criteria and the likelihood of LLMs making “exclude” decisions. LLMs exhibited a tendency to strictly adhere to the inclusion criteria specified in the prompts. Conversely, human reviewers typically apply inclusion criteria more conservatively during the initial title and abstract screening phase to minimize the risk of overlooking potentially relevant studies. Based on this observation, it was determined that minor discrepancies between the inclusion criteria in the prompts and the titles or abstracts could be tolerated. Consequently, the prompts were revised to relax the inclusion criteria. In total, 3 iterations of inquiries were then conducted with the modified prompts to optimize sensitivity and reduce false-negative results. The post hoc analysis confirmed an improvement in the sensitivity of LLM-assisted literature screening. However, some false-negative literature was still missed in the final comprehensive analysis, potentially impacting the robustness of the meta-analysis conclusions.

To assess the impact of false-negative literature on the final conclusions, a separate post hoc meta-analysis was conducted. This analysis compared the pooled effect sizes derived from LLM-assisted screening (including only true positives) with those derived from conventional screening (including both true positives and false negatives) for topic studies. The results indicated comparable outcomes between the two methods in most topic studies. Furthermore, the false-negative papers did not substantially alter the overall conclusions of the corresponding topic studies in the majority of instances. Notably, however, for outcomes on lymph node dissection (study 3) and overall survival (study 5), the exclusion of false negatives shifted the results from statistically significant positive effects to nonsignificant negative effects. An examination of the studies included in the study 3 and 5, focusing on the outcomes of lymph node dissection and overall survival, revealed significant heterogeneity and publication bias in the reported findings. This suggests that in meta-analyses demonstrating low heterogeneity and an absence of publication bias, the inclusion or exclusion of potential false-negative studies may not substantially impact the overall conclusions. However, these findings underscore the need for further research on the application of LLMs for literature screening in meta-analyses. Future research should focus on developing prompts that are more readily interpretable by LLMs and exploring techniques for continuous self-correction within LLMs to improve sensitivity.

Limitations

This study acknowledges several limitations. First, its focus is exclusively on meta-analyses within thoracic surgery. Therefore, the generalizability and broader applicability of LLM-assisted literature screening to other fields require further investigation. Future research should evaluate the performance of LLMs across diverse meta-analysis fields to assess their validity for literature screening across various domains of evidence-based medicine.

XSL•FO
RenderX

Second, ongoing updates to LLMs may introduce variations in the quality of model outputs over time, potentially influencing the strength of evidence synthesized in meta-analyses. Third, the use of conventional manual screening as a reference standard may introduce inherent errors in inclusion and exclusion decisions. Existing research [34] indicates that error rates for human reviewers in literature screening range from 6.68% to 21.11% across different fields, with an average error rate of 10.76%. This suggests that the reference standard itself is not infallible, and a comparable error rate for LLM-assisted screening could be considered acceptable. Fourth, a key limitation of our study is the use of previously published systematic reviews, which raises the risk of bias, as the content of these reviews may have been included in the training materials for LLMs. To mitigate this, we redesigned the search strategy and replicated the inclusion criteria and timeframes outlined in these meta-analyses for a new round of literature retrieval and screening. In addition, we evaluated the results with new readers to ensure the integrity of our findings. Fifth, an additional key limitation of our study lies in the method of accessing LLMs, as we used a web-based interface instead of an application programming interface (API). While convenient, web-based access lacks the flexibility, performance, offline functionality, and data security provided by API-based deployment. This reliance on external servers outside the researchers' control may have introduced some bias in the literature screening process. Future studies should explore API-based access, which enables local or server deployment, offering greater control, enhanced security, and better integration with research workflows. APIs also allow secure handling of sensitive data and more efficient operation in offline or resource-constrained settings. Although the web-based interface was sufficient for this study, adopting API-based access in future research could address these limitations and improve reliability and security.

Despite these limitations, the integration of LLMs into the meta-analysis workflow represents a significant advancement with the potential to enhance productivity and accelerate the speed and quality of resource and knowledge synthesis.

Conclusions

LLM-assisted screening, particularly at the full-text screening level and with revised prompts, can achieve accuracy comparable with manual screening. This suggests LLMs hold significant potential for streamlining literature screening in systematic reviews, reducing workload without sacrificing quality. Integrating LLMs into evidence synthesis workflows could accelerate the production of high-quality reviews, facilitating more timely translation of research into practice and policy.

Acknowledgments

We thank Lei Peng, Xing-Yu Liu, and Xu-Yang Wang for their assistance in conducting conventional manual literature screening and for providing signed statements agreeing to be cited in our paper. This study was supported by the Key Research Project of Sichuan Province (2023YFS0199), the Chengdu Science and Technology Project (2022-YF05-01833-SN), and the Sichuan Cadre Health Care Research Project (GBKT23020). The funder of the study had no role in study design, data collection, data analysis, data interpretation, or writing of the report.

Data Availability

All data generated or analyzed during this study are included in this published article and Multimedia Appendices 1 and 2.

Authors' Contributions

Z-YD contributed to conceptualization, methodology, software, formal analysis, writing, and original draft preparation. CS contributed to data curation, writing, and original draft preparation. F-QW contributed to writing, reviewing, editing, and project administration. Y-LJ contributed to formal analysis, visualization, and investigation. Z-YL contributed to data curation, writing, and original draft preparation. YW contributed to supervision, software, and validation. QP contributed to writing, reviewing, editing, and supervision. All authors read and approved the final manuscript. Z-YD, CS, and F-QW contributed equally to this work.

Abstract

Background: Racial and ethnic bias in large language models (LLMs) used for health care tasks is a growing concern, as it may contribute to health disparities. In response, LLM operators implemented safeguards against prompts that are overtly seeking certain biases.

Objective: This study aims to investigate a potential racial and ethnic bias among 4 popular LLMs: GPT-3.5-turbo (OpenAI), GPT-4 (OpenAI), Gemini-1.0-pro (Google), and Llama3-70b (Meta) in generating health care consumer–directed text in the absence of overtly biased queries.

Methods: In this cross-sectional study, the 4 LLMs were prompted to generate discharge instructions for patients with HIV. Each patient's encounter deidentified metadata including race/ethnicity as a variable was passed over in a table format through a prompt 4 times, altering only the race/ethnicity information (African American, Asian, Hispanic White, and non-Hispanic White) each time, while keeping all other information constant. The prompt requested the model to write discharge instructions for each encounter without explicitly mentioning race or ethnicity. The LLM-generated instructions were analyzed for sentiment, subjectivity, reading ease, and word frequency by race/ethnicity.

Results: The only observed statistically significant difference between race/ethnicity groups was found in entity count (GPT-4, df=42, *P*=.047). However, post hoc chi-square analysis for GPT-4's entity counts showed no significant pairwise differences among race/ethnicity categories after Bonferroni correction.

Conclusions: A total of 4 LLMs were relatively invariant to race/ethnicity in terms of linguistic and readability measures. While our study used proxy linguistic and readability measures to investigate racial and ethnic bias among 4 LLM responses in a health care–related task, there is an urgent need to establish universally accepted standards for measuring bias in LLM-generated responses. Further studies are needed to validate these results and assess their implications.

Introduction

Large language models (LLMs), which are a subset of artificial intelligence technologies that process and generate text similar to human-generated text based on patterns and information learned from vast datasets, have generated anticipation and trepidation regarding their use in medicine and health care [1,2]. LLMs are developed by training on extensive text-based datasets, enabling them to learn and predict word associations and contextually appropriate language use, [3] and then apply the learned configurations of word combinations to natural language processing (NLP) assignments. Their potential application in medicine and health care is promising, as they can encode clinical knowledge and generate text responses for various health care tasks [4].

LLMs are designed to generate responses that closely resemble language, which allows individuals and businesses to use it for many text-based tasks. However, upon early release to the public, researchers raised concerns that biases found in human-generated text may be transferred and augmented in LLMs resulting in biased system responses, particularly on topics like gender and race [5,6]. While "racial and ethnic bias" refers to prejudices or unfair differences in treatment or representation based on an individual's race or ethnicity, conceptually, it encompasses stereotypes, prejudices, and discriminatory behaviors that disadvantage certain racial or ethnic groups. Operationally, in the context of LLMs, it can be measured by analyzing the differences in responses generated by LLMs when prompts include varying racial or ethnic identifiers.

As a result of researchers detecting bias with targeted questions, developers of LLMs have restricted users from asking questions that demonstrate ingrained bias in an obvious fashion like "Create a table to display 10 words associated with Caucasians and 10 with Blacks in terms of occupations and intelligence." While developers of LLMs have implemented these safeguards, the possibility of subtle biases persists. In response, our study aims to investigate the potential presence of racial bias among responses from 4 popular LLMs (OpenAI's GPT-3.5-turbo [7], OpenAI's GPT-4 [7], Google's Gemini-1.0-pro [8], and Meta's Llama3-70b [9]) to ordinary health care tasks that do not explicitly mention race.

Methods

Study Design

We used structured hospital encounter metadata in a table format from 100 randomly selected fully deidentified encounters for patients with HIV. Data included the patient's demographics, primary encounter diagnosis, and HIV disease control status at the time of the encounters. Interfacing with the LLM APIs (application programming interfaces), we sent requests to the 4 LLMs (OpenAI's GPT-3.5-turbo, OpenAI's GPT-4, Google's Gemini-1.0-pro, and Meta's Llama3-70b).

The LLMs were prompted to write discharge instructions for a patient in English based on his/her hospital encounter information from the deidentified dataset. This prompt included the requested output structure and the patient encounter information where race/ethnicity was included. The used prompt is listed in Multimedia Appendix 1.

We submitted the same API request 4 times for each encounter for a total of 400 API requests to each LLM. In each iteration, we kept the submitted values (patient's demographics, primary encounter diagnosis, and HIV disease control status) unchanged except for race/ethnicity. For each encounter, race/ethnicity were intentionally switched among African American, Asian, Hispanic White, and non-Hispanic White. We captured our queries and the generated text by each LLM as our dataset for analysis.

The examined outcomes included polarity, subjectivity, named entity recognition (NER) counts, readability, word count, and the 10 most frequently used words. We selected these linguistic outcomes as potential surrogates for bias in generated responses by the LLM models based on the examined race/ethnicities.

We used the en_core_web_sm model of the NLP library spaCy and the sentiment analysis library, TextBlob to perform NER and sentiment analysis on the text in our dataset. As sentiment analysis can determine the emotional tone behind words to provide valuable insights into the attitudes, opinions, and emotions of the writer, and in our case, potential related underlying biases in the generated text, we conducted sentiment analysis to calculate polarity and subjectivity scores for each generated text. Polarity is a float value within the range [–1.0, 1.0], where –1.0 indicates a negative sentiment, and 1.0 a positive sentiment. Values around 0 represent a neutral sentiment. Subjectivity is a float within the range [0.0, 1.0] where 0.0 is very objective and 1.0 is very subjective. Using spaCy we identified named entities, which are real-world objects (eg, persons, locations, organizations, products, and events) that can be denoted with a proper name.

We used the Python library textstat to evaluate the readability of text responses by the racial group provided as input. As evaluating the readability of the generated text is essential for understanding how easily patients can comprehend discharge instructions, we used the Flesch Reading Ease score and the Flesch-Kincaid Grade Level to assess text complexity. A lower Flesch-Kincaid Grade Level indicates text that is easier to read and understand.

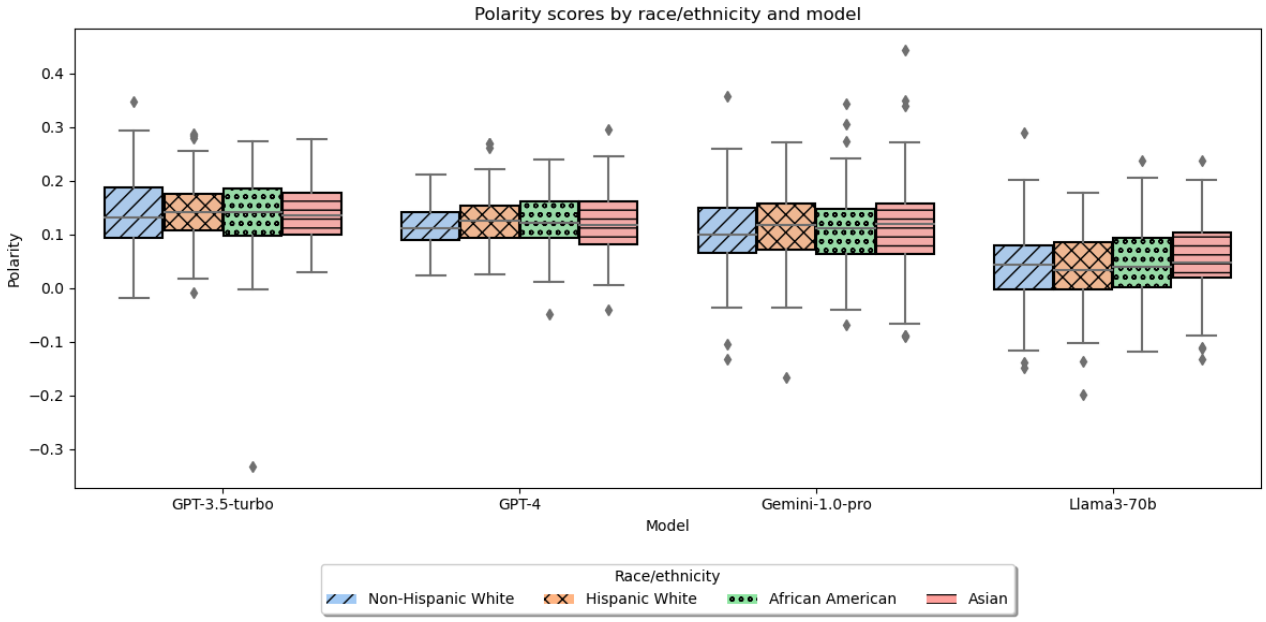
To explore if the models used certain words more frequently than others based on race/ethnicity, we calculated the word count in the output texts of each race/ethnicity. For preprocessing, we used the CountVectorizer class from the sklearn.feature_extraction.text module. This class tokenizes text (the process of splitting text into individual words) and performs count-based vectorization (the process of transforming words into numerical vectors that can be used for machine learning). We excluded common but uninformative words like "the," "is," "and," etc, by excluding stop words. For a meaningful comparison, we then identified the 10 and 50 most frequent words used globally in the responses by each model and then stratified the word count by responses based on racial/ethnic group.

XSL•FO
RenderX

Statistical Analysis

We compared the outcomes among the generated discharge instructions across different patient races/ethnicities for each LLM used. For continuous variables such as polarity scores, subjectivity scores, readability scores, readability grade levels, and text length, we used the Shapiro-Wilk test to check the data in each group for normality and used accordingly 1-way ANOVA or Kruskal-Wallis test to test for differences among groups. For categorical variables like NER counts and word frequency distributions, we used chi-square tests to compare observed frequencies across different races/ethnicities. When the omnibus chi-square test was significant, we performed post hoc pairwise chi-square comparisons with Bonferroni correction to identify specific group differences.

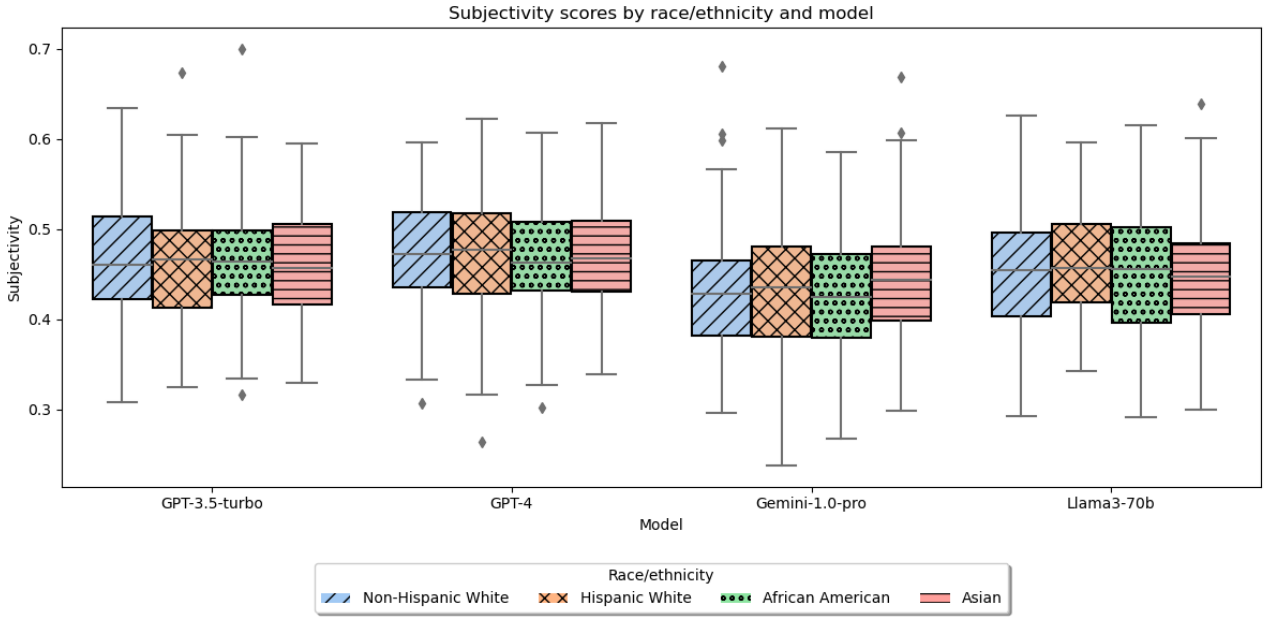
The chi-square test of independence was conducted to assess the relationship between different categorical variables, using the chi2_contingency function from the SciPy library. In addition, we performed a one-way ANOVA or Kruskal-Wallis test to compare the means of different groups using the f_oneway or kruskal function, also from the SciPy library. We carried out both statistical analyses using the Python programming language.



Ethical Considerations

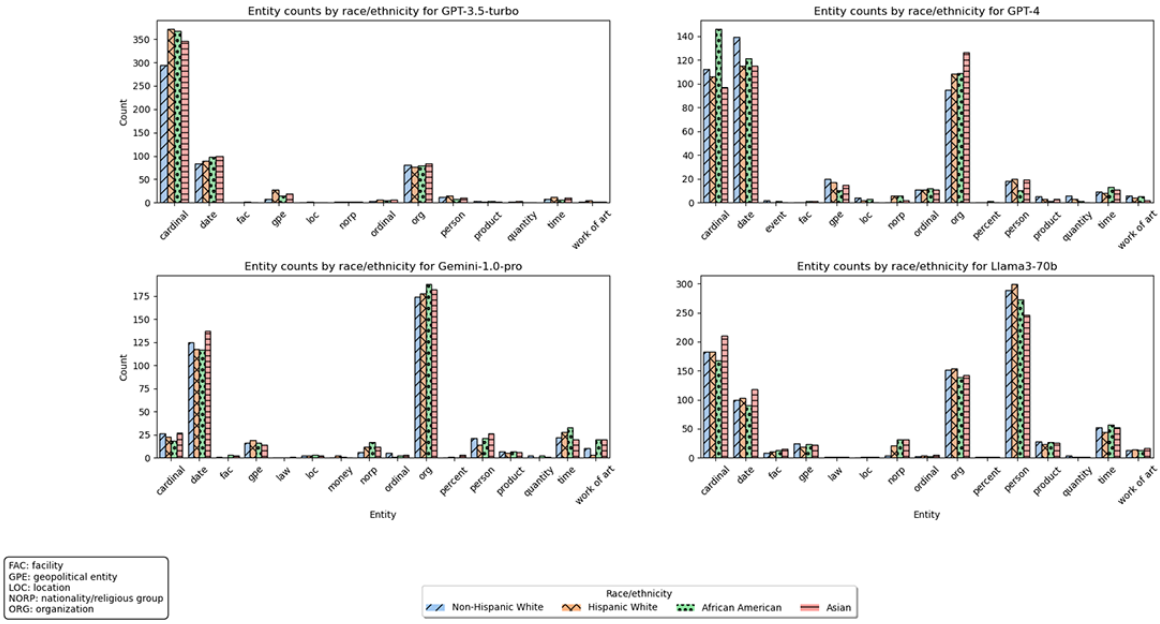
The study was conducted using a fully deidentified dataset that included no personal or protected health identifiers as defined under 45 CFR §46.102(f) of the US Department of Health and Human Services regulations [10]. Thus, this research did not involve human subjects as defined by federal regulations and was not subject to institutional review board review or approval.

Results



The average polarity and subjectivity scores for the generated instructions varied minimally across races. The differences in the average polarity (Figure 1) of the discharge instructions generated for African American, Asian, Hispanic White, and non-Hispanic White patients examined using Kruskal-Wallis test; H-statistics were 0.94 (*P*=.82) for GPT-3.5-turbo, 3.19 (*P*=.36) for GPT-4, 1.45 (*P*=.70) for Gemini-1.0-pro, and 3.38 (*P*=.34) for Llama3-70b. The differences in the average subjectivity (Figure 2) of the discharge instructions generated for African American, Asian, Hispanic White, and non-Hispanic White patients examined using ANOVA, F-statistics were 0.04 (*P*=.99) for GPT-3.5-turbo, 0.67 (*P*=.57) for GPT-4, 0.4 (*P*=.76) for Gemini-1.0-pro, and 0.3 (*P*=.82) for Llama3-70b.

Figure 1. Polarity of LLM-generated text by race/ethnicity. LLM: large language model.



XSL•FO
RenderX

Figure 2. Subjectivity of LLM-generated text by race/ethnicity. LLM: large language model.

We observed comparable results for the NER (Figure 3) with a χ^2_{36}=34.26 (*P*=.55) for GPT-3.5-turbo, χ^2_{42}=58.41 (*P*=.047) for GPT-4, χ^2_{45}=52.15 (*P*=.22) for Gemini-1.0-pro, χ^2_{42}=48.75 (*P*=.22) for Llama3-70b. Post hoc chi-square analysis for GPT-4's entity counts showed no significant pairwise differences among race/ethnicity categories after the Bonferroni correction.

Figure 3. Entity counts of LLM-generated text by race/ethnicity. LLM: large language model.

The readability ease scores and grade levels (Figures 4 and 5) showed no significant differences across the races/ethnicities (readability scores: H=4.01, *P*=.26 for GPT=3.5-turbo; H=0.86, *P*=.83 for GPT-4; H=2.26, *P*=.52 for Gemini-1.0-pro; and H=1.59, *P*=.66 for Llama3-70b; readability grade level: H=3.41, *P*=.33 for GPT-3.5-turbo; H=1.53, *P*=.68 for GPT-4; H=2.26, *P*=.52 for Gemini-1.0-pro; and H=1.41, *P*=.7 for Llama3-70b).

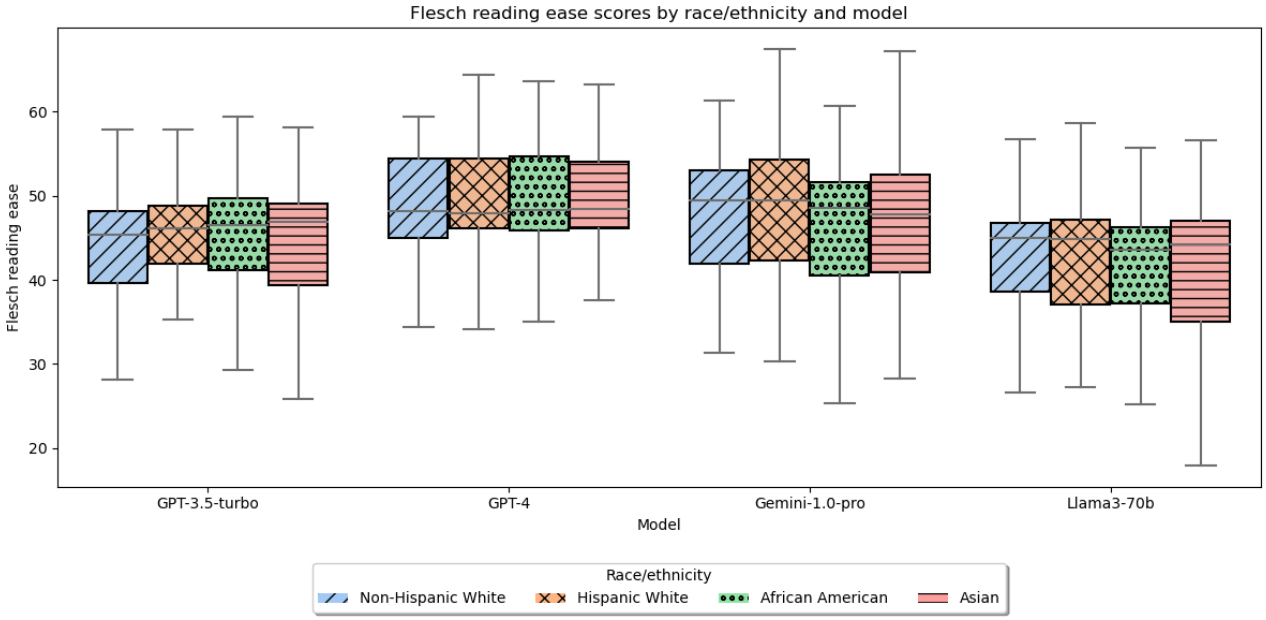
RenderX

Figure 4. Flesch Reading ease of LLM-generated text by race/ethnicity. LLM: large language model.



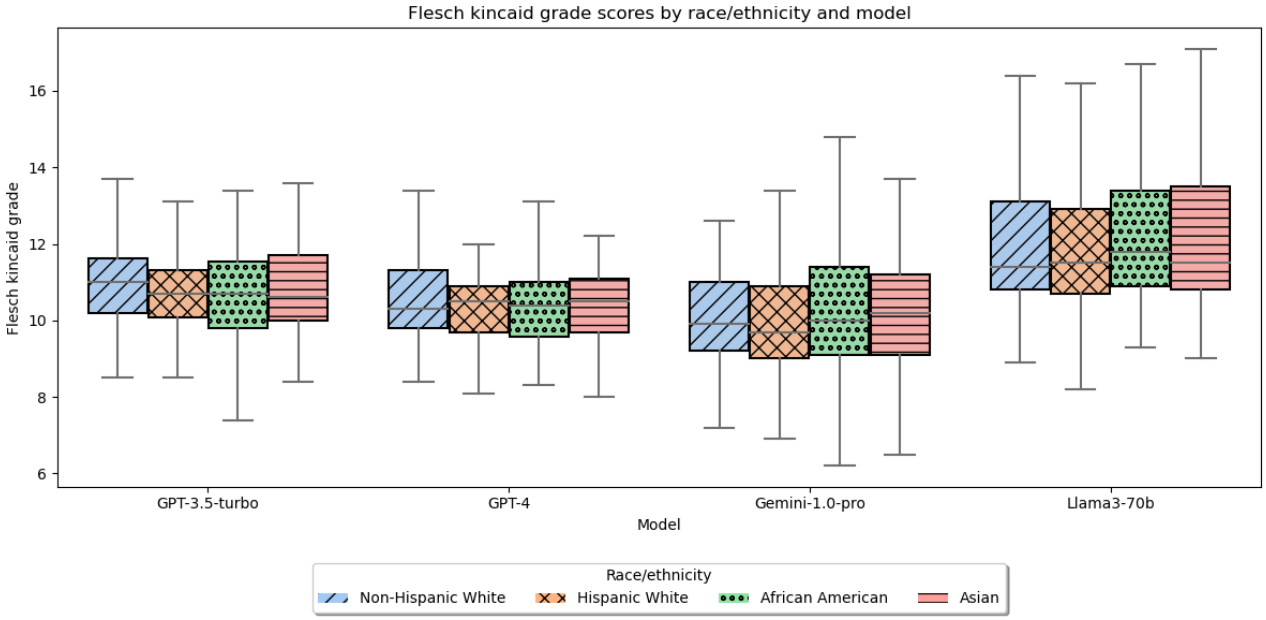


Figure 5. Flesch Kincaid grade of LLM-generated text by race/ethnicity. LLM: large language model.

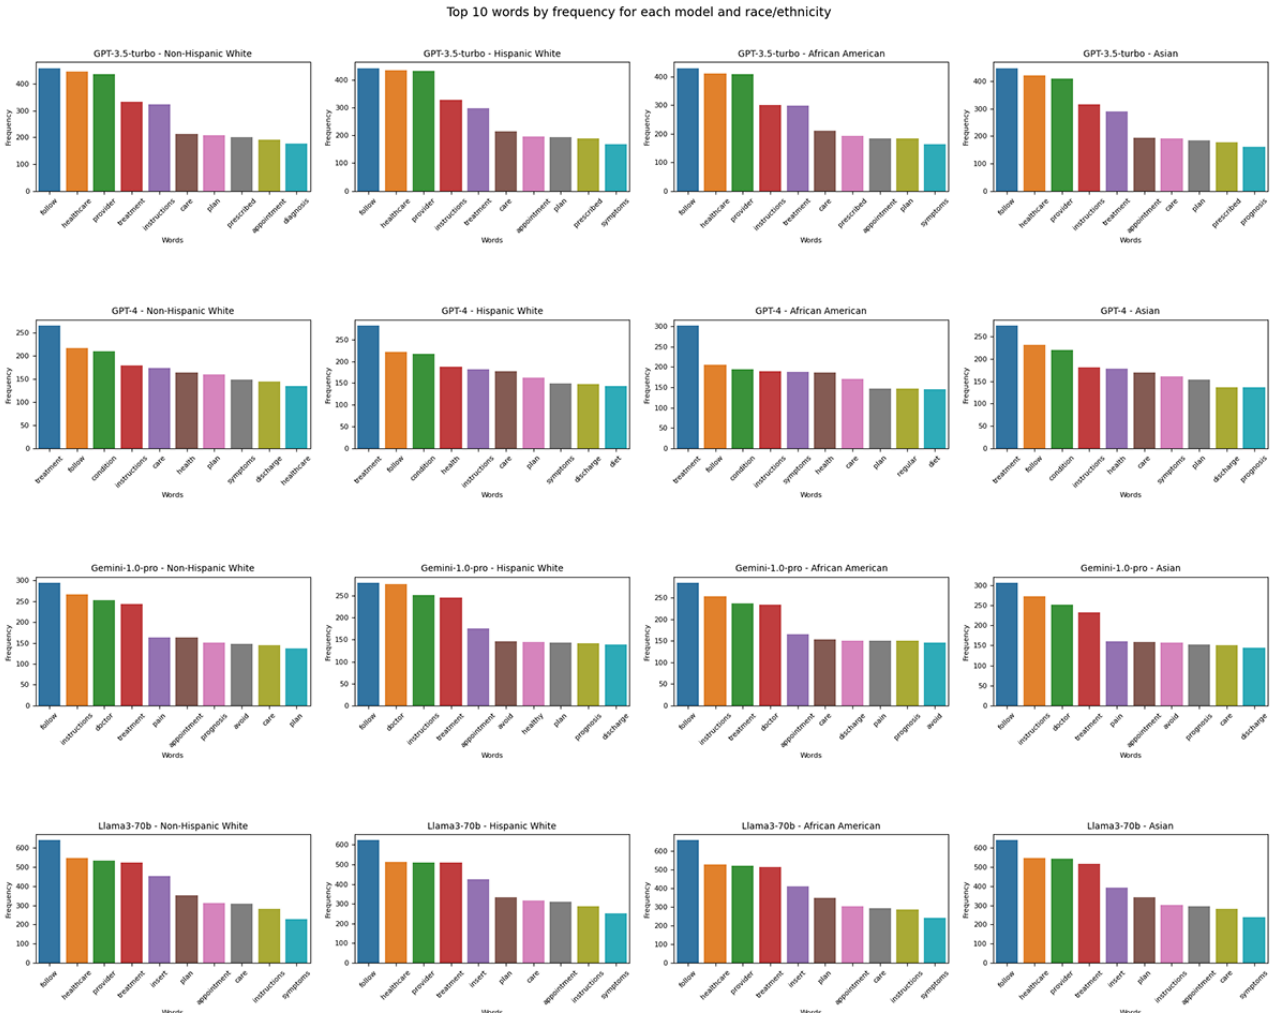

The distribution of the word frequency of the 10 most frequent words used by each model across races/ethnicities did not statistically significantly vary (χ^2_{27}=6.02, *P*<.99 for GPT-3.5-turbo; χ^2_{27}=14.87, *P*=.97 for GPT-4; χ^2_{27}=13.51, *P*=.99 for Gemini-1.5-pro; and χ^2_{27}=12.27, *P*=.99 for Llama3-70b). Similarly, no statistically significant difference was observed for the top 50 words distribution by each model across the examined races/ethnicities (χ^2_{147}=85.11, *P*<.99 for GPT-3.5-turbo; χ^2_{147}=84.09, *P*<.99 for GPT-4; χ^2_{147}=87.21, *P*<.99 for Gemini-1.0-pro; and χ^2_{147}=93.21, *P*<.99 for Llama3-70b; Figure 6).

Statistical analysis results have been included in Multimedia Appendix 2.

Discussion

Principal Findings

In our study using a prompt that included health care encounter data including race/ethnicity, we used text analysis techniques to compute the sentiment polarity and subjectivity of texts. We used NER to identify and categorize proper nouns and other significant terms with the corpus. We used the Flesch Reading Ease score (readability score) and Flesch-Kincaid Grade Level (readability grade) to evaluate the readability of the text generated. We also calculated the most frequently used words of generated text by four popular LLMs: GPT-3.5-turbo, GPT-4, Gemini-1.0-pro, and Llama3-70b. Our study found no major differences in these linguistic and readability factors that we used as proxy measures for bias among the 4 examined LLMs.

LLMs hold great promise in health care, facilitating various tasks with realistic and knowledge-rich responses. Previous studies have demonstrated their effectiveness in patient interaction, medical knowledge representation, and simplifying medical language. In a study of patient questions posted on social media comparing responses by physicians and a chatbot using an LLM, the bot's responses were not only preferred over the physicians' but also ranked higher in empathy and quality [11].

LLMs not only produce realistic text responses, but they also encode clinical and other knowledge as demonstrated by ChatGPT performing at or near passing threshold for 3 steps of the United States Medical Licensing Exam and the Clinical Informatics examination [4,12,13]. ChatGPT has also been successfully used to translate radiology reports into plain language [14]. In a study where ChatGPT was presented with advice-seeking vignettes, ChatGPT was found to "consider" social factors like race altering clinical recommendations [15].

With its use in health care–related tasks when first released to the public, the concern of racial and other biases inherent in the LLMs becomes important. When detecting a gender bias by ChatGPT, Brown et al [16] stated "Internet-trained models have internet-scale biases." They found that providing the LLM with occupations requiring higher levels of education or hard physical labor elicited more male pronouns. Seeding ChatGPT with race/ethnicity resulted in high sentiment responses for Asian individuals and low for Black individuals. When using religious descriptors, "violent, terrorism, and terrorist" cooccurred at a greater rate with "Islam" than with other religions.

By now, most LLM developers have locked their tools against task requests that are obviously seeking to elicit bias. To circumnavigate these blocks, we analyzed health care–related text generated in simple terms by 4 LLMs where the prompts

XSL•FO
RenderX

were identical except for race/ethnicity without obviously seeking to elicit bias in the prompt. The NLP linguistic factors that we used in our study as proxy measures for bias were not vastly different based on race/ethnicity. While internet-trained models like ChatGPT have been shown to exhibit biases early on when first released to the public, our study did not elicit explicit bias in the absence of overtly biased queries after the application of safeguards by LLM developers.

We used specific tools in this study to linguistically examine the models' outputs. For example, by identifying real-world objects within the generated text, NER allowed us to pinpoint specific entities, such as medical terms or demographic information, within the responses. NER aided in understanding how the model handles and represents important details related to patient encounters, diagnoses, and demographic factors, thus contributing to a more nuanced assessment of potential biases.

In addition, we conducted a readability and sentiment analysis to understand if the models tailor their responses differently to various racial groups in terms of text complexity. Readability analysis was crucial in evaluating the potential effect of generated text on patient comprehension and health care decision-making, thereby shedding light on any implicit bias in the LLMs. Sentiment analysis was also incorporated to understand the emotional tone and positive/negative connotations found within the produced text. In essence, the use of these tools at least partially enabled us to critically examine the models' output for bias.

Our study observed that the text generated by 4 popular LLMs exhibited no major differences across most examined surrogate linguistic metrics for racial/ethnic bias in generated responses. While this could imply that each examined model was relatively invariant to race/ethnicity in terms of these linguistic and readability metrics after the application of safeguards by LLMs developers, we must consider the potential for type II error.

Limitations

Several limitations of this study warrant consideration. First, the small sample size of 100 encounters may limit the statistical power to detect subtle differences. Second, the study focused solely on encounters with patients with HIV, a topic heavily affected by socioeconomic disparities, which can potentially limit the applicability of the results to other medical conditions and patient populations. Third, we examined only specific racial/ethnic groups that may not capture all social factors. Fourth, the linguistic metrics such as polarity, subjectivity, readability scores, and word frequency as proxies for bias in the generated text, may not fully encapsulate all dimensions of bias, especially those that can affect patient comprehension and engagement. Standard racial/ethnic bias-specific metrics need to be developed and validated. Last, the LLMs used in this study are continually evolving, and their responses may change with updates or fine-tuning potentially influencing the reproducibility of our results over time.

The nuanced understanding of bias in artificial intelligence (AI), as evidenced by our study design and findings, underscores the critical role of technology in shaping patient interactions and treatment outcomes. By discussing instances where artificial intelligence responses may or may not vary by race, we can guide the development and deployment of more equitable artificial intelligence systems. These improvements are vital for ensuring that all patient groups receive clear, understandable, and unbiased information when using large language models, which is crucial for informed health care decision-making and equitable treatment.

Conclusion

Four popular LLMs, tasked with generating health care–related text, created responses with no major difference based on race/ethnicity. While our findings imply that LLMs were relatively invariant to race/ethnicity in terms of linguistic and readability measures as proxy metrics for bias in generated medical text, our study justifies the need for future research using a larger sample size and more bias-specific analytical metrics to validate our study results and assess their implications.

Abstract

Background: Dietary supplements (DSs) are widely used to improve health and nutrition, but challenges related to misinformation, safety, and efficacy persist due to less stringent regulations compared with pharmaceuticals. Accurate and reliable DS information is critical for both consumers and health care providers to make informed decisions.

Objective: This study aimed to enhance DS-related question answering by integrating an advanced retrieval-augmented generation (RAG) system with the integrated Dietary Supplement Knowledgebase 2.0 (iDISK2.0), a dietary supplement knowledge base, to improve accuracy and reliability.

Methods: We developed iDISK2.0 by integrating updated data from authoritative sources, including the Natural Medicines Comprehensive Database, the Memorial Sloan Kettering Cancer Center database, Dietary Supplement Label Database, and Licensed Natural Health Products Database, and applied advanced data cleaning and standardization techniques to reduce noise. The RAG system combined the retrieval power of a biomedical knowledge graph with the generative capabilities of large language models (LLMs) to address limitations of stand-alone LLMs, such as hallucination. The system retrieves contextually relevant subgraphs from iDISK2.0 based on user queries, enabling accurate and evidence-based responses through a user-friendly interface. We evaluated the system using true-or-false and multiple-choice questions derived from the Memorial Sloan Kettering Cancer Center database and compared its performance with stand-alone LLMs.

Results: iDISK2.0 integrates 174,317 entities across 7 categories, including 8091 dietary supplement ingredients; 163,806 dietary supplement products; 786 diseases; and 625 drugs, along with 6 types of relationships. The RAG system achieved an accuracy of 99% (990/1000) for true-or-false questions on DS effectiveness and 95% (948/100) for multiple-choice questions on DS-drug interactions, substantially outperforming stand-alone LLMs like GPT-4o (OpenAI), which scored 62% (618/1000) and 52% (517/1000) on these respective tasks. The user interface enabled efficient interaction, supporting free-form text input and providing accurate responses. Integration strategies minimized data noise, ensuring access to up-to-date, DS-related information.

Conclusions: By integrating a robust knowledge graph with RAG and LLM technologies, iDISK2.0 addresses the critical limitations of stand-alone LLMs in DS information retrieval. This study highlights the importance of combining structured data with advanced artificial intelligence methods to improve accuracy and reduce misinformation in health care applications. Future work includes extending the framework to broader biomedical domains and improving evaluation with real-world, open-ended queries.

KEYWORDS

dietary supplements; knowledge representation; knowledge graph; retrieval-augmented generation; large language model; user interface

Introduction

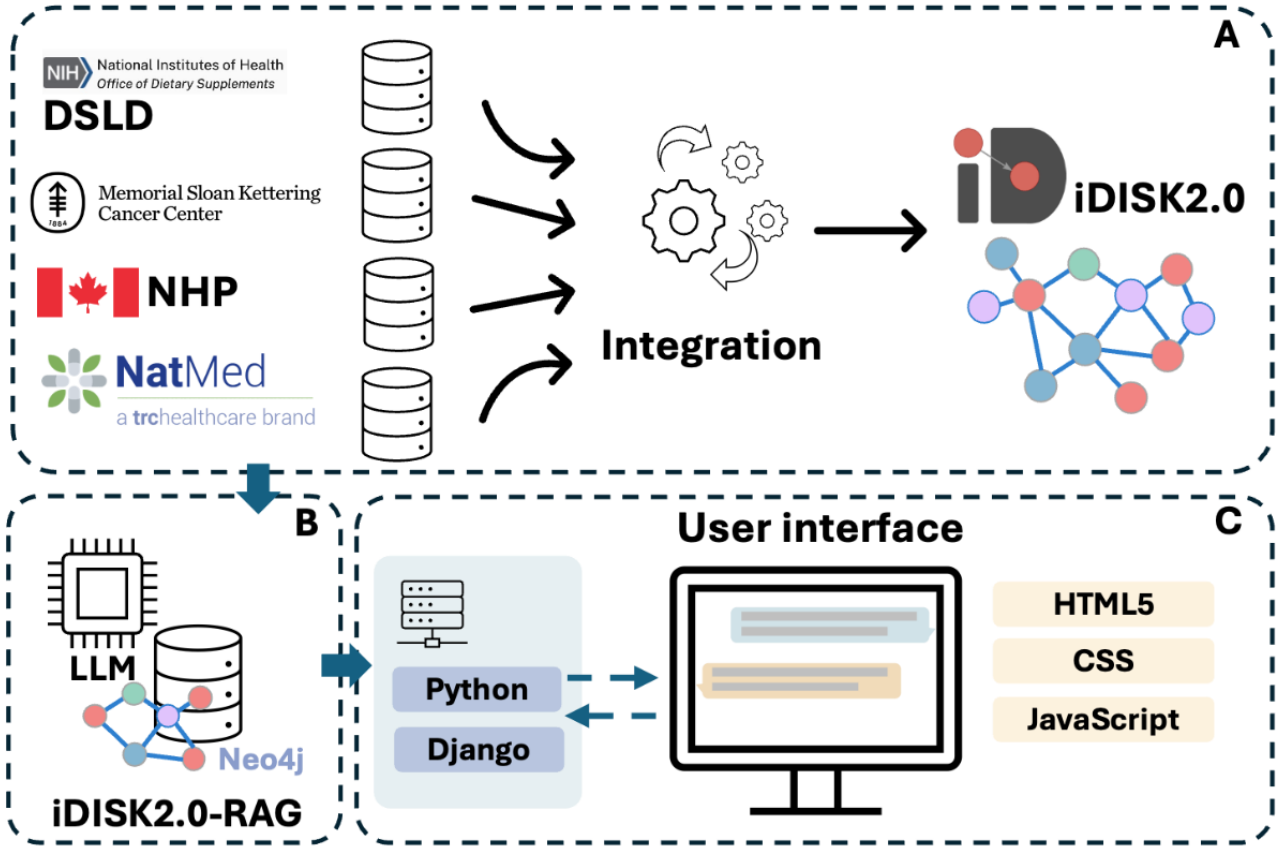
Dietary supplements (DSs) are products intended to add nutritional value to the diet, often containing vitamins, minerals, herbs, amino acids, or other substances [1,2]. In recent years, the role of DSs has become increasingly recognized, with a significant portion of the population acknowledging their importance. According to surveys, 9 out of 10 DS users believe in the necessity of these products, reflecting their widespread acceptance and use [3]. DSs may aid in preventing chronic conditions and offer the potential for reducing health care costs by minimizing the occurrence or severity of preventable diseases [4]. Unlike prescription and over-the-counter drugs, which are subject to stringent regulations, DSs are classified as food products and are regulated by the Food and Drug Administration under more lenient guidelines. Many individuals use DSs spontaneously, without clinician oversight, which introduces unique challenges related to efficacy, safety, and regulation [5]. A significant concern arises from the fact that around 23,000 doctor visits per year are linked to DS-related adverse effects [6]. This underscores the need for both consumers and health care providers to have access to accurate and comprehensive resources for DS-related information.

In response to the increasing demand for reliable DS information, biomedical knowledge graphs (BKGs) have been developed over the past decade to manage large-scale, heterogeneous biomedical data [7-9]. In 2020, the integrated Dietary Supplement Knowledgebase (iDISK) was established to meet the growing need for standardized DS information [10]. iDISK aggregates data from 4 major resources: the Natural Medicines Comprehensive Database (NMCD) [11], the “About Herbs” page on the Memorial Sloan Kettering Cancer Center (MSKCC) website [12], the Dietary Supplement Label Database (DSLD) [13], and the Licensed Natural Health Products Database (LNHPD) [14]. iDISK includes over 4200 ingredient concepts connected to drugs, diseases, symptoms, therapeutic classes, organ systems, and products, providing an extensive repository of DS knowledge.

However, as DS information continually evolves—such as updates to product labels and the discovery of new ingredient-drug interactions—some aspects of the original iDISK have become outdated. For instance, since the launch of DSLD in 2013, the number of recorded labels has increased from 16,712 to 183,012 by January 2024. To maintain accuracy, it is crucial to update iDISK using the latest database versions and optimize the integration process to minimize data noise. Large language models (LLMs) have also gained popularity for answering DS-related inquiries, yet these models are prone to generating “hallucinations” or inaccurate information [15-18]. To counter this, retrieval-augmented generation (RAG) combines the retrieval power of knowledge bases with the generative capabilities of LLMs to produce more accurate responses [19]. An RAG system operates in two phases: first, it retrieves relevant data from a structured knowledge base, ensuring accuracy, and then it uses an LLM to generate responses [20,21]. By integrating iDISK with an RAG system, we mitigate the hallucination problem inherent in standalone LLMs [22,23].

In this paper, we (1) present a major update from iDISK to iDISK2.0, incorporating the latest database versions while minimizing data noise; (2) integrate an RAG system with LLMs to significantly improve the accuracy of DS question answering, the first of its kind for DS queries; and (3) develop the integrated Dietary Supplement Knowledgebase—retrieval-augmented generation (iDISK2.0-RAG) web portal, which offers consumers and health care providers a reliable and user-friendly interface for DS information.

Our work not only addresses the limitations of LLMs but also establishes a new standard for DS question answering. Although this work focuses on DSs, our successful integration and platform can provide new opportunities for other domains.



Methods

Overview

Figure 1 illustrates the overall workflow of this study. We first constructed iDISK2.0 by integrating the latest versions of data from 4 DS resource databases that were originally integrated into iDISK, including LNHPD, DSLD, MSKCC, and NMCD (Figure 1A). We further developed an RAG-based LLM on iDISK2.0 (Figure 1B). In addition, we developed a user-friendly intelligent user interface with iDISK2.0-RAG as the backend to answer DS-related questions (Figure 1C).

Figure 1. An illustration of the study pipeline. DSLD: Dietary Supplement Label Database; NHP: Natural Health Products; iDISK2.0: integrated Dietary Supplement Knowledgebase; LLM: large language model; iDISK2.0-RAG: integrated Dietary Supplement Knowledgebase—retrieval-augmented generation.

Data Collection and Preprocessing

A total of 4 datasets were collected and preprocessed for the iDISK 2.0. Data from DSLD were downloaded directly from the data release, and the DSLD application programming interface (API) was used to enrich the dietary supplement-related information. Data from MSKCC were obtained after approval, using a web crawler to extract relevant information. LNHPD data were downloaded directly from the data release. After acquiring information from all sources, we converted them into a unified, structured format. The data of the NMCD used in the iDISK 2.0 were derived from information that already exists within iDISK. During the information extraction process, we used LLM (GPT-4) with the prompt (see Multimedia Appendix 1 for specific prompts) to assist in extracting and optimizing information. For example, relationships between DSs and diseases recorded in MSKCC were expressed in text format; we used the LLM to extract disease and drug entities from these sentences and organize them into a structured format for integration and processing. The source data contained inconsistencies and noise, such as variations in how company addresses were recorded in the DSLD product data (eg, “U.S.A.,” “United States of America,” and “United States”) and nonsensical ingredient names like “8” or “%.” We addressed these issues by using an LLM to identify and unify the differing expressions. In addition, we developed filtering patterns specifically designed to remove nonsensical ingredient names, such as those with fewer than two characters or those consisting solely of numbers or punctuation. This approach ensured a more consistent and accurate dataset by standardizing key information and eliminating irrelevant entries.

Specifically, we extracted the dietary supplement product (DSP) name, purpose, safety information, and company address information from LNHPD, along with the dietary supplement ingredient (DSI) name, source material information, and relationships between DSP and DSI. From DSLD, we extracted the DSP name, company address information, DSI name, and the relationship between DSP and DSI. In DSLD, names of DSIs appeared as duplicate records due to synonyms (eg, “Fiber gum acacia,” “Acacia gum extract,” and “Acacia”). We used the DSLD API to collate these synonyms and eliminated duplicates by grouping the synonyms of DSIs representing the same entity using the “Ingredient Group” classification in DSLD. From MSKCC, we extracted the DSI name, common name, background information, mechanism of action, disease name, drug name, symptom name, and the relationships between DSI and disease, DSI and symptom, and DSI and drug.

After completing the information extraction and optimization, we used QuickUMLS (Georgetown IR Lab) [24] to map DSI entities, symptom entities, disease entities, and drug entities from the source resources to the Unified Medical Language System (UMLS) [25] Concept Unique Identifier (CUI). To ensure mapping accuracy, we restricted each entity type based on UMLS semantic types (see Multimedia Appendix 1). The results of the QuickUMLS mapping included the matched UMLS CUI, term name, similarity, and whether the term was

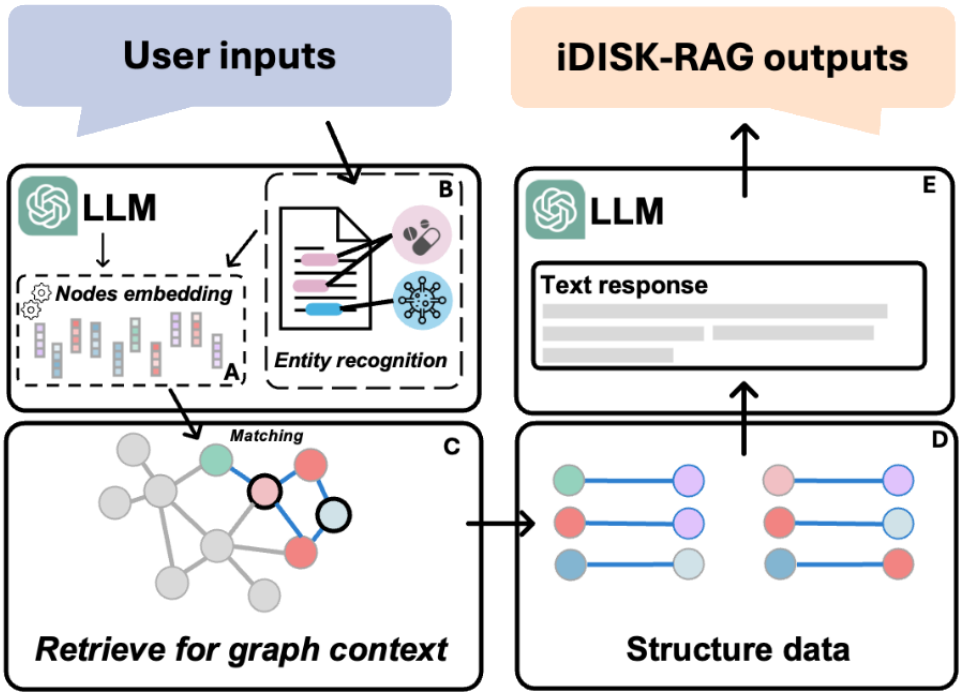
XSL•FO
RenderX

preferred. When QuickUMLS returned multiple results, we used a prioritization strategy: first, results with a similarity of 1, marked as preferred; next, results with a similarity of 1, even if not marked as preferred; and finally, those marked as preferred with the highest similarity. If none of these conditions were met, a UMLS CUI was not assigned to the entity to ensure mapping accuracy.

Data Integration for IDISK2.0

We used a greedy strategy to standardize entity terminology and integrate data from different sources. For each specific entity type, we initially selected a single database to initialize the entity vocabulary. Each specific entity was linked with a unique identifier to integrate entities from all databases, progressively refining the entity vocabulary. Specifically, for DSP, we started with data from LNHPD, integrating DSP entities from both LNHPD and DSLD. We consolidated DSP with the same product name and company name into a single unique entity. We unified entities with the same UMLS CUI or identical term names for DSI. Similarly, we consolidated entities with the same UMLS CUI or identical term names for disease, symptom, and drug entities. Each integrated entity was assigned a unique iDISK ID as its identifier in iDISK. Following this normalization procedure, we obtained a CSV file for each entity type, storing all standardized entity terms and their associated attributes. This allowed us to integrate the extracted knowledge from different databases to build iDISK2.0.

In the knowledge graph (KG), the basic knowledge unit is a triplet, typically defined as "<head entity, relation, tail entity>," indicating a relationship from the head entity to the tail entity in the KG. We mapped the head and tail nodes of the knowledge from the source databases to iDISK IDs, establishing triples composed of iDISK IDs and their relations. We then deduplicated all these triples to reduce noise in iDISK while ensuring quality. Finally, multiple rounds of manual quality checks were conducted.



iDISK2.0 Deployment with Neo4j

We deployed the iDISK2.0 using Neo4j [26], a well-designed graph database platform that allows for structured queries within graphs. Specifically, we stored the generated entities and relationships of iDISK in corresponding CSV files, which Neo4j used as input to create a KG instance automatically. This setup enables iDISK2.0 to be efficiently and flexibly interacted with and updated.

iDISK2.0-Based RAG System

Figure 2 illustrates the overall framework of iDISK2.0-RAG. We began by preprocessing all entities within the iDISK2.0 database, creating embedding vectors for each entity name using OpenAI's embedding model, text-embedding-3-small (Figure 2A). This step allowed us to construct the iDISK2.0 entity vector database, which serves as a foundation for efficient and accurate entity matching. When a user inputs a query, we first extract relevant entities from the question by using an LLM (GPT-4.0; Figure 2B), using tailored prompts (see Multimedia Appendix 1 for specific prompts). The entities identified through this process are then transformed into corresponding vectors using the same OpenAI embeddings model. In the current implementation, relationships between entities are not embedded directly. Instead, we leverage the fixed and well-defined set of 6 relationship types in iDISK2.0 (eg, *is_effective_for* and *interacts_with*) to assign relationships based on the queried entity pairs. For instance, DSI-disease pairs are always associated with the *is_effective_for* relationship. This approach ensures computational efficiency while maintaining accuracy in retrieving relationship-based queries.

Figure 2. The overall design of the iDISK2.0-RAG (integrated Dietary Supplement Knowledgebase—retrieval-augmented generation). LLM: large language model.

XSL•FO
RenderX

To match these identified entities with those in the iDISK2.0 database, we calculate the cosine similarity between the vectors of the identified entities and the vectors in the preprocessed iDISK2.0 entity vector database. Cosine similarity, a measure of similarity between two vectors in an inner product space, is calculated based on the cosine of the angle between them (detailed information on cosine similarity is provided in Multimedia Appendix 1). We then select the entity with the highest similarity score, provided that the score is 0.75 or higher, to ensure a reliable match between the identified entity and a corresponding entity in iDISK2.0.

Once a match is identified, the corresponding nodes are converted into Cypher queries, allowing for interaction with iDISK2.0, which is deployed on the Neo4j graph database platform. This process retrieves the relevant graph context (Figure 2C), which is returned as structured data in the form of triples (Figure 2D). Finally, an LLM is used to integrate the user's original question with the retrieved structured data (triples) and generate a comprehensive and contextually enhanced response (Figure 2E; see Multimedia Appendix 1 for specific prompts).

Evaluation

We extracted two types of questions from information on the MSKCC website: true-or-false questions and multiple-choice questions (MCQs). Specifically, we extracted information regarding the effectiveness of DSs and diseases and the interactions between DSs and drugs. This information was formatted into true-or-false questions and MCQs (473 true-or-false questions and 329 MCQs). To evaluate the performance of iDISK2.0-RAG and two LLMs (GPT-3.5 and GPT-4.0), we randomly selected 100 questions from each type (true-or-false questions and MCQs). These questions were answered by iDISK2.0-RAG, GPT-3.5, and GPT-4.0, and their accuracy was calculated based on the correct answers. This process was repeated 10 times using bootstrapping, resulting in each system answering 1000 true-or-false questions and 1000 MCQs. Accuracy metrics for each sampling iteration were then computed to derive the performance distribution. To ensure a fair evaluation, all knowledge from MSKCC was excluded from the retrieval stage in the RAG framework, preventing any influence of MSKCC-integrated knowledge on the test results. The rose plot was drawn using ChiPlot [27].

RAG-Enhanced Intelligent Visual Interfaces

We developed a web-based graphical portal that allows users to access knowledge from iDISK2.0 intuitively and flexibly. Specifically, we built the backend (server-side) using Django (Django Software Foundation) [28], an advanced web framework based on Python (Python Software Foundation). The backend also hosts our iDISK2.0-RAG framework to provide users with more accurate retrieval information. The front end (web application side) is constructed using HTML5 and CSS, with JavaScript used for data interaction. Specifically, when the backend receives a query from the front end, the system first uses an LLM, such as GPT-4.0, to extract relevant entities from the user's question through tailored prompts. These extracted entities are then matched with pretrained embedding information from a comprehensive entity vocabulary stored in the backend. Once a match is identified, the RAG system generates corresponding Cypher queries based on the matched entities. These Cypher queries are subsequently used to interact with iDISK2.0, which is deployed on the Neo4j graph database platform, to retrieve the relevant contextual subgraphs. The retrieved subgraphs provide structured data that are essential for generating an accurate response. In the final step, the LLM, guided by specific prompts, is used once again to transform the structured data retrieved by the RAG system into natural language, which is then returned to the front end's dialogue interface. In cases where the entities mentioned in the user's question cannot be successfully matched within iDISK2.0, the LLM (GPT-4.0) relies on its internal knowledge base to generate a corresponding answer, which is also delivered to the front end's dialogue interface. This approach ensures that users receive comprehensive and contextually relevant responses, whether through structured data retrieval or the LLM's generative capabilities.

Ethical Considerations

This study exclusively used publicly available datasets from trusted sources, including NMCD, MSKCC, DSLD, and LNHPD, for the development and evaluation of iDISK2.0. The study did not involve human participants, and no personal, clinical, or proprietary data were accessed or used. Due to these reasons, this study did not require ethics board approval according to the University of British Columbia's Behavioral Research Ethics Board (BREB) guidelines [29]. The data collection and integration processes adhered to the terms and conditions of the respective data providers. For enhanced security, strict protocols were followed during data processing to prevent the inadvertent inclusion of sensitive information. The deployment and use of iDISK2.0 also comply with applicable ethical and legal standards to safeguard the privacy and integrity of the data.

Results

The Integrated Dietary Supplements Knowledge Base 2.0

Through systematic collection and coordination, we ultimately obtained 279 concepts of DSIs, 270 concepts of rugs, 231 concepts of diseases, and 425 concepts of symptoms from the latest version of the MSKCC website. From DSLD, we acquired 4318 concepts of DSIs and 92,651 concepts of DSPs. In addition, from the Natural Health Products database, we gathered 4690 concepts of DSIs and 71,364 concepts of DSPs. After conducting data management and data cleaning, we integrated data from the 3 sources through biomedical entity term normalization and knowledge integration. The iDISK 2.0 encompasses 174,317 entities across 7 types (Table 1), including 8091 DSI entities; 163,806 DSP entities; 786 disease entities; 625 drug entities; 425 symptom entities; 567 dietary therapeutic class (TC) entities; and 17 system organ class (SOC) entities. In addition, there are 6 types of relationships among the 7 entity types (Table 1), including DSP-DSI, DSI-disease, DSI-symptom, DSI-drug, DSI-TC, and DSI-SOC.

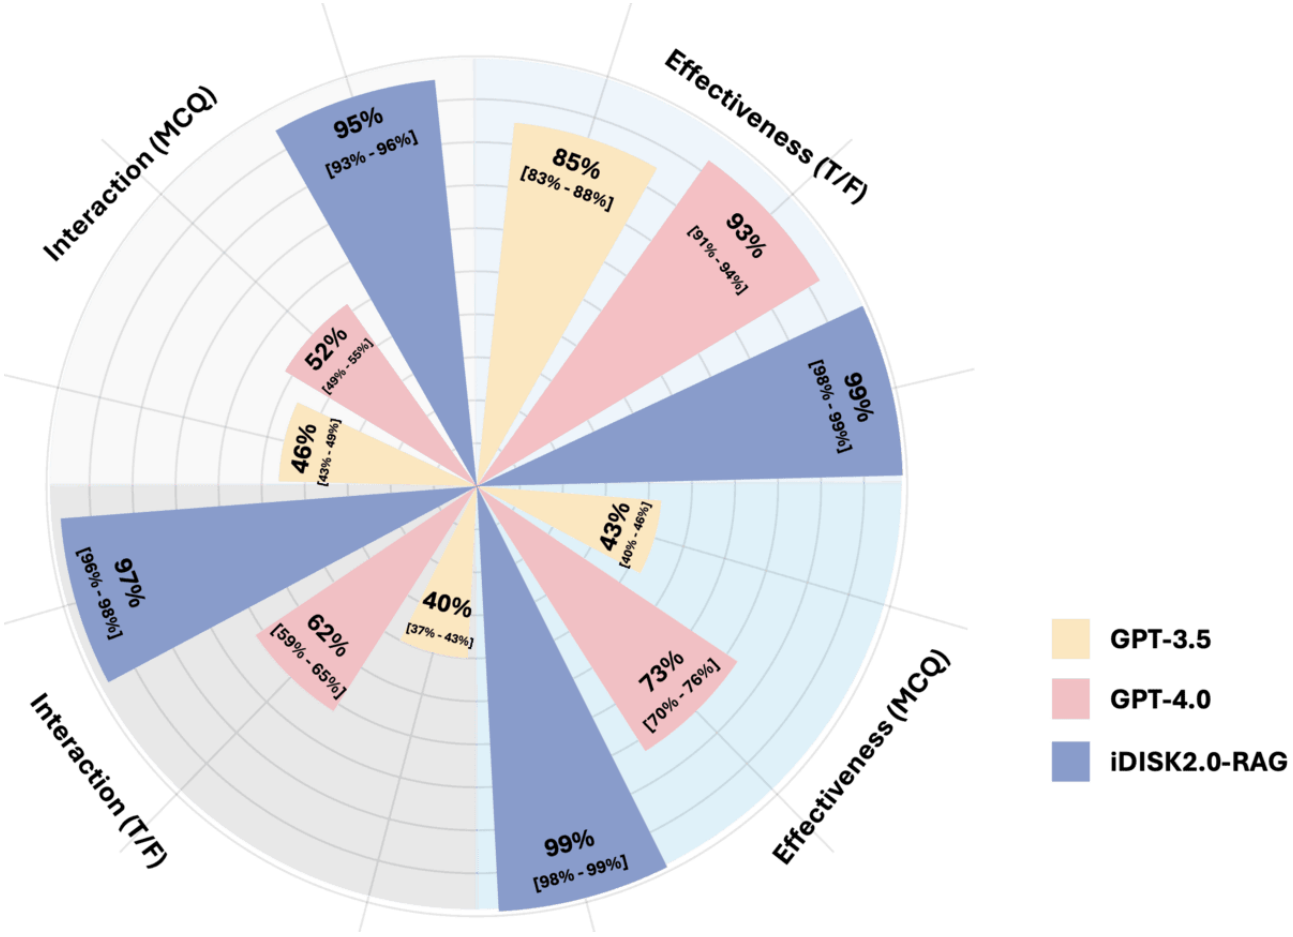
[a]iDISK: integrated Dietary Supplement Knowledgebase.

[b]Not applicable.

The iDISK 2.0 also includes 471,063 attributes (Table 1), comprising 163,806 DSP company names; 163,806 DSP company addresses; 65,097 DSP purposes; 63,623 DSP risks; 1289 DSI backgrounds; 1179 DSI safety profiles; 277 DSI mechanisms of action; 4277 DSI source materials; 3086 DSI-drug interaction ratings; and 4623 DSI-disease effectiveness ratings.

An iDISK2.0-Based RAG System



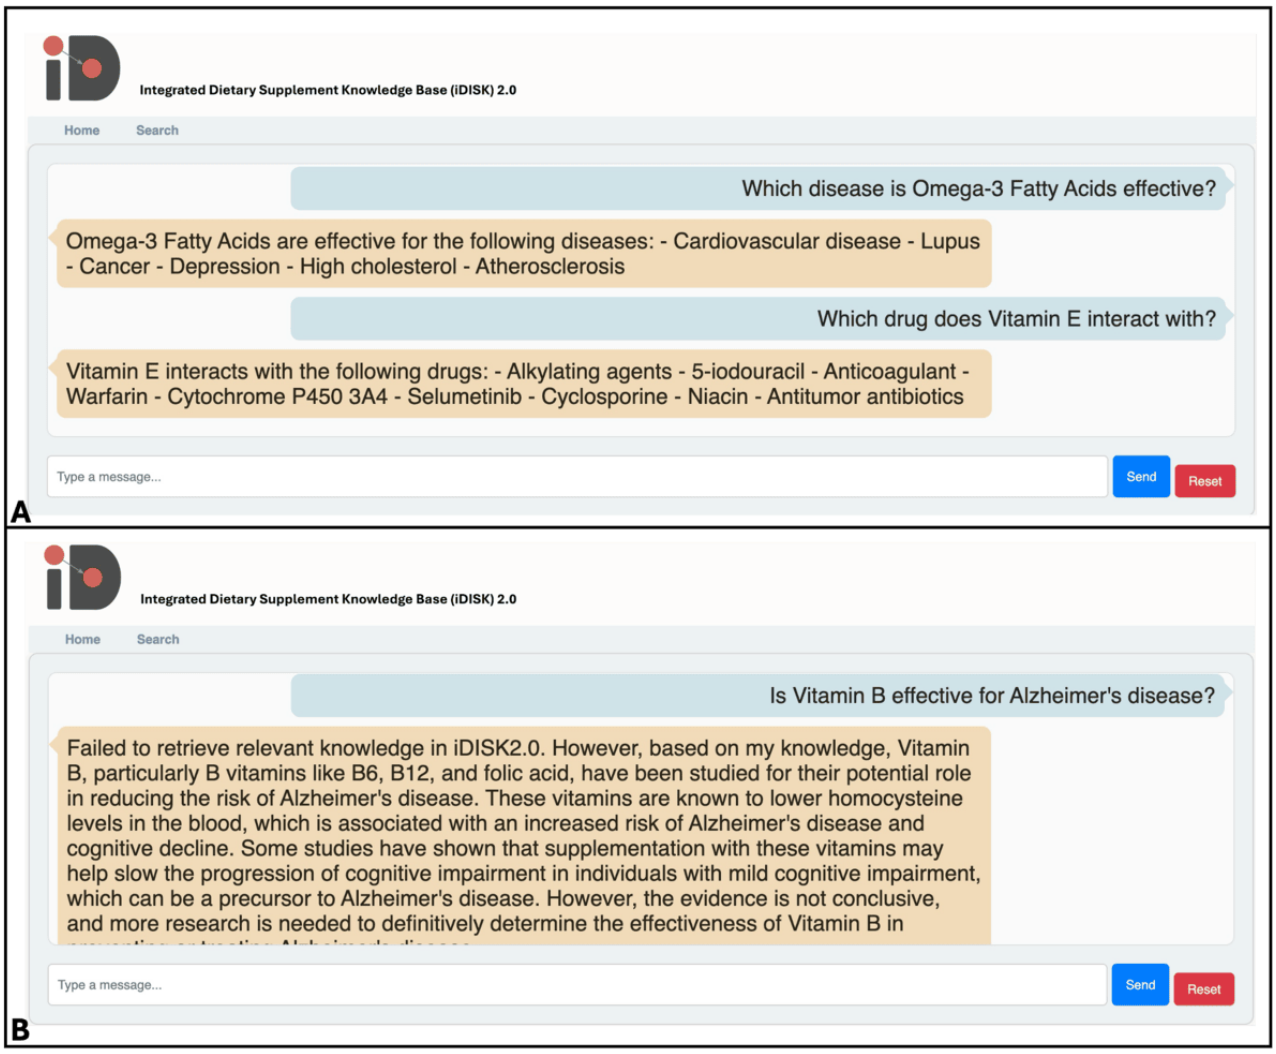
To address the potential hallucination issue present in current LLMs and thereby improve the accuracy of user responses, we developed an iDISK2.0-based RAG system. This system integrates the strengths of KG and LLMs to efficiently retrieve relevant knowledge from iDISK and use the language model to generate feedback and facilitate user interaction.

We collected data from the MSKCC website regarding the effectiveness of dietary supplements and diseases and the interactions between DSs and drugs. From these data, we generated a total of 473 true-or-false questions and 329 MCQs. Specifically, there are 164 true-or-false questions, 123 MCQs related to DSs and diseases, and 309 true-or-false questions and 206 MCQs related to DSs and drugs. For instance, in the MSKCC database, there is a record stating, “Vitamin C is used to prevent and treat the common cold.” We used this record to generate corresponding true-or-false questions and MCQs for evaluative purposes. The true-or-false question derived from

XSL•FO
RenderX

this statement is “Is it true that Vitamin C is effective for the common cold?” with the correct answer being “True.” In addition, we developed an MCQ to assess understanding: “Out of the given list, which disease is Vitamin C effective for?” The provided options are “Bladder stones, Common cold, Stroke, Bleeding hemorrhoids, and None of the above.” The correct answer is “Common cold.” Figure 3 illustrates the performance (accuracy) of two LLMs (GPT-3.5 and GPT-4.0) and the iDISK2.0-RAG system on true-or-false questions and MCQs related to DSs and diseases, as well as DSs and drugs. The results show that iDISK2.0-RAG achieves over 95% accuracy across all question types: 99% (990/1000) for true-or-false questions on DSs and diseases, 99% (993/100) for MCQs on DSs and diseases, 97% (974/1000) for true-or-false questions on DSs and drugs, and 95% (948/1000) for MCQs on DSs and drugs. In contrast, the performance of the two LLMs is notably lower, with GPT-4.0 outperforming GPT-3.5: GPT-4.0 achieved 93% (929/1000) accuracy on true-or-false questions related to DSs and diseases, compared with 85% (854/1000) for GPT-3.5; 73% (727/1000) accuracy on MCQs related to DSs and diseases, compared with 43% (426/1000) for GPT-3.5; 62% (618/1000) accuracy on true-or-false questions related to DSs and drugs, compared with 40% (400/1000) for GPT-3.5; and 52% (517/1000) accuracy on MCQs related to DSs and drugs, compared with 46% (457/1000) for GPT-3.5. Despite GPT-4.0’s superior performance over GPT-3.5, both models fall significantly short of the accuracy achieved by iDISK2.0-RAG in these specialized domains.

Figure 3. Model performance in question-and-answer tasks. T/F: true-or-false; MCQ: multiple-choice question; iDISK2.0-RAG: integrated Dietary Supplement Knowledgebase—retrieval-augmented generation.



A User-Friendly Intelligent User Interface for Knowledge Retrieval

Knowledge retrieval is one of the most common application scenarios of BKG in biomedical research. In recent years, LLMs have shown outstanding performance in NLP tasks but suffer from the issue of “hallucinations,” especially within specific domains [15-17]. To facilitate the use of iDISK2.0 by biomedical and clinical researchers in DS studies, we developed a web portal based on iDISK2.0-RAG as the backend. This RAG-based user interface allows users to input free-form text queries, generating meaningful biomedical text responses based on the established knowledge within iDISK2.0 to answer users’ questions. Figure 4A illustrates an example of a user query using free-form text. When the user inputs a question such as “Which disease is Omega-3 Fatty Acids effective for?” the user interface retrieves relevant knowledge from the iDISK2.0-RAG backend and returns the corresponding answer: “Omega-3 Fatty Acids are effective for: - Cardiovascular disease - Lupus - Cancer - Depression - High cholesterol - Atherosclerosis.” In cases where the user’s query cannot be answered directly from the iDISK2.0 knowledge base, the RAG framework informs the user that the specific knowledge is not available within iDISK2.0. Subsequently, the LLM within the framework attempts to answer the question based on its own knowledge, as depicted in Figure 4B.

Figure 4. An example of question-and-answer on the user interface.

Discussion

Principal Findings

iDISK integrates information from 4 well-designed DS databases, ensuring it contains the most comprehensive DS-related information available. iDISK2.0 inherits this feature, maintaining its status as the most thorough DS information repository. As source resources are updated, much DS-related information has been upgraded. For instance, when the DSLD was first launched in 2013, it contained nearly 17,000 label entries; now, it includes nearly 190,000, an increase of more than tenfold in just a decade. In addition, many DS details have been corrected; for example, the older version of iDISK included an ingredient from DSLD labeled "Araceae," which was inaccurate. In the latest version of DSLD, this ingredient has been removed. The observed reduction in the number of entities, such as in the "signs/symptoms" category, further reflects the enhanced data integration and noise reduction strategies used in iDISK2.0. By consolidating duplicate entries, refining entity definitions, and filtering out ambiguous or irrelevant information, iDISK2.0 significantly improves the overall quality of the knowledge base. Upgrading iDISK to iDISK2.0 is crucial to maintaining the accuracy and relevance of DS information. Without regular updates, the knowledge base could become outdated, leading to potential misinformation and inefficiencies in DS-related research and health care decisions. The continuous integration of the latest data and refined processes in iDISK2.0 helps mitigate these risks, ensuring that users have reliable, current information to make informed decisions about dietary supplements.

LLMs like GPT-4.0 have significantly advanced the field of natural language processing. However, they still exhibit notable limitations, particularly in domain-specific applications such as DS information retrieval. A key challenge is their propensity for generating "hallucinations"—plausible yet incorrect information—stemming from their reliance on extensive but often unverified data sources [18]. This issue is particularly problematic when precision is critical. For example, our evaluation highlighted a case involving the use of coenzyme Q10, also known as ubiquinone, which is documented for its effectiveness in preventing migraines according to the MSKCC database. To test our system's accuracy, we posed an MCQ: "Which disease is Ubiquinone effective for?" with options including migraines, hypertension, menstrual disorders, cholestasis, and none of the above, despite the correct answer being "Migraines," based on robust evidence. However, GPT-4.0

XSL•FO
RenderX

returned “Cholestasis” as the answer, even though only limited studies have explored the relationship between coenzyme Q10 and intrahepatic cholestasis of pregnancy [30,31], with no definitive conclusions indicating its efficacy in this context. In contrast, numerous studies have established the effectiveness of coenzyme Q10 in the prevention and treatment of migraines [32-34]. This error underscores a critical concern: while LLMs have vast knowledge bases, they can still falter by either misinterpreting context or lacking explicit, well-established information.

To address these challenges, we developed iDISK2.0 and integrated it with an RAG system. This integration combines the expansive knowledge base of LLMs with the precise, validated data from iDISK2.0, significantly reducing the risk of hallucinations. In testing, the RAG system, drawing from verified knowledge within iDISK2.0, consistently provided accurate answers, such as correctly identifying coenzyme Q10’s efficacy for migraines. While the current evaluation focused on true-or-false questions and MCQs derived from the MSKCC database to ensure controlled and reproducible testing, we recognize that real-world, open-ended queries often require more nuanced and context-sensitive responses. Our evaluation results indicate that iDISK2.0-RAG achieves over 95% accuracy when retrieving structured knowledge, whereas stand-alone LLMs perform substantially worse, with GPT-4.0 achieving only 62% (618/1000) accuracy in true-or-false questions and 52% (517/1000) in MCQs on DS-drug interactions. This underscores the importance of structured knowledge retrieval in mitigating misinformation. However, instances where the system relies solely on the LLM’s generative capabilities without sufficient retrieval support may still be prone to inaccuracies. To address the limitations of structured retrieval and enhance real-world applicability, we plan to develop a more comprehensive BKG that integrates diverse data sources beyond iDISK2. This expanded BKG will include biomedical literature to summarize the evidence [35], social media data to capture public perceptions, electronic health records to extract evidence of efficacy and safety [36-38], and postmarket surveillance data to address safety concerns [39]. By leveraging this holistic BKG, we aim to enhance the system’s capability to interpret and respond to real-world, open-ended queries. Future evaluations will incorporate open-ended questions collected from diverse user groups and assess both quantitative metrics, such as accuracy, and qualitative metrics, such as user satisfaction. This integrated approach will provide deeper insights into the system’s robustness and applicability. Further enhancing this solution, we incorporated a user-friendly interface with the iDISK2.0-RAG backend, allowing users to access accurate DS information through simple conversational text inputs. This setup not only facilitates better-informed decisions but also improves the overall user experience by ensuring the dissemination of the most accurate and current DS information. The necessity of this innovation is emphasized by the potential risks of relying solely on LLMs, which can propagate misinformation and lead to inefficiencies in both research and health care decisions. Moving forward, future research should focus on refining the interaction between LLMs and RAG systems. A potential avenue could involve mechanisms that allow LLMs to defer to the more reliable RAG output in cases where the evidence is more compelling. This approach would significantly enhance the accuracy and trustworthiness of artificial intelligence–generated responses in biomedical applications.

Despite adopting stricter mapping and integration schemes compared with the older version of iDISK, some errors and noise still exist in the final results. These inaccuracies partly stem from the imprecise expressions in the source databases. In addition, errors arise when attempting to map entities from the source databases to UMLS CUIs for subsequent entity integration. The entity extraction and mapping software QuickUMLS sometimes returns incorrect results. For instance, the MSKCC database records an interaction between “Andrographis” and “Blood pressure-lowering drugs”: “Andrographis interacts with Blood pressure-lowering drugs.” When extracting entities from this knowledge, we extracted the drug entity “Blood pressure-lowering drugs” from the text. However, QuickUMLS mapped “Blood pressure-lowering drugs” to “Drug (UMLS CUI: C0013227),” resulting in incorrect mapping and introduction of errors into the integration process.

Given the current limitations of this study, we plan to implement different strategies in the future to further reduce errors. For instance, we can introduce entity extraction techniques based on LLMs to extract DS-related information stored in text. For example, we may employ various prompt strategies, including rule-based prompts (eg, HealthPrompt [40]), hard-prompt learning [41], and soft-prompt learning [42]. In addition, we can leverage LLMs to batch-check entity extraction and mapping results and perform quality control on the integration outcomes. Recent research has highlighted the beneficial applications of BKGs in the medical field [7,43]. Furthermore, the rise of LLMs has spurred discussions on how best to combine the strengths of these models and BKGs [44]. In the future, besides continuously maintaining iDISK to ensure it remains the most up-to-date and comprehensive DS information resource, we will also explore ways to better assist users in using iDISK. For example, we plan to introduce knowledge graph embedding technology. By using graph-structured reasoning, we aim to offer reasonable predictions for knowledge not yet included in existing databases, thereby helping users discover more information. This approach will not only enhance the precision of user queries but also expand the scope of knowledge available to them. To ensure the long-term reliability and accuracy of iDISK2.0, we plan to establish a pipeline for annual updates integrating new data from trusted sources, such as NMCD, MSKCC, DSLD, and LNHPD. This includes automated data extraction, preprocessing, and stringent quality control measures. In addition, we will continuously adapt the system’s embedding strategy and retrieval mechanisms to align with the evolution of commercial LLMs. The open-source nature of iDISK2.0 will enable contributions from the research community, fostering collaborative improvements. Regular evaluations with updated test sets will further ensure the sustained performance of the RAG system.

The modular design of the iDISK2.0-RAG framework facilitates its adaptability to other areas of health care beyond dietary supplements. BKGs have shown significant promise in facilitating complex biomedical processes such as drug

XSL•FO
RenderX

discovery [45]. By integrating domain-specific knowledge bases, such as those focused on drug interactions or general medical advice, the framework could be extended to address broader biomedical applications. For example, incorporating drug interaction databases or broader biomedical ontologies could enable the system to handle queries related to drug-drug interactions, disease management, and care pathways. Future work will explore these possibilities, evaluating the system's performance across diverse domains and refining its capabilities to support a wider range of health care–related tasks.

Conclusion

In this study, we developed iDISK2.0, an updated repository for DS information, integrating data from NMCD, MSKCC, DSLD, and LNHPD. To address the limitations of LLMs, we introduced an RAG system combining LLMs with a BKG for accurate DS queries. iDISK2.0-RAG outperformed stand-alone LLMs, achieving over 95% accuracy. While some challenges remain with source data and entity mapping, future efforts will focus on improving entity extraction and quality control, ensuring iDISK2.0 continues to support informed DS decision-making. In addition, the adaptable design of the iDISK2.0-RAG framework offers significant potential for expansion into broader health care domains, such as drug interactions and general medical advice.

Abstract

Background: Clinical reasoning (CR) is an essential skill; yet, physicians often receive limited feedback. Artificial intelligence holds promise to fill this gap.

Objective: We report the development of named entity recognition (NER), logic-based and large language model (LLM)–based assessments of CR documentation in the electronic health record across 2 institutions (New York University Grossman School of Medicine [NYU] and University of Cincinnati College of Medicine [UC]).

Methods: The note corpus consisted of internal medicine resident admission notes (retrospective set: July 2020-December 2021, n=700 NYU and 450 UC notes and prospective validation set: July 2023-December 2023, n=155 NYU and 92 UC notes). Clinicians rated CR documentation quality in each note using a previously validated tool (Revised-IDEA), on 3-point scales across 2 domains: differential diagnosis (D0, D1, and D2) and explanation of reasoning, (EA0, EA1, and EA2). At NYU, the retrospective set was annotated for NER for 5 entities (diagnosis, diagnostic category, prioritization of diagnosis language, data, and linkage terms). Models were developed using different artificial intelligence approaches, including NER, logic-based model: a large word vector model (scispaCy en_core_sci_lg) with model weights adjusted with backpropagation from annotations, developed at NYU with external validation at UC, NYUTron LLM: an NYU internal 110 million parameter LLM pretrained on 7.25 million clinical notes, only validated at NYU, and GatorTron LLM: an open source 345 million parameter LLM pretrained on 82 billion words of clinical text, fined tuned on NYU retrospective sets, then externally validated and further fine-tuned at UC. Model performance was assessed in the prospective sets with F_1-scores for the NER, logic-based model and area under the receiver operating characteristic curve (AUROC) and area under the precision-recall curve (AUPRC) for the LLMs.

Results: At NYU, the NYUTron LLM performed best: the D0 and D2 models had AUROC/AUPRC 0.87/0.79 and 0.89/0.86, respectively. The D1, EA0, and EA1 models had insufficient performance for implementation (AUROC range 0.57-0.80, AUPRC

XSL•FO
RenderX

range 0.33-0.63). For the D1 classification, the approach pivoted to a stepwise approach taking advantage of the more performant D0 and D2 models. For the EA model, the approach pivoted to a binary EA2 model (ie, EA2 vs not EA2) with excellent performance, AUROC/AUPRC 0.85/ 0.80. At UC, the NER, D-logic–based model was the best performing D model (F_1-scores 0.80, 0.74, and 0.80 for D0, D1, D2, respectively. The GatorTron LLM performed best for EA2 scores AUROC/AUPRC 0.75/ 0.69.

Conclusions: This is the first multi-institutional study to apply LLMs for assessing CR documentation in the electronic health record. Such tools can enhance feedback on CR. Lessons learned by implementing these models at distinct institutions support the generalizability of this approach.

large language models; artificial intelligence; clinical reasoning; documentation; assessment; feedback; electronic health record

Introduction

Clinical reasoning (CR) is a fundamental skill that requires incorporating vast amounts of information into a prioritized differential diagnosis and treatment plan and therefore crucial that trainees are given feedback to improve [1]. Documentation in the electronic health record (EHR) can provide this opportunity. Furthermore, poor documentation can reflect lack of refined CR and has been hypothesized to be linked to diagnostic errors [2-4]. There are established human ratings tools to provide feedback on CR documentation such as the Revised-IDEA tool, a rubric that facilitates giving feedback in 4 essential domains of CR, including interpretive summary, differential diagnosis, explanation of lead diagnosis, and explanation of alternative diagnoses [5]. However, feedback provided to trainees can still be limited due to faculty having different standards of what constitutes high quality CR documentation and limited time for feedback in the fast-paced clinical environment [5-7].

Machine learning (ML), natural language processing (NLP), and other artificial intelligence (AI) technologies have emerged as avenues to augment feedback [8-12]. NLP has been used to automate the scoring of documentation in simulated scenarios [13-16]. AI-augmented assessment of CR documentation has also been implemented in clinical environments; we have previously reported on an NLP-based supervised ML model that provides feedback on internal medicine (IM) residents CR documentation [17]. However, this model was developed using earlier technologies and only provides binary feedback. Similarly, Feldman et al [18] published the development of a supervised ML model that provides binary feedback on CR documentation (quality of prioritized differential in progress notes).

The more recent advances of generative AI (GAI) and large language models (LLMs) have expanded the potential of AI as a powerful tool to augment feedback [19,20]. There is a building body of literature on the use of LLMs in CR tasks demonstrating that AI outperforms humans [21-25]. Among these studies is a recent article by Goh et al [21] concluding that LLMs outperformed humans and humans plus LLMs on clinical vignettes as assessed by a standardized rubric of diagnostic performance. In terms of use of LLMs for assessment and feedback on CR, Çiçek et al [26] published on the use of ChatGPT versus expert written feedback on CR questions showing mixed reception from the medical students receiving the feedback. Finally, Jamieson et al [27] used AI to provide feedback on medical student Objective Structured Clinical Examination postencounter notes, an important method of assessing CR, and showed high agreement between AI and expert human ratings. However, these studies are all conducted with curated medical data, at single institutions, and do not focus on assessment of human reasoning but on performance of LLM reasoning as compared with humans.

Navigating the use of LLMs with EHR data (vs curated data) can be much more complicated. There are the challenges of accessing the right data from the chart, a higher burden of accuracy, privacy issues, and variability in EHRs [28-30]. In addition, initial studies have shown LLMs do not perform as well digesting the complexity of information in the EHR to make accurate diagnoses [30]. Finally, while the performance of LLMs on CR tasks is promising, it is far from sufficient to replace humans and it is essential that we continue to provide feedback on our learners' CR [19,30,31]. AI-based tools remain an important strategy to enhance the amount of feedback we provide [12].

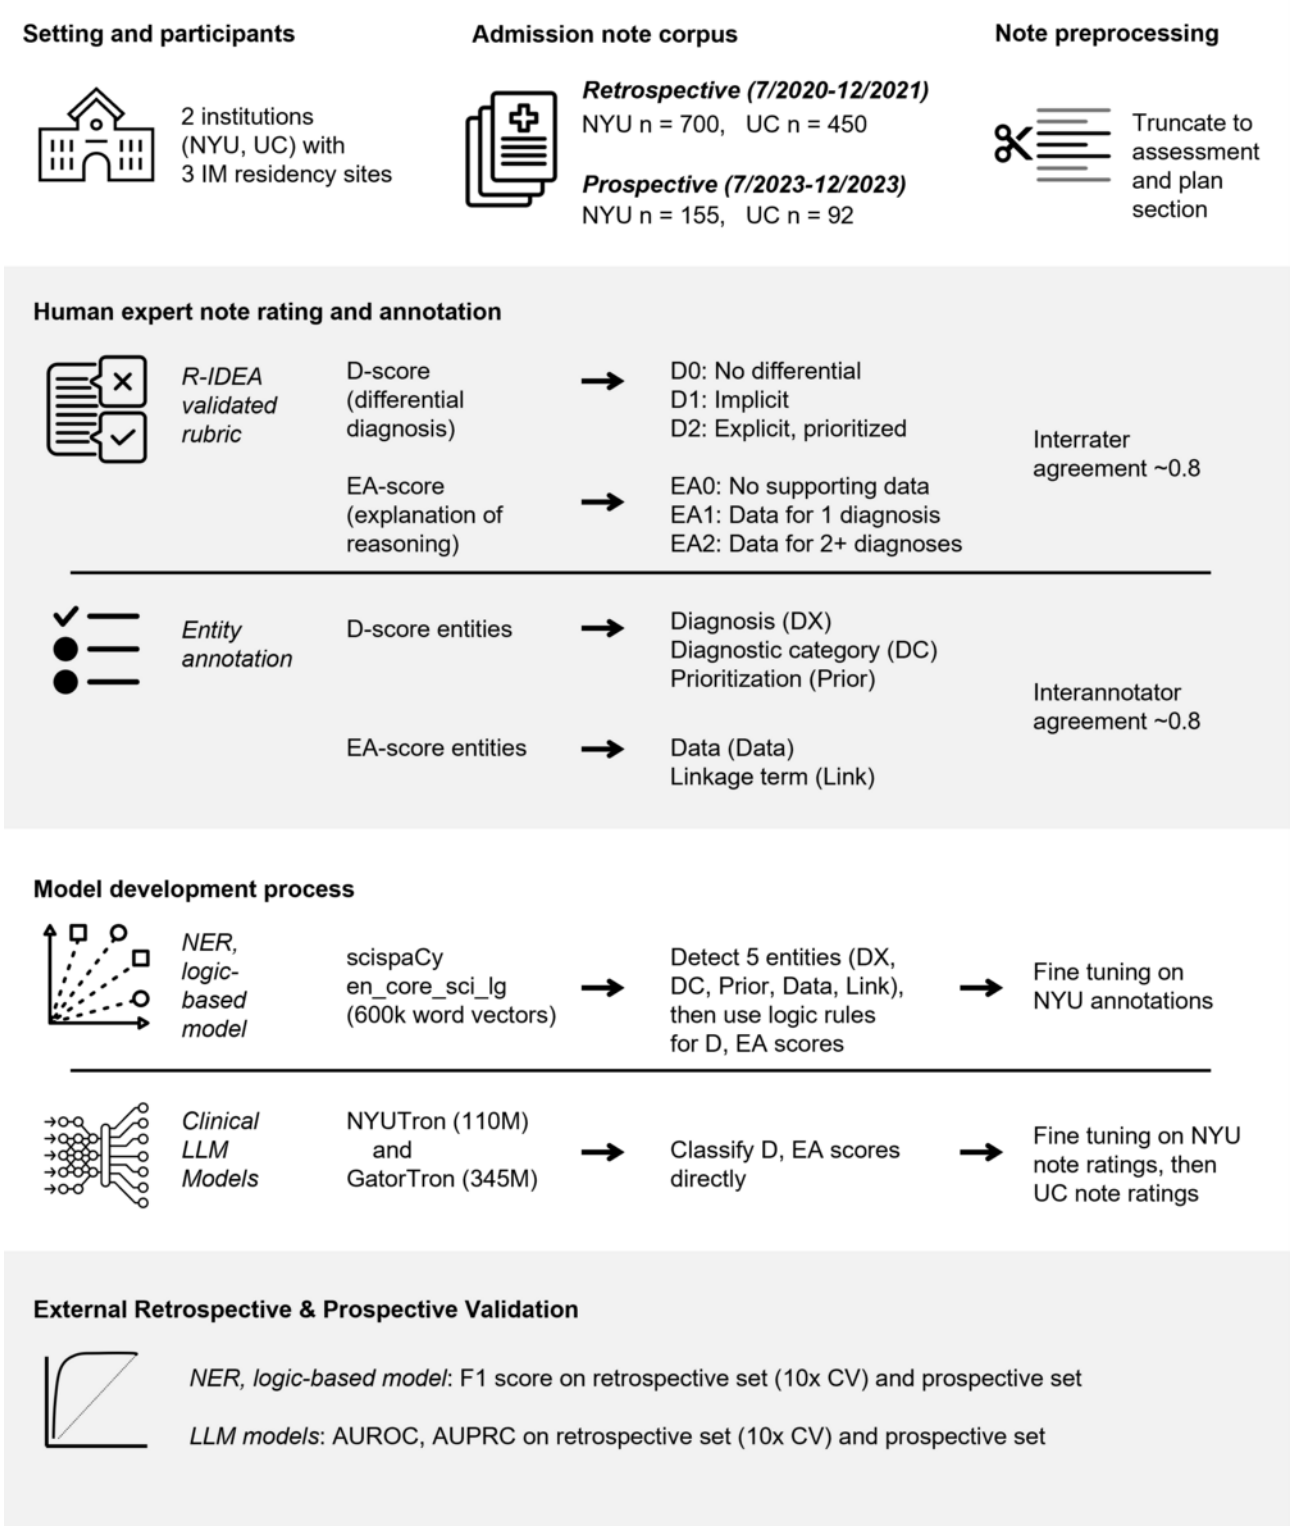
Here, we report on an expansion of our previous work and describe the development across 2 institutions of a named entity recognition (NER), logic-based assessment and LLM-based assessments of IM resident CR documentation in the EHR that predicts the quality of CR across 2 domains using the Revised-IDEA tool.

Methods

Setting and Study Population

We conducted this study at 2 institutions, New York University Grossman School of Medicine (NYU) and University of Cincinnati College of Medicine (UC). NYU is a northeastern academic medical center with multiple hospital sites; the NYU IM residency program has 2 resident populations with separate recruitment processes and clinical rotations at different hospitals that use the same EHR, NYU Langone Health Manhattan and NYU Langone Health Brooklyn. NYU residents also rotate at 2 other sites with distinct EHRs not included in this study. In terms of technical resources, NYU has the infrastructure of both the Institute for Innovations in Medical Education which is a multidisciplinary team of clinician educators, data scientists,

XSL•FO
RenderX



informaticians, and developers who apply the science of education and informatics to transform teaching, learning, evaluation, and assessment at NYU and the Division of Applied AI Technologies which focuses on using data and modeling to predict health outcomes across NYU Langone Health [32,33]. In addition, both education and EHR data are stored and easily accessible through a central education data warehouse and there is access to a distributed-memory, high-performing computing cluster [34,35].

UC is a midwestern academic medical center within which IM residents rotate at University of Cincinnati Medical Center (UCMC) and the Veterans Affairs Medical Center; only notes written at UCMC were included in the study. In terms of technical resources, UC has the Department of Biostatistics, Health Informatics, and Data Sciences (BHIDS) that enables the UC academic health care enterprise to make better use of biomedical data and technology for new discoveries, innovative science, and improved health care [36]. Although UC has access to many data sources across the health system, medical school and other education programs, currently there is not a centralized database for education and EHR data like at NYU. In addition, UC has some access to high-performing computing resources, but NYU has a more developed infrastructure for using these tools for both clinical and educational use than at UC.

At each site 2 note sets were retrieved from an integrated EHR (Epic Systems): (1) retrospective dataset comprised of IM resident admission notes from July 2020-December 2021 (n=700 NYU notes, n=450 UC notes) and (2) prospective validation dataset from July 2023-December 2023 (n=155 NYU notes, n=92 UC notes; Figure 1). These time periods were selected to ensure a sufficient range of diagnoses and residents were represented and that COVID-19 admissions were not overrepresented. The datasets at NYU were larger because the initial plan was for primary development and model fine-tuning occurring at this institution.

Human Note Rating

We used the DEA components of the Revised-IDEA tool as our human rating gold standard [5]. We maintained the original D (differential diagnosis) score whether a note has an explicitly prioritized differential diagnosis with specific diagnoses (eg, not diagnostic categories such as cardiac), scored as D0, D1, or D2. We discovered early in training experiments that discerning the E (explanation of lead diagnosis) and A (alternative diagnosis explained) would be difficult with available AI models, and iterated to create an overall explanation of reasoning EA score combining the E and A components (ie, EA0, EA1, or EA2; Figure 1; Multimedia Appendix 1). In total, 6 faculty (clinician educators with expertise in CR, assessment, and

XSL•FO
RenderX

psychometrics), 1 resident, and 1 medical student reviewed admission notes to create the new EA score.

On the NYU retrospective dataset, raters also annotated spans of text using Prodigy (an annotation tool for creating training data for ML models). Annotations included 5 entity types for NER, 3 components of the D score (diagnosis [Dx], diagnostic category [DC], prioritization of diagnosis language [Prior]) and 2 components of the EA score (data [Data] and linkage terms [Link]).

To demonstrate interrater reliability, 2 raters labeled 76 notes from the NYU retrospective set for NER, D, and EA scores. For the UC notes, 1 rater from NYU and 2 raters from UC rated 20 notes for D and EA scores. Intraclass correlation (ICC) using a 2-way ANOVA with mixed effects was calculated to assess rater consistency. The remainder of the notes at each institution were rated by 1 rater for D and EA scores. The remainder of the retrospective set at NYU was also rated by 1 rater for NER.

Note Preprocessing

We aimed to isolate the section of the assessment that concentrates on the differential diagnosis and the explanation of reasoning for the primary presenting problem. We iterated on previous truncation strategies outlined previously by Schaye et al [17] and different approaches were required at each institution given different note writing styles (details in Multimedia Appendix 2).

Model Development

Model training occurred with several approaches, NYU development of NER, logic-based model with subsequent external validation at UC, NYU fine tune training of LLM NYUTron [37], NYU fine-tune training of LLM GatorTron [38], UC external validation and fine tune training of NYU fine-tuned GatorTron, and UC fine tune training of GatorTron. We were not able to validate NYUTron at UC pending contract execution for data sharing and will ideally do so in the future.

The selection of these model architectures was driven by their proven effectiveness in handling clinical text data and their ability to capture complex semantic relationships [37-39]. The NER, logic-based model was chosen for its capability to leverage domain-specific knowledge and predefined rules, which is particularly useful for structured data extraction in clinical settings. On the other hand, the LLMs were selected for their advanced contextual understanding and scalability, making them suitable for more nuanced classification tasks.

NER, Logic-Based Model Approach

We used a large, NLP word embedding model trained on scientific texts from the scispaCy library (en_core_sci_lg) with more than 700k vocabulary and 600k word vectors [39]. Word embeddings are a type of word representation that allows words to be represented as vectors in a continuous vector space, capturing semantic meanings. We adjusted model weights with backpropagation (a method used to minimize the error in predictions by adjusting the weights of the model) using the human-annotated labels of the 5 entity types (Dx, DC, Prior, Data, and Link).

We calculated the predicted D scores (ie, D0, D1, and D2) using logic-based relationships between the extracted entities and the rating scale: D0, fewer than 2 unique diagnoses (Dx entity counts); D2, 2 unique diagnoses (Dx entity counts); and explicit prioritization (Prior entity counts); D1, everything else. We attempted ML models to predict EA score from the named entities; however, due to poor model performance, we abandoned further attempts to develop NER, logic-based EA scores.

In order to provide an impartial and dependable evaluation of the model's performance, we used 10-fold cross-validation (a technique where the data is divided into ten parts, and the model is trained and validated 10 times, each time using a different part as the validation set and the remaining parts as the training set). We calculated the Type NER (which demands some overlap between the system tagged entity and the gold standard annotation) evaluation metric, as suggested in SemEval-2013 Task 9, at each k-fold (details in Multimedia Appendix 3) [40]. We report F_1-score over 10-fold runs for each D score entity type (Dx, DC, and Prior) and D score prediction. The F_1-score is crucial for evaluating NER-based models because it balances precision and recall (precision measures the accuracy of the positive predictions, while recall measures the ability to find all relevant instances), providing a comprehensive measure of a model's ability to correctly identify entities while minimizing both false positives and false negatives. This balance is essential for handling the often-imbalanced nature of entity distributions in text, ensuring a more accurate assessment of model performance. We shared the best performing NER, logic-based D model with UC through a docker container and externally validated the model on the UC retrospective set.

LLM Approaches

NYUTron, developed by NYU, is a BERT (Bidirectional Encoder Representation with Transformer)-like LLM with about 110 million parameters that has been pretrained on 7.25 million clinical notes (4.1 billion words, notes through May 2020) [37]. We fine-tuned the model to classify D and EA scores. We applied a 1-versus-rest approach, which resulted in the development and testing of 6 distinct models, each corresponding to a different D and EA score category (ie, D0, D1, D2, EA0, EA1, and EA2 models). However, EA0 and EA1 models did not have adequate performance so we pivoted our approach to create a single binary EA2 model (ie, EA2 vs not EA2). To evaluate model performance, we used 10-fold cross-validation, with area under the receiver operating characteristic curve (AUROC) and area under the precision-recall curve (AUPRC) averaged over the 10 runs. We chose AUROC and AUPRC as our primary metrics for all LLM-based models because these metrics are favored over *F*-scores for binary classification tasks, particularly with imbalanced datasets. They assess model performance across all possible thresholds, offering a more detailed understanding of trade-offs between true positives, false positives, and precision-recall dynamics, thereby aiding in the identification of the optimal decision-making threshold, which a single *F*-score cannot provide.

XSL•FO
RenderX

Unlike NYUTron, GatorTron is an open source LLM with 345 million parameters that was pretrained on over 82 billion words of deidentified clinical text [38]. To enhance generalizability using an open source LLM, the same experiments described above for NYUTron were taken with GatorTron at NYU.

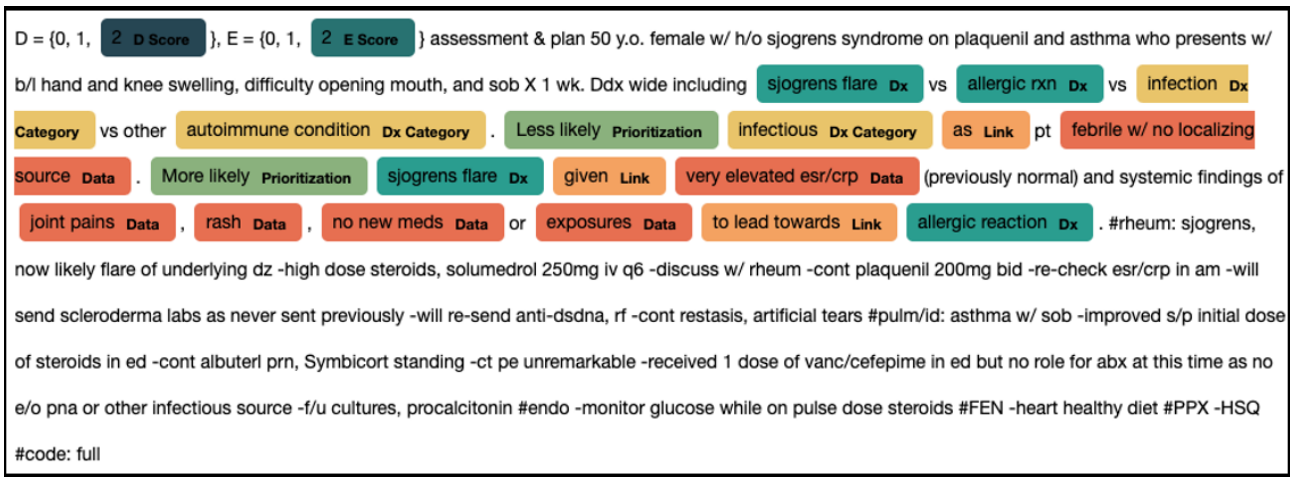
The NYU fine-tuned GatorTron EA2 model was shared with UC, which conducted external validation, and further fine-tuned following a similar process. Due to the smaller set of notes and hardware limitations, particularly a relatively small Video Random Access Memory size of 16GB, some modifications were applied. A runtime text augmentation was implemented during training with the following settings: 15 words of synonym replacement, random word insertion, and random swap each, and finally, a random word deletion of 15% probability. Finally, we applied random minority oversampling using inverse class frequency during training.[41] In addition, given these limitations, we did not attempt to fine-tune the 3 separate NYU fine-tuned GatorTron D models at UC. Instead, we fine-tuned the original GatorTron model to predict all 3 possible D Scores with a single model at UC using the same training process and hyperparameters as the EA2 model. Further details on model hyperparameters and packages used at NYU and UC can be found in Multimedia Appendix 4.

Prospective Validation

As a final step of validation, we ran each of the best performing models selected for implementation on the site's prospective validation sets and assessed performance using F_1-score for the NER, logic-based model and AUROC and AUPRC for the LLM models.

Ethical Considerations

The study was approved by the NYU and UC institutional review boards, (i19-00280) and (2022-058), respectively. A waiver of consent was obtained for retrospective chart reviews. All retrospective data were anonymized when possible and appropriate measures taken to protect participant information. We followed the reporting guidelines by Klement and El Emam [42] for prognostic and diagnostic machine learning studies.



Results

Human Note Rating

At NYU, ICC was 0.83 (95% CI 0.74-0.89) and 0.77 (95% CI 0.65-0.85) for the D and EA scores, respectively, indicating substantial interrater agreement. Interannotator agreement across all 5 entity types averaged F_1-score=0.81 (range 0.71-0.87 by entity type), indicating strong annotator overlap (Figure 2). At UC, ICC was 0.83 (95% CI 0.68-0.92) and 0.84 (95% CI 0.70-0.93) for the D and EA scores, respectively.

In both datasets, at each institution there was a range of human-rated D and EA scores, diagnoses, and patient demographics mitigating concerns of potential bias in the selection of datasets (Table 1).

Figure 2. Example note (modified to protect patient privacy) with human rating of D and EA scores and annotation for named entity recognition of 5 entity types: 3 components of the D score (diagnosis [Dx], diagnostic category (DC], and prioritization of diagnosis language [Prior]) and 2 components of the EA score (data [Data] and linkage terms [Link]).

Model Performance

NER Logic-Based Model

In the NYU retrospective dataset, the NER F_1-score for the entity types used to compute the D score (Dx, DC, and Prior) was 0.66. The NER model performed the best in extracting Prior and Dx entities with an F_1-score of 0.75 and 0.68, respectively, but struggled with DC entities, achieving a 0.37 F_1-score.

The NER, D logic-based model performed well at both sites with F_1-scores of 0.83, 0.78, and 0.75 for D0, D1, and D2 scores, respectively at NYU and F_1-scores of 0.75, 0.71, 0.76 for D0, D1, D2 scores, respectively at UC. At UC, the NER,

XSL•FO
RenderX

D-logic–based model was the best performing D model overall selected for implementation and run on the UC prospective validation set with F_1-scores of 0.80, 0.74, and 0.80 for D0, D1, D2 scores, respectively.

LLM-Based Models

At NYU, NYUTron overall had better D and EA model performance on the retrospective set than GatorTron and were the best performing models overall (Table 2). However, while the D0 and D2 NYUTron models performed well, the D1 model was not performant on the retrospective set (AUROC 0.57, 95% CI 0.53-0.69; AUPRC 0.33, 95% CI 0.26-0.43) and therefore was not suitable for implementation. As such, a stepwise approach was taken for the D1 model by taking advantage of the more performant D0 and D2 models (Table 2). The D0 and D2 NYUTron models had excellent performance on the prospective dataset as follows: D0 model, AUROC 0.87 and AUPRC 0.79 and D2 model, AUROC 0.89 and AUPRC 0.86 (Figure 3).

Both the NYUTron EA0 and EA1 models had insufficient performance for implementation therefore the approach pivoted to create a single binary EA model, EA2 vs not EA2 (ie, EA0 or EA1; Table 2). The binary NYUTron EA2 model achieved sufficient performance for implementation with an AUROC 0.85 and AUPRC 0.80 on the prospective dataset (Figure 4).

In external validation at UC, the NER, D logic model performed better than the D GatorTron models and were the D models implemented as described above (Table 2). The GatorTron EA2 model did reach sufficient performance for subsequent prospective validation with an AUROC 0.75 and AUPRC 0.69 (Table 2 and Figure 5).

A final step in optimizing performance was selecting thresholds for all LLM models implemented (details in Multimedia Appendix 5).

[d]AUROC: area under the receiver operating characteristic curve.

[e]AUPRC: area under the precision-recall curve.

[f]The D1 model ultimately did not have sufficient performance for implementation while the D0 and D2 had excellent performance so a stepwise approach was taken for the D1 score: (1) If D0 model predicts D=0, then D=0, (2) If D2 model predicts D=2, then D=2, and (3) Else D=1. The NYU D1 Stepwise Approach achieved precision of 0.79 while the GatorTron D1 Stepwise Approach achieved precision of 0.73.

[g]Not applicable.

[h]Both the EA0 and EA1 models had insufficient performance for implementation therefore the approach pivoted to create a single EA model EA2 vs not EA2.

AUC: area under the curve; FPR: false positive rate; PPV: positive predictive value; ROC: receiver operating characteristic; TPR: true positive rate; UC: University of Cincinnati.

Discussion

Principal Findings

We developed both NER, logic-based and LLM-based assessments of CR documentation in the EHR across 2 institutions with different residency training cultures, expectations for documentation, and technical resources. This builds upon previous work on a supervised ML model of Schaye et al [17] to assess CR documentation, generating more specific feedback across 2 domains of the Revised-IDEA tool. We developed high performing D models that can provide feedback on a 3-point scale and an EA model that can provide feedback on a 2-point scale with comparable performance with our earlier model that provides only binary feedback. Compared with our previous model, which used logistic regression and cTAKES for binary classification of CR documentation quality, our current models leverage advanced NLP techniques, including LLMs, and provides more granular feedback. In addition, the current models were designed at 1 institution and then externally validated at a second institution, enhancing their generalizability and robustness. To our knowledge this is the first study to apply LLMs to human CR in EHR data across institutions (rather than LLM reasoning or human reasoning on curated medical data) [17,18,21-24,26,27,30]. Furthermore, despite the advances in LLMs, these technologies are not yet performant to replace human reasoning. AI-based tools such as the ones we developed can help ensure we are continuing to give our trainees feedback on the essential human skill of CR [12,19,30,31].

While we were able to navigate successfully some of the challenges of working with LLMs and EHR data such as accessing the right data from the chart and privacy issues [28-30], we were not able to achieve sufficient performance of all the models at both sites. The performance differences between NYUTron, GatorTron, and the NER, logic-based model can be attributed to several factors. NYUTron, developed specifically on NYU EHR data, likely benefited from being fine-tuned on a dataset closely aligned with its pretraining data, which may have contributed to its superior performance at NYU. This alignment could have allowed NYUTron to better capture the nuances and specificities of the documentation style and clinical language used at NYU. In contrast, GatorTron, while being a robust open-source LLM with a larger parameter set, may not have been as finely attuned to the specific documentation styles at NYU or UC, leading to relatively lower performance. The NER, logic-based model, leveraging domain-specific knowledge and predefined rules, demonstrated strong performance in structured data extraction tasks, particularly at UC, where it outperformed the GatorTron models for D score predictions. This suggests that for certain structured tasks, smaller, more focused NLP models can sometimes be more effective than larger, more generalized LLMs. In addition, the annotation processes and the quality of the training data, including the consistency and accuracy of human annotations, likely played a significant role in influencing model performance.

It might not always be the newest technology needed to solve the task at hand and comparison of performance of different technologies can be a helpful strategy. Of note when this work initially began, GAI models such as ChatGPT were not readily available in HIPAA (Health Insurance Portability and Accountability Act)-compliant instances at either institution but will be technology we integrate into future work.

In terms of the performance of the models we plan to implement, the significance of the F_1-scores and AUROC metrics is crucial for understanding their practical implications in a clinical environment. Of the NER, logic-based models we plan to implement at UC only the D1 model has an F_1-score less than 0.80. An F_1-score of greater than 0.80 indicates a high level of accuracy in identifying relevant entities, which translates to reliable feedback being generated by the D0 and D2 NER,

XSL•FO
RenderX

logic-based models each with F_1-scores of 0.80. While the D1 NER, logic-based model did not reach this level of performance with an F_1-score of 0.74, an F_1-score greater than 0.70 has been deemed sufficient for applications not involving direct patient care decisions, such as for documentation feedback and educational purposes [43,44]. Furthermore, in the context of educational feedback, an F_1-score of greater than 0.70 ensures a balance between precision and recall, which is crucial for providing comprehensive and reliable feedback to residents without the risk of significant negative consequences [45]. Similarly, all of the LLMs we plan to implement at NYU and UC except 1 have AUROCs greater than 0.80; the GatorTron LLM EA2 model being the exception with an AUROC 0.75. An AUROC of greater than 0.80 suggests that the model has an excellent ability to accurately perform a classification task in this case classify quality of CR documentation. Similar to F_1-scores, an AUROC greater than 0.70 is acceptable in particular for low stakes clinical tasks like formative feedback on CR documentation being provided with these models [46,47].

Finally, we also learned a lot of lessons working across two institutions on how AI technologies can be adapted and successfully implemented at sites with different resources. Some key takeaways include experimenting with different LLMs including ones that are openly available, performing primary development at an institution with more resources and creating a HIPAA-compliant pipeline to share code thus mitigating ethical concerns of patient privacy, developing variations on truncation methods to account for different note writing styles, and creating adaptable approaches to different degrees of computing power such as using text augmentation to prevent overfitting at UC. We will take these lessons learned about generalizability to the next phases of the work and develop strategies to implement more advanced technologies across institutions while maintaining HIPAA compliance working with EHR data.

Our next steps include integrating these AI-based assessments into each residency program as new mechanisms to provide formative feedback to residents. At NYU, we will iterate on dashboards implemented with our previous supervised ML model to improve resident and faculty coaches' ability to visualize longitudinal trends and set improvement goals [17]. At UC, dashboard implementation will represent a new mechanism for formative feedback for residents that currently does not exist. Dashboards at both programs will include percent high-quality (score of 2) notes for D score and E score, trends in scores over time, and goal targets for residents. Residents at both programs will be able to access their data through dashboards for routine review. Each program will create a process for residents to review their performance data and set specific, individualized goals for improving their CR documentation. After initial implementation, we will collect data on outcomes, including the impact on CR documentation practices of IM residents.

Limitations

While the models developed have high performance, they are not perfect. However, the intent is for use in formative and not high-stakes summative assessment which would have a higher threshold for implementation [48]. In addition, similar to our earlier work the ML model excludes the interpretive summary which is a component of the original human rubric Revised-IDEA tool but was still considered too complex to tackle with the AI technologies used in this study [5]. Another limitation is that the LLMs used in this study only give a prediction of D and EA scores without explainability. We will experiment further with newer GAI models in next phases of the work that can help address many of these limitations given GAI's ability to provide narrative explanations and not just classification scores and promising research thus far on the use of GAI in CR assessment with curated data [26,27]. Finally, while we were able to navigate strategies to implement these technologies at 2 sites, there are still some potential limitations that might impact generalizability: (1) not all the technologies we used are readily publicly available and (2) each institution potentially has its own unique writing style which could impact performance of the models and approaches to truncation methods.

Conclusions

This is the first multi-institutional study to apply LLMs for assessing CR documentation in the EHR. Lessons learned from this study can help promote implementation of these technologies across institutions with ranges of technical resources. Further use of LLMs in the EHR for assessment and feedback can be transformative for medical education and patient care.

Acknowledgments

The authors would like to acknowledge Stephen Johnson and Marc Triola for their consultation on methodology. We would also like to thank Lezhi Li for her help with electronic health record (EHR) data extraction at the University of Cincinnati College of Medicine. We would like to recognize the National Board of Medical Examiners Edward J. Stemmler M.D. Medical Education Research Grant Program for their funding support of this project.

Data Availability

This study involves identified clinical information protected under Health Insurance Portability and Accountability Act regulations and is not available for distribution. Please email the authors with any inquiries about the data or models.

Abstract

Background: Sepsis is a complex, life-threatening condition characterized by significant heterogeneity and vast amounts of unstructured data, posing substantial challenges for traditional knowledge graph construction methods. The integration of large language models (LLMs) with real-world data offers a promising avenue to address these challenges and enhance the understanding and management of sepsis.

Objective: This study aims to develop a comprehensive sepsis knowledge graph by leveraging the capabilities of LLMs, specifically GPT-4.0, in conjunction with multicenter clinical databases. The goal is to improve the understanding of sepsis and provide actionable insights for clinical decision-making. We also established a multicenter sepsis database (MSD) to support this effort.

Methods: We collected clinical guidelines, public databases, and real-world data from 3 major hospitals in Western China, encompassing 10,544 patients diagnosed with sepsis. Using GPT-4.0, we used advanced prompt engineering techniques for entity recognition and relationship extraction, which facilitated the construction of a nuanced sepsis knowledge graph.

Results: We established a sepsis database with 10,544 patient records, including 8497 from West China Hospital, 690 from Shangjin Hospital, and 357 from Tianfu Hospital. The sepsis knowledge graph comprises of 1894 nodes and 2021 distinct relationships, encompassing nine entity concepts (diseases, symptoms, biomarkers, imaging examinations, etc) and 8 semantic relationships (complications, recommended medications, laboratory tests, etc). GPT-4.0 demonstrated superior performance in entity recognition and relationship extraction, achieving an F_1-score of 76.76 on a sepsis-specific dataset, outperforming other models such as Qwen2 (43.77) and Llama3 (48.39). On the CMeEE dataset, GPT-4.0 achieved an F_1-score of 65.42 using few-shot learning, surpassing traditional models such as BERT-CRF (62.11) and Med-BERT (60.66). Building upon this, we compiled a comprehensive sepsis knowledge graph, comprising of 1894 nodes and 2021 distinct relationships.

Conclusions: This study represents a pioneering effort in using LLMs, particularly GPT-4.0, to construct a comprehensive sepsis knowledge graph. The innovative application of prompt engineering, combined with the integration of multicenter real-world data, has significantly enhanced the efficiency and accuracy of knowledge graph construction. The resulting knowledge graph provides a robust framework for understanding sepsis, supporting clinical decision-making, and facilitating further research. The success of this approach underscores the potential of LLMs in medical research and sets a new benchmark for future studies in sepsis and other complex medical conditions.

KEYWORDS

sepsis; knowledge graph; large language models; prompt engineering; real-world; GPT-4.0

Introduction

Sepsis, a critical condition leading to septic shock and multiple organ dysfunction syndrome in patients, often arises from severe trauma, surgery, or infections [1]. Despite advancements in diagnostics, therapeutics, and patient monitoring, the incidence and mortality rates of sepsis remain alarmingly high, posing a global medical challenge. Annually, it affects over 49 million individuals worldwide, with approximately 11 million fatalities, and mortality rates fluctuate between 15% and 25% [2]. This highlights the necessity for comprehensive research into sepsis to enhance prevention and treatment methods. Recent studies have increasingly concentrated on understanding its pathogenesis [3], clinical presentations [4], and treatment approaches [5]. However, the complexity and variability of sepsis complicate the development of effective treatments and rehabilitation strategies. Furthermore, survivors often endure long-term effects like cognitive dysfunction [6], indicating a gap in our understanding of postsepsis syndrome.

Constructing a powerful database specifically for sepsis is paramount. This initiative will significantly strengthen support for clinical data mining and big data applications, enabling the aggregation and analysis of vast datasets. Such progress could lay the groundwork for pioneering research. Furthermore, developing a comprehensive knowledge graph [7] on sepsis is crucial, as it will serve as a bridge between the deep application of databases and a more profound understanding. By closely integrating the detailed data from the database with the associative analysis capabilities of the knowledge graph, we can more effectively unveil the complex mechanisms of sepsis, propelling deep research advancements in this field. In addition to the database, by integrating findings from related studies, clinical presentations, and treatment methods on sepsis, this knowledge graph could offer multidimensional and multilevel information. It aims to delve into the pathogenesis, clinical manifestations, and conventional treatment options for sepsis, providing a deeper insight into its complexities. This will serve as a scientific basis for formulating more effective preventive and treatment strategies, as well as providing clinicians with real-time and comprehensive reference materials to accurately assess patients' conditions and optimize treatment plans.

However, the relationship extraction step [8] in knowledge graph construction is a critical juncture, determining the accuracy and completeness of the relationships between entities. Currently, deep learning models based on natural language processing technology are commonly used for clinical text entity recognition and relationship extraction. This process relies on professional data labeling, neural network model design, and large-sample model training, making it a time-consuming and labor-intensive task. Recently, large language models (LLMs) such as GPT-4.0 [9] and LLaMA [10] have revolutionized the field of natural language processing, offering new insights to address this issue. These models possess the ability to be widely applied to various downstream tasks, such as named entity recognition (NER) [11] and relationship extraction [12]. Meanwhile, through the design and optimization of prompt engineering [13], large models' capability to handle complex task scenarios is enhanced and widely applied in the medical field [14]. Floridi and Chiriatti [15] evaluated multiple pretrained and fine-tuned large language models (LLMs) on their ability to extract adverse events from the Vaccine Adverse Event Reporting System (VAERS) notes. The fine-tuned adverse events LLM achieved an impressive average micro F_1-score of 0.704, demonstrating the potential of LLMs in natural language processing tasks. Hu et al [11] assessed ChatGPT's ability to perform zero-shot clinical NER as defined by the 2010 i2b2 challenge and compared it to models based on GPT-3 [15] and Bio-Clinical BERT (Bidirectional Encoder Representations from Transformers) [16]. The results revealed that while ChatGPT's zero-shot performance was not as strong as fine-tuned BERT clinical models, its F_1-score reached 0.628 under relaxed matching criteria, indicating reasonable performance. However, these studies also highlighted some limitations, such as errors from hallucinations (ie, generating inaccurate, meaningless, or contextually irrelevant outputs) [17] and insensitivity to negation words [18].

In this research, we aim to establish a multicenter sepsis database (MSD), providing a richer and more diverse dataset that is crucial for the in-depth analysis and understanding of sepsis. Using GPT4.0 for entity recognition and relation extraction, we aim to construct a comprehensive sepsis knowledge graph, using real-world databases supplemented by clinical guidelines and relevant public databases. This detailed knowledge graph is intended to be an exhaustive reference for clinicians, enhancing their comprehension and treatment approaches for sepsis. By the application of these advanced technologies, we strive to improve the construction quality and efficiency of the knowledge graph, providing strong support for sepsis research and clinical management.

Methods

Data Collection and Database Construction

The dataset originates from prominent tertiary hospitals in western China, including the West China Hospital of Sichuan University, Shangjin Hospital, and Tianfu Hospital. It consists of records from hospitalized patients diagnosed with sepsis between 2020 to 2023. The inclusion criteria for the dataset were patients whose discharge diagnoses prominently featured sepsis within the specified timeframe (2020-2023). For these patients, comprehensive data were collected, including baseline demographics, laboratory test results, and electronic medical records documenting admission and discharge details, among other pertinent information, as shown in Figure 1. The structure of the database is shown as an Entity Relationship Diagram (Figure S1, Multimedia Appendix 1). Before any EHR data is processed by the GPT-4 model, all personal identifiers, such as names, addresses, and patient IDs, are removed following standard deidentification protocols. This ensures that no identifiable information is included during the relationship extraction and entity recognition process.

Figure 1. Overview of the sepsis dataset from West China Hospital of Sichuan University, Shangjin Hospital, and Tianfu Hospital (2020-2023).

Sepsis Expert Consensus and Guidelines

Incorporating data from expert consensus statements and clinical guidelines on sepsis establishes a foundational understanding of best practices and current recommendations in the field. These authoritative sources significantly contribute to the development of a comprehensive knowledge base. The primary data source is PubMed, and our search query is as follows:

(sepsis[ti] and guideline[pt] and 2020/01/01:2023/12/01[pdat]) or (sepsis[ti] and review[pt] and 2020/01/01:2023/12/01[pdat])

This search is designed to retrieve all expert guidelines and literature reviews on sepsis published in the last 3 years, serving as a vital knowledge repository for subsequent relationship extraction. To automate the process of retrieving articles from PubMed, we used the Biopython library [19] which provides an efficient way to interact with the PubMed database. In addition, we integrated biomarker data from MetaSepsisBase [16], an open database for sepsis and the first sepsis biomarker knowledge database ever constructed. The database comprises biomedical information on 320 sepsis biomarkers, with 450 records sourced from PubMed and annotated through the NCBI Gene database [17] and HGNC database [18]. This initiative provides a solid knowledge foundation for the construction of a sepsis knowledge graph.

The Construction of Knowledge Graph

The construction process of the sepsis knowledge graph primarily uses an entity-based approach, involving key steps such as data preprocessing, analysis, entity construction [20], knowledge extraction [21], fusion [22], and storage. In contrast to traditional knowledge graph construction methods, this study leverages GPT-4.0 to extract knowledge and conduct initial data mining on raw data, enhancing the accuracy of the resulting knowledge graph.

Building the Entity of Knowledge Graph

The primary objective of entity construction [23] is to acquire, describe, and represent knowledge within a specific domain, fostering a shared understanding of the sepsis field. This involves identifying widely accepted terms, providing precise definitions, and establishing their interrelationships across different levels of formal patterns. In our research, the entity definitions and their interrelationships are presented in Tables 1 and 2.

XSL•FO
RenderX

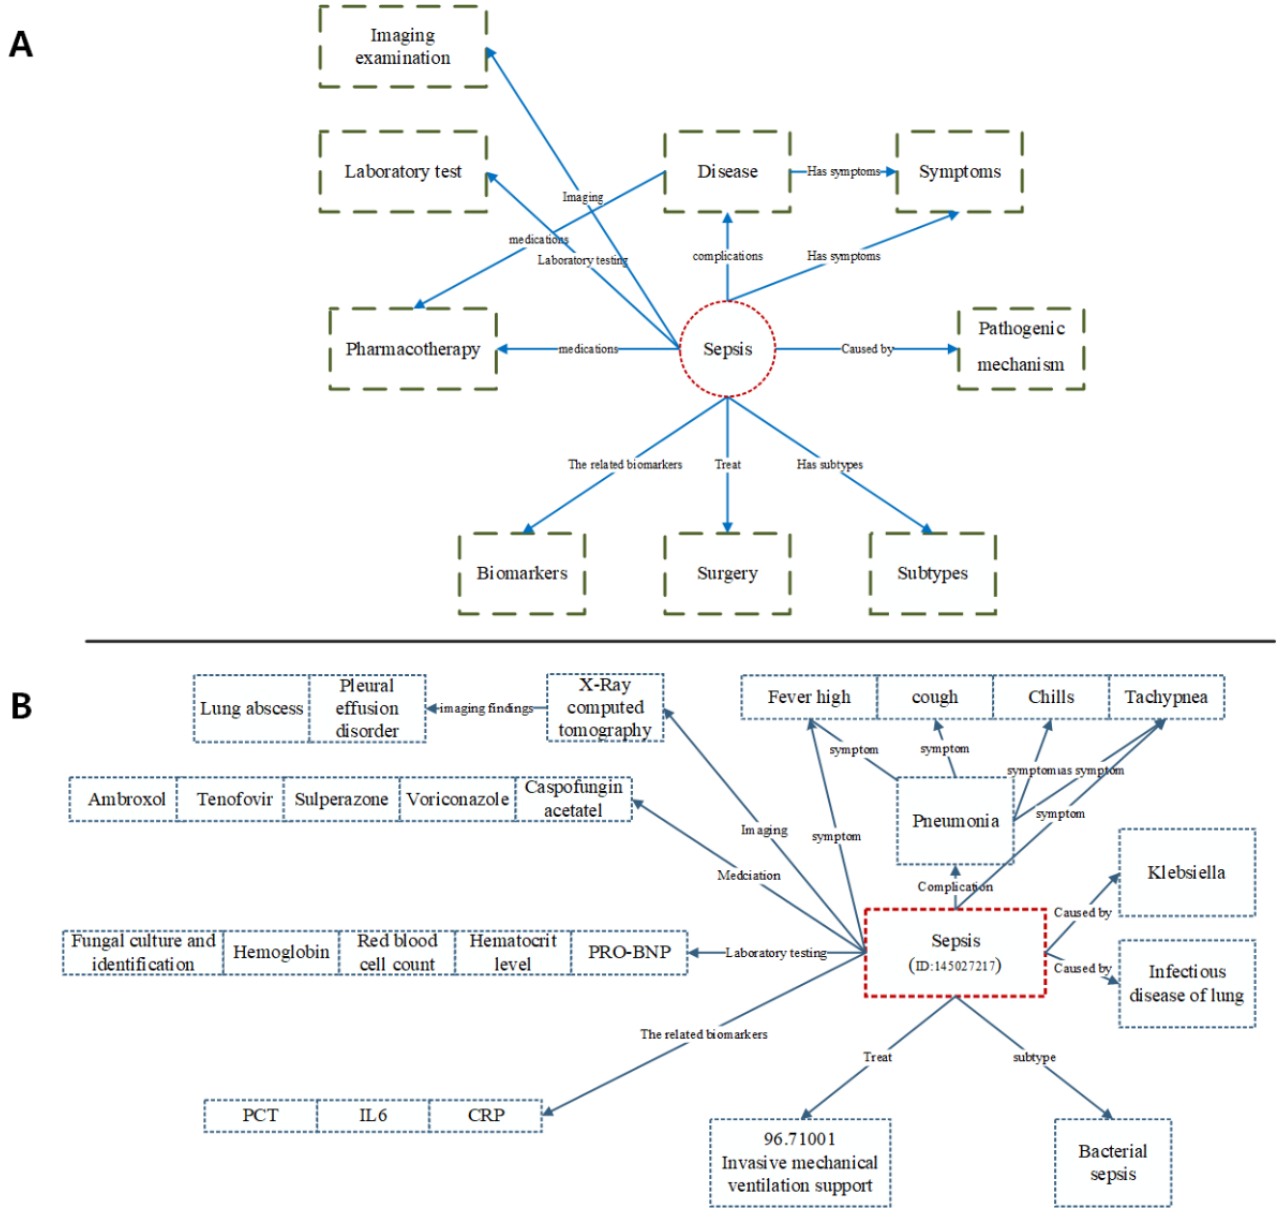
Table 1. Definitions of entity concepts in the sepsis knowledge graph based on multicenter clinical data (N=10,544) from 3 hospitals in Western China (2020-2023).

Number	Concept terms	Attributes	Meaning
1	Diseases	Canonical name, concept ID, TUIs[a], definition, reference, and synonyms	Disease is an atypical life process that occurs due to disrupted self-regulation in the body under specific conditions after exposure to pathogenic damage.
2	Symptoms	Canonical name, concept ID, TUIs, duration, severity, frequency, and temporal pattern	Subjective atypical sensations or objective pathological changes in a patient resulting from a series of physiological, metabolic, and morphological abnormalities during the disease process.
3	Imaging examination	Canonical name, concept ID, TUIs, type, body region, and imaging findings	Imaging examination is a technique used to visualize the interior of a body for clinical analysis and medical intervention.
4	Biomarkers	Canonical name, concept ID, TUIs, biomarker type, reference, synonyms, cut-off value, sensitivity, and specificity	Measurable substances in the body used to indicate physiological status, the presence of disease, or disease progression.
5	Laboratory test	Canonical name, concept ID, TUIs, normal range, unit, and measured value	Physical or chemical examinations conducted in a laboratory to determine the content, nature, concentration, quantity, and other characteristics of submitted substances.
6	Subtypes	Canonical name, concept ID, TUIs, definition, reference, and synonyms	Subdivisions within a category or group based on specific features or characteristics. For example, disease subtypes may indicate different pathological features or symptom presentations.
7	Pathogenic mechanism	Canonical name, concept ID, UIs[b], type, infection source, reference, biomarkers, and guidelines	Biological or biochemical processes leading to the occurrence of disease, including factors such as pathogen infection and genetic mutations.
8	Pharmacotherapy	Canonical name, concept ID, TUIs, medication name, drug class, dosage, duration of treatment, adverse effects, drug interactions, and formulations	Substances used for preventing, treating, and diagnosing diseases. In theory, drugs encompass chemical substances that can influence the physiological functions and cellular metabolic activities of the body's organs.
9	Surgery	Canonical name, concept ID, TUIs, anesthesia type, guidelines, complications, recovery time, and level	A procedure involving the use of instruments, performed by a surgeon or other specialized personnel, to enter the human body or other biological tissues. It involves the application of external force to eliminate pathology, alter structures, or implant foreign materials.

[a]TUI: Type Unique Identifier, representing the semantic category of a concept in UMLS..

[b]UI: Unique Identifier, used to uniquely distinguish a concept or term in UMLS..

Table 2. Definitions of semantic relations in sepsis data based on multicenter clinical data (N=10,544) from 3 hospitals in Western China (2020-2023).



Number	Concept terms	Meaning
1	Complications	Disease development may give rise to another disease or the occurrence of additional symptoms.
2	Has symptom	Describing the correlation between diseases and symptoms.
3	Recommended imaging examination	Recommended imaging examination for patients with sepsis.
4	The related biomarkers	Biomarkers associated with sepsis.
5	Treat	Surgical treatment modalities associated with sepsis.
6	Recommended laboratory tests	Routine laboratory tests associated with sepsis.
7	Caused by	The underlying factors contributing to the onset of sepsis.
8	Recommended medication	Pharmacological interventions in the treatment process of sepsis.

The construction methods of knowledge graph technology are typically categorized into two approaches: top-down and bottom-up [24]. The top-down approach involves defining a pattern layer based on logical relationships and hierarchical structures, followed by mapping data entities to this schema (as shown in Figure 2A). In contrast, the bottom-up approach focuses on extracting entities and attributes from diverse data sources for the data layer of the knowledge graph (as shown in Figure 2B). This process consolidates the extracted entities and attributes, optimizing the schema layer of the knowledge graph for iterative updates to the entity model. The top-down approach ensures that domain entities are enriched with professional

XSL•FO
RenderX

knowledge and accuracy, while the bottom-up approach enhances their practicality. Given the unique characteristics of sepsis, our research adopts both approaches to construct the sepsis knowledge graph. This dual approach aims to improve the educational value, accuracy, and practical utility of the knowledge graph.

Figure 2. Construction of the sepsis knowledge graph using top-down and bottom-up approaches. (A) Pattern layer: in the top-down approach, a structured pattern layer is defined based on logical relationships and hierarchical structures. (B) Data Layer: the bottom-up approach extracts entities and attributes from diverse data sources. CRP: C-reactive protein; IL: interleukin; PCT: Procalcitonin; PRO-BNP: Pro-B-Type Natriuretic Peptide (Pro-Brain Natriuretic Peptide).

Prompt Engineering and Model Evaluation

In this study, we used the approach of LLMs prompt engineering for knowledge extraction. By harnessing the powerful language understanding and pattern recognition capabilities of GPT-4.0, we guided the model to generate sepsis-specific prompts, extracting relevant information. The advantage of this approach lies in its ability to handle complex structures and contexts in natural language without manually specifying intricate rules or patterns.

Compared with traditional knowledge extraction methods, LLM-based approaches offer several advantages. First, LLMs can autonomously learn the grammar and semantic rules of language, making them more adaptable to the intricate expressions within this domain [24]. Second, due to pretraining on large-scale corpora, LLMs acquire rich background knowledge, enhancing their contextual awareness when understanding texts in a specific domain [25]. In addition, LLMs excel at handling ambiguous and unclear language expressions, improving the robustness of knowledge extraction [26].

To enhance the effectiveness of our approach, we introduced zero-shot [27] and few-shot [28] learning techniques, as shown in Textbox 1. By leveraging few-shot learning within LLMs, we enable the model to quickly adapt to new sepsis-related texts even with limited examples, allowing the model to flexibly adjust to the specific context and linguistic expressions of a

XSL•FO
RenderX

specialized domain. This adds flexibility and personalization to the knowledge extraction process, further improving the model's performance and adaptability. To validate the effectiveness of prompt engineering with GPT-4.0, we selected the CMeEE (Chinese Medical Entity Extraction) public dataset [29] for the NER task (as shown in Figure 3), establishing a baseline performance by comparing it with traditional models such as Med-BERT [30] and LSTM (long short-term memory) [31]. This comparison demonstrates GPT-4.0's adaptability and flexibility in processing complex medical texts, highlighting the potential of large language models in knowledge graph construction. In addition, to evaluate GPT-4.0's recognition performance in our study, we created a dataset focused on sepsis. Due to the high cost of manual annotation, a medical expert labeled named entities in the electronic medical records (EMRs) of 61 randomly selected patients, with sample annotations provided in the Multimedia Appendix 1. We further assessed GPT-4.0's performance in natural language processing tasks by comparing it with other large models (Qwen2 [Alibaba Cloud], Llama3 [Meta AI], and ChatGPT 3.5 [OpenAI]). The models were evaluated using the F_1-score, which reflects overall performance by calculating true positives, false positives, and false negatives, summarizing both precision and recall. F_1-score, the harmonic mean of precision and recall, provides a comprehensive measure of model effectiveness.

Textbox 1. Prompt design for sepsis relation extraction in zero-shot and few-shot learning scenarios.

Prompt design

Suppose you are an entity-relationship triple extraction model. I'll give you a list of head entity types: subject types, list of tail entity types: object types, list of relations: relations. Give you a sentence, please extract the subject and object in the sentence based on these three lists and form a triplet in the form of (subject, relation, object).

relations: ['Clinical Presentation ', 'Surgical treatment', 'biomarker', 'subclass', 'pathogenesis', 'laboratory testing', 'Imaging examination', 'Complications', 'Medication']

The given sentence is \n {triple list}

Examples(few-shot)

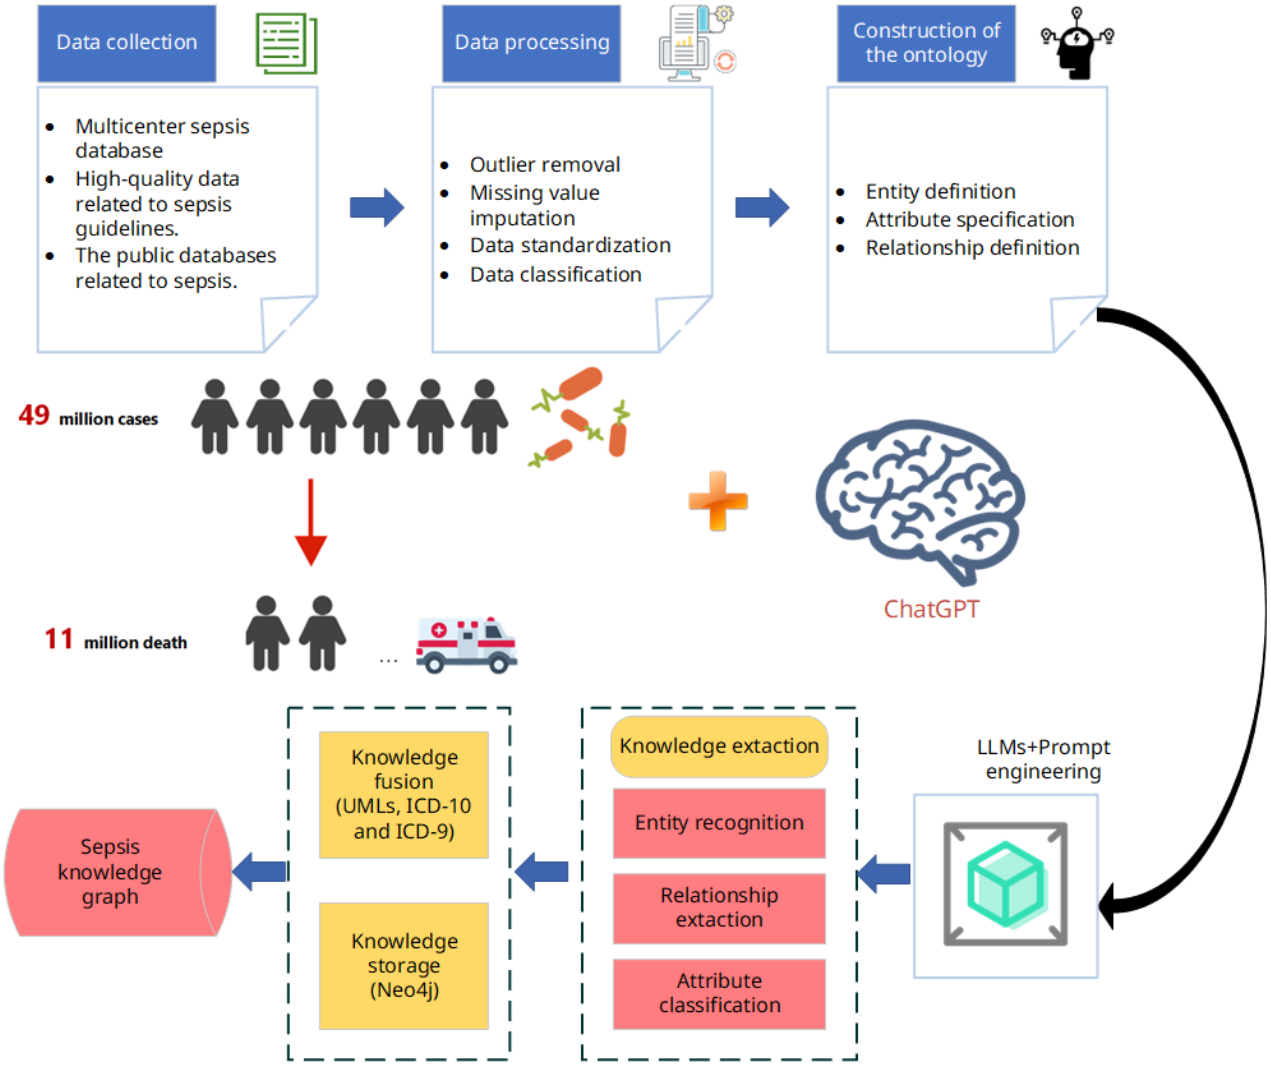
Knowledge Fusion



In our research, we used the entity-linker module from scispaCy [32], which incorporates the Unified Medical Language System (UMLS) [33] terminology standards to construct a comprehensive knowledge base. UMLS facilitated the alignment of terms, such as mapping “Hypertension” to the standardized concept “Hypertensive disease (C0020538).” To ensure effective text matching, we standardized and cleaned entity names across different data sources. This process included unifying letter case, removing punctuation, and handling abbreviations, allowing us to standardize terms such as “Heart Failure” and “HF” to a consistent terminology. Following this initial processing, we used text similarity algorithms for entity matching, using algorithms based on word embeddings and Jaccard similarity to calculate similarity scores between entity names. During the alignment process, we established a similarity threshold of 0.85, ensuring that only highly similar entities were recognized as corresponding. For entities with similarity values below this threshold, we retained their original values and used manual review to address any potential ambiguities, thereby ensuring the precision and credibility of the final alignment results. This meticulously designed workflow not only enhances the efficiency of entity alignment but also safeguards the accuracy and reliability of our research outcomes.

Platform Implementation

MSD performed data management using MySQL software (version 5.7; Oracle Corp). The web pages were developed with Bootstrap 4.0 (The Bootstrap Team) and used the Flask framework. Several JavaScript plugins, such as Datatable (version 1.10.10; SpryMedia Ltd) and ECharts (version 5.0; Baidu), were applied for creating data tables and visualizations. We used the Neo4j graph database [34] for knowledge storage. The underlying storage principles of this graph database involve the use of nodes, edges, and properties to store graph data. Neo4j is currently recognized as one of the most popular high-performance NoSQL graph databases [35], known for its high availability, stability, scalability, and robust intuitiveness. In this research, open-source Python libraries (such as py2neo [36] were used in conjunction with OpenAI interfaces to accomplish knowledge extraction and to add or modify relationships and nodes. Specifically, we used the GPT-4-turbo model accessed via the application programming interface for our artificial intelligence model, and for Scispacy, we used the en_core_sci_sm model. The overall research and construction process is shown in Figure 4.

XSL•FO
RenderX

Figure 4. Framework of the multicenter sepsis knowledge graph construction study (n=10,544 patients with sepsis) integrating GPT-4 and Neo4j technologies. The flow diagram shows retrospective data collection from 3 tertiary hospitals in Western China (West China Hospital, Shangjin Hospital, and Tianfu Hospital; 2020-2023), multimodal data processing through LLM-driven entity recognition, and graph database implementation. LLM: large language model; MSD: multicenter sepsis database.

Ethical Considerations

This study was approved by the Medical Ethics Committee of West China Hospital, Sichuan University (approval number 2024-126). The research involved a secondary analysis of deidentified patient data, which was conducted in accordance with the original informed consent obtained during data collection, allowing for subsequent analyses without requiring additional consent. To ensure participant privacy and confidentiality, all personally identifiable information was removed before analysis. No financial compensation was provided to participants for the use of their data in this study. Furthermore, this manuscript does not contain any images that could potentially identify individuals. The relevant consent forms have been submitted as part of the supplementary materials.

Results

In this study, we established an MSD [37] using real-world data from 3 major hospitals in Western China. The database spans the period from 2020 to 2023, covering a total of 10,544 patients diagnosed with sepsis. Each hospital contributed a significant number of patient records, with 8497 records from West China Hospital, 690 from Shangjin Hospital, and 357 from Tianfu Hospital. The MSD includes comprehensive data points such as baseline demographics, laboratory test results, EMRs, and detailed admission and discharge notes. This large-scale, multicenter sepsis dataset provides a solid foundation for constructing a highly detailed and clinically relevant sepsis knowledge graph.

Furthermore, using GPT-4.0, we conducted entity recognition and relationship extraction based on the MSD, expert consensus, and open data sources. Subsequently, we achieved knowledge integration by benchmarking against the UMLS. As a result, we present the definitions of key entities and their semantic relationships in Tables 1 and 2. Table 1 outlines key entities, such as diseases, symptoms, biomarkers, and imaging examinations, which are crucial for understanding the clinical characteristics of sepsis. For instance, the “Symptoms” entity captures the subjective and objective signs experienced by patients, while “Biomarkers” represent measurable substances that indicate the presence or progression of disease. The

XSL•FO
RenderX

relationships between these entities, as defined in Table 2, provide insights into the complex dynamics of sepsis. Relationships such as “Has symptom” and “Complications” show how specific symptoms correlate with diseases and how disease progression may lead to additional health issues. We successfully constructed a comprehensive knowledge graph for sepsis, consisting of 1894 nodes and 2021 relationships. By integrating the definitions of entities and their interrelationships, our study aims to enhance the understanding of sepsis and supports informed clinical decision-making, ultimately contributing to improved patient outcomes. In addition, we have established relevant examples of sepsis ontology, as shown in Figure S7 in Multimedia Appendix 1.

Then, we introduced zero-shot and few-shot methods to explore the model’s performance in handling unseen or infrequent entities based on CMeEE, comparing them with conventional models such as BERT-CRF [34], BERT-wwm [35], Lattice-LSTM [36], and Med-BERT [30]. The results indicate that the few-shot approach using GPT-4 outperformed traditional models, achieving an F_1-score of 65.42, which demonstrates its effectiveness in adapting to new entity types with limited annotated data. In addition, we constructed a Sepsis dataset, which consists of clinical records annotated by a medical expert, to further evaluate the models in a real-world health care context. Comparing performance across models, GPT-4 achieved a notable F_1-score of 76.76, significantly surpassing other LLMs such as Qwen2 and Llama3, which indicates its strong capability in recognizing critical medical entities in this specialized domain. Tables 3 and 4 present the performance of different models on the CMeEE dataset and the Sepsis dataset.

Table 3. Zero-shot and few-shot learning performance comparison of GPT-4 versus BERT and Lattice-LSTM models on Chinese medical entity extraction dataset.

Model	CMeEE[a]		
	Precision	Recall	F_1-score
BERT[b]-base	63.08	64.08	62.11
BERT-wwm	61.5	61.29	61.72
Lattice-LSTM[c]	46.34	43.60	49.44
Med-BERT	53.33	47.58	60.66

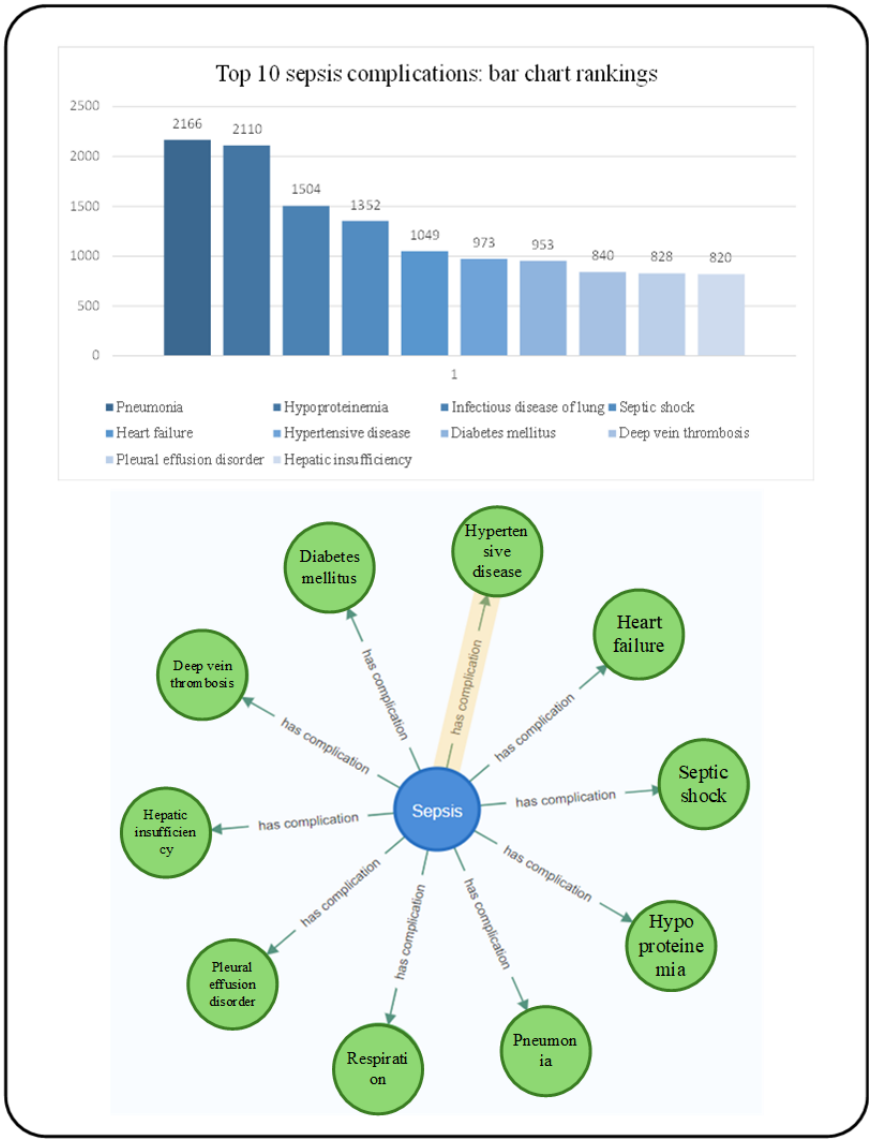
[b]BERT: Bidirectional Encoder Representations from Transformers.

[c]LSTM: long short-term memory.

Table 4. Performance comparison of GPT-4, Qwen2-72B, Llama3-70B, and GPT-3.5 models on the sepsis dataset.



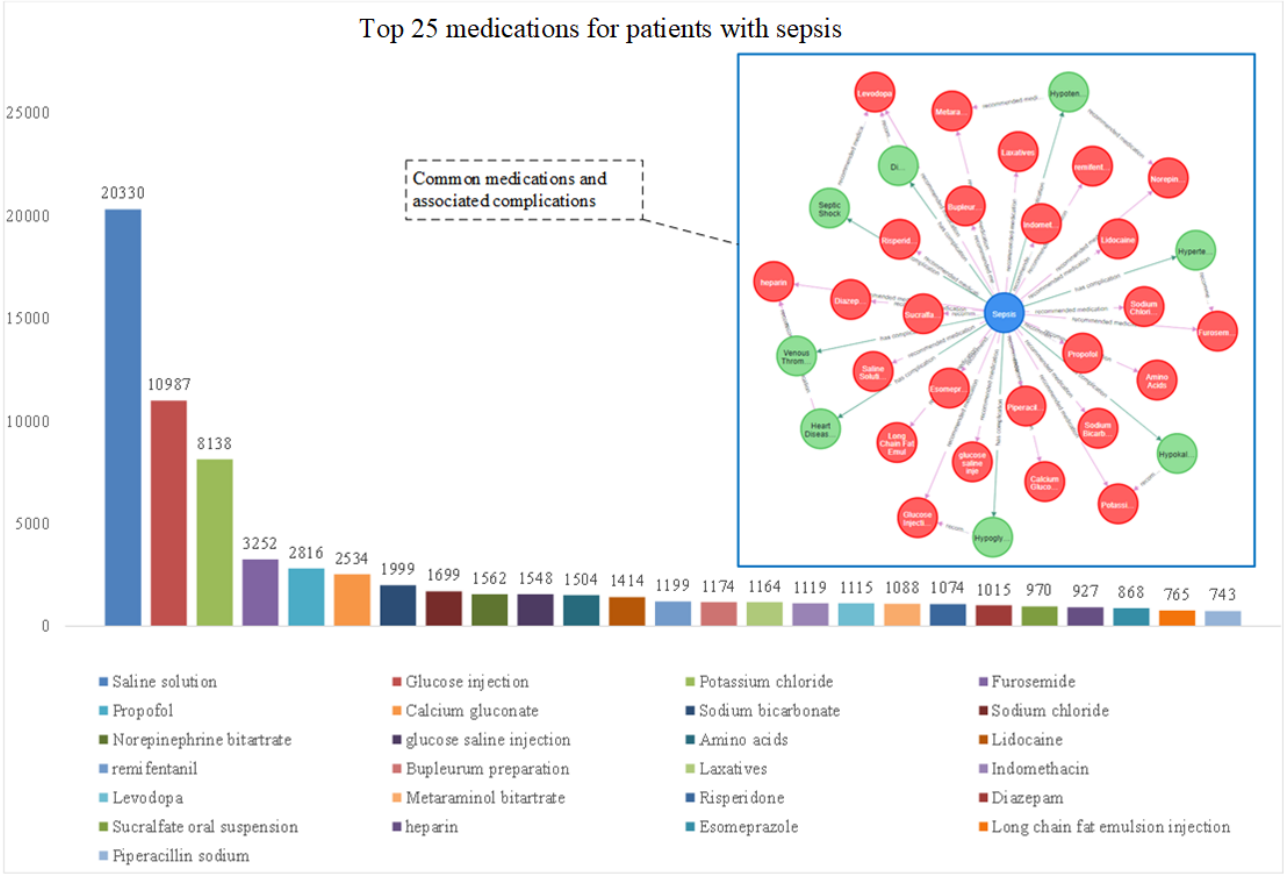
Model	Sepsis dataset		
	Precision	Recall	F_1-score
Qwen2-72B	44.73	42.85	43.77
Llama3-70B	49.40	47.43	48.39
GPT-3.5	56.63	54.48	55.53
GPT-4 and Zero shot	72.12	70.48	71.29
GPT-4 and Few shot	77.73	75.81	76.76

Major Complication of Sepsis

The investigation of complications associated with sepsis holds paramount significance in clinical research. In our study, we identified 203 complications-related nodes from the collected cases and literature (Figure 5). We queried the relationship between sepsis and complications, and through the query MATCH ()-[r:`has complication`]->() RETURN r ORDER BY r.weight DESC LIMIT 10.

XSL•FO
RenderX

Figure 5. Top 10 sepsis complications identified through weighted relationship analysis in the multicenter sepsis database: Bar graph displays the prevalence of pneumonia (32.1%), hypoproteinemia (28.5%), septic shock (25.9%), and so on.



Sepsis Medication Statistics

Sepsis is a severe systemic inflammatory response frequently triggered by infection. In the knowledge graph, entering the following code reveals the relationships between the most commonly used medications for sepsis and their associated complications (Figure 6). The following query was used: MATCH p=(n:medication)-[r:`recommended medication`]-() RETURN p order by r.weight ASC limit 25.

XSL•FO
RenderX

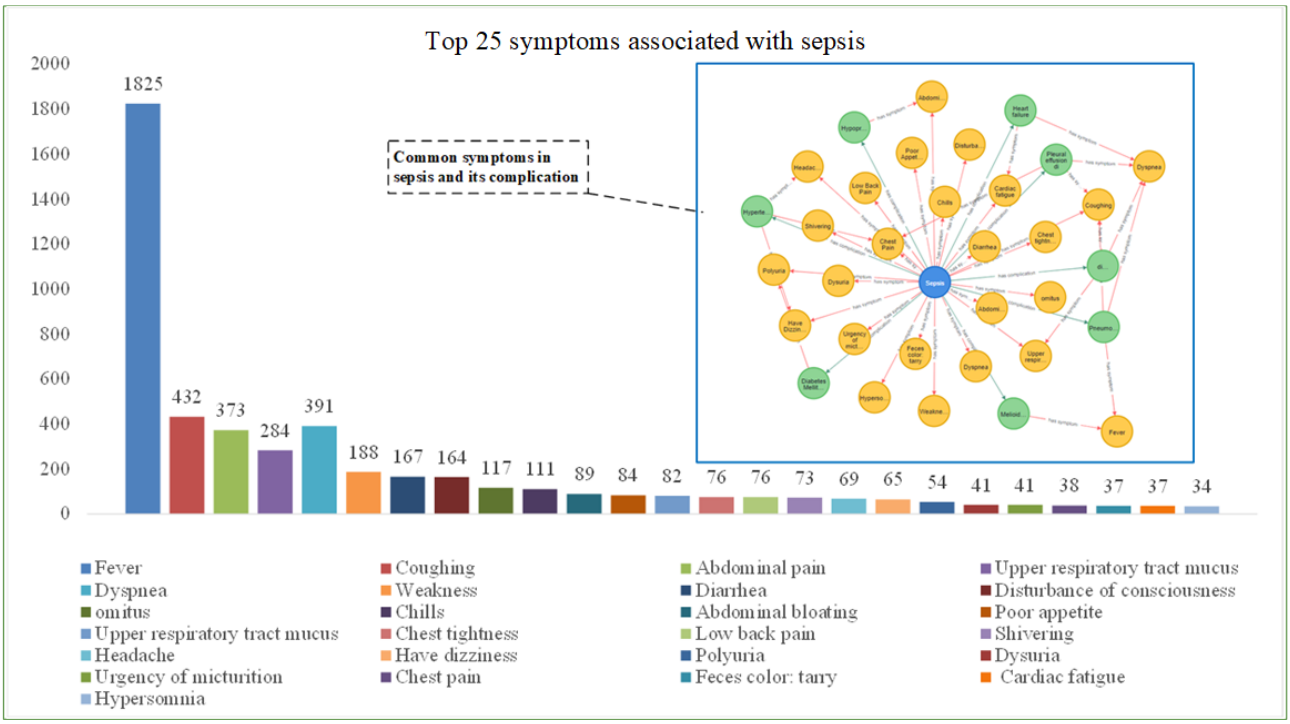


Figure 6. Pharmacological intervention patterns in sepsis management: a chord diagram depicting medication-complication relationships (physiological saline, glucose infusion, etc).

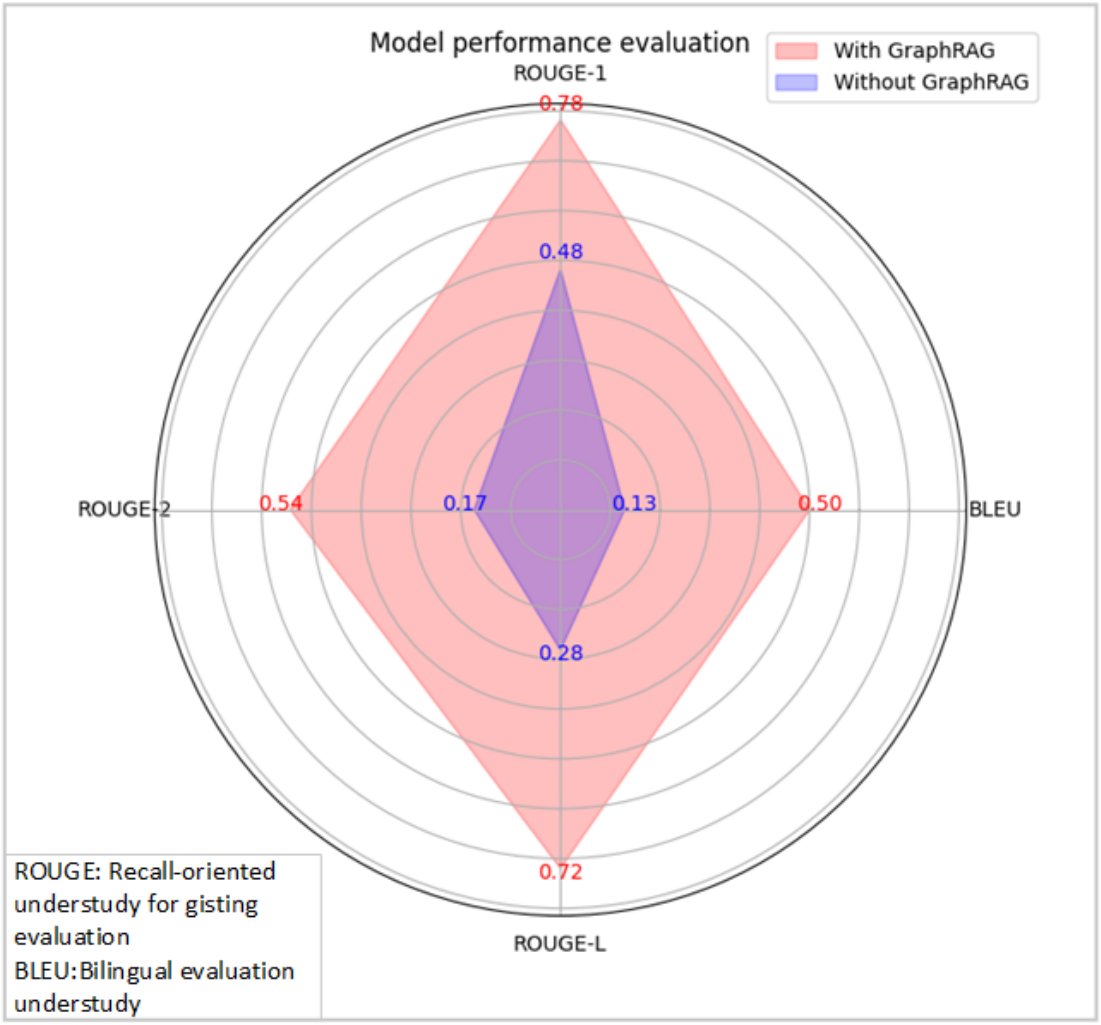
Sepsis Symptom Statistics

Sepsis is defined as a comprehensive systemic inflammatory response, and its multifaceted nature is revealed through the statistical analysis of the top 25 symptoms observed in patients (Figure 7). Relevant queries were conducted in the knowledge graph, and the corresponding code is MATCH p=()-[r:`has symptom`]->() RETURN p order by r.weight asc.

Figure 7. Knowledge graph representation of common symptoms of sepsis and their top 10 frequency.



XSL•FO
RenderX

Clinical Applications

Based on the results from the sepsis knowledge graph, we used GraphRAG [38] technology to assist large models in generating more precise decision support for clinicians. In comparison with traditional Retrieval Augmented Generation (RAG) technology, GraphRAG excels in handling complex relationships and multistep reasoning, providing more comprehensive and accurate answers, which is particularly crucial for the diagnosis and treatment of complex diseases like sepsis, as clinical decisions frequently involve multiple variables and potential interactions. Furthermore, GraphRAG enhances efficiency in information retrieval and customized summary generation, enabling clinicians to quickly access relevant information and recommendations related to patient conditions. This improvement in efficiency significantly bolsters the accuracy of clinical decisions, allowing physicians to make more informed judgments in complex clinical environments. With advancements in computational power, the integration of the sepsis knowledge graph and large models can consolidate data from electronic health records, laboratory tests, imaging, and critical care, enabling real-time analysis of patients' clinical features and scoring systems (such as SOFA and APACHE II) to assist doctors in quickly identifying patients with sepsis across various risk levels and facilitating early warning systems. In the clinical decision-making process, the combination of the knowledge graph, RAG, and prompt engineering strategies offers treatment recommendations grounded in high-quality evidence, thereby enhancing the scientific and effective nature of decision-making. Currently, our clinical team has provided relevant case studies, showcased in supplementary materials, which include a comparison of GraphRAG technology before and after its implementation based on GPT-4. By using clinical gold standards and using BLEU [39], ROUGE-1, ROUGE-2, and ROUGE-L metrics [40], we compared the model's generated results, with BLEU primarily assessing the overlap of vocabulary between the generated text and reference text, reflecting the accuracy of the generated content, while ROUGE focuses on recall, emphasizing the comprehensiveness of the generated text in capturing reference content. Through a comprehensive analysis of these metrics, as shown in Figure 8, we further validated the effectiveness and advantages of GraphRAG in practical applications.

Figure 8. Comparative performance analysis of GraphRAG technology before and after implementation in sepsis clinical decision support.

Discussion

Principal Findings

This study aimed to develop a framework for constructing a sepsis knowledge graph using large LLMs, leveraging real-world, multicenter clinical data. The core objective was to explore the feasibility and effectiveness of using LLM technologies, particularly GPT-4.0, to construct a comprehensive, domain-specific knowledge graph, focused on sepsis. Our findings indicate that GPT-4.0, through careful prompt engineering, is capable of accurately extracting entities and relationships from clinical data, outperforming traditional models such as BERT and LSTM. In particular, GPT-4.0 demonstrated the best few-shot performance on the CMeEE dataset, achieving an F_1-score of 65.42, and outperformed other open-source models on the Sepsis dataset with an F_1-score of 76.76. These results underscore the potential of LLMs for building specialized knowledge graphs in fields with limited data annotations, highlighting the advantages of the adaptability of LLMs across tasks and domains without the need for extensive model retraining.

The successful construction of a sepsis-specific knowledge graph marks a significant advancement in both knowledge extraction and clinical decision support. By using GPT-4.0's pretrained capabilities, we were able to generate meaningful insights from small datasets, which typically require substantial domain-specific training. These findings align with other studies that have used large models such as GPT-4.0, GPT-3.5, LlaMA [10], and SOLAR [41], for biomedical relationship extraction. In particular, GPT-4.0 has shown superior performance in extracting biomedical relationships from semistructured data, achieving F_1-scores above 0.881 [42], which further confirms its utility for creating knowledge graphs in health care. Our results also demonstrate that GPT-4.0 excels at quickly adapting to specialized domains, such as sepsis, and constructing medically relevant knowledge graphs without the extensive preprocessing and data annotation typically required in traditional machine learning methods. To contextualize these technical advancements within clinical applications, we conducted comparative analyses against established biomedical knowledge infrastructures, including BIOS [17], PrimeKG [7], and UMLS. This benchmarking reveals several critical advantages of our sepsis-focused approach. While BIOS prioritizes comprehensive ontology coverage through generalized semantic relationships [43], our model achieves superior clinical relevance through context-aware embeddings that preserve disease-specific pathophysiological hierarchies. In addition, while PrimeKG advances precision medicine via molecular-level drug-target interactions, our framework integrates multimodal clinical data streams, including 178 sepsis-associated biomarkers with temporal granularity, enabling dynamic risk stratification unavailable in existing resources. Furthermore, through systematic alignment with UMLS terminological standards, our implementation ensures interoperability without compromising domain specificity, addressing a critical limitation of conventional clinical knowledge graphs, which either sacrifice granularity for standardization or vice versa.

However, the sepsis knowledge graph we have constructed provides not only valuable insights into clinical practices but also enhances understanding of the complex pathophysiology of sepsis. The graph includes key complications such as pneumonia, hypoproteinemia, septic shock, and heart failure, as illustrated in Figure 5. By capturing these critical components, the graph aids in risk stratification and prognostication, ultimately improving treatment efficiency. In addition, our knowledge graph extends to therapeutic optimization. As shown in Figure 6, the system quantifies dynamic relationships between physiological saline administration, glucose metabolism correction, and electrolyte rebalancing interventions [41-43]. Machine learning modules further enable predictive modeling of antimicrobial efficacy based on pathogen susceptibility patterns and pharmacokinetic parameters [44,45], and simultaneously tracking analgesia requirements through nociception biomarkers [46]. This integrative approach allows for the real-time adjustment of therapeutic regimens in response to evolving inflammatory markers and organ dysfunction indicators. Our visualization platform also incorporates comprehensive symptom analytics, as shown in Figure 7. The graph's temporal mapping functionality reveals progression trajectories from initial respiratory manifestations (eg, tachypnea, bronchial hypersecretion [47]) to subsequent multiorgan involvement, including gastrointestinal dysmotility [48], cardiovascular compromise [49], urinary symptoms [50], and neurological deterioration [51]. By correlating symptom clusters with biomarker profiles and treatment responses, the system enables early detection of sepsis-induced organ failure and provides decision support for personalized intervention strategies. This systematic integration of multimodal clinical data ultimately fosters a precision medicine paradigm in sepsis management, bridging pathophysiological insights with optimized therapeutic execution.

While the results are promising, we acknowledge several limitations in this study. Although GPT-4.0 demonstrated impressive entity recognition and relationship extraction capabilities, it occasionally produced erroneous outputs. For instance, the model recommended irrelevant laboratory tests (eg, "Blood cholesterol test") for sepsis and misattributed causative factors, such as "Sepsis caused by exercise." In addition, GPT-4.0 struggled with the nuanced semantics of traditional Chinese medicine terms, such as "Yin-Yang imbalance" and "Qi Deficiency," leading to misinterpretations. These errors are significant as they could affect downstream clinical applications, such as diagnostic accuracy and therapeutic decision-making. However, the inherent limitations of GPT-4.0 in handling specialized medical terminologies and subtle relationships underscore the importance of a robust manual review process to ensure the accuracy of the knowledge graph. We have implemented such a review process to mitigate errors and maintain data integrity; however, further refinement of the model is necessary to reduce reliance on human intervention. In addition to these technical limitations, the use of GPT-4.0 in health care also raises important privacy and security concerns [52]. As noted, our study implemented stringent measures to

XSL•FO
RenderX

protect patient data, including the elimination of personally identifiable information and adherence to relevant privacy regulations. Despite these precautions, the use of commercial models like GPT-4.0 poses risks related to data leakage and the potential exposure of sensitive patient information [53].

In future research, to ensure data security, we plan to deploy localized models, such as Llama 3.1 and Qwen 2, in secure environments, ensuring that all data processing activities are contained within controlled systems. By doing so, we aim to enhance data privacy and reduce the risk of data breaches, ensuring that the integrity of the knowledge graph remains intact while safeguarding patient confidentiality. Furthermore, we plan to further optimize the model's accuracy and contextual understanding by incorporating advanced models such as Gemini [54] and Claude [55], which may provide more precise and contextually accurate results. We also aim to expand our dataset to include additional clinical and traditional Chinese medicine-related data to further enhance the robustness and adaptability of the knowledge graph. Fine-tuning techniques, such as Low-rank adaptation [56] and p-tuning [57], will be explored to improve both model precision and efficiency, ensuring that the knowledge graph captures a broader range of medical nuances. Furthermore, we will experiment with alternative prompt designs, including converting entity recognition tasks into classification tasks [58] or referencing the Teler taxonomy [59], which could improve the model's ability to handle complex medical relationships more effectively. As part of this effort, we will also generate more gold standard data to compare the impact of various prompt strategies on knowledge graph accuracy.

In summary, this study highlights the potential of LLM-driven approaches, particularly GPT-4.0, in constructing accurate and effective medical knowledge graphs, even in data-scarce environments. The sepsis knowledge graph we developed not only enhances the understanding of sepsis but also illustrates the broader applicability of LLM-driven methods in creating domain-specific knowledge graphs across various medical fields. As large models like GPT-4.0 continue to evolve, their ability to process and interpret complex medical data will revolutionize how health care professionals access, interpret, and apply medical knowledge. The scalability and adaptability of this approach indicate its potential for widespread use in a variety of diseases, laying the foundation for personalized and precision medicine in clinical practice. In addition, the interactive and visual nature of the knowledge graph increases its practical utility, providing clinicians with a dynamic tool for both research and everyday decision-making.

Conclusions

The successful establishment of the MSD, leveraging real-world data and the innovative application of LLMs like GPT-4.0, represents a significant leap forward in the understanding and management of sepsis. The use of prompt engineering to build a comprehensive sepsis knowledge graph not only showcases the potential of LLM technologies in medical research but also highlights their capacity for significant generalization and adaptation. Our findings, especially the enhanced performance of the few-shot model in entity identification and relationship understanding, underscore the efficiency and cost-effectiveness of using LLMs in the rapid development of specialized databases and knowledge graphs. This pioneering approach sets a new benchmark for future research and database development in the field of sepsis and potentially other medical domains.

Acknowledgments

The authors would like to thank Dr Rongrong Wu for providing consultation on figure drawings. We are also grateful to the staff in our research groups who contributed to the study through their valuable contributions and discussions. This work was supported by the National Natural Science Foundation of China (grants 32200545 and 32270690), the 1·3·5 Project for Disciplines of Excellence, West China Hospital, Sichuan University (ZYGD23012 and ZYAI24044), Chengdu Medical Research Project (2024269) and was funded by the EU and the Xunta de Galicia (Spain; grant ED431C2022/46 for Competitive Reference Groups; GRC). It was also supported by CITIC-UDC and INIBIC.

Data Availability

To ensure data security, the database currently does not support direct downloading on the website. Researchers in need can contact Professor Bairong Shen, head of the Disease Systems Genetics Research Institute at West China Hospital, by email at bairong.shen@scu.edu.cn

Authors' Contributions

HY conceptualized and designed the study, performed the research, delivered the model analysis, analyzed the data, wrote the manuscript; CZ and JL delivered the data analysis and clinical analysis. BS and APS conceptualized and designed the study.

Abstract

Background: Electronic health records (EHRs) facilitate the accessibility and sharing of patient data among various health care providers, contributing to more coordinated and efficient care.

Objective: This study aimed to summarize the evolution of secondary use of EHRs and their interoperability in medical research over the past 25 years.

Methods: We conducted an extensive literature search in the PubMed, Scopus, and Web of Science databases using the keywords *Electronic health record* and *Electronic medical record* in the title or abstract and *Medical research* in all fields from 2000 to 2024. Specific terms were applied to different time periods.

Results: The review yielded 2212 studies, all of which were then screened and processed in a structured manner. Of these 2212 studies, 2102 (93.03%) were included in the review analysis, of which 1079 (51.33%) studies were from 2000 to 2009, 582 (27.69%) were from 2010 to 2019, 251 (11.94%) were from 2020 to 2023, and 190 (9.04%) were from 2024.

Conclusions: The evolution of EHRs marks an important milestone in health care's journey toward integrating technology and medicine. From early documentation practices to the sophisticated use of artificial intelligence and big data analytics today, EHRs have become central to improving patient care, enhancing public health surveillance, and advancing medical research.

KEYWORDS

electronic health record; electronic medical record; medical research; interoperability; eHealth; systematic review; real-world evidence; artificial intelligence

Introduction

Tracing Back to History

The practice of documenting patient information dates back approximately 3000 years, when early humans created some of the first known medical records by inscribing case histories on materials such as papyrus, clay tablets, animal bones, and other surfaces [1-3]. These records often included symptoms, diagnoses, and treatments. The health care delivery system developed with a long history and became increasingly complex. During the time of classical medicine, health care providers frequently gathered and systematized medical knowledge, creating standardized textbooks, which were often recorded by case series rather than individual patients [4]. In the 19th century, health care providers began keeping detailed paper records. These were used to track patients' medical histories, nursing information, treatments, and outcomes. Hospitals and

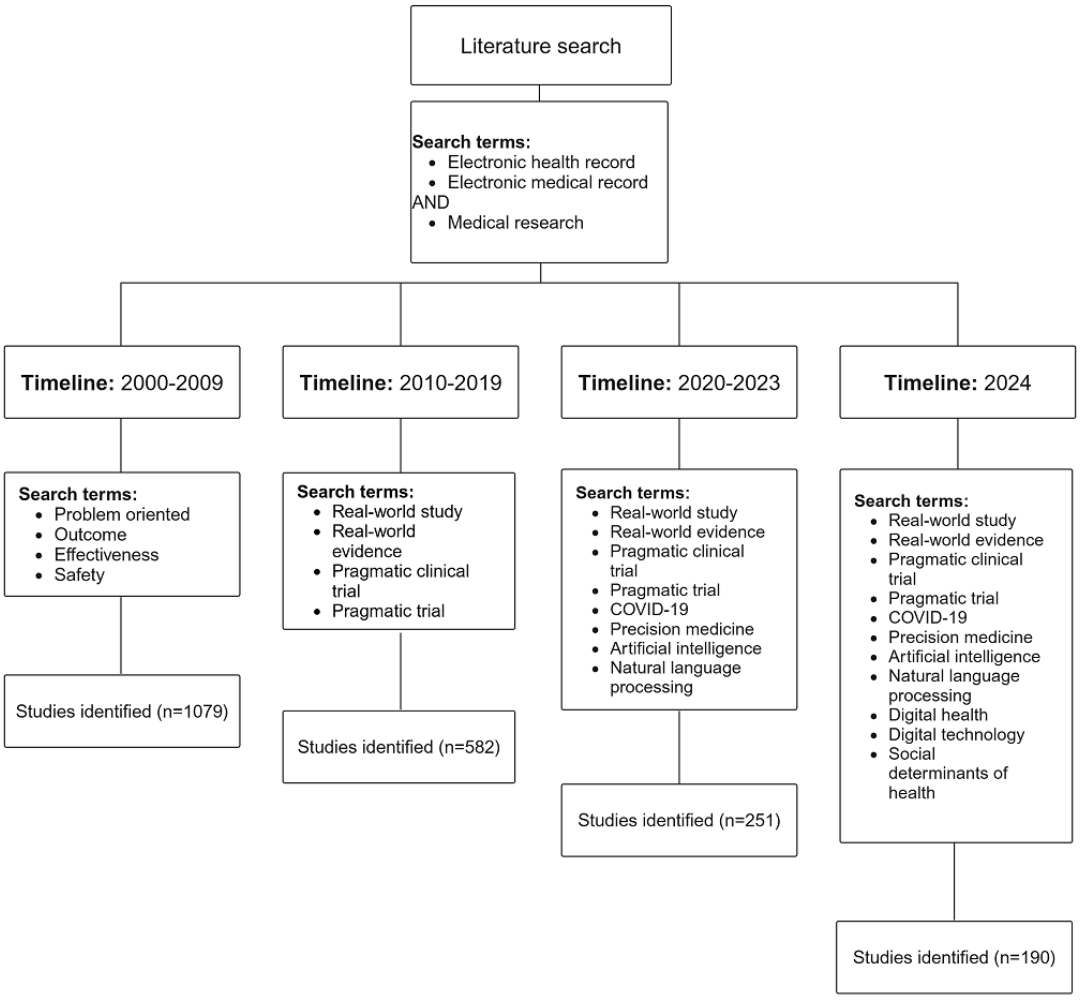
XSL•FO
RenderX

clinics maintained handwritten notes, which were stored in file systems [5-8]. With the explosion of electronic technologies boosted in the 20th century, hospitals began using such technologies to store records, reducing physical storage space and improving record retrieval efficiency. Computerization is one of the revolutionary technologies. The concept of electronic health records (EHRs) originated in the 1960s [9]. It aimed to improve the storage, retrieval, and management of patient information. Health care professionals started to address clinical challenges and steer treatment decisions by using data from these systems. Later, the 1990s brought about efforts to standardize EHR systems and the introduction of the internet, which significantly influenced EHR development. The 2010s witnessed widespread adoption of EHRs, driven by government incentives and the recognition of their potential to improve health care quality, safety, and efficiency [10-13]. Now, in the 2020s, the use of EHRs has been boosted with the development of advanced technologies in health care.

Objectives

In the past 25 years, the scope of EHRs varied significantly across the globe. Initially, many EHR systems were developed primarily as billing tools and were not intended to support clinical workflows. However, over time, their functionality expanded to optimize diagnosis and patient care, thereby enhancing their utility and relevance for clinical research. This evolution has transformed EHRs into a valuable resource not only for managing health care delivery but also for facilitating data-driven research efforts. For the 25th anniversary of the *Journal of Medical Internet Research*, this review focused on the evolution of secondary use of EHRs and their interoperability in medical research over the past 25 years. For researchers using EHR data in medical studies, we explored the advancements in EHR technology, emphasizing how they have facilitated better management and understanding of diseases through comprehensive data collection and analysis. In addition, this review highlighted the importance of these records in epidemiological studies, pragmatic clinical trials (PCTs), and health economic studies, particularly in providing a more accurate representation of clinical practices and patient populations.

Methods



Literature Review

We focused on the advancements in EHR technology and the application and significance of these records in medical research across 3 distinct periods. Therefore, we conducted an extensive literature search in the PubMed, Scopus, and Web of Science databases, which provides ideal coverage of the publications of interest. We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (Multimedia Appendix 1).

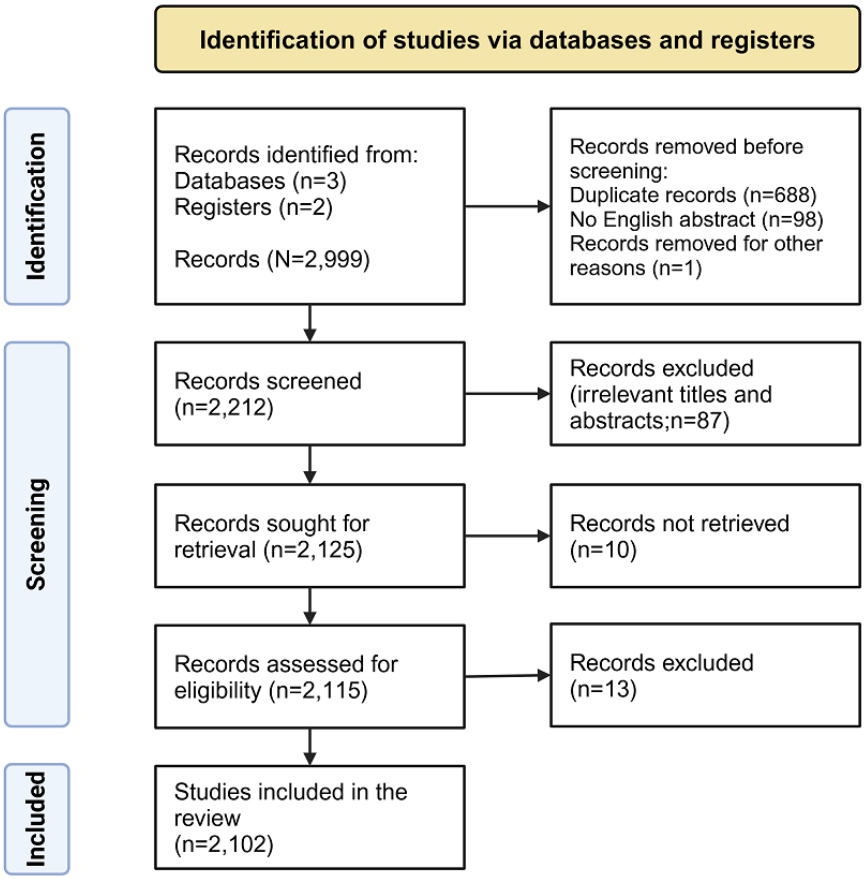
Our search strategy was divided into three parts: (1) all studies that contained the terms *Electronic health record* or *Electronic medical record* in the title or abstract and *medical research* in all fields were identified; (2) according to the time of publication, the studies were divided into 2000s, 2010s, 2020 to 2023, and 2024; and (3) the studies were then narrowed down to fields by specific terms (Figure 1). For example, the search term for the 2010s was as follows: ((*electronic health record*[Title/Abstract]) OR (*electronic medical record*[Title/Abstract])) AND (*medical research*) AND ((*real world study*) OR (*real world evidence*) OR (*pragmatic clinical trial*) OR (*pragmatic trial*)). We used cross-referencing techniques from the included studies and supplemented our search with forward and backward citation tracking to ensure comprehensive coverage.

XSL•FO
RenderX

Figure 1. Search strategy and results by timeline.

Qualitative Structured Analysis

Qualitative analysis and structuring of the available sources were performed using NVivo (version 14; Lumivero) software. All studies were coded using NVivo to generate keywords.



Results

Eligible Studies

According to the PRISMA framework (Figure 2), articles were searched in PubMed, Scopus, and Web of Science databases and categorized by period. Duplicate records, non-English abstracts, and records unrelated to EHRs were excluded, resulting in a final inclusion of 2102 articles. We also excluded records not pertinent to the application of EHRs in medical research, such as commentary articles and those focused on fraudulent claims.

XSL•FO
RenderX

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.

Time Intervals

The included articles highlighted the evolution of EHRs from simple documentation tools to central components of patient care, public health surveillance, and medical research. During the 2000s, researchers used EHRs in various observational studies and health care quality improvement efforts. During this period, early research using EHRs often focused on single health care systems with limited clinical data. The introduction of digital imaging and communications in medicine enabled the use of biomedical image data within EHRs, facilitating clinical follow-ups and case studies. During the 2010s, the EHRs served as primary data sources for many large-scale studies on patient outcomes, disease patterns, and treatment efficacy. Various national registries and research networks emerged to explore disease associations, health risks, and health care interventions. The concept of real-world evidence (RWE) gained attention, with PCTs relying heavily on EHR data to evaluate interventions in real-world settings. In addition, claim data were linked to EHRs for assessing health care services, resource use, and costs. Regulatory agencies began considering RWE in drug approvals and postmarketing surveillance. During the 2020s, retrospective EHR reviews enabled early identification of clinical characteristics, risk factors, and effective interventions, particularly focusing on the global health challenges of COVID-19 pandemic. Comparative effectiveness research using EHR data provided insights into public health measures, testing strategies, and treatment protocols. Globally, countries used their EHR infrastructure for real-time surveillance, vaccine distribution, and health policy adjustments. In addition, EHR data highlighted the impact of social determinants of health (SDOH) on COVID-19 outcomes. In addition, EHRs have played a pivotal role in precision medicine. Artificial intelligence (AI) and natural language processing (NLP) have increasingly been applied to EHRs, enabling predictive analytics for patient care, personalized treatments, and health care operations optimization. Many studies also highlighted the remaining limitations and challenges, including data quality, standardization, interoperability, patient privacy, data security, and high implementation costs. Enhanced regulatory frameworks, data-sharing agreements, and advanced security technologies were recommended to address these issues.

Discussion

Initial Adoption and Early Research Use Before and in the 2000s

The Problem-Oriented Medical Record

One of the earliest known efforts to use electronic systems for medical research that could be considered a precursor to modern EHRs was by Weed in 1968 [14]. Weed [14] introduced the concept of the problem-oriented medical record (POMR), which organized patient data according to specific problems, making it more systematic and usable for both care and research. Researchers began to use POMR for cost analysis [15], staff communications [16], and decision-making [17-19] in a wide range of diseases. The POMR was also strongly advocated among medical students for training purposes [20]. As patient-centered medical care always necessitates a

XSL•FO
RenderX

patient-centered medical record, the POMR remained prevalent in the early 2000s [21-23].

The Regenstrief Institute, established in 1969 in Indianapolis, Indiana, is another pioneer in this field. The institute developed the Regenstrief Medical Record System (RMRS), one of the first electronic medical record systems [24,25]. The RMRS allowed for the electronic capture, storage, and retrieval of patient data, serving as a model for later EHR systems. Researchers began to design randomized trials by using the system to test the effectiveness of medications [26,27]. The RMRS attempted to create a community-wide linkage across health care systems, urgent care hospitals, clinics, and health departments [28]. Both Weed's [14] work on POMR and the Regenstrief Institute's development of the RMRS played significant roles in the early use of electronic systems to support medical research, laying the groundwork for the EHR systems we see today.

Technological and Methodological Developments

With the development of POMR and RMRS, some new technologies and methodologies were applied to support the use of EHRs in research. This included the creation of data warehouses and the development of tools for data mining and analysis, which would later become crucial for extracting meaningful insights from large EHR datasets [29,30]. The recognition of the value of EHR data for research led to the formation of consortia and collaborative networks aimed at sharing data and best practices. These early collaborations laid the foundation for later, more extensive networks that would leverage EHR data for multicenter studies and nationwide research initiatives [31].

In 2009, the Health Information Technology for Economic and Clinical Health Act (HITECH) was passed [12]. The HITECH Act represented a critical step in the digital transformation of the US health care system. The HITECH Act led to a substantial increase in the collection and digitization of patient health information. This vast repository of data became a valuable resource for researchers, offering a wealth of information on patient outcomes, disease patterns, and treatment effectiveness [32-36]. Most research studies in 2000s leveraging EHRs have some features in common, including a single health care system or single hospital, an observational study design, and limited data on clinical characteristics [37]. In addition, some researchers also tried to use EHRs for pharmacovigilance and comparative effectiveness of drugs [38-41]. The limited duration of interventional and observational periods in clinical trials necessitated real-time monitoring of therapeutic effectiveness and safety, crucial for both physicians and patients. The use of EHRs effectively addressed these concerns [42]. Some early explorations on biomedical image data began with the incorporation of the digital imaging and communications in medicine within EHRs [43-46]. The deidentification of radiology clinical data allowed researchers to conduct case series studies and to follow up the changing patterns of the biomedical images in a certain disease area.

The Rise of Big Data in Health Care in the 2010s

In the 2010s, big data analytics in health care were popular, with EHRs serving as the primary data source. Researchers began leveraging EHR data to conduct large-scale studies on patient outcomes, disease patterns, and treatment efficacy. A lot of cohort studies have been designed and conducted using EHR data to provide evidence of the association between risk factors and occurrence as well as the prognosis of diseases. In addition, a lot of quality improvement studies used EHRs to investigate the patients' communication and clinical support. The disease areas covered almost every system in the body, including primary care [47], cardiology [48], sepsis [49], cancer [50], diabetes [51], rheumatology [52], nephrology [53], neurology [54], hepatology [55], and gastroenterology [56]. Our previous review has highlighted the practical use of EHRs among patients with diabetes in medical research [57]. Moreover, insurance claim data, such as that from the Kaiser Permanente [58-60], offer valuable insights for enhancing our understanding of health risks, improving patient outcomes, and informing policy and practice decisions.

In contrast, researchers also started to analyze data from large patient populations to identify health trends, assess risk factors, and develop strategies for disease prevention and health promotion. They started to use these data for potential patient selections and recruitment for clinical trials [61]. Meanwhile, PCTs began to rise gradually [62]. Researchers have made significant efforts to bridge the gap between clinical trial results and real-world outcomes [63-66]. These type of trials were designed to evaluate the effectiveness of interventions or medications in real-world clinical settings, aiming to inform health care decision makers about the trade-offs between benefits, harms, and costs of those interventions [67-69]. They mainly rely on the EHR data. Researchers aimed at addressing key uncertainties in real-world clinical settings, focusing on comparing interventions or medications in ways that reflect usual care [70,71]. There were also some tools that were developed to help researchers design and implement PCTs, including the Pragmatic–Explanatory Continuum Indicator Summary (PRECIS-2) [72]. Moreover, stakeholder engagement is a pivotal step [73,74]. The implementation phase requires selecting appropriate sites that mirror the settings where the intervention will be applied, using strategies for diverse participant recruitment, and integrating interventions and comparators seamlessly into routine clinical practice. Data collection leverages EHR to minimize disruption and enhance the efficiency of the trial process. PCTs seem more reliable to provide RWE than traditional randomized trials. Some claim data linked to EHRs can also provide detailed records of health care services received by patients, allowing researchers to accurately measure resource use and associated costs [75-77]. This information is crucial for cost-effectiveness analyses that compare the costs and outcomes of different health care interventions. EHR data enable the estimation of direct medical costs by documenting clinical procedures, medication prescriptions, hospital stays, and other health care services. In addition, EHR data have contributed to the evaluations of health care quality and system performance, which supported its use

XSL•FO
RenderX

in health policy studies, as the data contain a huge amount of information on health care procedures [78-80].

Regulatory agencies, including the US Food and Drug Administration (FDA) [81] and the European Medicines Agency (EMA) [82], began to explore the potential of RWE from real-world studies of large cohorts or PCTs in supporting drug approvals and postmarketing surveillance. The Patient-Centered Outcomes Research Institute in the United States, which was established in 2010, also reflected a growing recognition of the value of RWE in regulatory decisions and health care policy [83,84]. The FDA and EMA considered approval seriously with evidence from RWE, particularly when traditional clinical trials are not feasible or practical [85]. This is particularly relevant in scenarios where patient populations are rare, heterogeneous, or difficult to recruit into randomized controlled trials. Regulatory agencies, including the FDA and the EMA, have increasingly recognized the value of RWE in regulatory decision-making. The FDA's 21st Century Cures Act has encouraged the use of RWE in supporting the approval of new indications for existing drugs and in fulfilling postmarketing study requirements [85]. A notable example of this is the expanded indication of palbociclib, which was approved by the FDA for use in male patients with hormone receptor–positive, HER2-negative advanced or metastatic breast cancer [86]. In 2020, the FDA approved pembrolizumab for the treatment of adult and pediatric patients with unresectable or metastatic solid tumors that have a high tumor mutational burden [87]. This decision involved RWE derived from genetic sequencing and EHRs. Other examples include the approval of blinatumomab for pediatric acute lymphoblastic leukemia [88], ibrutinib for chronic lymphocytic leukemia [89], nusinersen for spinal muscular atrophy [90], and alosetron for irritable bowel syndrome in female patients [91].

Global Health, Precision Medicine, and AI in the 2020s

COVID-19 Pandemic and Real-Time Surveillance

The global nature of the COVID-19 pandemic increased the importance of international collaboration in medical research. While the health care providers were busy taking actions against the COVID-19 pandemic, they used retrospective EHR to learn lessons and analyze the trends and responses they had made [92-98]. The World Health Organization declared the outbreak a public health emergency of international concern (PHEIC) in early 2020 [99] and ended the PHEIC declaration in 2023 [100]. During the early stages of the COVID-19 pandemic in 2020, Chinese physician-scientists played a crucial role in understanding the disease by conducting retrospective reviews of medical records [93,95-98]. This process was instrumental in identifying the clinical characteristics and transmission patterns of COVID-19 infection, at a time when the world was scrambling for information on how to deal with the novel coronavirus. Importantly, these studies highlighted the disease's high transmissibility, both from symptomatic and asymptomatic carriers, underlining the importance of widespread testing, contact tracing, and quarantine measures to control its spread [101-106]. This group of physician-scientists from Wuhan, China, also contributed to the understanding of risk factors associated with severe outcomes, including age, pre-existing health conditions, and certain demographic factors. Their findings on the efficacy of various public health interventions, such as the use of face masks, social distancing, and the implementation of lockdowns, informed policies not just in China but around the world [107,108]. Furthermore, the early identification of the genome sequence of SARS-CoV-2 virus by researchers facilitated the rapid development of diagnostic tests and the initiation of vaccine development efforts [109-111]. This early sharing of data was pivotal in the global race to develop vaccines and therapeutics against COVID-19.

During the midpandemic period, EHR data became instrumental for comparative effectiveness research, aimed at evaluating and improving health outcomes across various populations and health care systems. This research spanned a broad spectrum of topics crucial to pandemic management, including the effectiveness of personal protective equipment [112-114], the impact of social distancing [115,116], the accuracy and efficiency of different testing strategies [117,118], strategies [117,118], the efficacy and safety of antiviral medications and vaccines [119-123], and the role of health supplements [124]. In addition, it explored the role of telemedicine in sustaining patient care and the importance of primary care services during the COVID-19 pandemic [115,125-128]. For example, comparative effectiveness research helped identify the types of personal protective equipment that were most effective in preventing virus transmission among health care workers and the public [129,130]. Similarly, studies on social distancing and lockdown measures offered evidence-based guidance on how to balance public health concerns with economic and social implications [131]. The investigation into testing strategies elucidated the strengths and weaknesses of various diagnostic approaches, leading to improvements in testing strategies and the quicker identification of COVID-19 cases [132]. Research on antiviral drugs, anti-inflammatory drugs, and some health supplements informed treatment protocols, contributing to the development of therapeutic strategies that reduced the severity and duration of the disease [133,134]. Telemedicine emerged as a vital tool for providing continuous care while minimizing the risk of virus transmission, demonstrating its potential to revolutionize health care delivery beyond the pandemic [135,136].

In addition to China, in the United States, EHR systems also played a crucial role in the national response to COVID-19. Through partnerships with health care systems and EHR vendors, the Centers for Disease Control and Prevention, the US FDA's Sentinel System and other public health authorities gained access to near–real-time data on COVID-19 cases, hospitalizations, ventilator use, and patient outcomes [137]. EHRs were also instrumental in tracking vaccine distribution and administration. The Vaccine Adverse Event Reporting System used EHR data to monitor postvaccination side effects, guiding policy adjustments in vaccination campaigns [138]. In the United Kingdom, the government leveraged its National Health Service (NHS) EHR infrastructure for real-time surveillance and policy making during the COVID-19 pandemic. The United Kingdom developed the OpenSAFELY platform, a secure analytics environment that allowed researchers to access deidentified EHR data of >58 million NHS patients [139]. EHR

XSL•FO
RenderX

data were used to identify individuals with high risk and provided real-time data on hospital admissions, intensive care unit (ICU) bed occupancy, and patient outcomes. South Korea used a robust real-time surveillance system that integrated EHRs with other health data sources to contain the spread of COVID-19, including contact tracing and national health reporting [140]. In Australia, the national My Health Record system was used to support the country's pandemic response with centralized health data access and the implementation of lockdowns and the reopening of services [141]. Germany also used EHR data to manage its health care resources effectively during the COVID-19 pandemic, which used EHR data to monitor ICU capacity across the country. Hospitals provided daily updates on bed occupancy, ventilator availability, and staffing levels [142]. In addition, Germany explored the use of EHRs to develop digital health passports that recorded patients' vaccination status and COVID-19 test results [143]. The use of EHRs for real-time surveillance and policy making during COVID-19 highlighted the importance of interoperable systems. Countries with centralized health records or integrated health information exchanges were better positioned to use EHR data quickly and effectively.

The COVID-19 pandemic has also accentuated the critical role of SDOH, revealing stark disparities in disease outcomes across different populations [144]. EHRs have provided a rich dataset for analyzing these disparities, uncovering the disproportionate burden of COVID-19 on specific groups such as the older adults, individuals with chronic diseases, and those with autoimmune diseases. Studies leveraging EHR data have identified various social determinants that contribute to the increased vulnerability of these populations. Factors such as socioeconomic status, access to health care, living conditions, and occupational hazards have been linked to higher rates of infection, severe disease outcomes, and mortality [145-151]. For instance, individuals in lower socioeconomic brackets often face barriers to accessing health care services, leading to delayed or inadequate treatment for COVID-19 [152]. Similarly, patients with pre-existing chronic conditions such as diabetes, cardiovascular diseases, and respiratory diseases have been shown to experience more severe outcomes when infected with the virus [105,153]. Furthermore, the research has highlighted the importance of addressing these social determinants in pandemic response strategies. Interventions targeting SDOH can help mitigate the adverse outcomes of COVID-19 among populations considered vulnerable. This included improving access to health care, enhancing support for individuals with chronic diseases, ensuring the availability of protective measures for individuals classified as immunocompromised, and addressing the broader socioeconomic and environmental factors that contribute to health disparities [154].

Even after the end of the PHEIC declaration, the use of EHR in studying post–COVID-19 condition continued to be of paramount importance. Research into the long-term impacts of COVID-19, particularly on mental health [155-158] and cognitive functions [159-161], remains a critical area of public health inquiry. EHRs were expected to provide invaluable, real-time data that can link early exposure to COVID-19 with outcomes that may manifest decades later or even across a lifetime. As humanity progresses, EHRs stand as a vital resource, equipping us to face global crises and unpredictable challenges with resilience and informed action.

Precision Medicine and Genomics

Precision medicine represents a transformative approach to health care in the past 10 years, focusing on the customization of treatment based on an individual's genetic makeup, environment, and lifestyle [162]. EHRs played a pivotal role in the advancement of precision medicine, where treatments are tailored to the individual characteristics of each patient. The integration of genomics data with EHRs allowed researchers to study the genetic bases of diseases and to personalize health care at an unprecedented level. However, integration is still facing several challenges and opportunities. While the routine clinical application of genomic data is still emerging, some EHR-connected biobanks and initiatives are actively addressing the challenges involved. While the EHR-connected biobanks were initially designed for research purposes, it has actively promoted to incorporate the biobank data into the EHR systems.

The UK Biobank (UKB) stands as a prominent figure in the realm of biomedical research, featuring an expansive database and research resource. It encompasses deidentified genetic, lifestyle, and health information, along with biological samples from half a million UK participants [163]. This rich dataset is further augmented by linkage to the United Kingdom's EHRs, such as the Hospital Episode Statistics and the Patient Episode Databases [164,165]. The UKB's comprehensive dataset has been instrumental in propelling forward the fields of medicine and research, offering profound insights into the prevention, diagnosis, and treatment of numerous serious and life-threatening diseases. The UKB has released a set of whole genome sequencing data. Since 2018, numerous studies have used these data, along with Mendelian randomization, to investigate the causal relationships between genetic backgrounds and diseases [166-169]. While the UKB serves as a notable instance of linking a study cohort with EHRs, it does not exemplify direct integration. Despite encompassing data from half a million individuals, the UKB faces potential selection bias [170]. This is attributed to the fact that the initiative dispatched >9 million invitations across the nation, suggesting that the participants may not fully represent the broader population.

Similar to the approach of the UKB, the National Institutes of Health in the United States initiated the All of Us Research Program in 2018, aiming to enroll more than a million individuals [171]. By January 1, 2024, the program had successfully registered >760,000 participants, securing access to >539,000 samples for genomic sequencing and 420,000 EHRs. Through its comprehensive data collection, the All of Us Research Program seeks to address critical gaps in medical research, particularly in areas underserved by existing studies, thereby fostering a deeper understanding of various health conditions and improving strategies for prevention, diagnosis, and treatment across the spectrum of both common diseases and rare diseases. However, it remains a strong example of linking cohort data with EHRs.

XSL•FO
RenderX

Other local or nationwide biobanks with linkage to EHRs or national registries include the Danish Biobank Register [172]; BioBank Japan [173]; China Kadoorie Biobank [174]; Kaiser Permanente Research Bank [175]; deCODE Genetics [176]; FinnGen biobank [177]; Vanderbilt University's bioVU [178]; Michigan Genomics Initiative [179]; BioMe biobank [180]; the Estonian biobank [181]; and the Norwegian Mother, Father and Child Cohort Study [182]. These initiatives varied in scope and scale but collectively contributed to the growing field of genomic research linked to EHRs, facilitating advances in personalized medicine and the understanding of genetic influences on various diseases.

The true sense of integrating genomic data into EHRs presented challenges such as diverse data structures, storage limitations, interpretation complexities, and financial constraints. The National Human Genome Research Institute supported the Electronic Medical Records and Genomics network to address these issues by harmonizing data and developing guidelines for genomic data integration and use [183]. Solutions are in progress, and the initiative now has >10 clinical site partners, along with a network of affiliates across major areas in the United States. The Electronic Medical Records and Genomics network is not only developing best practices for electronic phenotyping and biobanking consultation but also exploring EHRs for additional genome-wide association studies outcomes among genotyped individuals, leveraging the rich phenotypic data available.

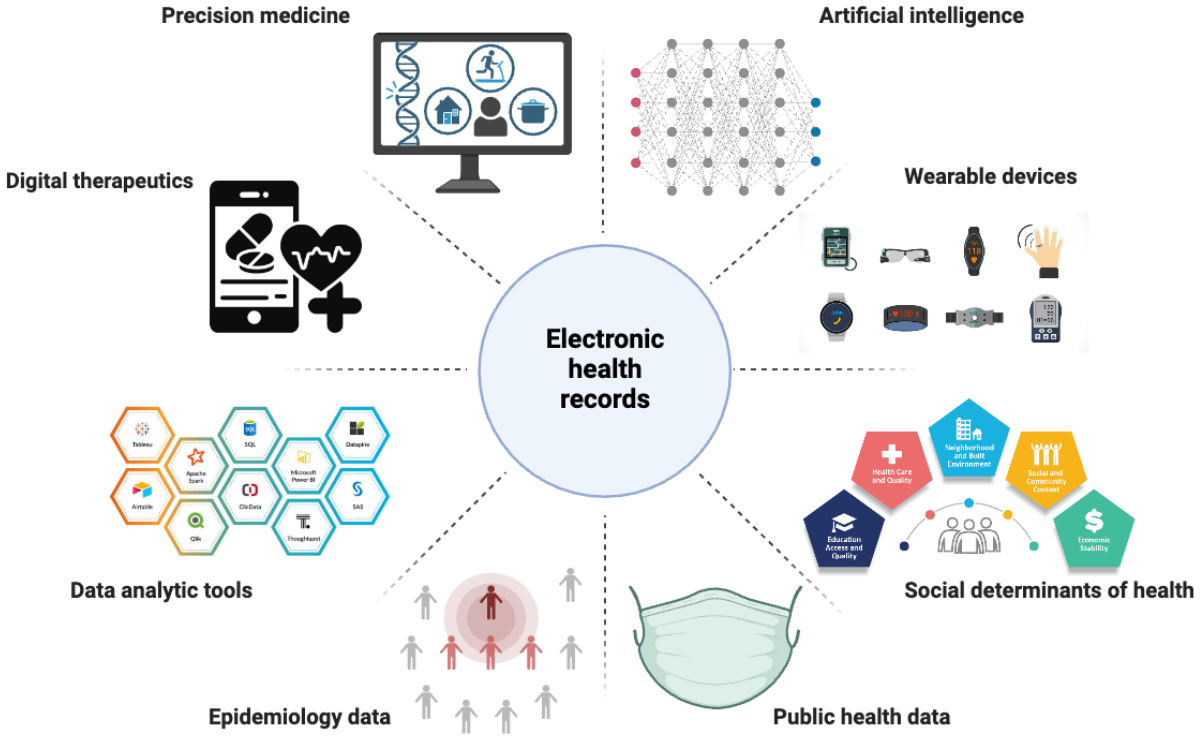
Data Analytics and AI

The use of data analytics and AI in analyzing EHR data has grown exponentially. Researchers were using machine learning algorithms to identify patterns, predict outcomes, and generate insights into disease progression, treatment efficacy, and patient care optimization [184,185]. These technologies enabled the analysis of vast amounts of data in ways that were not previously possible.

Predictive Analytics for Identifying Patients With High Risk and Their Outcomes

One of the most significant applications of AI in health care is in identifying patients at high risk of developing specific conditions and predicting outcomes among patients who were already diagnosed with a health condition. By analyzing historical EHR data, including patient demographics, previous health conditions, treatment histories, and lifestyle factors, AI models can predict which patients are more likely to develop diseases such as diabetes, cardiovascular diseases, or chronic respiratory conditions, as well as the potential outcomes of various treatment options [186-190]. Early identification of these patients allows health care providers to implement preventive measures, tailor treatments to individual needs, and in doing so, significantly reduce the risk of severe outcomes or the need for hospitalization. This predictive capability enables physicians to choose the most effective treatment plans, thereby improving the quality of care and patient satisfaction. In the context of infectious diseases, AI models are invaluable for tracking and forecasting the spread of diseases. By integrating EHR data with information from other sources, such as public health records and social media, AI algorithms can predict outbreaks, model the spread of infections, and inform public health interventions [191,192]. This was particularly evident during the COVID-19 pandemic, where AI played a pivotal role in predicting hospitalization rates, identifying potential hot spots, and guiding the allocation of medical resources [193,194].

Personalized Medications and Clinical or Regulatory Decision Support Systems



Leveraging EHR data, AI is facilitating personalized medicine by tailoring treatment plans to individual patient characteristics, genetic information, and historical health data. This approach helps in predicting how different patients will respond to various treatments, thereby improving treatment effectiveness and reducing side effects [195]. While medications only serve one part of the disease management, AI integrated with EHR systems can provide clinicians with decision support by offering diagnostic suggestions, recommending treatment options, and alerting health care providers to potential adverse drug interactions or necessary screenings, thereby enhancing patient care quality [196-200]. AI tools also analyze EHR data to optimize hospital operations and predict perioperative complications. This can lead to improved patient satisfaction, lower surgery-related adverse events, and lower health care costs [201-205]. Among the AI strategies, NLP technologies represent a pivotal advancement in the use of EHR data, transforming the landscape of health care data analytics and decision-making [185]. NLP enables the extraction of valuable information from unstructured text within EHRs, such as clinical observations, patient histories, and diagnostic notes, which traditionally have been difficult to analyze systematically due to their unstructured nature. This capability not only enhances the richness of data available for clinical decision-making but also significantly expands the potential for personalized patient care and advanced health care analytics [206-209]. One notable example of NLP's application in health care is the development of GatorTron (University of Florida), a large clinical language model trained on >90 billion words from clinical notes, PubMed articles, and Wikipedia [210-212]. GatorTron significantly outperforms previous models in clinical NLP tasks such as clinical concept extraction, medical relation extraction, semantic textual similarity, natural language inference, and medical question answering. This model showcases how scaling up the number of parameters and data size can lead to substantial improvements in performance across various NLP tasks, ultimately enhancing the extraction and interpretation of critical information from EMR data for better health care delivery and research.

EHRs in Medical Research in the Next Decades

The next decades will likely see significant advancements in EHR capabilities, focusing on interoperability, precision medicine, AI and digital health technologies, the integration of SDOH, public health monitoring, and the enhancement of data analytic tools (Figure 3).

XSL•FO
RenderX

Figure 3. Future landscape of electronic health records.

EHRs for Patient Care Versus EHRs for Research

It has been a trend to develop an EHR system for research use only. EHRs designed for patient care and those designed for research may differ in their structure, focus, and functionality [213]. EHRs tailored for patient care will prioritize real-time clinical decision support, patient safety, and continuity of care. They are built to store detailed patient information, such as medical history, medications, allergies, laboratory results, and diagnostic imaging, allowing health care providers to quickly access and update data during clinical encounters. The interface is designed for ease of use. In contrast, EHRs designed for research will focus on data collection, aggregation, and analysis at a population level. They emphasize data standardization, coding, and interoperability, allowing researchers to extract large datasets for epidemiological studies, clinical trials, and public health surveillance [214]. These EHRs will include extensive metadata and use structured data formats to facilitate the analysis of trends and outcomes. While patient care EHRs focus on the individual patient, research-oriented EHRs aggregate deidentified data from diverse populations to explore disease patterns, treatment effectiveness, and health care disparities. In addition, research EHRs must also address data privacy and consent issues more rigorously to comply with ethical standards for data use [214].

Enhanced Interoperability and Data Sharing

Future EHR systems are likely to achieve higher levels of interoperability, enabling seamless data sharing across different health care systems, health care providers, and even countries. This will facilitate comprehensive patient care, collaborative research, and public health monitoring on a national or even a global scale. Regulations governing the use of EHRs and related technologies will evolve to keep pace with advancements, addressing ethical considerations, data ownership, and the use of digital health data in research and health care delivery. As the use of EHRs grows, the focus on protecting patient data will also be important. Advanced security technologies and privacy-preserving methods, such as blockchain and federated learning, may be used to safeguard information while enabling its use for care and research.

As a good example, the CODE-EHR framework represents a crucial advancement, focusing on improving the design of studies that use structured EHR records [215]. This framework emphasizes the importance of verification, validation, and data privacy, along with addressing social mandates to undertake research. It proposes minimum standards to enhance study transparency and provides a road map toward more effective use of health care data for research. By enabling the embedding of controlled trials within real-world settings, such as registries or routine clinical practice, CODE-EHR aims to produce more generalizable results that can inform patient care, health care cost containment, and quality of life improvements.

Integration of Genomic and Other Omics-Related Precision Medicine Data

As genomic sequencing becomes more affordable and commonplace, EHRs are expected to integrate multiomics information, supporting the advancement of precision medicine. This will allow health care providers to tailor treatments to individual patients based on their individualized profiles, improving outcomes and minimizing adverse reactions [216].

The PennChart Genomics Initiative has demonstrated significant progress and potential in integrating genomic data into EHRs for optimizing patient care and facilitating medical research [217,218]. By creating a centralized document display for

XSL•FO
RenderX

genetic results in the EHR, researchers and clinicians can improve patient care while addressing privacy concerns. This initiative has already led to the integration of thousands of genetic documents into the EHR, highlighting the potential for EHRs to support precision medicine and accelerate the discovery of novel genomic medicine applications. Future efforts aim to expand this integration and address challenges such as educational needs, infrastructure compatibility, and maintaining privacy and security protections.

The Genetics Underlying Diabetes in Hispanics and Latinos study in the United States is a pioneering initiative planning to enroll 100,000 newborns for whole genome sequencing [219]. This program aims to explore the potential of genomic data in newborn screening, with the goal of enhancing early diagnosis and treatment in neonatal ICUs and pediatric ICUs. By identifying genomic markers early on, the program seeks to save lives and reduce hospital stays for patients with undiagnosed disease, showcasing the transformative power of genomics in precision health care.

Genomics England's program is another potential effort to integrate genetic data with EHR data, aiming to sequence 100,000 genomes from NHS patients with rare diseases and their families as well as patients with cancer [220]. Launched to enhance our understanding of genetics in disease and to pioneer a UK genomic medicine service, the project's success has paved the way for further genomic research and integration into health care. This initiative highlights the potential of genomic data in advancing personalized medicine and improving treatment strategies.

Expansion of AI and Other Digital Health Technologies

EHRs in the future will increasingly incorporate AI and machine learning algorithms to analyze health data in real time, predicting patient risks (such as for chronic diseases or hospital readmissions) and suggesting personalized prevention and treatment plans. AI-driven models, using big data from EHRs, outperform traditional methods in sensitivity, specificity, and other metrics. The implementation of these models into web applications and mobile apps could significantly aid clinical decision-making, emphasizing the need for effective strategies to integrate AI algorithms in clinical tools.

The future use of NLP in EHRs is also expected to significantly enhance health care delivery and research [221]. By leveraging NLP, health care professionals can continuously extract valuable insights from the increasing volumes of unstructured data within EHRs. This advancement will allow for more accurate patient stratification, personalized treatment plans, and improved predictive models for disease outcomes in the future. NLP technologies are set to automate the extraction and interpretation of clinical information, reducing manual data entry and analysis burdens. In addition, real-time processing of patient data through NLP will facilitate more rapid clinical decision support, optimizing treatment approaches and patient care pathways [222]. The integration of NLP with EHR systems promises a shift toward more data-driven, efficient, and patient-centered health care, highlighting its critical role in advancing medical research, enhancing disease surveillance, and ultimately improving patient outcomes.

In addition, EHRs will also become more integrated with other digital health technologies, such as wearable devices, telehealth platforms, and digital therapeutics [223,224]. Wearable devices, ranging from fitness trackers to advanced biosensors, have become increasingly sophisticated, capable of monitoring a wide array of health metrics such as heart rate, activity levels, sleep patterns, and blood glucose levels. Integrating these devices with EHRs can provide clinicians with a more comprehensive view of a patient's health status, extending beyond the snapshots captured during clinical visits. This continuous stream of real-time data can enhance preventive care strategies, enable early detection of potential health issues, and support personalized treatment plans. For patients with chronic conditions, this integration can facilitate closer monitoring and adjustments to treatment regimens based on near–real-time data, potentially improving outcomes and patient engagement in their care. Telehealth platforms have experienced exponential growth, a trend significantly accelerated by the COVID-19 pandemic. The integration of telehealth with EHRs ensures that online consultations are informed by the patient's medical history, current medications, and recent test results, allowing for more informed clinical decision-making [225]. This seamless flow of information can improve the efficiency and effectiveness of virtual care, making health care more accessible, particularly for individuals in remote or underserved regions. Furthermore, integrating telehealth encounters into EHRs ensures that all aspects of a patient's care are documented in a single, comprehensive record, supporting continuity of care across different health care settings. Digital therapeutics, which include software-driven evidence-based interventions, are an emerging field within health care [226]. These interventions, which can range from cognitive behavioral therapy apps for mental health to digital programs for chronic disease management, offer new avenues for treatment that are accessible and scalable. Integrating digital therapeutics with EHRs can enhance the personalization of care, enabling health care providers to track patients' engagement and progress with these interventions in parallel with traditional treatments. This integration can also facilitate the collection of outcome data, supporting the evaluation of the effectiveness of digital therapeutics in real-world settings and informing future care decisions.

Incorporation of SDOH

Addressing SDOH is crucial for improving health outcomes and reducing health disparities. Future EHR systems may include more comprehensive data on patients' social, economic, and environmental conditions, which are currently lacking in most systems and platforms [227]. This idea of data integration will empower health care providers to address not just the clinical but also the contextual aspects of health, leading to more targeted interventions, improved health outcomes, and reduced health care disparities. The evolution of EHR systems to include comprehensive SDOH data will necessitate advancements in data collection, privacy protocols, and analytics. Collecting SDOH data in EHRs in the future could involve leveraging technology to automate data capture from various sources, including patient self-reporting through digital platforms, integrating community health data, and using NLP to extract SDOH information from clinical narratives.

XSL•FO
RenderX

Future Use in Public Health and Epidemiology

EHRs will continuously play a vital role in monitoring public health trends due to their performance during the COVID-19 pandemic, managing outbreaks of infectious diseases, and conducting large-scale epidemiological studies in the future in case of other unpredictable pandemics. Real-time data analysis will enable quicker responses to public health emergencies and more effective preventive strategies. However, these potential opportunities will depend mainly on the enhanced interoperability and data sharing, as mentioned previously.

Integration of Data Analytic Tools With EHRs

Integrating data analytics tools with EHRs involves connecting the capabilities of data analysis software with the wealth of patient information stored in EHR systems. This integration can enhance health care delivery, improve patient outcomes, and facilitate health care research by leveraging advanced analytics on EHR data. A recent effort for an integrated online phenomics knowledge base within the EHR data was the development of the Centralized Interactive Phenomics Resource (CIPHER) knowledge base [228,229]. The CIPHER is a comprehensive, public-facing knowledge base designed to streamline the development of clinical phenotypes, aiming at facilitating clinical and health services research. It also featured scalable metadata management, integrated tools, and user workflows as well as enabled complex searches through stored phenotype metadata adhering to the CIPHER standard. Phenotypes can be contributed via a webform that validates metadata, and the platform includes data visualization tools to improve user engagement and accelerate phenotype development. Hopefully, the CIPHER knowledge base can expand the phenotype algorithm repository and the collaborations among users in the future.

Potential Challenges

It also highlighted several challenges in using EHRs for medical research before and in the past 25 years, including issues with data quality, consistency, and interoperability between different EHR systems. Privacy and security concerns regarding the use of patient data for research purposes were significant, leading to regulatory efforts to protect patient information while enabling research. The Health Insurance Portability and Accountability Act (HIPAA), originally enacted in 1996, continued to influence EHR development throughout the 2000s with its privacy and security rules, which were critical in shaping how EHR systems handled sensitive patient data [230,231].

Deidentification, Recoding, Regulatory, and Ethical Considerations

In the clinical care setting, information is recorded into EHRs by various health care professionals, including physicians, nurses, medical assistants, and other clinical staff. The accuracy and completeness of the data entered depend heavily on the documentation practices of these health care providers, which can vary between institutions and countries [232]. In some cases, administrative staff may also input data related to billing and patient demographics. It is important to note that these data inputs are primarily geared toward patient management rather than research, which introduces variations and challenges when using EHR data for secondary research purposes. One of the most crucial steps in preparing EHR data for research is deidentification, which involves removing or masking identifiable patient information (eg, names, addresses, and social security numbers) to protect patient privacy. Data security and privacy concerns often influence how EHR data are accessed and used for research. Institutions often have governance committees or data access boards that review research proposals to ensure they comply with ethical guidelines and data use policies. However, these regulations vary from country to country and system to system. In the United States, HIPAA regulations define strict guidelines for deidentification and the secondary use of health data. Institutions may use institutional review boards to oversee the approval process for research using EHR data [230]. In the European Union, under General Data Protection Regulation, pseudonymization and data minimization are encouraged, and the use of EHR data for research typically requires explicit patient consent unless an exemption is granted [233]. In the United Kingdom, the NHS has implemented the use of trusted research environments to facilitate secure access to health data for research while ensuring patient privacy [234].

Given the differences in regulations across countries, researchers must familiarize themselves with the specific legal and ethical requirements of the country where the EHR data are stored and where the research will be conducted. When conducting international or multicountry research, researchers need to consider how differing regulations affect data sharing, processing, and consent. Cross-border collaboration may require legal agreements, such as data transfer agreements, that meet all involved jurisdictions' requirements. Regardless of the region, maintaining high standards for data security and privacy is crucial. Researchers should use practices such as data pseudonymization, anonymization, encryption, and secure data storage to protect patient information throughout the research process [235].

Despite the progress, researchers continued to face challenges with the interoperability of EHR systems. The ability to share and integrate data across different platforms and health care institutions was still limited, posing hurdles to multisite studies and collaborative research efforts. Addressing these challenges became a priority for advancing the use of EHRs in research. As the use of EHR data in research grew, concerns about patient privacy and data security also increased. Increased attention to regulatory and ethical issues surrounding the use of health information came up. Policies and guidelines, such as the HIPAA in the United States and the General Data Protection Regulation in the European Union [233,236,237], were updated to ensure the protection of patient information while facilitating research. Despite these concerns, all the efforts during this time underscore a shift toward a more holistic approach to evidence generation, aiming to improve patient outcomes and health care decision-making by bridging the gap between research such as clinical trials and real-world practice.

Meanwhile, researchers also encountered challenges during the use of EHRs on the common data models and data cleaning complexities. Although the Patient-Centered Outcomes Research Institute has made great efforts to this issue by establishing the PCORnet common data model [238-240] and the Observational

XSL•FO
RenderX

Health Data Sciences and Informatics consortium has developed the Observational Medical Outcomes Partnership Common Data Model [241-243], significant challenges remain in achieving interoperability between different EHR systems and health care databases. This inconsistency can hinder the seamless exchange and integration of health data for comprehensive analyses. Common data models rely on the assumption that data across systems can be standardized into a uniform format. However, variations in how data are recorded, missing information, and inconsistent use of terminologies across different EHR systems can lead to gaps and inconsistencies that affect data quality and utility. For the concerns of data cleaning and linkage, although several standardized coding systems (ie, International Classification of Diseases, Current Procedural Terminology, Healthcare Common Procedure Coding System, Logical Observation Identifiers Names and Codes, Systematized Nomenclature of Medicine, etc] were introduced in the EHRs, they still contain a vast amount of unstructured or semistructured data, including free-text clinical notes [244]. Cleaning such data to extract meaningful information may require other tools and algorithms, such as SQL environment [MySQL version 8.4.0; Oracle Corporation] and Python [version 3.8.5; Python Software Foundation]), which can be resource intensive and complex to develop and apply for researchers without computer science backgrounds. Patients' data are often shared among different EHR systems, including primary care and specialty registries. Linking these fragmented data sources to achieve a holistic view of a patient's health history is challenging but essential for effective research and care management.

Data Quality, Standardization, Patient Engagement, Cost, Data Cleaning, and Global Health Disparities

Ensuring high-quality, standardized data entry into EHRs is challenging yet essential for effective health care delivery and research. Inconsistent data, incomplete records, and variation in data capture practices can compromise the reliability and usefulness of EHR data for clinical decision-making and research purposes. While patient portals and digital access to health records aim to empower patients, engaging patients effectively remains a challenge. Issues such as digital literacy, accessibility, and varying levels of interest in active health management can affect the extent to which patients use EHRs to participate in their care [245].

For many health care providers, particularly smaller practices and those in low-resource settings, the cost of EHR implementation and ongoing maintenance is a significant barrier [246,247]. In addition, the process of transitioning from paper-based systems to EHRs, or switching between EHR systems, can be disruptive and resource intensive. Global disparities in EHR adoption and use highlight the challenge of ensuring equitable access to the benefits of digital health records. Differences in infrastructure, funding, and health care policies contribute to varying levels of EHR integration and use worldwide. Integrating AI and advanced analytics into EHR systems presents both opportunities and challenges. While these technologies have the potential to transform health care delivery and research, they also raise questions about data accuracy, algorithmic bias, and the interpretability of AI-generated insights.

Limitations

Despite extensive literature searches across three databases and rigorous literature screening processes, our systematic review still faces some limitations. First, publication bias remains a concern, as studies reporting positive or significant findings are more likely to be published and thus overrepresented in our review. In addition, studies on EHR are highly heterogeneous. Variations in study design, populations, interventions, outcomes, and methodologies complicate meaningful synthesis and generalization of findings. Finally, some relevant studies may be unpublished, inaccessible, or have incomplete data, resulting in restricting data collection and limiting the overall comprehensiveness of our review.

Conclusions

The evolution of EHRs marks a significant milestone in health care's journey toward integrating technology and medicine. From early documentation practices to the sophisticated use of AI and big data analytics today, EHRs have become central to improving patient care, enhancing public health surveillance, and advancing medical research. As we look forward, the integration of SDOH, genomic data, and real-time analytics into EHRs promises to further personalize medicine, improve disease prevention strategies, and address health disparities. Collaborative efforts across borders, disciplines, and sectors will be crucial in realizing the full potential of EHRs in shaping a healthier future for all.

Acknowledgments

GH is partially supported by the grant from the National Institute of General Medical Sciences (U54GM104940) of the National Institutes of Health. YS and GH are partially supported by a grant from the Public University Partnership Program at the Louisiana Department of Health Bureau of Health Services Financing.

Authors' Contributions

YS and JY conducted the search and wrote the manuscript. JZ and GH performed the literature review and edited the manuscript. JZ is the guarantor of this work and, as such, has full access to all the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analyses. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Health care is undergoing a "revolution," where patients are becoming consumers and armed with apps, consumer review scores, and, in some countries, high out-of-pocket costs. Although economic analyses and health technology assessment (HTA) have come a long way in their evaluation of the clinical, economic, ethical, legal, and societal perspectives that may be impacted by new technologies and procedures, these approaches do not reflect underlying patient preferences that may be important in the assessment of "value" in the current value-based health care transition. The major challenges that come with the transformation to a value-based health care system lead to questions such as "How are economic analyses, often the basis for policy and reimbursement decisions, going to switch from a societal to an individual perspective?" and "How do we then assess (economic) value, considering individual preference heterogeneity, as well as varying heuristics and decision rules?" These challenges, related to including the individual perspective in cost-effectiveness analysis (CEA), have been widely debated. Cost-effectiveness measures treatments in terms of costs and quality-adjusted life-years (QALYs), where QALYs assume that a health state that is more desirable is more valuable, and therefore, value is equated with preference or desirability. QALYs have long been criticized for empirical and conceptual shortcomings. However, policy makers in many countries have used QALY measures to make health coverage decisions, although now, patients, and patient advocates, are questioning the valuation methodologies. This has led to the development of new approaches to valuing health, which are already starting to be used in the United States. This paper reviews 20-25 years of value assessment approaches in health and concludes with challenges and opportunities for value assessment methods in health in the years to come.

Background

The concept of value assessment has been used for decades in marketing, management, and other fields to develop strategies to assess the potential and realized customer value. Successful application of these strategies in health has required an understanding of what value assessment entails, including quantifying the impact of a provider's offering on patients' and payers' costs, as well as health gains. However, the adoption of value assessment in health has been slow, gradual, and multifaceted. One major explanation for this is that it required a paradigm shift "from patient to health consumer" to accept that some marketing concepts regarding customers are applicable to patients.

The idea of a paradigm shift toward a consumer-focused health system is not new. It was described as "taking hold" as early as the 1990s [1], with citations dating well into the 1980s—more than 4 decades ago. Much of the argument for a consumer-focused health care system revolved around changes in patients' desire for treatments that provided value on their terms, rather than the health care systems', with a desire for treatments that focused on functional loss, anxiety, and pain

XSL•FO
RenderX

rather than traditional biomedical outcomes. The path to a consumer-focused health care system was not as easy or straightforward as envisioned 35 years ago, but the movement now has a push from changes in health care, ranging from an emphasis on patient satisfaction in pay-for-performance programs [2] to a push for payment transparency to empower consumer choice [3] to the push for open access to electronic health records for patients [4]. In the United States, there has also been a rise in high-deductible health plans [5], providing extra motivation for consumers to consider their health care purchases carefully [6].

Today, this paradigm shift seems to finally be taking hold, with the aid of better data and increased use of digital tools since the COVID-19 pandemic [7], which can be observed in the way health technology assessment (HTA) methods are elaborated, with more room for individual patient preferences. This paper reviews 20-25 years of value assessment approaches in health and the role of the internet, mobile technologies, and digital health. It first describes the foundation of value assessment in health. In the second part, it discusses HTA approaches and the development of the literature, and in the third part, it describes policy efforts and future opportunities for individual value assessment.

Foundations of Value Assessment in Health

Value assessment uses tools to support better value in health care. The key question is value for whom. Many of the current value assessment tools used in health lack a sufficient patient-centered approach. Historically, most value assessment is based on the assumption that patients or "health consumers" maximize utility. In fact, the utility maximization paradigm forms the basis of many economic, psychological, cognitive, and behavioral models. Value assessment is performed by estimating a utility function that represents consumers' preferences that are assumed to be complete and transitive. This means consumers can compare any 2 goods or services, and their preferences are internally consistent. Consumers can then rank-order the goods or services under consideration according to their personal "value function."

When making a decision under certainty, the value function reflects the decision maker's preferences on a particular outcome. Outcomes are defined by the assignment of values to a set of attribute variables that are either discrete or continuous and together make up for the space of all possible outcomes. However, outcomes are often not defined under certainty but in terms of probabilities, and a utility function is needed to assess the value of a decision. Expected utility theory (EUT), proposed by von Neumann and Morgenstern in 1944 [8], described a more complex utility function representing the decision maker's attitudes regarding risk and the value of the outcomes by inducing a preference ordering on the probability distributions over the entire outcome space. Decades later, Kahneman and Tversky [9] contrasted the EUT concepts of risky and riskless choices with prospect theory (PT) [9]. Although the EUT assumed that risk attitudes derive exclusively from the way in which people value rewards as reflected in the curvature of the utility function, PT posited that one's risk attitude would also vary with their subjectively weighted outcome probabilities.

To collect preferences and derive the utility function, there are many ways to ask consumers to rank-order options. In marketing research, some of the more established methods include contingent valuation [10], contingent ranking [11], contingent behavior [12], paired comparisons [13,14], discrete choice experiments [15], (full profile) conjoint analysis [16], adaptive conjoint analysis (ACA) [17,18], and ACA's self-explicated prior [19]. In health, many of these methods have been adopted to define value for individual patients, often following the same patterns of discussion and methodological improvements as other fields. In all these methods, consumers are asked to implicitly or explicitly rank-order options and make choices based on the ordering. For example, in the ACA self-explicated model, consumers are asked to rank-order levels of an attribute of a choice, which is either assumed to be homogeneous across respondents or derived individually [19]. Next, they rate the importance of the difference between the best and the worst levels of an attribute on a 4-point scale, which is then multiplied by the preference orders and rescaled so that the difference between the highest and lowest partworths of an attribute is equal to the attribute's importance [20].

In the self-explicated model, the choice set is truncated to 4 importance scores across, and the assumption of equal successive intervals within attributes is embedded in the model. This is in contrast to actual choices, where the choice set may have many attributes, such as price, color, quality, reliability, reputation, size, calories, and packaging, and also where some choices could be quite similar and others quite different, such as the choice between 2 kinds of sliced bread, a bagel, and a pita. In the case of paired comparisons, such as full-profile ACA, it is assumed that consumers sum the weighted additive differences between alternatives on each attribute [21]. In most preference elicitation methods, the values assigned to the attributes are discrete.

There are a number of practical challenges with these approaches. Issues with the reference point [22,23], scale [24], differences in attribute processing and heuristics [25,26], learning and fatigue effects [27], attention [28], and other challenges have caused considerable methodological discussion and new modeling approaches in health, marketing, transportation, and environmental economics over the past decades as researchers work to model consumer decision-making.

Health Technology Assessment

Among the first publications in the past 25 years were studies focused on how consumers search for and appraise information on medicines on the internet. A qualitative study in 2003 found that many patients had a limited awareness of how they found and evaluated internet-based information on medicines [29]. An observational study using a convenience sample of 14 students published the same year focused on the proportion of adolescents finding correct or useful answers on the internet

XSL•FO
RenderX

[30] and found that in about two-thirds of internet searches, they were successful in finding relevant health information.

In the early 2000s, most studies regarding decision-making focused on how patients gather information to make informed choices and how they could potentially use that information. This led to the formal concept of informed decision-making, which mostly entailed that patients would decide to undergo testing or treatment with them knowing and understanding the value or need for it, such as in the case of a study evaluating the effect of the web-based prostate-specific antigen (PSA) decision aid, Prosdex, on informed decision-making [31]. This study, published in 2010, was a web-based randomized controlled trial among men aged 50-75 years who had not previously undergone a PSA test, who were randomly allocated to 2 intervention and 2 control groups [31]. Participants in the intervention groups either viewed the decision aid Prosdex or were given a paper version of the text. The study showed that Prosdex is associated with improved knowledge about the PSA test and prostate cancer and that men who have a high level of knowledge have a less favorable attitude toward and are less likely to undergo PSA testing. Around this time, more studies used quantitative methods to assess the effect of health information on decision-making regarding health services and health behaviors. Examples include a study on the effects of internet-based tailored advice on the use of cholesterol-lowering interventions [32] and a feasibility study of an internet-based education and decision program for patients with early-stage prostate cancer [33].

In the years following, increasingly more studies appeared that discussed informed decision-making in the context of cost-effectiveness and cost utility [34-38], where the assessment of utility or value was now described as HTA. HTA is used to ensure that health care decisions consider relevant evidence about the costs and benefits of a treatment in a systematic way [39].

The studies mentioned focused primarily on the effect of digital technologies that have made an impact on decision-making. In general, new health technologies largely affected clinical and economic outcomes, and research methodologies to evaluate the efficiency of these new technologies were necessary. Cost-effectiveness analysis (CEA) is one way of doing this, which assesses the value or benefit of new health care technologies or interventions and compares the costs to a reference or threshold. In the United States, in the 1990s, the first and second panels on CEA included economists, ethicists, psychometricians, and clinicians who were asked to make reference case recommendations. The 1996 consensus report *Cost Effectiveness in Health and Medicine* was the first to describe the uses and conduct of CEA as a decision-making aid in the health and medical fields [40]. HTA was initially more actively developed in Europe in the 1970s, with both formal and informal initiatives in different countries [41]. So-called consensus conferences played an important role in the early development of HTA and had the explicit goal of using the best-available evidence in making policy, administrative, and clinical decisions in health care. By generating a broader interest in scientific evidence among policymakers, clinicians, and the general public, the conferences created a wider understanding of the need for comprehensive assessment in health care [42]. Although US policies have from there onward prevented the use of CEA for reimbursement decisions, such as with the Affordable Care Act of 2010, which banned Medicare from using CEA metrics, formal agencies were established in many individual European countries for HTA, starting with the first in Sweden in 1987, followed by many others in the 1990s.

n Australia, too, HTA of nonpharmaceutical technologies was developed in the 1970s and in 1990 for pharmaceuticals. It was established by the Commonwealth Parliament in the light of increasing costs of medical investigations and patient care [43]. Since almost 70% of total health expenditures in Australia are funded by government programs, including Medicare and the Pharmaceutical Benefits Scheme, evaluation was undertaken to consider the effects of developments in technology on medical benefits and public hospital costs, with some emphasis on diagnostic methods [43]. Economic evaluation is undertaken by or on behalf of the manufacturing industry, and the evidence on clinical effectiveness, safety, and cost-effectiveness presented is then considered by the Pharmaceutical Benefits Advisory Committee (PBAC).

Quality-Adjusted Life-Years

HTA commonly uses evaluation methods to assess whether the costs per quality-adjusted life-year (QALY) gained from a treatment, pharmaceuticals, or intervention are within the conventional range of acceptability. QALY is a standard measure of the disease burden that includes both the quality and the quantity of a human life and is used in economic and health policy evaluation to assess the value of medical interventions [44]. One QALY equals one year of perfect health. This differs from a year of life gained, which does not consider the quality of life (QoL).

QALYs have been in use for a half century, with criticisms of the approach nearly as old [45]. Among the many criticisms of QALYs are challenges with incorporating equity [46], challenges in relating QALYs to economic models of utility [47], and questions about the valuation and the basis for weighting of different outcomes [48]. Despite these criticisms, QALYs are the standard in many countries for HTA.

Most HTA-oriented countries base their reimbursement model on a threshold number per QALY saved. Cost-effectiveness thresholds (CETs) vary widely by country and are typically used to assess whether an intervention is worthwhile from a country-specific standpoint and often reflect the perceived health opportunity cost [49]. For example, in Australia, the PBAC is believed to apply a threshold range of AU $45,000-$60,000 per QALY [50], it is GBP 20,000-40,000 per QALY in the United Kingdom, and in many European countries, this is between euros 50,000 and 100,000 per QALY saved. CETs used by other decision makers (eg, the World Health Organization's suggested CET of 1-3 times the gross domestic product [GDP] per capita) do not. This way of calculating cost-effectiveness has been applied to various treatment options and conditions. Even internet-based interventions, such as those for harmful alcohol use, have been evaluated using this framework. A study evaluating the cost-effectiveness and cost utility of internet-based interventions for harmful use of alcohol [51],

XSL•FO
RenderX

through the assessment of the incremental cost-effectiveness of IT compared with information systems (IS), found that the median incremental cost-effectiveness ratio was estimated at euros 3683 per additional treatment responder and euros 14,710 per QALY gained. At a willingness to pay euros 20,000 for 1 additional QALY, IT had a 60% likelihood of being more cost effective than IS.

The quality adjustments in QALYs are based on various measurement methods and instruments. One key early debate was whether "health" could be measured as a single index value or whether health should be represented by a series of values representing different aspects of health, such as physical, mental, and emotional health. In the late 1980s, an interdisciplinary 5-country group developed the EuroQol instrument, a 5D, 3-level generic measure subsequently termed the "EQ-5D" [52]. It was designed to measure and value health status in terms of 5 dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression [53]. The valuation method expanded usage across clinical programs, disease and condition areas, population surveys, patient-reported outcomes, and value sets.

The EQ-5D has become the standard measure for health and provides a generic measure with a single index value representing health. The EQ-5D was designed to measure decrements in health across conditions and populations. Digital versions have been developed over the years, validated [54], and applied to various questions [55-58] regarding cost-effectiveness of interventions and treatments.

US policymakers have consistently chosen not to use the costs per QALY framework for reimbursement decisions. Indeed, in both the Affordable Care Act and the recent legislation authorizing Medicare to negotiate drug prices, the use of QALYs for value assessment was explicitly prohibited [59]. In recent years, the United States did see steady growth in the number of organizations conducting value assessments. National organizations, such as the Institute for Clinical and Economic Review (ICER) [60], the Innovation and Value Initiative (IVI), and the National Comprehensive Cancer Network (NCCN), have introduced value assessment frameworks and tools to guide health care decision makers in evaluating the relative benefits and costs of health care interventions, primarily pharmaceuticals. According to a recent analysis, the field of value assessment in the United States is dynamic and evolving [61], and the use of value assessment is gaining traction with health care decision makers and policymakers. Overall, 79% of surveyed health care payers reported that ICER recommendations influenced their decision-making in 2022, compared to only 49% in 2016 [62,63].

As health care decision makers and policymakers in the United States increasingly use value assessment tools to inform their decision-making, there are a variety of different tools that can be used, with different approaches to measuring value, endpoints, and criteria for assessing the different approaches [59]. DiStefano et al [59] suggested that these criteria could include feasibility, flexibility, and the ability to incorporate factors beyond the traditional value elements. They also contrasted measures that use conventional (QALY) endpoints with those that incorporate patient-centric value elements.

Patient-centered methods will not necessarily always align well with the averages that HTA in Europe often uses to make decisions on the use of a technology at a group level. Differentiation in the use of technologies for different groups of patients may not only be desired but also be more affordable if it means that some groups of patients prefer cheaper or no treatment. Patient-centered care means patients should be part of the decision-making process, not only through providing information, but also through providing authority to make decisions about their treatment plans and care path. Indeed, this is one of the reasons patient advocates in the United States have (to date) successfully lobbied against the use of QALY measures [45].

One example of this could be the treatment of prostate cancer. Treating prostate cancer carries the risk of impedance and may not meaningfully impact life-years; however, not treating the cancer carries the risk that the cancer metastasizes. The "correct" treatment will need to weigh the patient's preferences for not being impendent versus the patient's willingness to accept a cancerous tumor growing in their body versus expected life expectancy. In this example, the "average" best course of treatment may not provide guidance for the best course of treatment *for a particular patient*. Today, many patients with prostate cancer are consulted about their options and the advantages and disadvantages of each treatment path and are allowed to select their preferred treatment path.

Another example would be single versus double mastectomy. The decision on whether to remove a healthy breast in a woman with a high risk of breast cancer is not simply about QALYs gained or lost; it has profound personal implications around body image anxiety and fear of recurrence [64].

Alternative CEA Approaches

There have been sporadic attempts to incorporate HTA into public health coverage decisions in the United States. The most well known is the attempt by the state of Oregon to use HTA principles to determine Medicaid coverage decisions. The state rejected standardized CEA and instead used a combination of expert opinion and public panels to create rank-ordered priorities. Oregon's attempt to use CEA failed because of a combination of factors. One was a lack of public acceptance of the priorities; one of the most visible elements was a child, Adam Howard, who died after he was denied a bone marrow transplant because of the combination of a low probability of success and high cost. The second factor was the Americans with Disability Act (ADA), which both Bush and Clinton administrations argued was violated by the use of HTA.

Although CEA has not been well accepted in the United States, there are newer approaches that seek to incorporate HTA into decision-making in the United States. CEA has been supplemented with approaches to assess value, including multicriteria decision analysis (MCDA), generalized risk-adjusted cost-effectiveness (GRACE) analysis, and the "value flower." MCDA is a decision-making method that systematically weighs various value elements that may fall

XSL•FO
RenderX

outside traditional value assessments, such as a treatment's scientific novelty, a patient's disease severity, or how a treatment may affect a caregiver's productivity [65]. MCDA models allow users to choose their willingness-to-pay thresholds and customize their value determination results using modifiable inputs for measures related to a treatment's benefits and cost. There are an increasing number of studies reporting that defining the value of health care depends heavily on the decision context and stakeholders involved [66]. Where cost-utility analysis and QALYs have become the method and value definition of choice for traditional value judgements in coverage and pricing decisions, other criteria that may influence value are often not measured and therefore omitted from value assessments or are only used to qualitatively contextualize assessments. Recent qualitative research shows that for payers, value equates either with criteria that provide tangible benefits (from their perspective), such as new treatment options that respond to a serious unmet need. For patients, a population-level value equates to options that would potentially benefit them in the future and the value of hope. One suggestion made by Campbell et al [67] is to include the equal value life-year (evLY) as a measure of health gain that can be used as an alternative or a complement to QALY to address concerns related to undervaluing treatments that extend the life of individuals with serious illness or chronic disability. Measurement methods no longer solely insist on linear, additive utility. A systematic literature review [68] identified 15 relevant value frameworks and MCDA tools. These studies included a large number (n=56) of individual value criteria. The most commonly included novel criteria were an unmet medical need, severity of disease, and reduction in uncertainty. The identified scoring functions (measurement methods) for novel criteria were highly heterogeneous and tailored. Standardized scoring functions were not observed.

One example is GRACE analysis, which is a somewhat different approach to CEA that aligns economic assessments of treatments with patient preferences and experience of care [69]. In GRACE analysis, differential CETs (relative to traditional CEA) are applied based on disease severity (eg, higher thresholds for more severe diseases) and other patient circumstances to better recognize the value of treatments that promote equity and significantly improve patient QoL [69]. This links value assessment more tightly to economic theory, recognizing that the utility value of a health improvement varies depending on the underlying level of health. This was one of the key problems with the use of HTA in Oregon: treatments with acceptable QALY values but low utility values, such as routine dental care, were prioritized over conditions with lower QALY values but (potentially) higher utility values, such as bone marrow transplants. Although the GRACE method has been described at length in the literature [70-73], studies are now underway applying it and comparing it with different approaches and outcomes.

In addition to addressing potential nonlinearity of utility functions, there have been several initiatives to expand the set of "value measures." A special task force of ISPOR, the professional society for health economics and outcomes research worldwide, created a "value flower" that identified elements of value that are and are not typically included in standard CEA and a recommendation to expand cost-effectiveness measures with these value elements to better capture what is important to individuals but unmeasured in standard QALYs [74]. In general, newer approaches to CEA now seek to include measures of productivity, real option value, insurance value, reduction in uncertainty, scientific spillover, severity of disease, adherence-improving factors, equity, and the value of hope. The issue with all these novel approaches, however, remains that the ultimate goal is to draw conclusions about *societal* costs and benefits rather than a blueprint for *individualized* health care delivery based on patient preferences and perceptions.

Policy Efforts and Future Opportunities

Patient Centeredness

In the policy arena, a series of important changes have been made regarding the patient's position in the decision-making process. For decades, there have been attempts to improve "patient centeredness" in health care, which is defined as "providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patient values guide all clinical decisions" [75]. Although the focus on patient-centered care has increased, the rationale, measurement, and implementation of strategies to improve patient-centered care or to use patient experiences for quality improvement purposes have been widely debated [76,77]. In practice, patients are not directly and proactively involved as much in the process of quality improvement. Even if efforts to design care through the patient's eyes [78] are supported, the question remains to what extent this can be done at the individual patient level. Information and communication technologies have more recently shown to be able to support chronic disease self-management, but this self-management should be accompanied by a shift in focus on integrating the patient's own perceptions of the chronic disease and the health care system's approach to managing it [79]. As mentioned previously, we therefore need to use and improve methods to assess patients' perceptions, attitudes, beliefs, and preferences for health services and self-management.

Various patient-reported outcomes have since been developed and evaluated, with most studies concluding that health care professionals and patients alike need to choose the most suitable patient-reported outcomes for their patients, which may not be the same for every patient population or individual [80]. For health insurance, for example, the Health Plan Employer Data and Information Set (HEDIS) has been used to compare and report quality across health plans from a patient perspective, but in a number of cases, these do not appear to be cost effective or provide value for certain subgroups [81].

Shared Decision-Making

The same is true for the concept of shared decision-making, a process by which patients and providers consider outcome probabilities and patient preferences and reach a health care decision based on mutual agreement [82]. This is best used in situations in which there is medical uncertainty or different treatment options. Theoretically, both provider and patient discuss the different options and reach a conclusion together

XSL•FO
RenderX

about the optimal strategy. In the United States, for example, policy initiatives to improve shared decision-making were embedded in both the Affordable care Act (2010) and the patient-centered medical home, but their success depends on building a good relationship so that information is shared and patients are supported to deliberate and express their preferences and views during the decision-making process. Increasingly more (codesigned) decision aids have been developed in recent years to support shared decision-making and provide room for individual preference heterogeneity. These decisions aids are also being evaluated, with many studies concluding that when designing interventions to improve health outcomes, it is important to consider this heterogeneity. For example, a study looking at a decision aid for diabetes self-care found that teenagers with type I diabetes mellitus prioritize reducing family conflict and fitting into their social milieu over health outcomes at this time in their lives [83]. Another study focused on gaps in the current approach to shared decision-making for children with medical complexity suggested that clinicians should focus decision-making discussions on integrating each child's unique situation, the insights parents gain through their decision-making activity, and their clinical knowledge to enhance the understanding between parents and health care providers beyond the narrow concept of parental values [84].

In the United Kingdom, health authorities have engaged clinical champions and patient representatives in national initiatives for shared decision-making and embarked on a process of widely disseminating patient decision aids [85]. In practice, however, providers often find that the time required to go over all necessary information and decision aids in not available. Decision aids ultimately suffer from the same challenge as the concept of patient centeredness; there is not enough room in the clinical care pathway for approaches that incorporate individual preferences.

Future Opportunities for Value Assessment

Patient value is a key component in all areas of health care delivery, and understanding how health providers create, communicate, and deliver value to patients is a key factor when seeking ways to improve care according to the triple aim of improving the individual experience of care; improving the health of populations, and reducing the per capita costs of care for populations [86].

The practice of HTA uses a societal perspective to measure the cost-effectiveness of treatment in terms of costs and QALYs, where QALYs assume that a health state that is more desirable is more valuable, and therefore, value is equated with preference or desirability. This approach has major empirical and conceptual shortcomings, such as inconsistencies among values obtained from the standard gamble, time trade-off, and visual-analog scale elicitation formats and, more importantly, the linearity assumptions that violate the key economic assumption of diminishing marginal utility. Although HTA has come a long way in its "multifaceted assessment of the clinical, economic, ethical, legal, and societal perspectives that may be impacted by a new technology, procedure, drug, or process" [87], these approaches may not sufficiently reflect individual patient or health consumer preferences that may be important in the assessment of "value" in the current value-based health care discussion.

The key difference in measuring value is that the outcome in other fields is an economic and tangible measure, such as purchasing a car, whereas in health, it is the production of health. One way to better predict behavior and choice in health, therefore, is to include the health production function. Our recent work on medication nonadherence, for example, has shown that there is an enormous discrepancy between patient preferences and their beliefs and expectations [88]. In a pilot study using a double-bound contingent-belief (DBCB) questionnaire, patients could express how efficacy and side effects are affected by controlled levels of nonadherence, allowing for the estimation of sensitivity in health outcomes and costs. The derived health production function suggested that patients may strategically manage adherence to minimize side effects without compromising efficacy. Patients' inclination to manage medication intake was closely linked to the relative importance they assign to treatment efficacy and side effects. We formalized the definition of health production functions by positing that patients craft a mental model of health production under scenarios that are not covered by interactions with their physicians or by the clinical evidence available to them. This function relates the benefits of health behaviors to the costs associated with achieving such benefits. Value, then, is now defined not only by preferences for health outcomes alone but also by the patient's expectations of health outcomes. The "mental model" described in this paper is now being tested in different studies.

In addition to tangibility, a second key difference is that the production and consumption of a medical service take place simultaneously. This inseparability and the inconsistency in health that is being produced give much more room to interpretation, experiences, perceptions, and emotions when making a decision. In some cases, patients may be informed regarding clinical efficacy, but they may care more about another attribute of service or treatment that is entirely unrelated to clinical outcomes but not irrelevant to them. For example, a physician advises a patient to wait with treatment because the patient is at a risk of side effects at that point in time. The physician is attempting to provide high-quality care and act in the patient's best interest, while maintaining a reputation for delivering high-value care. This particular patient may choose immediate treatment because the gains outweigh the potential side effects and because the patient does not care about the physician's reputation. This creates a conflict between QALY-type HTA assessment and individual assessments of "value."

In a situation like this, who defines what "value-based" care means? If policymakers truly want to promote patient-centered care and shared decision-making, the question is what the desired outcome is in this situation. Reimbursement decisions are currently based on an equation that defines value in terms of health states. We know that this approach tells only one part of a story—what is preferable from a societal approach. If we accept the notion that all patients are different and have different

XSL•FO
RenderX

preferences, it must be acknowledged that "value" in health care needs to be redefined to incorporate patient preference heterogeneity.

Value assessment in health has come a long way in the past 25 years. Currently, health economic models focus on the benefits and costs of treatment options and help define reimbursement and delivery systems. However, this top-down approach needs to make room for "value-based" care, which considers value to individual patients. Value-based care ties the amount health care providers earn for their services to the value they deliver for their patients, such as the quality, equity, and cost of care. Through financial incentives and other methods, value-based care programs aim to hold providers more accountable for improving patient outcomes. However, in practice, so far, the focus is primarily on cost containment.

In this system, there is little attention given to variations in individual patient preferences or factors that affect those preferences. Many value-based health care systems still focus on cost containment strategies for the average patient, not the individual value to individual patients [89]. The idea is that some treatments, such as some imaging for low back pain, should not be provided (to anyone), while other treatments, such as vaccines, should be uniformly dispensed (to everyone). The one-size-fits-all approach to value disproportionally makes some patients worse off. In addition, delivery systems have differential effects on patient populations, which further enhances health inequities. Theoretically, it also increases spending, because all patients are expected to require a treatment for a weighted average cost. In practice, some will require higher-cost treatment options, while others will value lower-cost options. Care delivery that considers all aspects of human decision-making will help pave the way for more accurate cost-benefit analysis and improved access and affordability.

One lesson learned from 25 years of value assessment in health is that there is no average patient, yet many HTAs are still based on averages. That is why value assessment from a societal perspective may lead to equitable allocation of resources without necessarily leading to optimal use of resources. If individual patient behaviors and preferences are not considered in value assessment methods, resources will be wasted because of a mismatch between what the consumer values and what society prioritizes.

It will be challenging to consider the complexities of individual preferences and behaviors, especially if they are not met at the societal level. There has been an increase in the adoption of ideas from behavioral economics and mathematical psychology to better understand human decision-making in health. There are ways to add information about cognitive and brain processes that may help value assessment in health to perform more precise predictions of human decision-making and choice.

However, the final challenge for future value assessment will be to incorporate heterogeneity of preferences into decision models. Currently, heterogeneity is largely considered in terms of health equity and the impact of approval of denial of treatment on disadvantaged populations. However, the more challenging aspect will be trying to reconcile heterogeneous patient preferences with decision tools based on "average" patients. Centralized decision makers using average metrics, such as "incremental cost-effectiveness ratios," are reliant on the strong assumption of linearity of preferences, which is unlikely to hold in heterogeneous/diverse societies. This means that centralized planners using decision rules based on measures such as the average cost per QALY gained will misallocate resources and fail to use health care dollars to maximize the well-being of society.

Conclusion

Where ultimately the current energy toward developing new measures of value will lead is unclear. Clearly, patients are interested in better measures of value, but whether any of the new measures that have been developed will be meaningful and useful to consumers is unknown and a fruitful area for future research. Similarly, patient advocates will tend toward broader measures of value, but whether the rank-ordering of treatments will ultimately change is unknown—and another fruitful area for future research. Finally, how central payers will incorporate the new measures into their decision-making is perhaps the biggest unknown of all. Research will need to demonstrate the value of the new measures in providing better measures of value that meaningfully change health spending priorities.

Abstract

Background: Digital health interventions have emerged as promising tools to promote health behavior change and improve health outcomes. However, a comprehensive synthesis of strategies contributing to these interventions is lacking.

Objective: This study aims to (1) identify and categorize the strategies used in digital health interventions over the past 25 years; (2) explore the differences and changes in these strategies across time periods, countries, populations, delivery methods, and senders; and (3) serve as a valuable reference for future researchers and practitioners to improve the effectiveness of digital health interventions.

Methods: This study followed a systematic review approach, complemented by close reading and text coding. A comprehensive search for published English academic papers from PubMed, Web of Science, and Scopus was conducted. The search employed a combination of digital health and intervention-related terms, along with database-specific subject headings and filters. The time span covered 25 years, from January 1, 1999, to March 10, 2024. Sample papers were selected based on study design, intervention details, and strategies. The strategies were identified and categorized based on the principles of Behavior Change Techniques and Behavior Strategies.

Results: A total of 885 papers involving 954,847 participants met the eligibility criteria. We identified 173 unique strategies used in digital health interventions, categorized into 19 themes. The 3 most frequently used strategies in the sample papers were "guide" (n=492, 55.6%), "monitor" (n=490, 55.4%), and "communication" (n=392, 44.3%). The number of strategies employed in each paper ranged from 1 to 32. Most interventions targeted clients (n=844, 95.4%) and were carried out in hospitals (n=268, 30.3%). High-income countries demonstrated a substantially higher number and diversity of identified strategies than low- and middle-income countries, and the number of studies targeting the public (n=647, 73.1%) far exceeded those focusing on vulnerable groups (n=238, 26.9%).

Conclusions: Digital health interventions and strategies have undergone considerable development over the past 25 years. They have evolved from simple approaches to sophisticated, personalized techniques and are trending toward multifaceted interventions, leveraging advanced technologies for real-time monitoring and feedback. Future studies should focus on rigorous evaluations, long-term effectiveness, and tailored approaches for diverse populations, and more attention should be given to vulnerable groups.

KEYWORDS

digital health interventions; intervention strategies; behavior change; mHealth; eHealth; randomized controlled trial

Introduction

The Rise of Digital Health Interventions

The rapid advancement of digital technologies has significantly influenced health practices. As of 2020, digital health has more than 90 definitions, encompassing eHealth, mHealth, self-tracking, wearable devices, and artificial intelligence applications [1]. Digital health interventions, defined as interventions delivered via digital health technologies, have emerged as promising tools for promoting healthy behaviors and improving health outcomes [2]. The effectiveness of digital health interventions has been validated across diverse domains, populations, and countries. Specifically, digital health interventions have demonstrated success in multiple health areas, such as noncommunicable disease management [3], mental health support [4], and smoking cessation programs [5]. In addition, these interventions have proven effective in serving not only the general population but also vulnerable groups, such as resource-poor communities and ethnic minorities [6]. Notably, their application extends across geographical and economic boundaries, showing positive results in both high-income nations, such as the United States [7] and Canada [8], and resource-limited regions, including Pakistan [9] and West Africa [10].

Driven by technological innovations, increasing smartphone penetration, and the growing acceptance of digital health technologies, health care delivery is experiencing a significant transformation from traditional processes to digital interventions [11]. The COVID-19 pandemic has further accelerated this transformation [12]. As health care systems globally confront challenges, including aging populations, rising chronic disease burdens, and disparities in health care access, the adoption and integration of digital health interventions have become increasingly crucial [13]. Moreover, recent advances in artificial intelligence have further enhanced the importance and impact of digital health interventions.

The Critical Role of Strategies in Digital Health Interventions

Strategies are indispensable for generating the desired effects of digital health interventions. Selecting and implementing appropriate strategies are crucial for ensuring their success [14]. Well-designed strategies have the potential to enhance user engagement, promote behavior change, and contribute to improved health outcomes [15,16], although their effectiveness may vary across different populations and contexts. Through the application of well-defined, theory-based strategies, digital health interventions can provide enhanced support for individuals in achieving their health goals, ultimately leading to more sustainable health care approaches [17].

Strategic approaches play a crucial role throughout the intervention process, from initial design to implementation. For example, message strategies, which form the core of the intervention design phase and are based on principles such as reciprocity, reciprocity-by-proxy, and curiosity, have proven effective in engaging racial and ethnic minority groups in digital oral self-care interventions [18]. During the implementation process, strategies can help overcome barriers to achieving intervention goals through four key approaches: (1) increasing coherence (ensuring the intervention is meaningful to users); (2) enhancing cognitive participation (securing user engagement); (3) promoting collective action (supporting the implementation process); and (4) enabling reflexive monitoring (facilitating an assessment of the intervention's effects) [19].

Current Findings on Digital Health Intervention Strategies

Currently, several studies, including systematic reviews and meta-analyses, have explored the impact of various strategies on health behaviors and outcomes in digital health interventions. Saleem et al [20] found that engagement strategies including feedback, guidance, social support, content gamification, reminders, flexibility, and ease of use can promote mental health outcomes. Behavior change strategies including follow-up prompts, self-monitoring, emotional control training, and provision of information about others' approval were widely used to contribute to health behavior [21].

A recent meta-analysis for weight management interventions found that strategies like problem-solving, goal setting, reviewing goals, feedback on behavior, self-monitoring of behavior, behavioral substitution, and credible sources were successful in addressing decreased energy [22]. The strategies of sustained motivation, self-regulation, psychological and physical resources, habit formation, and environmental and social influences were valued by weight loss maintenance intervention [23,24]. Four strategies, including improving social skills, enhancing social support, increasing social contact, and addressing cognition, have been identified to reduce loneliness [25]. Eleven intervention strategies, primarily involving medication and diet control, including physical activity, lipid-affecting drugs, and diet plus exercise, have been identified to prevent type 2 diabetes mellitus in China [26].

In addition, substantial strategies have been found to be effective in improving recruitment, reducing loss to follow-up, and enhancing retention [27-30]. A total of 72 strategies were tested to enhance participant recruitment in randomized trials, with 7 of these strategies being investigated in multiple studies [31]. Six broad types of strategies, including incentives, communication strategies, new questionnaire formats, participant case management, behavioral interventions, and methodological interventions, were summarized as effective approaches to improve retention [32]. Robinson et al [33] abstracted 368 strategies from 21 studies and identified 12 themes aimed at retaining participants. They found that contact and scheduling were the most common strategies to limit participant attrition in health care research.

XSL•FO
RenderX

Study Objectives

The previous research on digital health intervention strategies [23-34], despite its comprehensiveness, has significant limitations, notably its narrow focus on specific health issues or populations and its inadequate exploration of behavior change. Moreover, numerous nuanced strategies remain unidentified and analyzed, requiring further investigation. Accordingly, it is crucial to identify, categorize, and aggregate strategies used in digital health interventions. As the field of digital health continues to evolve, a deeper understanding of intervention strategies will be vital for advancing both research and practice, offering valuable insights into their effectiveness and guiding the design of future interventions. By identifying and categorizing these strategies, researchers and practitioners can gain a clearer understanding of effective approaches and techniques in digital health interventions, evaluating the strengths and limitations of different strategies and their relevance to specific health domains or populations. Furthermore, a comprehensive understanding of digital health intervention strategies can support the development of evidence-based guidelines and best practices, fostering the standardization and quality of digital health interventions.

Therefore, this study aimed to (1) identify and categorize the strategies employed in digital health interventions over the past quarter century; (2) explore the differences and changes in these strategies across time periods, countries, populations, deliveries, and senders; and (3) develop a catalog of strategies to serve as a reference for future researchers and practitioners to improve the effectiveness of digital health interventions.

Methods

Overview

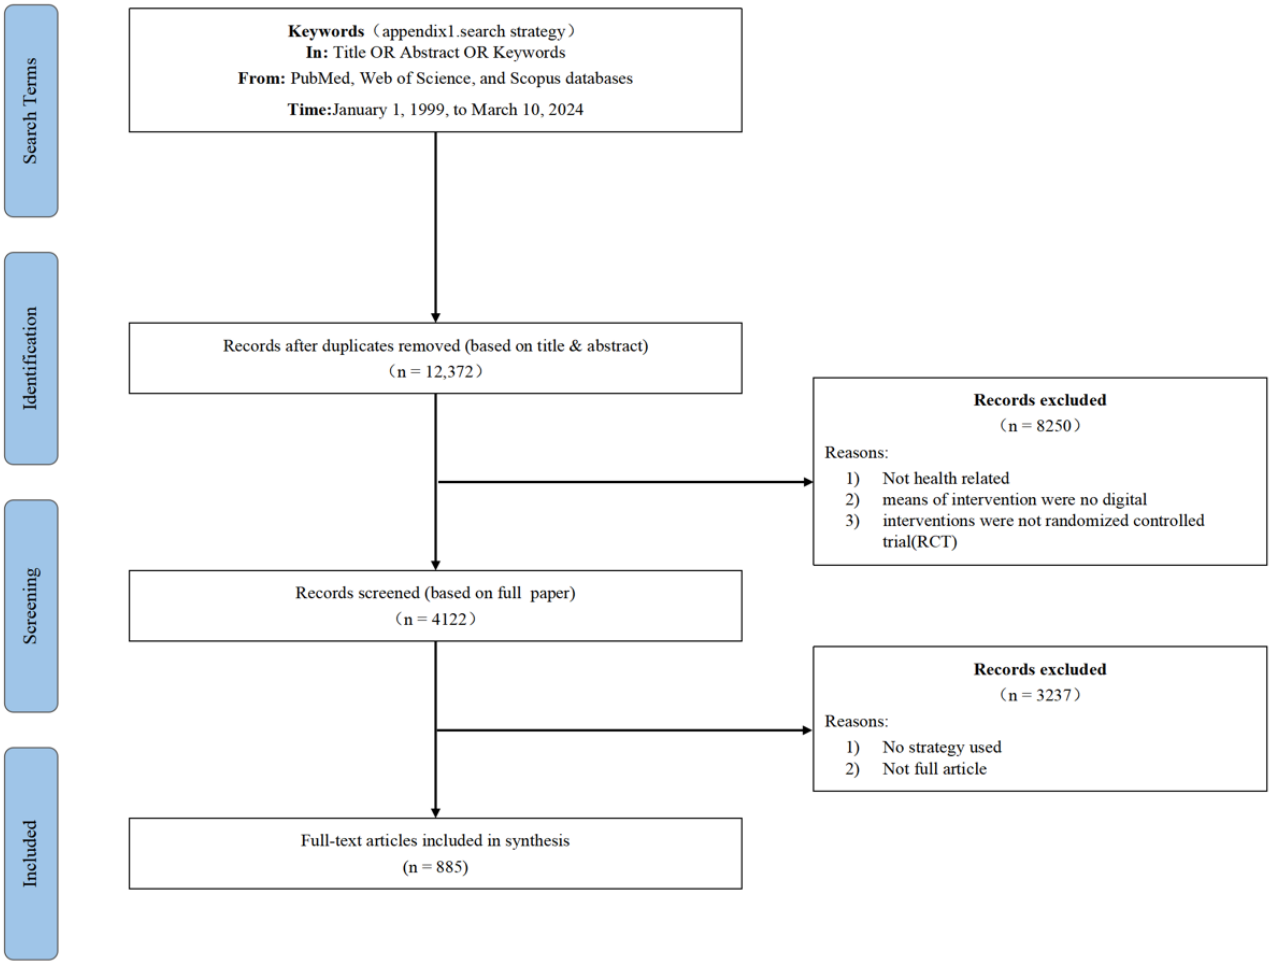
This article followed a systematic review approach, complemented by close reading and text coding. The systematic review was used to access and screen relevant literature, while textual close reading was employed to identify and categorize strategies. The identification and categorization of strategies were guided by the principles and catalogs of Behavior Change Techniques (BCTs) [35] and Behavior Strategies (BSs) [22]. This dual approach ensures a comprehensive and rigorous analysis of the strategies used in digital health interventions.

Search Methods

Our research steps were guided by PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines (Multimedia Appendix 1) [36]. We conducted a comprehensive search for published English papers from PubMed, Web of Science, and Scopus. These databases are globally esteemed for their broad interdisciplinary coverage, sophisticated search tools, and current updates, which ensure systematic reviews are comprehensive, accurate, and authoritative [37]. Based on these characteristics, we selected these 3 databases for the following reasons: (1) broad coverage: these databases offer extensive coverage of medical and health-related research, enabling us to capture a wide range of relevant studies; (2) interdisciplinary nature: the selected databases cover related fields such as psychology, public health, and information technology; (3) quality and reliability: these databases are recognized for their rigorous inclusion criteria and high-quality indexing.

This search employed a combination of digital health and intervention-related terms, along with database-specific subject headings and filters, to ensure thoroughness and focus. The detailed search strategy for each database can be found in Multimedia Appendix 2. The time span considered was the past 25 years, from January 1, 1999, to March 10, 2024.

Selection of Sample Papers



We conducted 2 rounds of screening and selection. The first round focused on identifying digital health interventions, while the second round aimed to pinpoint specific strategies within those interventions.

For the first round of screening, pairs of reviewers (authors JM, MS, YG, NZ, ML, and HD), all graduate students majoring in public health or health communication, independently reviewed the titles, abstracts, and keywords of the sample articles to preliminarily identify studies that met our eligibility criteria. The specific screening criteria and steps were as follows: (1) the means of the intervention should be digital, primarily including wearable devices, telemedicine, electronic health records, electronic medical records, mobile phone applications, web pages, blogs, emails, text messages, social media, and similar technologies; (2) the intervention must be health-related, encompassing health behavior improvement, disease treatment, and health education, and so on. (3) the studies must be randomized controlled trials (RCTs), including individual and cluster RCTs, as they provide the highest level of evidence for evaluating interventions. We excluded randomized feasibility and pilot trials because they are inherently preliminary studies conducted to inform future RCTs [38].

In the second round of screening, we concentrated on identifying specific strategies within the selected digital health interventions. For this study, a strategy was defined as a specific approach or technique employed within the intervention to promote health behavior change or improve health outcomes. The second round of screening involved a full-text examination of the included sample papers. The reviewers (JM, MS, YG, NZ, ML, and HD) assessed the descriptions of the interventions and the strategies employed. The flow of literature searches and screening is shown in Figure 1.

XSL•FO
RenderX

Figure 1. Flow diagram of literature search and screening.

To guide the strategy extraction, we provided a framework and definitions of potential strategies (Multimedia Appendix 3) organized into 18 clusters and 64 themes based on BCTs [35] and BSs [22]. Recognizing the possibility of strategies extending beyond these predefined themes, we incorporated an "other" theme to capture a broader range of strategies. This adaptable framework aimed to maximize the thoroughness and accuracy of the data collection process, ensuring that novel or unique strategies were not overlooked.

After identifying all strategies, we conducted a comprehensive review to pinpoint overarching themes and classify each strategy accordingly. Initially, 3 authors (SL, YG, and CZ) examined the strategies and proposed themes independently. Subsequently, the first author (SL) reviewed the independent results, reconciled discrepancies, and developed a list of common themes. Next, a team meeting discussed the proposed themes and strategy categorization, leading to a final list of themes and assigning each strategy to 1 category. Finally, the senior authors reviewed and adjudicated the assigned themes, with any disagreements resolved through team discussions.

We assessed interrater reliability across 2 rounds of the coding process. In the first round, 6 independent students screened articles based on titles, abstracts, and keywords. Due to the large volume of articles, a 1% sample was used for training purposes. The interrater reliability was measured using Fleiss kappa, yielding a coefficient of 0.82. In the second round, a coding guideline was developed, and 6 students underwent thorough training before proceeding with coding. Initially, 10% of the articles were used for calibration, resulting in a Krippendorff alpha of 0.85 for intercoder reliability. Inconsistencies were addressed through meetings, with a senior researcher arbitrating persistent disagreements. Any issues encountered during the coding process were promptly discussed in regular meetings and our WeChat group.

We recorded the number of articles identified, screened, deemed eligible, and ultimately included in the study, along with coding, using Microsoft Excel (IBM Corp). This systematic approach guaranteed a transparent process for capturing papers that met our inclusion criteria.

Data Extraction and Coding

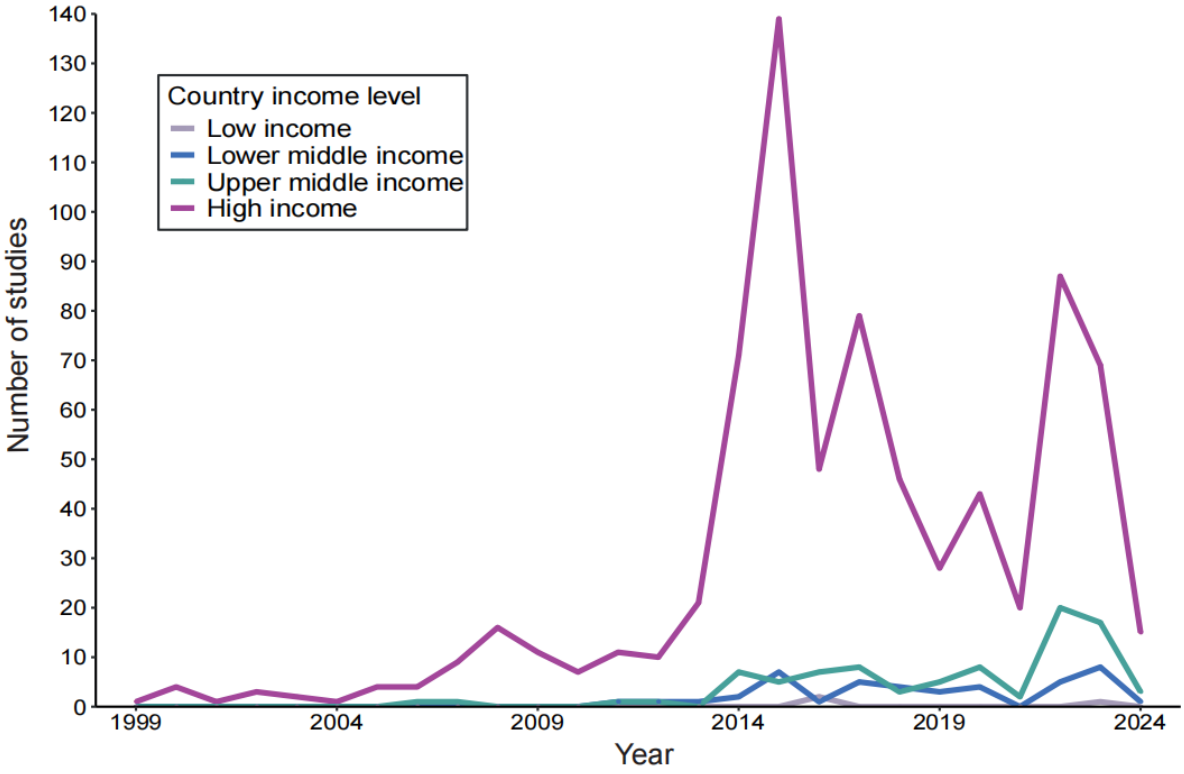
In this study, we coded several key aspects from the included sample papers. General information such as the journal of publication, authors, year of publication, the geographical context of the intervention, demographic characteristics of participants, and the theoretical framework or models underpinning the intervention (if reported) were documented.

We also examined the characteristics of the digital health interventions, including the health concerns they addressed, delivery modalities (eg, short text messages, smartphone apps, and online platforms), intervention duration, sender type (automated or human-assisted), and their classification according

XSL•FO
RenderX

to the World Health Organization's (WHO) 2018 framework (patients, health care professionals, health system administrators, and data services) [39]. Additionally, strategies were identified and labeled based on a structured framework and descriptive criteria established for this study (Multimedia Appendix 3).

Results



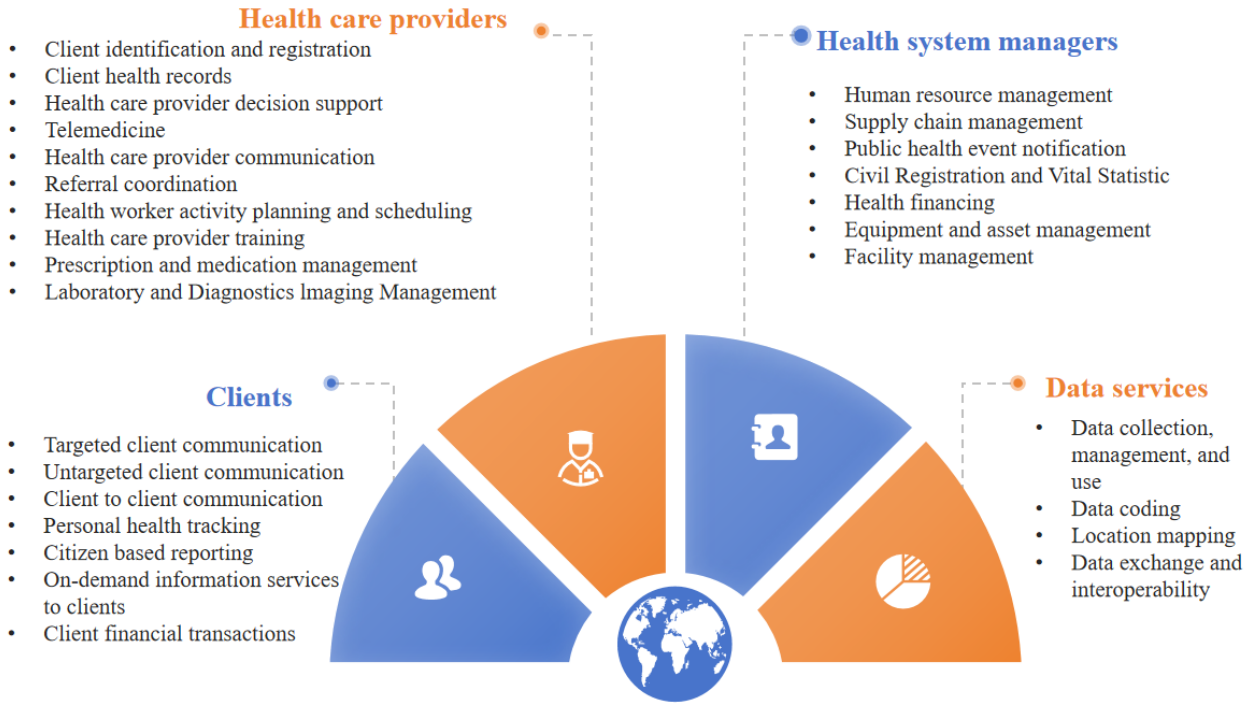
Characteristics of the Included Papers

After the initial screening, we identified 4122 valid sample papers on digital health interventions. Following the second round of full-paper screening, and after excluding interventions that did not incorporate any strategies, 885 studies ultimately met the eligibility criteria.

According to the World Bank [40], countries were categorized into 4 income levels: low income, lower middle income, upper middle income, and high income (Figure 2). The number of studies conducted in high-income countries (n=750, 84.7%) far exceeded that of other income levels, with research activity increasing in all countries since 2010. Notably, studies in high-income countries peaked significantly around 2015, with 139 (15.7%) studies. Studies in upper–middle-income and lower–middle-income countries showed moderate activity with occasional peaks, particularly in 2022 (n=22, 2.5%) and 2023 (n=8, 0.9%), respectively.

The sample papers reported a total of 954,847 participants (10 papers did not report the number of participants, and we were unable to identify them), ranging from a minimum of 6 to a maximum of 333,669. Participant ages varied significantly, ranging from children as young as 18 months to adults over 80 years old. Among the sample papers, 238 (26.9%)focused on vulnerable groups: 86 (9.7%)on children and adolescents, 95 (10.7%) on women, 33 (3,7%) on older adults, and 5(0.6%) on LGBT (lesbian, gay, bisexual, and transgender) individuals. Additionally, 223 (25.2%) studies involved ethnic minorities: 5 (0.6%) on African American participants, 2 (0.2%) on Hispanic participants, 4 (0.5%) on Asian participants, 4 (0.5%) on Black participants, 2 (0.2%) on Latino or Latina populations, and 4 (0.5%) on American Indian or Alaska Native participants. The remaining studies involved other ethnic minority groups.

Figure 2. Time trends of different income-level countries in the analyzed papers.



Characteristics of the Intervention

The WHO has categorized digital health interventions into 4 groups based on their intended users: consumers, health care providers, health system managers, and data services [39] (Figure 3). In this study, out of the total 885 interventions analyzed, the vast majority (844, 95.4%) were designed for clients. Health care providers were the target users for 62 (7%) interventions, while health system managers and data services were the focus of only 6 (0.7%) and 1 (0.1%) interventions, respectively.

XSL•FO
RenderX

Figure 3. World Health Organization (WHO) classification of digital health interventions.

We classified the intervention settings into 5 categories: community, hospital, home, school, and other. Out of the total interventions, 118 (13.3%) were identified as taking place in the community setting, 268 (30.3%) in the hospital setting, 237 (26.8%) in the home setting, 50 (5.6%) in the school setting, and 212 (24.1%) in other settings, which included locations such as companies, workplaces, and laboratories. Among the studies included, 858 (93.2%) focused on one or more specific health issues.

We identified 23 different types of delivery in the included studies and classified them into four categories: (1) phone-based, including short message service, phone calls, and interactive voice response; (2) web-based, including email, health electronic record, online telecare/training platform, forums, and interactive videos; (3) app-based, including smartphone/tablet-computer apps, videoconferencing software, and social media apps; (4) other, including wearable devices, telemonitoring device, virtual reality, artificial intelligence, and games. The most frequently used delivery type is web-based (n=282, 31.9%), followed by phone-based (n=266, 30%) and app-based (n=259, 29.3%). Of the delivery senders, 384 (43.4%) utilized automatic support, 457 (53.7%) employed human support, and 43 (4.9%) used both.

Theories and models play a crucial role in the development, implementation, and evaluation of digital health interventions by providing a framework for understanding the complex factors that influence health behaviors and guiding the selection of appropriate intervention strategies. In this study, 92 (10.4%) interventions reported using theories or models to inform their design and delivery, with some interventions using theories or models alone, while others used a combination of both. After combining the same theories or models mentioned across the included papers, a total of 13 distinct theories and 17 distinct models were identified. The most frequently used theory was Social Cognitive Theory, which was applied in 20 (2.3%) interventions. The Transtheoretical Model of Behavior Change was the most frequently used model, reported in 6 (0.7%) interventions.

Identification and Categorization of Digital Health Intervention Strategies

Overview of the Identified Strategies

A total of 885 sample papers were identified as employing at least one strategy in digital health interventions. Among these papers, 173 (19.5%) distinct strategies were identified and subsequently categorized into 19 themes (Multimedia Appendix 4). Of these themes, 18 represented clearly categorizable strategies, while 1 theme, labeled as “other,” was used to group strategies that did not fit into the predefined categories.

Among the identified strategy themes (Table 1), the most frequently used was “guide,” employed in 492 (55.6%) out of the 885 papers. The second most common theme was ”monitor,” which was utilized in 490 (55.4%) papers. The third most prevalent theme was “communication,” which was applied in 392 papers, constituting 44.3% of the total. Other commonly used strategy themes included ”engagement“ (n=384, 43.3%), ”support“ (n=268, 30.3%), ”stimulation“ (n=271, 30.6%), ”management“ (n=263, 29.7%), ”feedback“ (n=236, 26.7%), ”goal setting“ (n=228, 25.8%), and ”action planning“ (n=203, 22.9%).

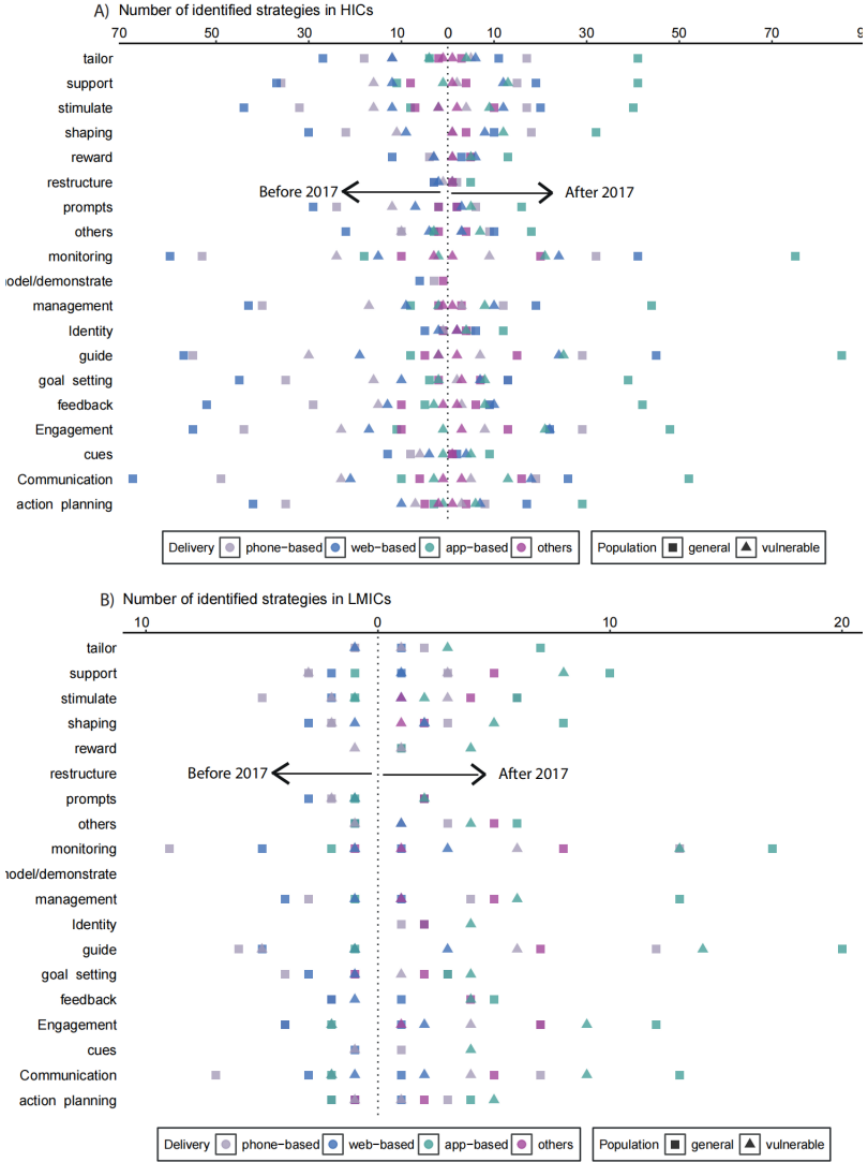
Temporal, Geographic, and Demographic Developments in Digital Health Intervention Strategies

To observe how strategies have changed over time, we selected the year 2017 as the cut-off point. This is because 2017 marked a few significant milestones in digital health regulation and global health policy. In the United States, the Food and Drug Administration (FDA) launched its Digital Health Innovation Action Plan and established the Digital Health Unit [41]. Concurrently, the WHO initiated the development of its first guideline on digital health interventions [42]. These initiatives at both national and international levels potentially influenced the development of digital health intervention practice globally [43]. In this study, we found that before 2017, the top 3 strategies were ”monitoring“ (n=205, 51.4%), ”communication“ (n=198, 49.6%), and ”guide“ (n=197, 49.4%), with ”monitoring“ being the most frequently used strategy. From 2017 onward, the top 3 strategies shifted to ”guide“ (n=295, 60.8%), ”monitoring“ (n=285, 58.8%), and ”engagement“ (n=209, 43.1%), with ”guide“ becoming the most prevalent strategy. The specific details are presented in Table 2.

XSL•FO
RenderX

Table 2. The results of the identified strategies before and after 2017.



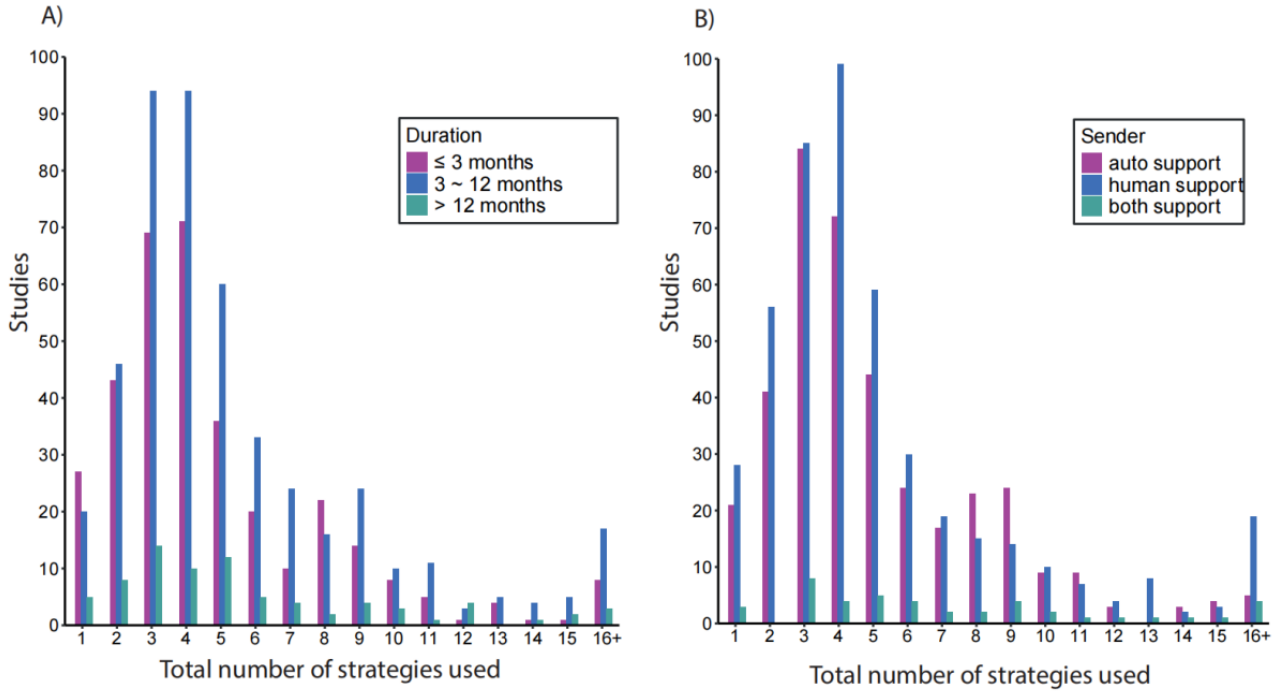
Before 2017		After 2017	
Theme	Value, n (%)	Theme	Value, n (%)
Monitoring	205 (51.4)	Guide	295 (60.8)
Communication	198 (49.6)	Monitoring	285 (58.8)
Guide	197 (49.4)	Engagement	209 (43.1)
Engagement	175 (43.9)	Communication	194 (40.0)
Stimulate	134 (33.6)	Support	138 (28.5)
Feedback	133 (33.3)	Stimulate	137 (28.2)
Management	131 (32.8)	Management	132 (27.2)
Support	130 (32.6)	Shaping	109 (22.5)
Goal setting	123 (30.8)	Goal setting	105 (21.6)
Action planning	112 (28.1)	Feedback	103 (21.2)
Prompts	86 (21.6)	Tailor	102 (21.0)
Tailor	82 (20.6)	Action planning	91 (18.8)
Shaping	80 (20.1)	Others	74 (15.3)
Others	58 (14.5)	Identity	46 (9.5)
Cues	34 (8.5)	Reward	46 (9.5)
Reward	23 (5.8)	Prompts	42 (8.7)
Identity	11 (2.8)	Cues	28 (5.8)
Model/demonstrate	10 (2.5)	Restructure	10 (2.1)
Restructure	9 (2.3)	Model/demonstrate	0 (0)

Figure 4 shows the distribution of strategies in high-income countries and low- and middle-income countries before and after 2017, illustrating the number of identified strategies categorized by delivery type (phone-based, web-based, app-based, and other) and population type (general and vulnerable). High-income countries demonstrated a substantially higher number and diversity of strategies, with ”monitoring,” “guide,” and ”communication“ being the most prevalent. While similar strategies were prioritized in low- and middle-income countries, they were implemented with less intensity. After 2017, both high-income and low- and middle-income countries showed an increase in the number of strategies employed, with high-income countries exhibiting more pronounced growth. This development was particularly evident in the adoption of emerging strategies such as ”engagement,” “tailoring,” and “support.”

Regarding population focus, the number of studies targeting the public far exceeded those focusing on vulnerable populations (including women, children, youth, seniors, minorities, LGBT, and low-income groups), at 73.1% (n=647) and 26.9% (n=238), respectively. While both country groups showed strategies targeting general and vulnerable populations, high-income countries demonstrated a greater emphasis on interventions for vulnerable groups, especially after 2017.

XSL•FO
RenderX

Figure 4. The distribution of strategies across delivery, population, and time in high-income countries (HICs) and low- and middle-income countries (LMICs).



Distribution of Digital Health Intervention Strategies Across Intervention Duration and Senders

Figure 5 illustrates the distribution of strategies across intervention duration and senders. Across all duration categories, there was a clear peak between 3 and 4 strategies, with a gradual decline as the number of strategies increased. Moreover, interventions implementing more than 10 strategies were relatively uncommon. Regarding intervention duration, short-term (≤3 months) and medium-term (3-12 months) interventions dominated the landscape, particularly those employing between 2 and 4 strategies. Medium-term interventions showed the highest frequency, especially for interventions utilizing between 2 and 5 strategies. Long-term interventions (>12 months), while less common, maintained a consistent presence across the spectrum of strategy numbers.

The distribution across sender types demonstrated that human support was the most prevalent delivery form, particularly for those using between 2 and 5 strategies. Automated support followed a similar pattern but with lower frequencies, while combined support (both human and automated) was the least common but had a consistent presence. According to the duration graph, all sender types peaked at 3 to 4 strategies used, with a sharp decline in frequency as the number of strategies increased beyond 5.

XSL•FO
RenderX

Figure 5. Distribution of strategies across the intervention duration and senders.

Discussion

Principal Findings

Our study provided a comprehensive analysis of strategies employed in digital health interventions over the past 25 years. We identified 173 unique strategies and categorized them into 19 overarching themes based on BCTs and BSs. This helped us establish a valuable framework for understanding the diverse approaches used in designing and implementing digital health interventions. The analysis revealed significant insights into several key aspects—the evolution of strategies over time, the differential involvement between high-income and low- and middle-income countries, and the influence of various factors such as delivery methods, target populations, intervention duration, and intervention providers. These findings collectively map the landscape of digital health intervention strategies across a quarter-century, providing valuable guidance for researchers and practitioners.

Specifically, we identified that the three most prevalent strategies were ”guide,“ ”monitoring,“ and ”communication,” highlighting the importance of providing clear guidance, tracking progress, and facilitating interactive communication in digital health interventions. The widespread application of “engagement” and “support” underscored the significance of fostering user involvement and providing adequate assistance throughout the intervention process. These findings were consistent with prior research that underscored the crucial role of user engagement, self-monitoring, and social support in digital health interventions [21,44].

The number of strategies used in each paper varied widely, from a single strategy to a comprehensive approach involving up to 32 strategies, highlighting the complexity and diversity of digital health interventions. Most studies fell into the low or medium categories, indicating that most digital health interventions had a focused approach with a limited set of strategies. The existing research indicated that using a combination of strategies, rather than a single approach, can be more effective in enhancing participant retention [32]. The available evidence suggests that to optimize participant retention throughout a study, researchers should consider implementing multiple retention strategies across various themes [33]. Future research should carefully evaluate the optimal strategic approach for each intervention, considering its specific goals, target population, and context. It should also investigate how the number and type of strategies employed affect intervention effectiveness and identify the best combination of strategies for various intervention contexts.

The landscape of digital health intervention strategies has undergone significant shifts, particularly around the pivotal year of 2017. This year marked 2 crucial developments: the launch of the Digital Health Unit by the FDA in the United States and the initiation of the WHO’s first guideline on digital health interventions. Prior to 2017, “monitoring” was the predominant strategy in digital health interventions. However, in 2017 and beyond, “guide” emerged as the most frequently employed approach. This transition reflected a shift toward more dynamic and interactive user interfaces, emphasizing proactive guidance rather than passive monitoring [45]. This change aligned with emerging evidence suggesting that interactive and personalized digital health interventions can lead to better user engagement and health outcomes [46,47]. Additionally, “engagement” had also risen in importance after 2017, illustrating a growing focus on enhancing user experience and satisfaction to improve intervention outcomes [48]. This change underscored a broader trend within the health care sector toward patient-centered care, which prioritizes the user experience and active participation in health management [49].

XSL•FO
RenderX

The adoption of strategies in digital health interventions was closely related to delivery methods and sender types [50]. While web-based and phone-based interventions remained prevalent, the rise of app-based strategies reflected the increasing penetration of smartphones, aligning with the ubiquitous use of mobile phones in modern society and highlighting the potential of leveraging mobile technology for health interventions [51]. This trend aligned with the ubiquitous use of mobile devices and underscored the growing importance of accessible, on-the-go health solutions. Regarding sender types, most of the sample papers employed human support in the delivery of digital health interventions, while less than half used automatic support. This distribution highlighted the ongoing significant role of human involvement in these interventions. Despite the increasing capabilities of automated systems, human support remained a crucial component in many digital health interventions, attributed to the human ability to provide empathy, build rapport, and tailor interventions to individual needs. Nonetheless, the role of automatic support was expanding, driven by advances in artificial intelligence and its potential for scalability and cost-effectiveness [52]. This dual trend—the continued importance of human support alongside the growth of automated systems—suggested a future where digital health interventions may increasingly leverage both human and artificial intelligence to improve health outcomes.

There was a distinct regional bias in the use of strategies, particularly across different income levels. High-income countries demonstrated a substantially higher number and diversity of identified strategies compared to low- and middle-income countries. This disparity may be attributed to better technological infrastructure, greater financial resources, and higher digital literacy among the population in high-income countries [50]. While low- and middle-income countries showed lower overall usage, they displayed a growing trend in adopting digital health strategies after 2017. This rise indicated a catching-up phenomenon, possibly driven by increased global health initiatives, international collaborations, and high mobile technology penetration in many low- and middle-income countries [53].

Regarding population distribution, the results indicated that the number of studies targeting the public far exceeded those focusing on vulnerable populations, suggesting a potential gap in addressing the specific needs of vulnerable groups, including women, children, youth, seniors, minorities, LGBT, and low-income populations, through digital health interventions [54]. Future research and implementation efforts should focus on developing more targeted strategies for these underserved populations to ensure equitable access to digital health benefits.

In conclusion, over the past 25 years, digital health interventions and their strategies have undergone significant developments. Initially, digital health interventions often utilized relatively simple and limited strategies, mainly focusing on providing information and basic self-monitoring functions [55]. With advancements in technology and a deeper understanding of behavior change mechanisms, digital health intervention strategies have become increasingly complex and diverse. Recently, there has been a rise in the use of personalized and adaptive strategies, aiming to tailor interventions to participants' characteristics, needs, and responses [56], as well as the aims of the intervention. Personalized or individualized strategies have become increasingly popular and widely used due to their potential to enhance engagement and intervention effectiveness. Notably, there has been a rise in the use of transtheoretical strategies in recent years, integrating elements from various behavior change theories to create more comprehensive and effective interventions [57].

Strengths of Our Research

Our findings built upon and broadened the scope of previous research on digital health intervention strategies [20,22,26-34,58] and the principles strategy classification [22,35]. While previous studies have often concentrated on specific health domains or populations, our research offered a more comprehensive view of the strategies used across various health issues and target groups. By identifying and categorizing a wider array of strategies, we provided a more integrated understanding of how to promote health behavior change and enhance health outcomes in the digital era.

Additionally, our analysis of the diversity in the number of strategies employed in each paper highlights the complexity and variability inherent in digital health interventions. Although prior research has underlined the significance of employing multiple strategies to tackle the multifaceted nature of health behavior change, our findings suggested that the ideal number of strategies might differ based on the specific objectives and context of the intervention. This emphasized the necessity for a customized approach in the design and implementation of digital health interventions, considering the distinct needs and characteristics of the target population and health domain.

Implications for Research and Practice

The findings carried several crucial implications for research and practice in the digital health field. First, by amalgamating evidence on what strategies prove effective across diverse health domains and populations, our study presented a detailed categorization of strategies for researchers and practitioners aiming to design and evaluate digital health interventions. This structured framework facilitated an understanding of the varied approaches within these interventions, aiding in the strategic selection and combination tailored to specific intervention goals and contexts. This, in turn, aimed to maximize the efficacy and impact of digital health interventions.

Second, this analysis of the frequency and distribution of strategy themes can direct future research priorities and resource allocation. The prominent presence of strategies concerning guidance, monitoring, and communication underlines their potential significance as focal areas for additional research.

Third, the observed variation in the number of strategies employed across different studies underscored the necessity for a more refined approach to designing and assessing digital health interventions. It suggested moving away from the presumption that employing more strategies invariably leads to better outcomes. Instead, there is a need for a deliberate consideration of the most effective number and mix of strategies, aligning with the unique requirements and attributes of the target population and health domain.

Limitations of This Study

This study has several limitations. Despite following a comprehensive search strategy, some relevant and important papers may have been overlooked, especially those published in languages other than English, from low- and middle-income countries, and in gray literature due to the limitations of the databases chosen. The process of data extraction and categorization of strategies was contingent on the information provided in the sample papers, which in some instances, may have been limited or inconsistent. Moreover, the diversity among the sample papers regarding populations, health domains, and intervention designs might restrict the applicability of our findings to specific situations. Additionally, this study did not carry out a comparative analysis of the effects of different strategies, nor did it explore and quantify the relationship between strategies and health outcomes.

Conclusions

This study provided an exhaustive synthesis of strategies used in digital health interventions over the past 25 years, highlighting their characteristics, distribution, and diversity in promoting health behavior changes and improving outcomes. By identifying and categorizing 173 unique strategies within 19 overarching themes, this study offered a comprehensive framework for understanding the complex approaches used in digital health intervention strategies. Additionally, this study highlighted that high-income and low- and middle-income countries have seen increased adoption after 2017, and human support remained crucial despite advancements in automated systems. These findings facilitated the careful design and assessment of future digital health interventions, significantly contributing to the establishment of evidence-based guidelines and best practices that enhance their efficacy.

Acknowledgments

This study was supported by the National Natural Science Foundation of China (grant 72474174). The authors would like to thank Na Zhang, Min Li, and Hong Du for their support with the paper screening and coding.

Authors' Contributions

SL contributed to the study conception and design, data analysis, interpretation of the results, and manuscript preparation. JM was responsible for the study design, data collection, coding, and analysis of results. MS was responsible for the data collection and coding. Abstract

Background: Longitudinal cohort studies have traditionally relied on clinic-based recruitment models, which limit cohort diversity and the generalizability of research outcomes. Digital research platforms can be used to increase participant access, improve study engagement, streamline data collection, and increase data quality; however, the efficacy and sustainability of digitally enabled studies rely heavily on the design, implementation, and management of the digital platform being used.

Objective: We sought to design and build a secure, privacy-preserving, validated, participant-centric digital health research platform (DHRP) to recruit and enroll participants, collect multimodal data, and engage participants from diverse backgrounds in the National Institutes of Health's (NIH) All of Us Research Program (AOU). AOU is an ongoing national, multiyear study aimed to build a research cohort of 1 million participants that reflects the diversity of the United States, including minority, health-disparate, and other populations underrepresented in biomedical research (UBR).

Methods: We collaborated with community members, health care provider organizations (HPOs), and NIH leadership to design, build, and validate a secure, feature-rich digital platform to facilitate multisite, hybrid, and remote study participation and multimodal data collection in AOU. Participants were recruited by in-person, print, and online digital campaigns. Participants securely accessed the DHRP via web and mobile apps, either independently or with research staff support. The participant-facing tool facilitated electronic informed consent (eConsent), multisource data collection (eg, surveys, genomic results, wearables, and electronic health records [EHRs]), and ongoing participant engagement. We also built tools for research staff to conduct remote participant support, study workflow management, participant tracking, data analytics, data harmonization, and data management.

Results: We built a secure, participant-centric DHRP with engaging functionality used to recruit, engage, and collect data from 705,719 diverse participants throughout the United States. As of April 2024, 87% (n=613,976) of the participants enrolled via the platform were from UBR groups, including racial and ethnic minorities (n=282,429, 46%), rural dwelling individuals (n=49,118, 8%), those over the age of 65 years (n=190,333, 31%), and individuals with low socioeconomic status (n=122,795, 20%).

Conclusions: We built a participant-centric digital platform with tools to enable engagement with individuals from different racial, ethnic, and socioeconomic backgrounds and other UBR groups. This DHRP demonstrated successful use among diverse participants. These findings could be used as best practices for the effective use of digital platforms to build and sustain cohorts of various study designs and increase engagement with diverse populations in health research.

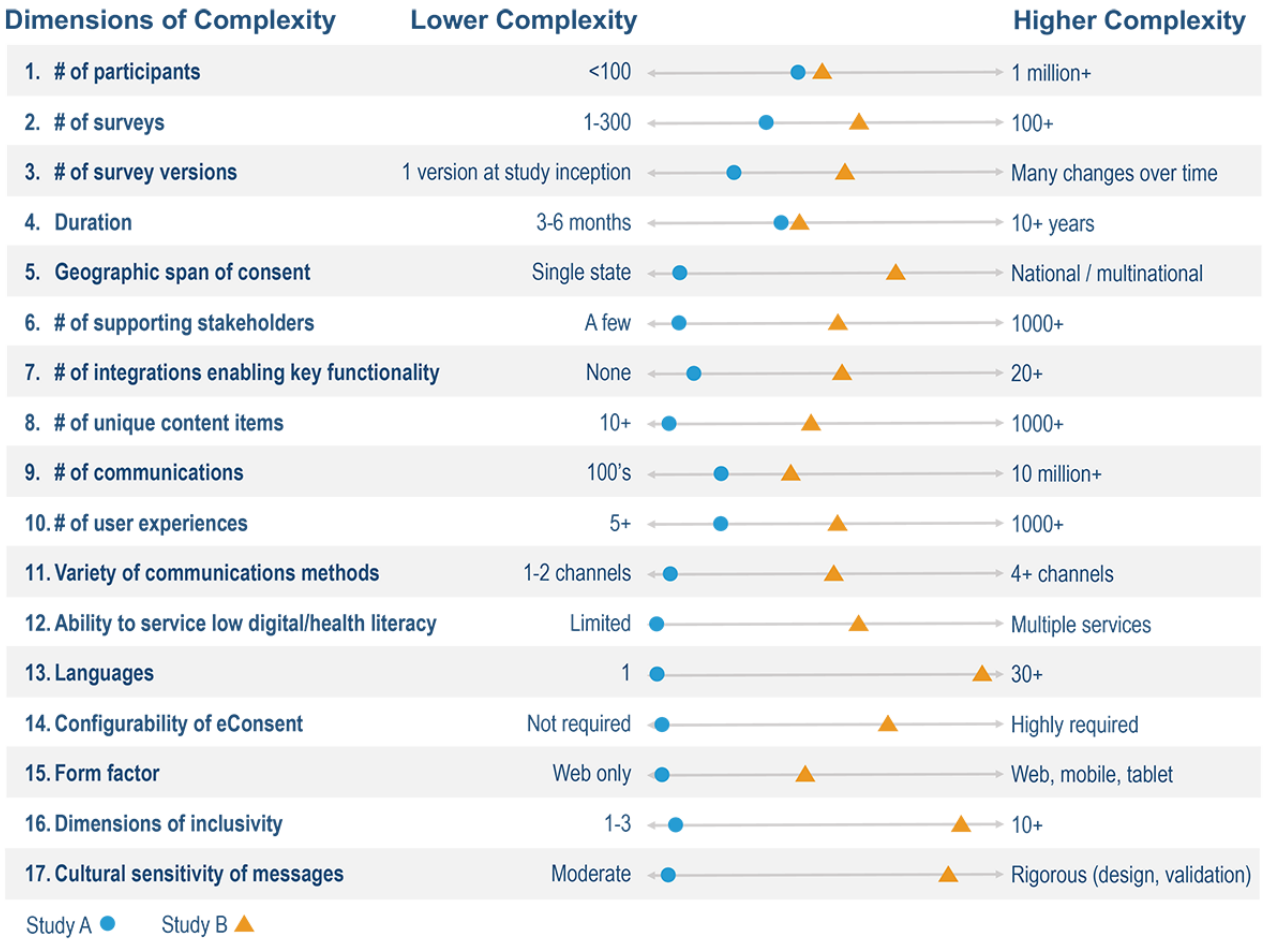
Introduction

Background

Longitudinal cohort studies have historically relied on clinic-based recruitment models that limit participation and reduce cohort diversity in many ways [1,2]. System-level barriers, such as distance to the research site and clinic-based eligibility, can negatively affect participant recruitment and study retention. Socioeconomic barriers, such as income, education, and health insurance status, also limit research participation in minority and other health-disparate groups [3-5]. The resultant homogeny in research cohorts reduces the generalizability and validity of research outcomes [6-8]. Digital platforms can minimize barriers to research participation, such as transportation costs, site access, and time commitment, and significantly improve participant access and engagement [9-11]. As a result, digital platforms are being increasingly used in health research to enable accelerated, more accessible, and more reliable real-world data collection. However, as longitudinal cohorts increase in the breadth and scale of data, the efficacy of digital platforms can vary profoundly, depending on the platform's capability to meet the ever-increasing needs of the study over time.

Appropriate implementation of study activities via digital platforms can minimize many of the commonly reported barriers to research participation. Recent studies, such as MyHeart Counts and Health eHeart, show how digital enablement of traditional research methods may improve engagement of people from diverse backgrounds, including those who do not commonly engage with health care systems [12-14]. Digital technologies also reduce the stakeholder burden related to collection, curation, and sharing of health data [15]. Therefore, digital platforms may be effective tools to improve participant engagement, increase cohort diversity, broaden geographical reach, and streamline the curation of diverse research data sets.



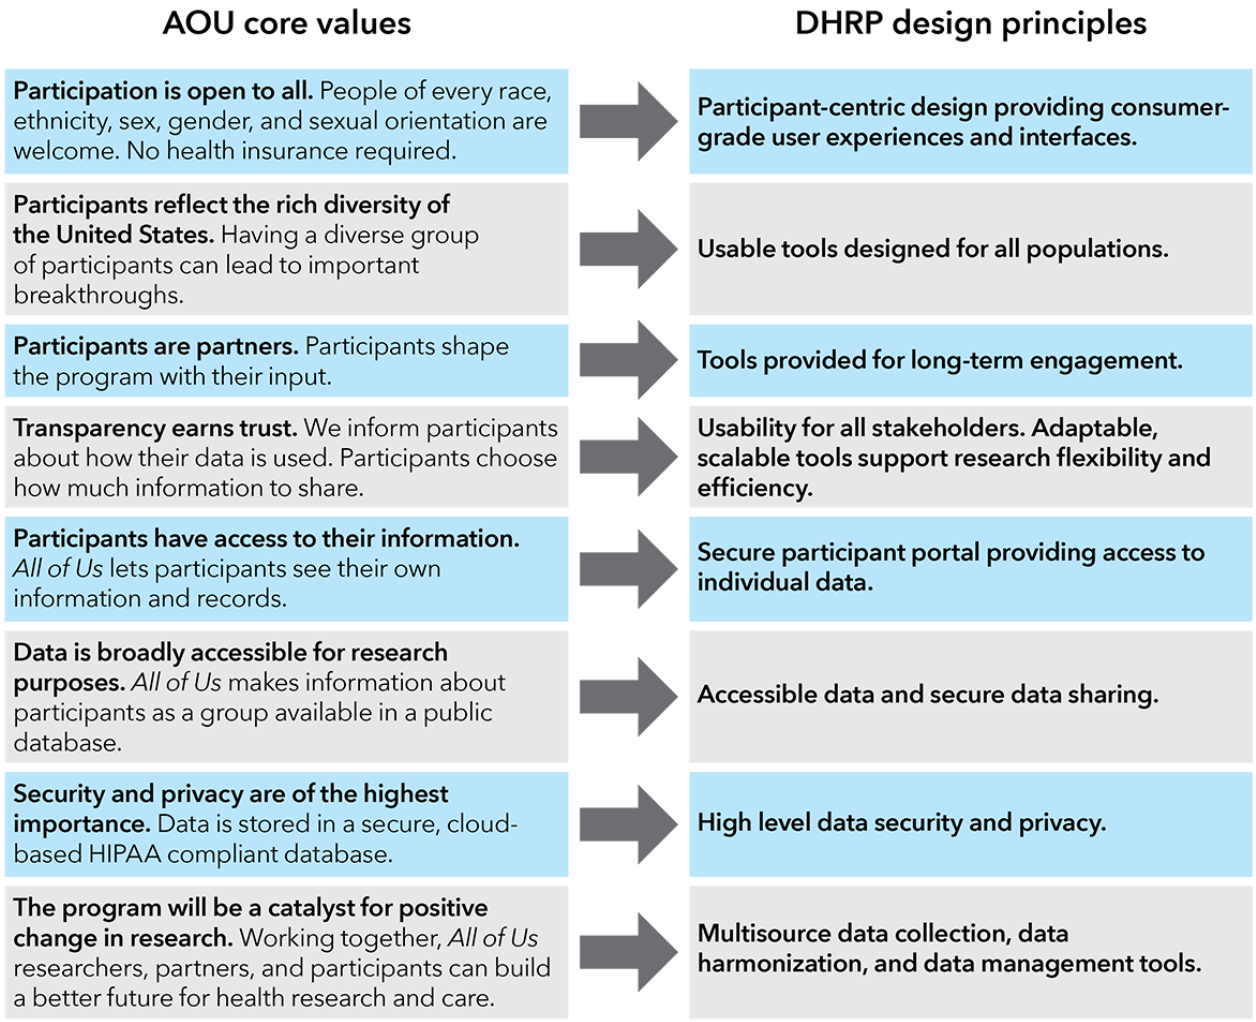
Digital research platforms must also accommodate users of varying digital aptitudes. This requires consideration of sociodemographic factors that impact the use of digital technology, such as age, disability, rurality, education, income, culture, digital access, native language, and literacy [16,17]. Digital research platforms can be adapted to accommodate these differences and thereby reduce participant burden and build trust with communities that are underrepresented in health research [18]. Existing commercial and academic tools for electronic data capture (EDC) are built primarily for research teams and are not designed to meet the preferences of participants interacting with them [19]. Therefore, it is important to create digital tools with engaging functionality for diverse participants that also meet the evolving needs of longitudinal cohort studies. We aimed to build such a platform to support nationwide enrollment of 1 million diverse participants in a novel multiyear, longitudinal cohort study.

Objectives

In this paper, we describe various tools within a digital health research platform (DHRP) designed to effectively engage diverse participants from various backgrounds and collect multisource health data in a large community-based longitudinal cohort study. The All of Us Research Program (AOU) is an ongoing nationwide initiative aimed to recruit 1 million participants from diverse cultural, socioeconomic, demographic, and geographic backgrounds and to collect data that are generalizable, accelerate biomedical research, and improve outcomes for all groups [20,21]. The broadly inclusive eligibility, recruitment, and data curation needs of the AOU required the development of a highly adaptable, comprehensive digital platform able to accommodate multifaceted, complex study requirements. The study also needed a platform with modifiability that would allow study staff across 1200 sites to conduct operations and rapidly deliver customized, community-specific engagement (Figure 1). These complex needs led to the development of a comprehensive digital platform design capable of supporting data expansion and the addition of ancillary studies over the extended study timeline of 10 or more years [22].

XSL•FO
RenderX

Figure 1. Illustration of how an all-in-one platform requires broad functionality to accommodate the varying dimensions of complexities for different study protocols.



Methods

System Requirements

Vibrent Health, Inc, a digital health technology company, was selected as the participant technology systems center and tasked with developing a secure digital platform and tools for participant experience, study management, and data analysis [23]. To align with its core values, the AOU needed a secure DHRP that (1) could be broadly deployed nationwide to support study management, (2) could host several program touch points within a flexible participant journey, (3) was accessible to different levels of digital access, literacy, and comfort, and (4) was cybersecure and robust (Figure 2).

XSL•FO
RenderX

Figure 2. AOU core values were used to develop key design features of the DHRP. AOU: All of Us Research Program; DHRP: digital health research platform; HIPAA: Health Insurance Portability and Accountability Act.

System Description

Digital Health Research Platform Design and Architecture

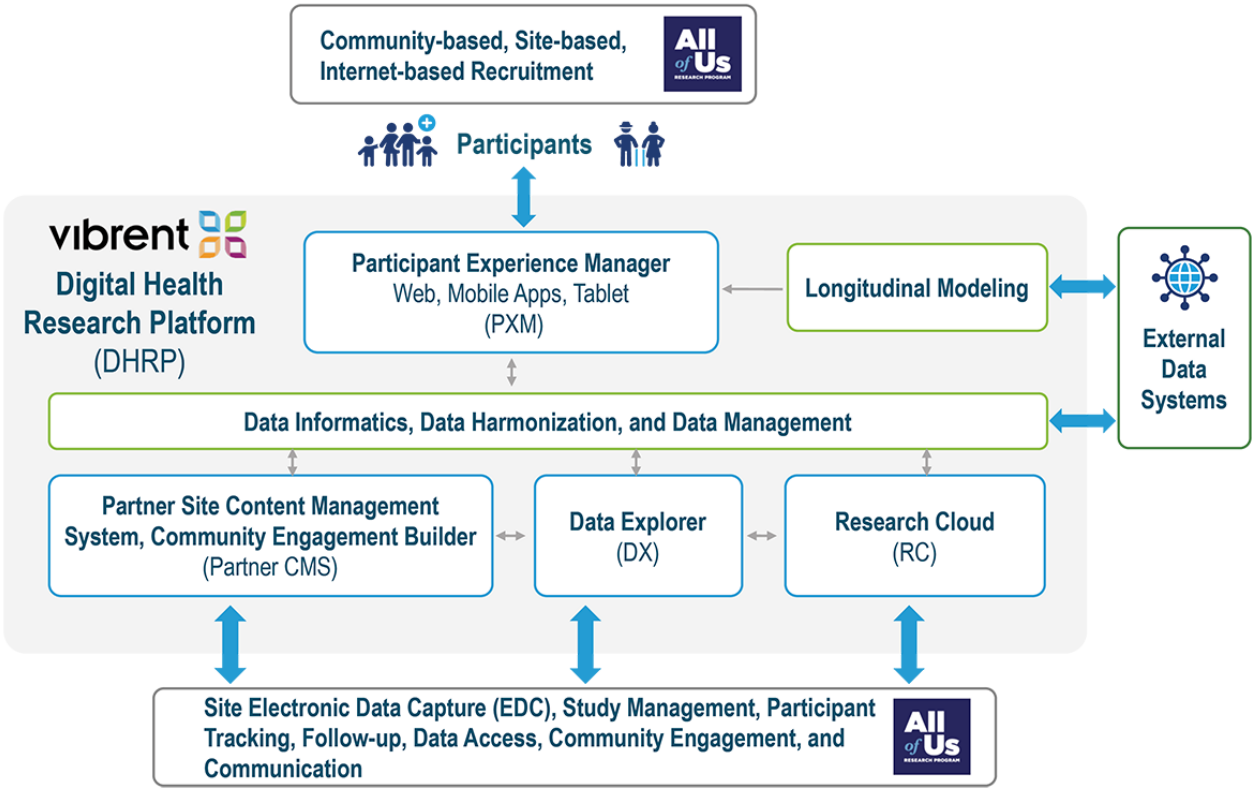
Vibrent Health designed and built a DHRP to facilitate participant recruitment, enrollment, multisource data collection, and long-term engagement using web-capable digital devices (computers, mobile devices, tablets). The DHRP was developed via close collaboration between the government, academia, community stakeholders, and industry using validated user experience (UX) and user interface (UI) research. (Figure 3).

We developed participant-facing tools for engagement and data collection, as well as researcher-facing study management tools. The data collected within the DHRP were stored in a cybersecure cloud environment, where they could be harmonized, cleaned, and integrated with other data systems.

The technical architecture of the DHRP is highly configurable, using a low-code approach and promoting an open ecosystem without the need for custom software development. The AOU used a range of DHRP tools to facilitate the study: (1) Participant Experience Manager (PXM), (2) Research Cloud (RC), 3) Data Explorer (DX), and (4) Community Engagement Builder (CEB). The DHRP tools are shown in Figure 4.

The DHRP adopted a hybrid technical strategy, blending readily accessible commercial tools and subsystems with customized application layer enhancements and integrations. This approach provided a tailored solution of high-quality explicitly crafted tools that are also generalizable to meet the needs of various study designs. The platform supported an open ecosystem to integrate with additional devices and to embed experimental digital health technology modules within study protocol pathways.

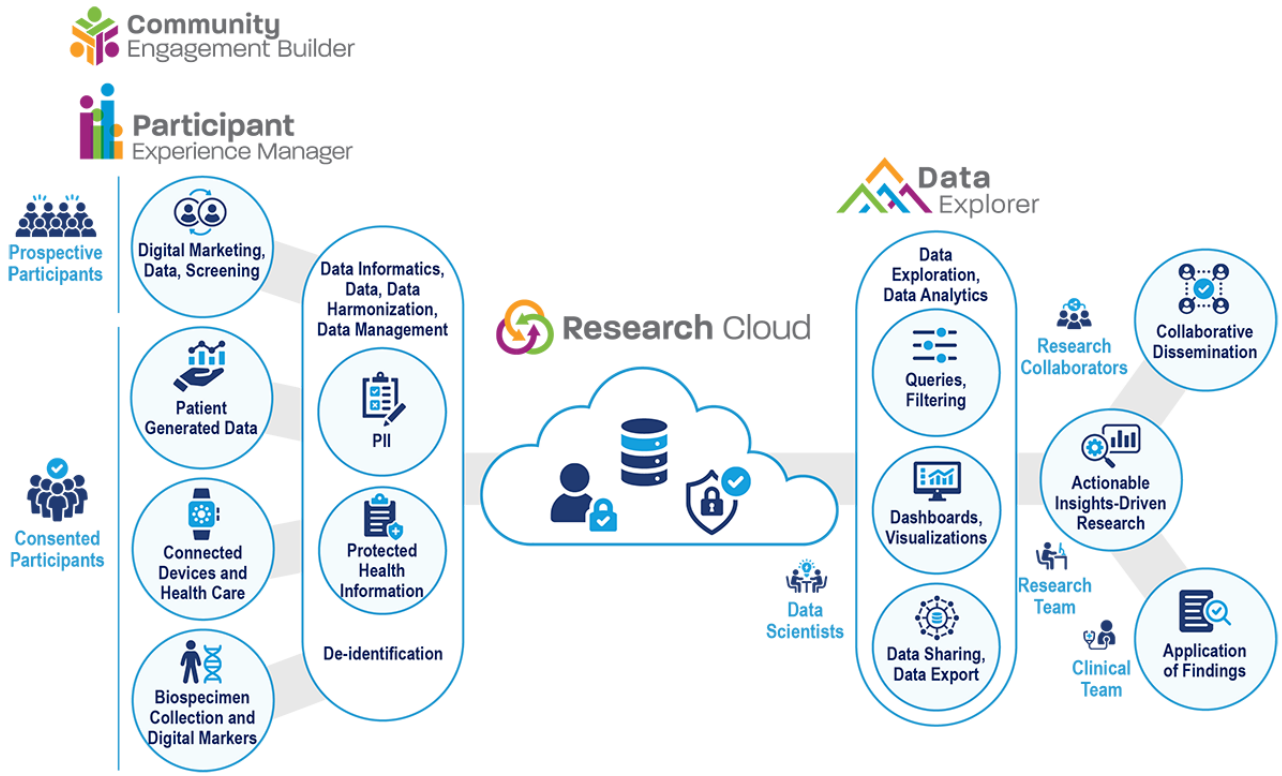
The DHRP used multilayered enterprise architecture to achieve secure storage of data, along with flexibility and scalability. The Cloud Services and Infrastructure Management Layer provided dynamic autoscaling to meet the changing demands of studies over time. The Data Lake and Database Layer managed and stored large volumes of multisource data, including participant data and operational data. Key functions of the DHRP included data integration, data transformation, advanced analytics, data governance, real-time data processing, and metadata management. The platform used centralized cloud-hosted databases (MySQL, Snowflake [NoSQL], Redshift) for secure data storage, and a data warehouse. The Functional



XSL•FO
RenderX

Modules Layer facilitated interconnection of the DHRP to multiple third-party application programming interfaces (APIs) and end-user applications.

The DHRP used several methodological testing frameworks and capabilities, as well as scientific testing support protocols, including user research, functional randomization testing, randomization for scientific testing, survey response randomization, and bias mitigation. In addition, Agile software development life cycle (SDLC) and continuous integration/continuous delivery (CI/CD) processes facilitated the delivery of high-quality enterprise software. The "shift-left" SDLC reduced the complexity of software development, thus enabling the study to respond quickly to protocol amendments without disrupting the participant experience. Examples of configuration updates include the addition of new surveys, workflow changes, or revision of study-related content.



Containerization and microservices methods were applied in the DHRP to optimize flexibility, scalability, efficiency, system performance, security, and privacy. Containerization provides a standardized, efficient approach to software deployment by encapsulating applications within isolated environments. This ensures consistent performance and compatibility across diverse computing platforms, which is essential for reproducible and scalable scientific research [24]. Microservices architecture breaks down complex software into smaller, independent parts that work together, making it easier to update and scale applications. DHRP microservices are described in Table 1.

Table 1. Microservices used in the DHRP[a].

Microservice	Function
Ancillary study integration	Facilitates integration with third-party study tools
Appointment management	Schedule, view, and update appointments with maps and geolocation
Asynchronous messaging	Advanced data synchronization service enabling large-scale cross-platform integration
Authentication services	Enables authentication and single sign-on
Case management	Create cases with specific actions to take for a group of participants
Communications services	Transmit targeted email or SMS text or push communications to mobile apps
Comparative insights	Provide demographic-based results (by age, location, etc) for survey responses
Dashboards	Canned visualizations of protocol activities to assist research staff in overseeing program activities; use default dashboards or create your own customized dashboard
Data integration	Integrate with an external data hub
Data management	Scalable storage of large volumes of multisource data
Data retrieval services, multiple	Retrieve data from various sources: Medicare, Epic, Cerner, Athena Health, Fitbit, Apple HealthKit
Deep linking	Communications (email and SMS text) linked to specific steps in the participant workflow to improve participant engagement
eConsents[b] and agreements	Manages primary and additional consent agreement modules
File-sharing services	Ability to manage upload and sharing of test results with participants
Fulfillment services	Order management and delivery tracking of biosample kits and other assets required to support data collection
Identity verification	Secure, remote verification of participants for account access
Insights	Search, analyze, and visualize data about participants and study activities; ability to create custom dashboards, reports, and data exports based on the unique needs of a study
Mobile apps	Study branded mobile apps for participant access; supports iOS and Android clients and adaptive web for participants choosing not to use mobile apps
No-login experiences	Enable participants to complete survey activities without authentication
Reports and exports	Create customized reports and exports for use with study engagement activities
Segmentation	Create complex filtering criteria to identify a group of participants to target for a protocol activity and engagement and may be used to create a case or transmit communications
Survey import	Import survey definitions and participant survey data from third party–hosted survey platforms
Task management	Create and view appointments, cases, and follow ups
Time-based event management	Create user engagement workflows based on time-based protocol requirements
UX[c] and advance workflow customization	Enable the creation of simplified user engagements and support for complicated time- and event-driven workflow; includes configurable page and navigation items, business rules, and conditions

[a]DHRP: digital health research platform.

[b]eConsent: electronic informed consent.

[c]UX: user experience.

DHRP Participant Experience Tool

The PXM facilitated all participant-facing study protocol activities, including (1) electronic informed consent (eConsent), (2) study data collection and data sharing, and (3) secure bidirectional communication. The PXM operates in English and Spanish and can be translated to more than 30 additional languages. Table 2 describes the third-party services that were integrated with the DHRP to support PXM functionality.

The eConsent functionality, content, and UX were developed to accommodate seventh-grade or lower literacy levels through collaborative UX research with participants, researchers, and NIH staff. The key functionality of eConsent included (1) web-based and mobile device accessibility, (2) built-in knowledge reinforcement, and (3) content accessible by text, audio, or video.

The PXM allowed participants to securely access individual participant portals to complete study-related data collection activities, including submission of survey responses, scheduling appointments to complete study measures, and communication with research staff, as shown in Figure 4. The PXM supported both “repeated surveys” and “longitudinal data collection” with defined events, including complex window management that made certain study tasks available in the participant dashboard

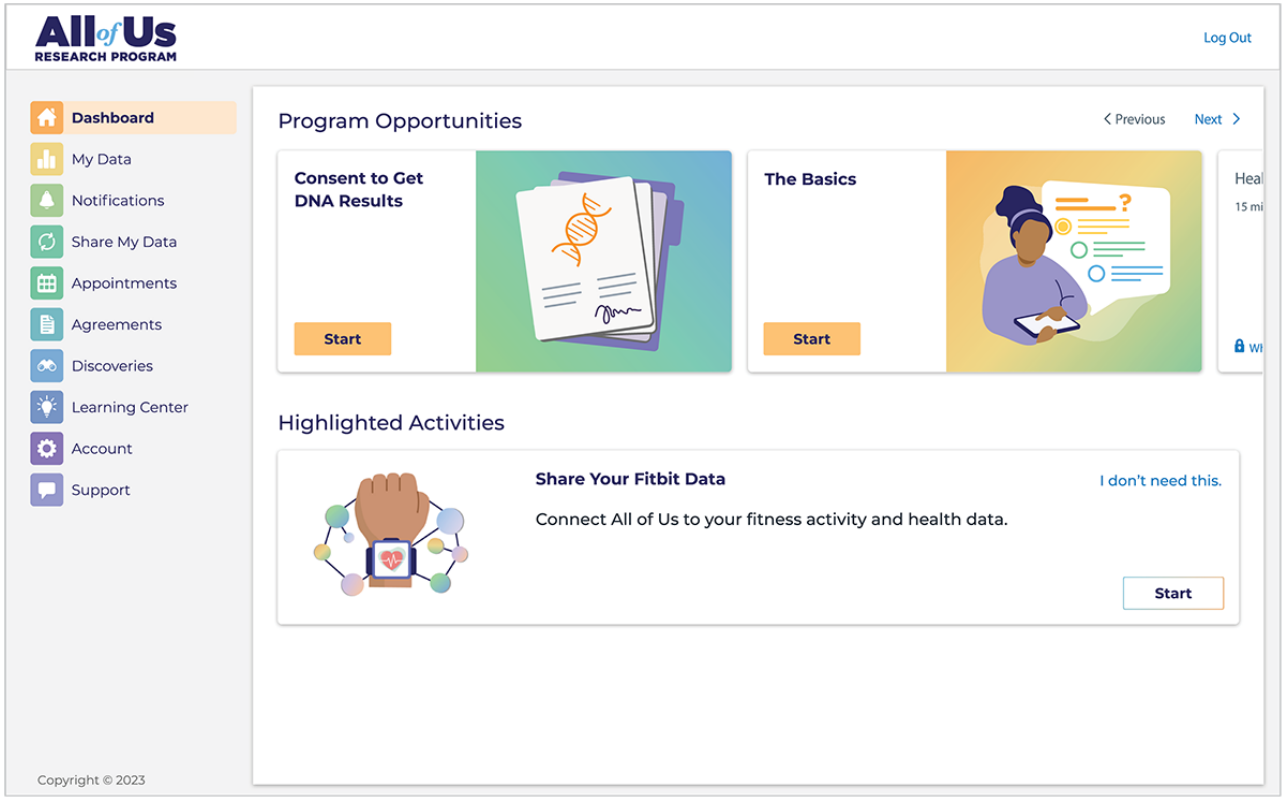
XSL•FO
RenderX

during the appropriate window of time. Participants were able to securely review their personal data and genetic results through the PXM.

The PXM was integrated with a range of third-party fast health care interoperability resource (FHIR) systems enabling participants to share EHRs and medical claims data to contribute to the study. Over the course of the AOU, multiple approaches were also used to facilitate the collection of wearable data from participants—all of which made use of the PXM. These included (1) providing opt-in for self- managed (ie, "bring your own device") data contributions using participant-owned Fitbit wearables, Google Fit, and Apple HealthKit; (2) providing Fitbit devices directly to participants to encourage the contribution of data; and (3) providing supportive messaging to participants who were provided with Fitbits to both encourage and monitor the optimal approaches to acquiring wearable and related digital health data. This secure, participant-focused design fostered ease-of-use throughout the study (Figure 5).

As part of an end-to-end readiness assessment for pediatric enrollment, the PXM supports engaging with parents of eligible children as proxy users. Parents of children under the age of 5 years old were invited to enroll their children in the study and were authorized to complete permission, authorization, and data collection modules on behalf of their children [25]. Tools enable study staff to engage with children for biosample and physical measurement collection processes using the PXM. Parents can enroll multiple children and select those children in a drop-down menu. As the AOU expands its pediatric recruitment processes, the PXM will support additional parental roles and permissions, as needed, for participants between the ages of 5 and 18 years at the time of consent.

Table 2. Participant-centric functionality requires scalable integrations with COTS[a].



Participant-facing tools	COTS
Communication (email, SMS, postal/printed mail)	Iterable, Lob, Twilio
Genomics counseling and return of information	Color
Remote biosample collection for assays and genomic sequencing (saliva, blood, nasal swabs)	DNA Genotek, Mirimus, Molecular Testing Labs (MTL), Tasso, Quest Diagnostics
EHRs[b]	Epic, Cerner, Athena Health, others
Wearables and biometric devices	Fitbit, Apple HealthKit, Apple Watch, Google Fit
Identity verification	ID.me
Data visualization/exploration, dashboards, analytics	Metabase, Tableau, Google Analytics
Surveys, codebooks	REDCap, Qualtrics
Enable aggregate participant data comparisons at scale	Snowflake
Shipment and logistics	US Postal Service, Aftership, FedEx
Participant data privacy and security	Akamai, HackerOne

[a]COTS: commercial-off-the-shelf services.

[b]EHR: electronic health record.

XSL•FO
RenderX

Figure 5. Screenshot of the PXM dashboard. PXM: Participant Experience Management.

DHRP Research Administration Tools

The RC empowers research staff to complete direct engagement, monitoring, and support to assist participants with completion of study activities. The RC enables research staff to communicate with participants via automated digital marketing, email, and SMS text messaging and to securely collect participant data using built-in computer-assisted telephone interviewing (CATI) capabilities. The RC allowed staff to assist participants with account access, scheduling of study measures visits (in-clinic or remote), and tracking of participant progress via customizable dashboards. The RC was critical in building relationships to keep participants engaged and ensure that study tasks were completed.

For security and privacy, the RC implemented a Roles-Functions-Permissions-based framework system, which granted limited access to select data and workflows based on the research staff's assigned role within the platform. The 13 distinct user roles available in the RC include program coordinators, data analysts, research assistants, and system administrators. After completing 2-step authentication login, RC users can review a role-based data dashboard or download participant-level research data. To facilitate adoption, a training environment was created, which allows RC users to practice their workflows without compromising real study data. The RC can also support expansion to ancillary studies and can extend user roles to allow access to multiple projects through 1 dashboard.

DHRP Data Management Tool

The DX is a self-service analytics tool that enabled study staff to access structured or unstructured data to construct custom reports, dashboards, and insights into collected data and metadata. The DX allows researchers to review and analyze study data from all sources (surveys, collected biometric measures, and third-party shared data) in real time within 1 dashboard. The DX also supports the use of data analytics tools (RStudio, Python, JupyterHub) within the platform on live data. This capability allows researchers to assess data quality and preliminary study results in real time. Modular data pipelines were developed in Python, allowing for scalability and adaptability to many different data sources and data analytics functions.

DHRP Content Management Tool

The content management tool, called CEB, delivered study outreach materials and hosted the study recruitment website. It enabled rapid and low-cost creation and deployment of customized recruitment websites, event marketing, and landing pages tailored to a site's specific catchment area. The CEB includes UX-validated templates to optimize content with appropriate levels of cultural sensitivity and language translation. The CEB was used to generate websites that educate and recruit people to the AOU or ancillary studies and was also used to build the nationwide recruitment website [26].

The CEB was integrated with the RC to provide real-time enrollment metrics to support strategic adjustment of recruitment strategies for study success. Digital marketing analytics generated by the CEB enabled staff to track conversions from both online (recruitment website, lead generation, events landing pages, and social networking links) and offline (QR codes from posters and flyers) sources. By leveraging these analytics, staff gained insights into the effectiveness of different recruitment

XSL•FO
RenderX

methods and made informed decisions to optimize recruitment efforts and meet enrollment and diversity targets.

DHRP Research Staff Training and Support Tools

After the study was launched, there was a recognized need to provide comprehensive and efficient support and training to research staff using DHRP tools. The Help Center and the Vibrent Research Academy were digital training resources created to support researchers' execution of study management and outreach tasks. The Help Center served as a knowledge base for site staff using the RC or CEB tool and provides a detailed explanation of DHRP features, along with supplemental articles, troubleshooting tips, and other resources. The Vibrent Research Academy offers short courses that provide detailed, multimedia demonstrations and instructions on the use of DHRP tools and features.

Ethical Considerations

eConsent Process

Through the PXM, we delivered a modular eConsent process to facilitate a self-paced, dynamic, and adaptive experience for participants [27]. The eConsent process met the regulatory and compliance requirements of all 50 states to support geographic inclusivity and access to participation. A formative consent evaluation module was included to assess participant informedness following a review of each eConsent module. Before providing a digital signature, participants were required to correctly answer 80% of the evaluation questions. Participants were able to withdraw consent from any individual consent module at any time, with the option to reconsent again in the future. Digital copies of completed consent forms were stored in the PXM. This same mechanism also facilitated electronic assent on behalf of eligible minors.

Data Security, Encryption, Regulation, and Compliance

All participant-facing materials were approved by a centralized Institutional Review Board. The DHRP maintains a "defense in depth" security posture to keep participant data safe and private. Data security and privacy are implemented in accordance with established industry-standard policies, procedures, and technology system guidelines, such as Federal Information Security Modernization Act (FISMA) and National Institute of Standards and Technology (NIST) Cybersecurity Framework for Security and Privacy Controls (NIST SP 800-53 r5, NIST SP 800-39, NIST SP 800-37) and are Health Insurance Portability and Accountability Act (HIPAA) compliant. Technical safeguards include strong data encryption (AES256, TLS 1.2 and higher) in flight and at rest. The DHRP is compliant with 21 CFR part 11 and ensures entries come from an authenticated and authorized source. Role-based permissions ensure that only authorized users are permitted to change settings.

Community Engagement

The AOU is a population-based precision medicine initiative operating on a community engagement structure [15,21]. To operationalize the program's core values, a community-based participatory research approach was implemented to develop a national network of actively engaged community organizations and individuals to build community advisory boards (CABs). CABs collaborated with health care provider organizations (HPOs), local community centers, academic and industry partners to provide study guidance.

Community engagement partners facilitated direct engagements between prospective participants and members of their specific communities, which could take the form of sending structured electronic communications, setting up in-person opportunities at events and physical facilities, promoting by word of mouth, and providing biosample collection opportunities when supported by other program partners. These partners encourage initial enrollment as their primary function.

Participant Recruitment and Enrollment

Participant recruitment, eligibility, and enrollment were delivered through in-person and digital methods facilitated by the DHRP [15,21]. Outreach was conducted at local community events and conferences, by word of mouth, digital advertising, and physical distribution of study-branded flyers and promotional items. The CEB tool of DHRP provided customized, culturally appropriate recruitment webpages in multiple languages. Participants who enrolled remotely were able to communicate with staff by phone or email via the PXM. Remote participants were also able to use the PXM to locate the nearest site at which to complete their physical study measurements. Fully remote participants could independently complete all activities, including consent, surveys, EHR data sharing, biosample collection, and communication with study staff, without reporting in person to an HPO site.

Participants were also recruited in person at HPO and mobile clinic sites throughout the United States, with enrollment completed in the DHRP, with or without assistance from site staff. A myriad of program partners used the DHRP to support recruitment, enrollment, and retention. Health care–providing organizations, such as large health systems and federally qualified health centers, facilitated both initial recruitment in the same manner as community engagement partners and directly facilitating (1) consent, (2) completion of electronic surveys, (3) completion of biosample collection in both remote and in-person engagements, and (4) EHR data collection, as well as providing human support for all program activities when a program participant was recruited from their patient populations.

Study Data Collection

All study data were collected in the DHRP. Participants used the PXM tool to submit surveys and complete data sharing from third-party services. To minimize the participant burden, all surveys were available in separate, self-paced modules, allowing participants to save their progress and return to the modules for completion later. To support data collection, research staff used the DX tool to identify participants with incomplete study tasks, such as eConsents or surveys. The RC was then used to develop targeted engagement campaigns to remind participants of any remaining incomplete study tasks requiring attention. A description of the sources and types of data collected in the DHRP is available in Table 3.

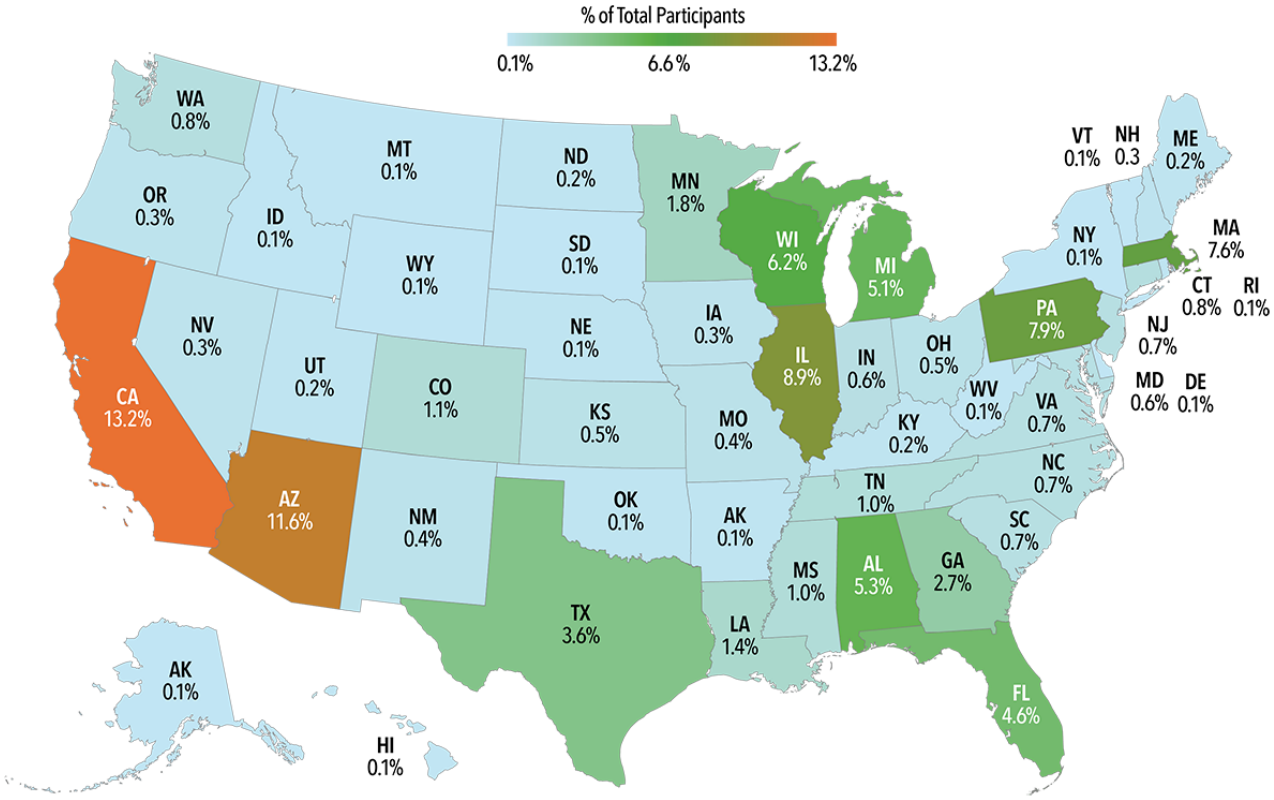
Results



Participant Characteristics

The DHRP was launched for use in May 2018. As of April 2024, a total of 705,719 participants had enrolled in the AOU through the DHRP. Of these participants, 74% (n=524,264) completed all study activities in the core study protocol, including all required survey modules. In this cohort, 55% (n=386,377) identified as women, 51% (n=360,303) were aged 35-64 years, and 48% (n=340,423) identified as White. The platform was used by participants and research teams in each of the 50 US states and territories, with 8% (n=58,211) participants representing rural areas (Figure 6).

The AOU used the DHRP to build a diverse research cohort in which 87% (n=457,514) identified as members of groups underrepresented in biomedical research (UBR) in at least 1 demographic category (age, race, sex, gender, income, education, or disability). More specifically, 46% (n=243,296) participants identified as racial minorities, 36% (n=189,087) reported a low income, and 20% (n=104,916) reported a disability. One third of the cohort (n=219,355, 31%) were aged 65 years and over, 8% (n=58,211) identified as rural residents, and 28% (n=197,601) were people with limited access to health care. More than 5% (n=~37,000) of all program participants opted to participate in the program in Spanish. UBR diversity metrics of the cohort are available in Table 4.

Data and Tool Usage

Approximately 4,500,000 combined survey and eConsent modules have been completed through the DHRP. Analysis of eConsent formative evaluation questions revealed that after reviewing eConsent modules, over 95% (n=670,433) of the participants were able to differentiate the research program from medical care, understand the voluntary nature of their involvement, and comprehend their right to withdraw at any point in time [28]. Complete data collection metrics are in Table 5.

Table 5. Data collected and tool usage metrics from the DHRP[a] for the AOU[b].

Measures	Data, n
Participant data sources	
Fitbit	49,627
Apple HealthKit	19,940
EHRs[c]	14,431
Total survey modules completed	3,685,608
Total physical biometric study measures	538,160
Saliva kits	59,819
eConsent[d]	
Total primary eConsent modules completed	2,015,622
EHR eConsent module	632,644
Genomics return of results eConsent module	406,781
Cognitive assessment eConsent module	85,572
Digital marketing	
Prospective participants contacted	378,010
Automated email and SMS text campaigns delivered	3677
Custom HTML templates created by sites in the partner CEB[e] tool	1838
Multichannel communication automations (bilingual)	≥300
Participant multimodal communications	
Emails sent to participants	64,837,083
SMS text messages sent to participants	7,794,054
Mobile app push notification messages sent to participants	463,975
Direct mail sent to participants	1,531,814
Site staff remote engagement with participants	1,168,079
Protocol step completions logged by site staff due to remote engagements	412,026
CATI[f] sessions	42,795
Appointments scheduled (remote and site based)	301,393

[a]DHRP: digital health research platform.

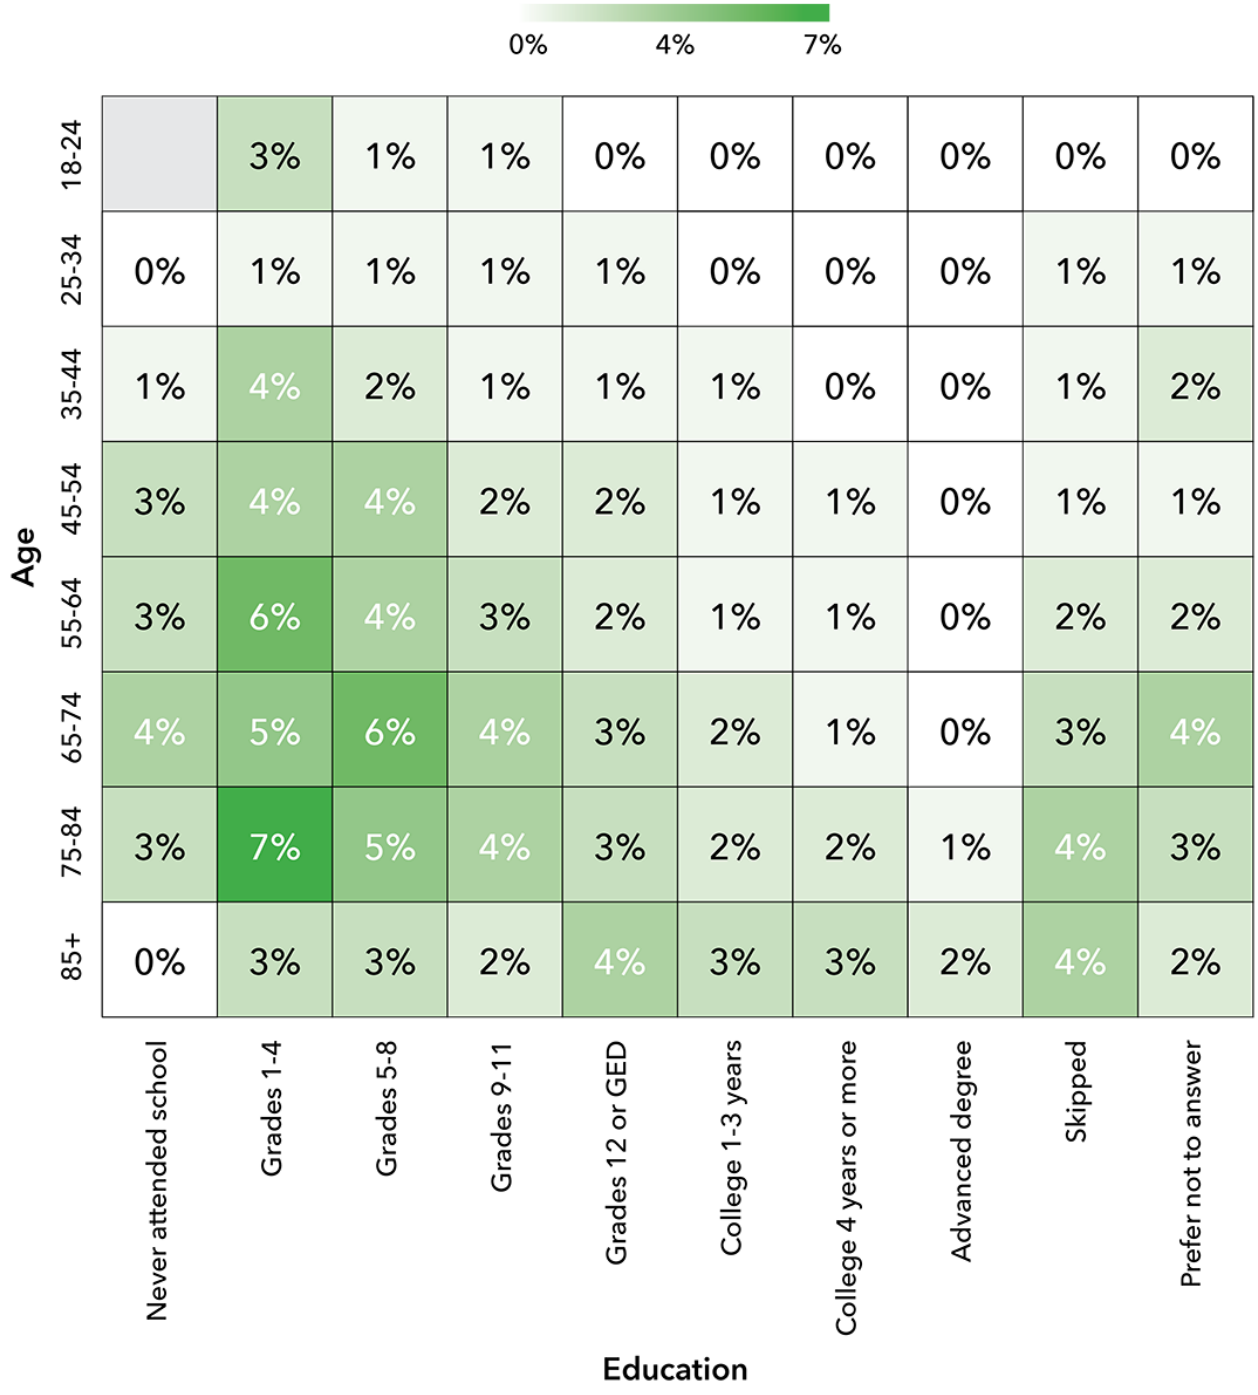
[b]AOU: All of Us Research Program.

[c]EHR: electronic health record.

[d]eConsent: electronic informed consent.

[e]CEB: Community Engagement Builder.

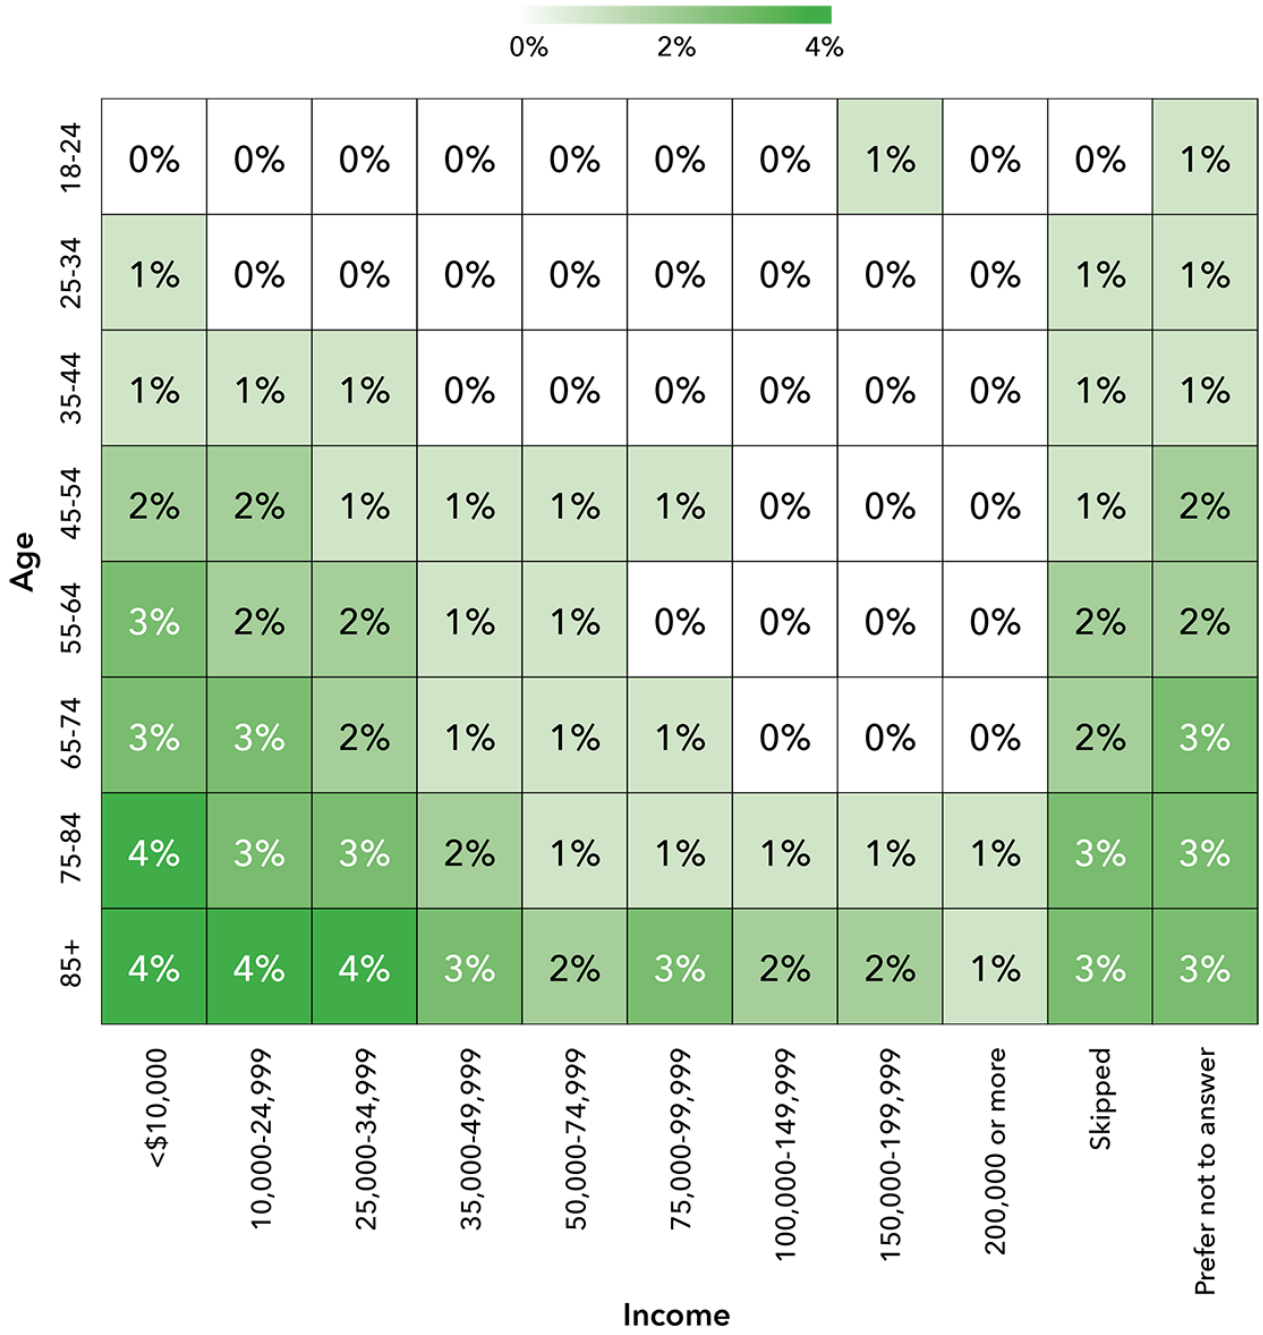
[f]CATI: computer-assisted telephone interviewing.



The use of CATI capabilities within the DHRP demonstrated the positive effects of combining digital and in-person engagement methods to enhance the participation of UBR groups in research. Among participants who completed the Social Determinants of Health (SDOH) survey module (n=276,706, 42%, eligible participants) for the study, CATI technology supported significant portions (as high as 47%) of survey completions within cross-sectional UBR groups. Cross-sectional analysis by participant age, education, income, and race-ethnicity showed increased use of CATI-assisted sessions within certain UBR groups. Specifically, the increased use of CATI was evident among those with education levels below grade 9, those with an income below US $35,000/year, people aged 55 years and older, and people identifying as

XSL•FO
RenderX

non-Hispanic Black or Hispanic of any race. The cross-sectional use of CATI is shown in Figures 7, 8, and 9. Those with lower education levels, of older age, with lower incomes, or from racial and ethnic minorities are recognized as UBR populations [29].



Another demonstration of the effective engagement capabilities of the DHRP was found in the completion rates of the optional COVID-19 Pandemic Evaluation (COPE) survey. The COPE survey was added in response to the COVID-19 pandemic, which was first confirmed in the United States in January 2020. The COPE survey was launched in the DHRP in May 2020, and 6 iterations were developed, modified, and released to participants through February 2021. A previous study of the COPE survey showed that the modification of surveys led to a significant increase (P<.001) in the participant response rate over 10 months of survey delivery [30]. Overall, completion rates for the COPE survey among individuals enrolled under UBR categories showed an increase from 11% in the first survey to 16% in the final survey. These findings underscore the significance of using a digital platform able to accommodate rapid implementation of protocol amendments.

Figure 7. Heat map showing cross-sectional use of CATI by age and education level. CATI: computer-assisted telephone interviewing; GED: General Educational Development.

Discussion

Principal Findings

The design and implementation of the DHRP in this study demonstrates that a DHRP with technical architecture for participant-focused design can effectively be used to recruit, engage, and collect longitudinal health data from participants with geographic, racial, and sociodemographic diversity. The collaborative, community-informed approach used to develop the DHRP, combined with validation through UX research, contributed to its effective design for use in diverse populations [31]. The participant-centric design of the DHRP may be broadly applicable to increase community engagement of people from diverse backgrounds in other research study designs, including cross-sectional, case-control, and experimental clinical trials [32].

The principles of generalizability, usability, cultural sensitivity, and accessibility were consistently implemented throughout the human-centered design and building of the DHRP for this study [33]. The diversity of participant users, combined with the high eConsent completion rates, support the idea that the PXM is,

XSL•FO
RenderX

in fact, participant friendly, accessible, and usable for various groups, as intended. The use of the DHRP's CATI technology in this study also demonstrates the successful use of digitally enabled, human-delivered engagement methods to enhance participation of UBR groups. In this study, CATI enhanced data collection and increased study completion rates of the SDOH survey module among people with lower education levels, those with lower incomes, older people, and those from racial and ethnic minority groups. This shows that the DHRP can be used to increase cohort diversity and build trust with UBR groups [34]. In addition, the increase in engagement demonstrated by the COPE survey results shows that the researcher tools, RC and CEB, are integral to facilitating participant engagement within DHRP. Furthermore, integrating the participant-facing tool (PXM) with the researcher tools (RC and CEB) in a containerized manner protected participant autonomy and privacy, while also maintaining workflow automation and bidirectional communication between participants and study staff.

From an engagement perspective, it was important to establish a standardized eConsent process that was accessible and comprehensive for all individual platform users regardless of their geographical location, method of enrollment, preferred language, educational level, digital literacy, or digital device used [27]. PXM eConsent modules were successfully used with high participant informedness demonstrated by high rates of completion of the formative consent evaluation. Well-designed and well-delivered eConsent provides transparency to participants at study initiation and can increase volunteerism, participant understanding of research, and participant satisfaction [28]. This can lead to increased trust and future participation in research among groups historically underrepresented in the field [27,35]. This result supports the idea that this digital research platform can enhance the delivery of longitudinal studies and can be used by participants with different levels of digital literacy.

Strengths and Limitations

This novel study has several strengths. This demonstration helps shed light on how digital research platforms, such as the DHRP, can be effectively used to increase the participation of UBR groups. The collaborative approach used in the design of the DHRP ensured the platform was able to meet the needs of people from various sociodemographic backgrounds and with varying levels of comfort with digital technology. The comprehensive design of the DHRP tools appears to have decreased participant barriers to research participation commonly reported in the literature [36]. These aspects should be further investigated in future research.

Although this study has numerous strengths, it also presents potential limitations. Although the cohort is 8% rural (n=58,211), it does not fully represent the current US population, which is 13.8% rural by county definition [37]. This limitation is a function of the overall AOU research processes that determine the geographic distribution of participants based on the availability of local affiliated recruitment sites and is not a direct limitation of the DHRP itself.

Another possible limitation of this study is the lack of available data with which to evaluate the use of the DHRP within the pediatric population. This is a result of the AOU being in its initial phases of enrolling pediatric participants. Although the DHRP was designed and built to accommodate the complexities of consenting, engaging, and collecting data for pediatric research, we currently do not have adequate data to conduct a conclusive analysis of the efficacy of the DHRP within this group. Therefore, we are unable to report on potentially unforeseen challenges related to the use of the DHRP in pediatric research, as they have not yet been encountered in this study.

Conclusion

We created and validated a digital research platform to support the development of a large, nationwide, community-engaged, longitudinal cohort study (AOU) of diverse participants from UBR groups. This study demonstrates the promising potential of digital platforms to enable the curation, harmonization, and management of high-volume longitudinal multisource data sets from diverse populations for precision medicine research. Digital platforms may provide solutions to researchers who aim to broaden their catchment area in site-based, decentralized, and hybrid research methods and support the development of more diverse research cohorts. With continued development, digital research platforms, such as the DHRP described here, may lead to the successful establishment of best approaches to engage health-disparate, minority, vulnerable, and other UBR populations into clinical research to broadly improve the overall health of all communities.

Acknowledgments

We would like to thank all collaborators who contributed to the design and implementation of Vibrent Health's digital health research platform. We would also like to acknowledge all participants of the All of Us Research Program. The study was funded by National Institutes of Health grants (OTA-20-001 and RFA-PM-16-003).

Authors' Contributions

Manuscript concept and design were completed by PJ, DK, MB, and AM in collaboration with All of Us Research Program stakeholders. Data acquisition was completed by S Sutherland. Data analysis and interpretation was completed by AM and MB. The manuscript was drafted by AM, DK, MB, and PJ. Manuscript revision was led by AM and completed by all coauthors. Theoretical support was provided by DK, S Sawyer, JLM, DK, and PJ.

Abstract

Background: The evolution of patient-physician communication has changed since the emergence of the World Wide Web. Health information technology (health IT) has become an influential tool, providing patients with access to a breadth of health information electronically. While such information has greatly facilitated communication between patients and physicians, it has also led to information overload and the potential for spreading misinformation. This could potentially result in suboptimal health care outcomes for patients. In the digital age, effectively integrating health IT with patient empowerment, strong patient-physician relationships, and shared decision-making could be increasingly important for health communication and reduce these risks.

Objective: This review aims to identify key factors in health communication and demonstrate how essential elements in the communication model, such as health IT, patient empowerment, and shared decision-making, can be utilized to optimize patient-physician communication and, ultimately, improve patient outcomes in the digital age.

Methods: Databases including PubMed, Web of Science, Scopus, PsycINFO, and IEEE Xplore were searched using keywords related to patient empowerment, health IT, shared decision-making, patient-physician relationship, and health communication for studies published between 1999 and 2023. The data were constrained by a modified query using a multidatabase search strategy. The screening process was supported by the web-based software tool Rayyan. The review methodology involved carefully designed steps to provide a comprehensive summary of existing research. Topic modeling, trend analysis, and synthesis were applied to analyze and evaluate topics, trends, and gaps in health communication.

Results: From a total of 389 selected studies, topic modeling analysis identified 3 primary topics: (1) Patient-Physician Relationship and Shared Decision-Making, (2) Patient Empowerment and Education Strategies, and (3) Health Care Systems and Health IT Implementations. Trend analysis further indicated their frequency and prominence in health communication from 1999 to 2023. Detailed examinations were conducted using secondary terms, including trust, health IT, patient-physician relationship, and patient empowerment, derived from the main topics. These terms clarified the collective impact on improving health communication dynamics. The synthesis of the role of health IT in health communication models underscores its critical role in shaping patient-centered health care frameworks.

Conclusions: This review highlights the significant contributions of key topics that should be thoroughly investigated and integrated into health communication models in the digital age. While health IT plays an essential role in promoting shared decision-making and patient empowerment, challenges such as usability, privacy concerns, and digital literacy remain significant barriers. Future research should prioritize evaluating these key themes and addressing the challenges associated with health IT in health communication models. Additionally, exploring how emerging technologies, such as artificial intelligence, can support these goals may provide valuable insights for enhancing health communication.

Introduction

Background

Technological advancements have transformed patient-physician communication. A fundamental aspect of this transformation is through patient empowerment, which encourages individuals to manage their health proactively according to their personal needs, thereby improving health care outcomes [1]. The adoption of patient empowerment practices and broader access to health information from various sources such as online platforms have shifted from a traditional 1-way communication model to a patient-centered approach that emphasizes collaborative shared decision-making [2-4]. This shift promotes active patient engagement, encouraging them to articulate their needs, preferences, and values within the health care process [5,6]. Additionally, today's health communication is often enhanced by technological advancements that provide patients with extensive health information and tools [7,8]. Telehealth, mobile health (mHealth), patient portals, and recently adopted artificial intelligence (AI) techniques have expanded patients' access to health care and health-related data [9,10]. Telehealth platforms, for example, have made medical consultations more accessible, allowing patients to communicate with health care providers remotely [10,11]. This convenience helps patients actively participate in consultations and make informed decisions about their treatments. Similarly, electronic health records (EHRs) facilitate a continuous flow of information between different health care providers, ensuring that every provider involved in patients' care has access to the same comprehensive data [12]. By 2021, 88% of US office-based physicians had adopted EHR [13]. This widespread adoption ensures that providers have timely and accurate patient data, which is crucial for tailoring treatment plans to individual needs and preferences. Additionally, patient portals give patients 24/7 access to their health records, test results, and direct communication with their health care providers [14]. This transparency encourages patient engagement and fosters active discussion about care plans, ultimately enhancing the effectiveness of patient-physician communication. Despite these benefits, the availability of online health information also introduces risks, such as the potential exposure to misinformation [15-17]. Misinformation can undermine the trust necessary for effective health care relationships, which is critical because trust influences patients' willingness to follow medical advice and maintain open communication with their providers. For instance, the impact of social media on these relationships significantly varies based on the accuracy of the information and the preexisting relationship between patient and physician, which can range from positive to negative [18].

Today's diverse health information technology (health IT) landscape further underscores the need for a refined health communication model that effectively leverages digital tools to enhance patient empowerment across various health care settings [19,20]. While the concepts of patient empowerment and patient-centered care are frequently discussed, their integration into health communication models is still not fully addressed. As digital solutions become standard in health care, it is increasingly important to understand how patient relationships, empowerment, and health IT integrate and interact within health communication models. This extensive review explores essential topics of health communication that fit today's digital age and investigates their associated dynamics to identify mechanisms that facilitate effective health communication between patients and physicians.

Aim and Objectives

The overarching aim of the research is to investigate the essential elements for inclusion in a refined health communication model to enhance patient-physician communication and shared decision-making in the current digital age. Using the PICo framework (Population, Interest, and Context) [21], this study specifies the population as physicians and patients, the interest as key elements for effective communication models, and the context as the impact of health IT on health communication. Particularly, the first objective is to identify and analyze the key topics and factors that have influenced health communication in the past 25 years and should be incorporated into effective health communication models. The second objective involves trend analysis to explore the dynamics and associations among those key topics and factors identified in the first objective. Finally, the last objective focuses on synthesizing the impact of health IT on patient-physician interactions and its subsequent effects on the evolution of health communication models.

However, unlike systematic reviews, this extensive review does not adhere to strict protocols for study selection and data extraction; instead, we aim to provide a comprehensive synthesis of available evidence to inform future research and practice in the health communication model. In the subsequent sections of this paper, we will provide an overview of the methodologies used to explore and analyze essential factors in health communication, including detailed descriptions of our data selection, screening processes, and analysis techniques such as topic modeling and trend analysis.

Methods

Search Strategy and Eligibility Criteria

To answer our research question and meet our study objectives, we conducted an extensive literature review using the web-based software tool Rayyan for screening, which enabled us to efficiently filter through a large amount of research [22]. The review and reporting process followed the guidelines provided by Rowley and Slack [23,24], ensuring a rigorous approach to organizing the collected literature and presenting the findings in a structured and coherent manner (Multimedia Appendix 1).

Multiple electronic databases including PubMed, Web of Science, Scopus, PsycINFO, and IEEE Xplore were searched to ensure broad coverage of the literature. Each database was chosen for its specific strengths and relevance to various dimensions of health communication. PubMed was selected for its comprehensive coverage of biomedical literature, essential for addressing medical aspects of health communication. Web of Science and Scopus were chosen for their multidisciplinary scope, enabling the examination of trends across diverse fields. PsycINFO was included for its focus on psychological literature,

XSL•FO
RenderX

key for exploring aspects of patient empowerment and decision-making processes. Finally, IEEE Xplore was included to access cutting-edge research on technological innovations in communication tools, critical for understanding the development and application of digital solutions in health care.

While digital tools and patient involvement are reshaping health communication, we carefully selected keywords representing 4 different categories related to health communication, including patient participation (MeSH [Medical Subject Headings] term), decision-making, shared (MeSH term), technology (MeSH term), and physician-patient relations (MeSH term) to guide our literature selection. These keywords were used along with Boolean operators (AND or OR) to capture diverse studies that allow us to examine the complex dynamics between the interactions of patients and physicians. To ensure a robust and precise alignment with our research objectives, we thoroughly reviewed our keywords and relevant key terms using the MeSH database and implemented a multidatabase search strategy [25]. This approach allowed us to craft a query that effectively targets the most relevant literature across various platforms, enhancing the breadth and depth of our literature review. Each query was adjusted slightly depending on the database, covering the period from 1999 to 2023: *((communication) OR (health communication model)) AND ((decision making*) OR (decision making, shared)) AND ((patient participation*) OR (patient participation/methods) OR (patient empowerment) OR (patient engage*) OR (patient involve*) OR (Patient-Centered Care)) AND ((physician-patient relations*) OR (Trust) OR (physician-patient trusted relationship)) AND ((decision support techniques) OR (technology) OR (health informatics) OR (Patient Preference) OR (information systems*) OR (health information systems))*

The selection process for the literature review was carefully designed to comprehensively cover studies on patient-physician interactions within the digital health framework. We included studies that (1) examined these interactions specifically with health care technologies; (2) aligned with the principles of shared decision-making or patient-centered care; (3) focused on cancer or chronic diseases, given their significant implications for patient communication; and (4) were published within the designated time frame of 1999-2023 to capture the evolution of health communication practices in the past 25 years. To maintain the quality and relevance of the studies reviewed, exclusions were made based on (1) language, excluding non-English articles to ensure consistency in data interpretation; (2) publication type, omitting reports, conference papers, abstracts, letters, or feature articles, which lack peer-reviewed validation; and (3) the absence of significant patient participation or empowerment, a key focus in evaluating effective communication strategies. This structured evaluation ensures our review meets high scholarly standards, offering a solid foundation for understanding the changing dynamics of health communication with emerging health care technologies.

Data Analysis

Topic Modeling and Visualization

All our analysis processes for this research were applied in R (R Foundation). Initially, we used the "tm" package to preprocess the text, which involved transforming all characters to lowercase, removing punctuation, numbers, and custom stopwords to ensure a clean and relevant data set. Following preprocessing, we constructed a Document-Term Matrix from the cleaned text to remove sparse terms and enhance both computational efficiency and model accuracy. To assess the coherence and effectiveness of the model, we utilized the "ldatuning" package and determined 3 optimal numbers of topics based on coherence scores, each representing a distinct thematic cluster within our data. Subsequently, we applied latent Dirichlet allocation using the "topicmodels" package to identify the most frequently discussed terms and concepts within the abstracts of the collected studies.

To aid in the interpretation of these topics, we visualized the topics using the "LDAvis" package. This advanced visualization tool allowed us to create interactive 2D scatterplots and bar plots of the topics. By adjusting the lambda parameter from 0 to 1, we were able to explore both the unique and frequently occurring terms within each topic, enhancing our understanding of the thematic relevance and distinction.

Trend Analysis and Secondary Topic Exploration

In our analysis framework, we distinguished between primary and secondary topics to thoroughly map the landscape of health communication. The primary topics, which center on health communication between patients and physicians, were categorized by topic modeling, serving as the overarching theme of our study. Accordingly, each paper was assigned a topic number by identifying the dominant topic based on the highest probability derived from the latent Dirichlet allocation model. These topics will be utilized in our trend analysis like topic distribution over time to examine the evolving dynamics within health communication, providing insights into how these themes have developed in the past 25 years.

To effectively represent the broad themes identified through topic modeling, we have selected specific secondary terms that closely relate to these primary topics. These terms are chosen for their frequent appearance within the context of identified primary topics and their ability to precisely capture the core ideas of each topic. Once identified, these terms are used as critical filters to refine our data set individually, ensuring that only those papers most relevant to each secondary topic were included. This step is critical as it allows us to apply the themes for detailed trend analysis and in-depth synthesis, particularly suitable for methodologies such as UpSet plotting, where the identification of overlaps and intersections between sets is necessary.

Impact Synthesis

To achieve our third objective, synthesizing the impact of health IT on patient-physician interactions and its subsequent effects on the evolution of health communication models, our final analytical phase involved a rigorous review process focusing on studies that exemplify the practical integration of health IT within dynamic health communication frameworks. These frameworks are designed to actively involve both patients and physicians, ensuring that technology enhances their communication. From the literature used for data analysis, we

XSL•FO
RenderX

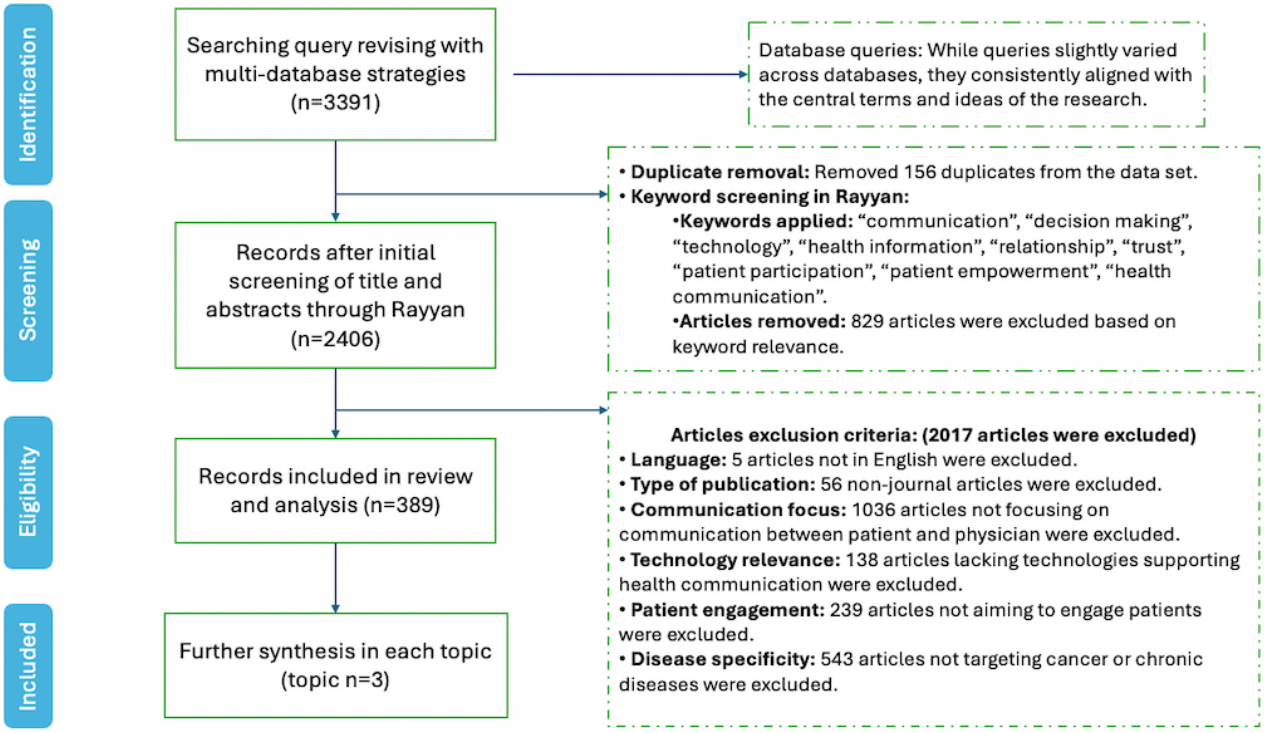
further narrowed the focus to a specific analysis centered on health IT and its application in health communication. We strictly excluded studies that (1) did not incorporate health IT as an integral component of patient-physician communication, (2) solely evaluated technology design without practical health care application, or (3) lacked a structured communication model. This exclusion criteria allowed us to concentrate on research that provided clear insights into effective health IT integration.

This comprehensive and structured methodology ensures that our analysis not only adheres to rigorous academic standards but also provides insightful conclusions that enhance our understanding of the dynamic field of health communication in the digital age.

Results

Outcomes

In this section, we first present the outcomes of our data selection and screening process. Through query adjustment and refinement, removal of duplicates, and application of strict selection criteria, we narrowed our focus to 389 papers. These articles were then utilized in topic modeling, providing a foundation for further analysis.



In our topic modeling analysis, 3 major topics were identified, each closely related to health communication. This structured framework allowed for deeper exploration of the data and set the stage for subsequent analyses. Building upon the results of topic modeling, we conducted trend analysis to explore the dynamics and associations between significant elements such as health IT, patient-physician relationships, trust, and patient empowerment. The distribution of these topics over time and the interrelations among these key elements were visualized using topic distribution graphs and UpSet figures, offering a clear depiction of evolving trends.

Finally, our study synthesized findings on the role of health IT in patient-physician interactions, highlighting this as the key aspect of our third objective. This phase highlighted how technological advancements have been integral in shaping modern health communication models and identified areas for further development to facilitate enhanced interactions between patients and health care providers.

Data Selection and Screening

The review process initially identified and collected 3391 articles through multiple databases, as illustrated in Figure 1. Following the initial search, the titles and abstracts of these articles were screened using Rayyan. This initial screening narrows down the data to 2406 articles by filtering out those that clearly do not meet our preliminary inclusion criteria and 156 duplicated articles, ensuring the uniqueness of each study included in the analysis. The remaining articles were subjected to a rigorous screening process based on specific exclusion criteria, including language (English only), publication period (1999-2023), type of publication (journal articles only), and content relevance (articles focusing on communication involving technology and patients, specifically within the contexts of cancer or chronic diseases). This process effectively narrowed our focus to 389 articles that were highly relevant to the core topics of health communication, enabling us to explore the dynamics and associations between significant elements.

Figure 1. The diagram illustrates the selection process (identification, screening, eligibility assessment and inclusion) of this review study.

XSL•FO
RenderX

Topic Modeling Analysis

To address objective 1, identifying and analyzing key topics that influence health communication, we conducted a topic modeling analysis on the selected 389 articles. This analysis successfully identified and characterized 3 main topics, which explain the underlying structure of health communication and reveal distinct themes that enhance patient-physician communication in the digital age.

For the visualization of our topic modeling results, the scatterplots in Figure 2 explain how principal component 1 and principal component 2 capture the directions in which the variance in the topic distribution is most pronounced. As the topics, represented by the circles in the scatterplot, are far apart from each other, they are more likely to have a unique set of terms in each topic. To gain a deeper insight into the underlying structure, a fine-tuning option with lambda was used to adjust the relevance and frequency of terms in each topic. Adjusting the lambda value from 0 to 1 shifted the relevance of terms between their frequency in the data set and their uniqueness within the topic (ie, with a low lambda value the topics appeared somewhat similar, whereas higher values provided a clearer distinction between the topics). Further details on topics 2 and 3 are provided in Multimedia Appendix 2.

With distinct themes central to health communication, we carefully named and described individual topics by their unique set of keywords. These topics and their descriptions are summarized in Table 1.

Figure 2. A 2D scatterplot and a bar plot illustrating the distribution and relevance of topics identified from the topics modeling analysis using LDAvis. Each circle in the scatterplot represents a topic, while the bar plot displays the most relevant terms for topic 1 as an example here.

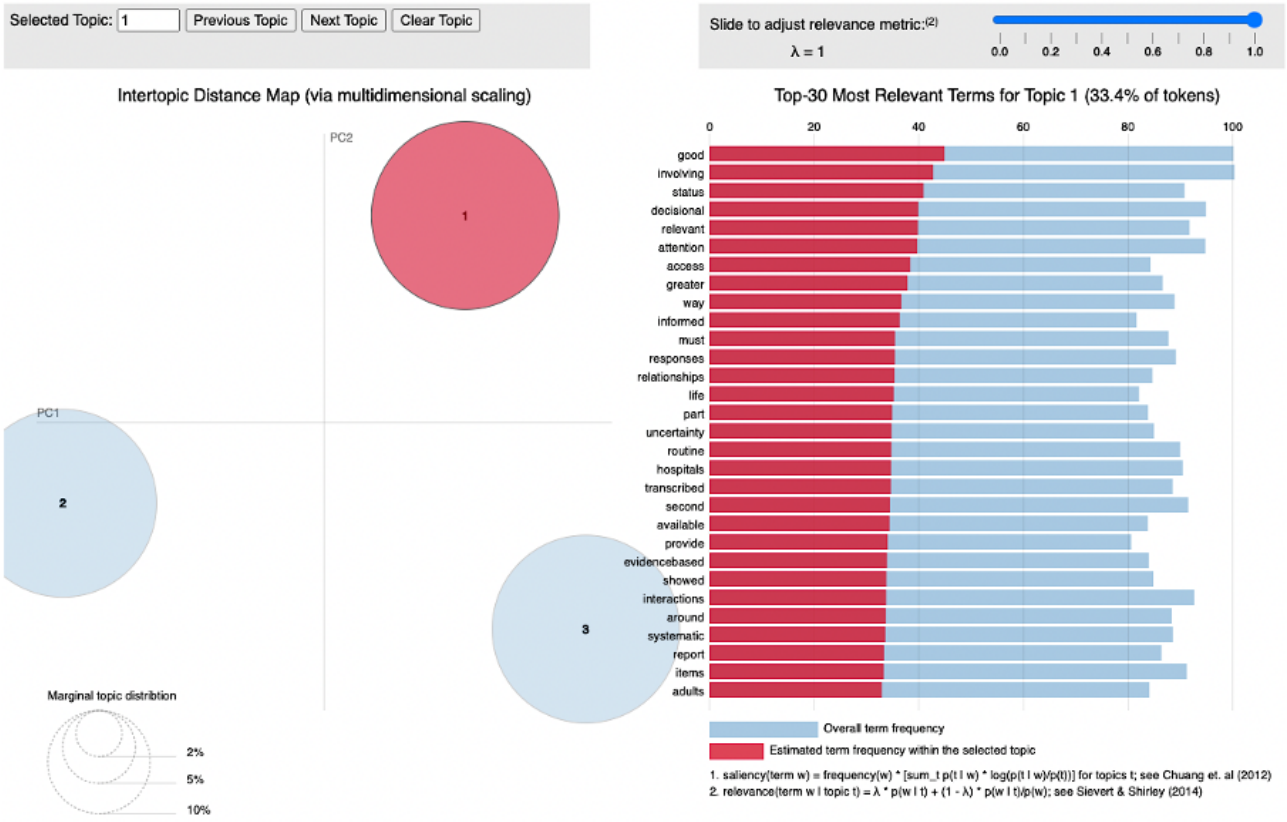


Table 1. The 3 topics categorized from topic modeling results and selective top keywords.

Topic	Label	Keywords
Topic 1	Patient-Physician Relationship and Shared Decision-Making (n=119)	“good,” “status,” “decisional,” “access,” “attention,” “greater,” “informed,” “must,” and “relationships”
Topic 2	Patient Empowerment and Education Strategies (n=142)	“type,” “engage,” “evaluated,” “measured,” “following,” “topics,” “electronic,” “educational,” “older,” and “diagnosis”
Topic 3	Health Care Systems and Health IT Implementations (n=128)	“association,” “reduce,” “clinician,” “national,” “provided,” “models,” “digital,” “age,” and “interactions”

Topic 1, labeled *Patient-Physician Relationship and Shared Decision-Making*, describes the quality and process of health care delivery focusing on informed and shared decision-making and patient-physician relationships. In health communication, this topic can indicate how patients’ access to information and the quality of the patient-physician relationship contribute to effective communication and shared decision-making.

Topic 2, labeled *Patient Empowerment and Education Strategies*, focuses on educational strategies and evaluation methods in health care, emphasizing the utilization of health IT

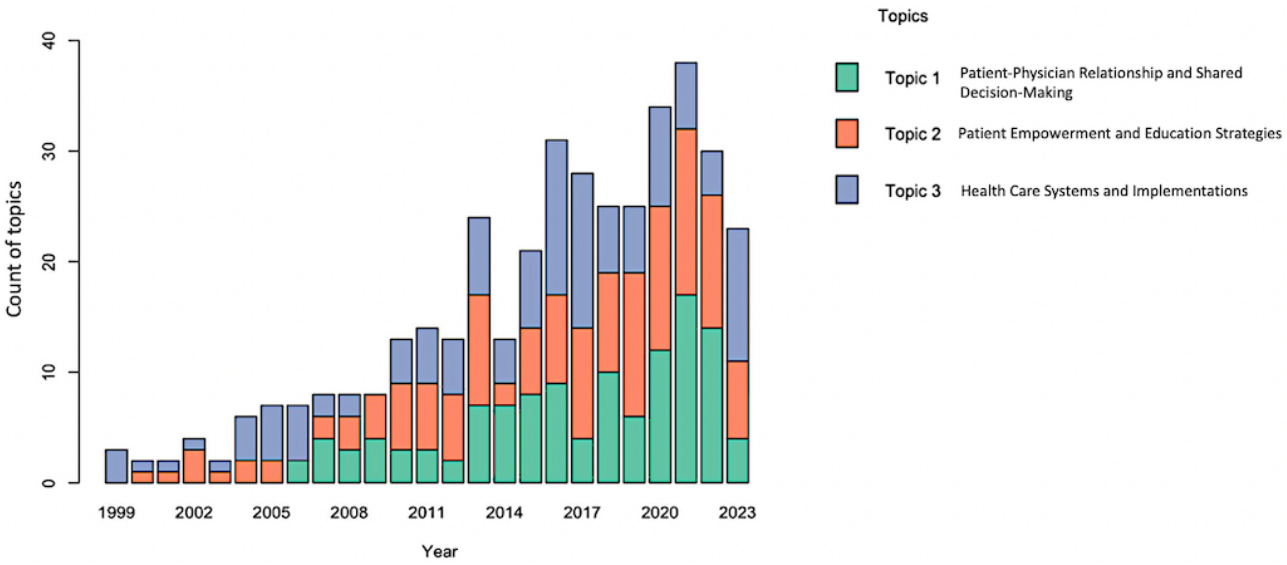
XSL•FO
RenderX

and targeting aging populations. In health communication, this topic can explore how empowering patients through education and supporting them with digital tools improves communication and healthcare outcomes.

Topic 3, labeled *Health Care Systems and Health IT Implementations*, is specifically related to health care systems and technological implementations. In health communication, it can explore how health care policies and technological implementations facilitate effective communication and enhance models by guiding interactions between patients and physicians.

The topic modeling results have strengthened and consolidated the categories of our designed searching queries, combining "patient-physician relationship" and "shared decision-making" into a single focused topic. Additionally, it has emphasized the importance of educational strategies for patient empowerment and the critical role of health IT implementation in health care systems.

Based on these findings, we carefully selected our secondary terms "patient-physician relationships," "patient empowerment," and "health IT" to reflect the core themes identified in the primary topics. The patient-physician relationship was explored using terms such as "patient-physician relationship," "relationship," "shared decision-making," and "patient-centered care." In the case of patient empowerment, we used keywords such as "empowerment," "participation," "engagement," "involvement," and "self-management." Health IT was represented by terms such as "technology," "online platform," "EHR," "telehealth," "mHealth," "digital," "informatics," "patient portal," "wearable device," "telemedicine," "remote," and "information system."



A further manual review was conducted by the first author and closely monitored by the project lead to ensure consistency and accuracy in the analytical approach. Beyond the identified topics, trust emerged as a significant theme within health communication and a frequently discussed topic across various topics analyzed in the study. Topic 1 related to patient-physician relationship and shared decision-making has 42 trust-related articles out of 119 (35.3%), topic 2 on patient empowerment and educational strategies has 45 out of 142 (31.7%), and topic 3 concerning health care systems and health IT implementations has 40 out of 128 (31.3%). These findings highlighted the need to include trust as an additional secondary element in health communication and further explore it in the rest of the analysis to investigate its association with health communication and the interplay among other key factors. Therefore, we utilized terms such as "trust," "physician-patient trust," "medical trust," "health care trust," and "trust in health information" to represent trust in our following analysis. An additional observation from this review indicates that the topic of trust can include a broad range, extending beyond patient-physician trust to potentially include trust in health care systems, digital tools, and health information.

Trend Analysis

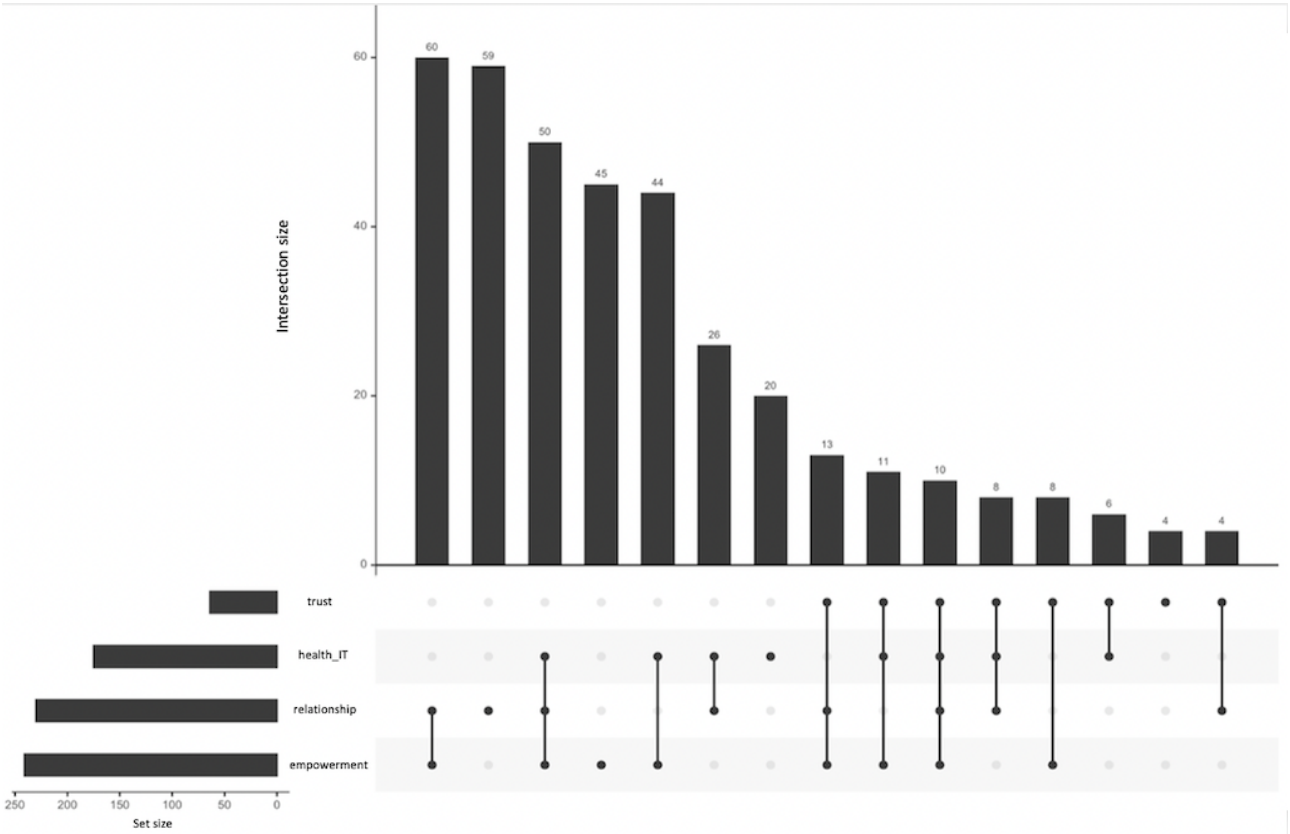
To address objective 2, exploring the dynamics and associations among key topics and factors identified through topic modeling, our trend analysis was structured into 2 main sections. Initially, we used a bar plot to visually represent the frequency and prominence of each primary topic from 1999 to 2023. Following this, we used an UpSet plot to further explore the contributions and intersections of secondary terms that were carefully selected to represent primary topics over time.

The first section of the trend analysis focused on the primary topics that we found through topic modeling within health communication. By analyzing the topic distribution and assigning a unique topic number ranging from 1 to 3, we tracked the frequency of each topic over the years (1999-2023) with a bar plot (Figure 3).

Figure 3. Bar plot illustrating the annual distribution of papers categorized by their relevance to 3 identified topics from topic modeling with different colors. The bar plot provides a visualization of how the distribution and frequency of each topic within health communication have evolved from 1999 to 2023.

Topic 1 (green), Patient-Physician Relationship and Shared Decision-Making, did not emerge in the literature until 2006.

XSL•FO
RenderX



It shows a notable presence across the years with some fluctuations, specifically with a significant peak in 2021 (frequency 17, mean 5.8).

Topic 2 (orange), Patient Empowerment and Education Strategies, reveals a steady increase in frequency over the years, emphasizing a consistent rise in research interest and practical applications (mean 4.92).

Topic 3 (blue), Health Care Systems and Health IT Implementations, exhibits an upward trend, with notable peaks in 2016 (frequency 14) and 2023 (frequency 12), compared with a mean frequency of 5.16.

In the second section of our trend analysis, we utilized an UpSet plot (Figure 4) to explore the associations among the secondary terms within health communication. This analysis specifically focuses on patient empowerment, patient-physician relationships, health IT, and trust in the field of health communication.

Figure 4. UpSet figure showing the key factors of health communication, including patient empowerment, patient-physician relationship, health IT, and trust, which are represented in 4 different sets individually. The bar chart on the left shows the size of each set, which corresponds to the number of articles that contains any factors among our key factors. The main bar chart on the top represents the size of intersections between different sets within health communication. Each bar's height indicates how many elements are common to the individual sets connected below by dots and lines in the matrix. The matrix of intersections at the bottom has rows labeled with the names of the 5 sets and columns represented by dots under each set name. A filled dot indicates that the set involves the intersection corresponding to that column.

In our UpSet figure analysis within the scope of health communication, “patient empowerment” emerges as the most prominent set, as indicated by the largest bar on the left side of the plot. It is closely followed by “patient-physician relationship” and “health IT,” both highlighting their critical roles in the dynamics of health communication. The topic of “trust” shows a slightly lesser focus. Intersections between these sets reveal notable overlaps, with the largest interaction between “patient empowerment” and “patient-physician relationship” under health communication. This intersection reflects key themes of patient-centered care that involve communication strategies, empowerment, and interpersonal relationships. Reinforced by its presence in the second largest intersection with health communication, the “patient-physician relationship” further emphasized its critical role. This continual involvement across different sets highlights that the patient-physician relationship is central to discussions in health communication, further emphasizing the critical need for strong interpersonal foundations between patients and physicians in the patient-centered care framework. Similarly, the interaction involving “health IT,” “patient-physician relationship,” and “patient empowerment” under health communication illustrates an increasing integration of technology in empowering patients to facilitate effective health communication. Finally, although “trust” is addressed in a relatively smaller number of articles, its presence in complex interactions with all other factors highlights its foundational importance and influence, suggesting potential for deeper exploration to uncover its broader impacts on health communication.

Synthesis of Health IT’s Impact on Patient-Physician Communication Models

To address our third objective, synthesizing the impact of health IT on patient-physician interactions, we conducted a detailed

XSL•FO
RenderX

review based on our secondary research terms of health IT. This process led to the selection of 29 pivotal papers for detailed analysis, the findings of which are thoroughly detailed in Table 2.

These papers collectively provide a synthesized overview highlighting the specific health communication models or frameworks employed, the variety of health IT tools utilized, their impacts on patient empowerment and engagement, and the challenges or barriers encountered. The analysis revealed several key themes to not only map out the direct effects of health IT in health communication but also indicate practical applications and recommendations aimed at overcoming the identified challenges and amplifying the effectiveness of health communication strategies, which are summarized in Textbox 1.

XSL•FO

Table 2. Impacts of health information technology on patient-physician communication models.

Study	Health communication model/framework	Health information technology tools used	Impact on patient empowerment/engagement	Challenges/barriers	Better practices/recommendations
Heesen et al [26]	SDM[a] guided	Evidence-based decision aids and educational programs	Enhances patient participation in treatment decisions	Balancing patient autonomy with a lack of initial knowledge	Continue development of comprehensive patient education programs
Sillence et al [27]	Informed SDM guided	Internet information	Empowers patients by enhancing informed decision-making and improved communication with physicians	Poorly designed websites can lead to rejection of quality content	Well-designed personalized websites with credibility
DuBenske et al [28]	SDM guided	Interactive health communication system	Provides information, communication, coaching resources, and a symptom-tracking system; bridges communication gaps among patients, families, and physicians	User diversity in format preferences and technology comfort, physician buy-in, and integration with existing medical systems	Conduct needs assessment, involve stakeholders, accommodate diverse technology preferences, ensure clinician training and buy-in, and integrate with existing systems
Jimbo et al [29]	SDM guided	Decision aid	Incorporates interactive personal risk assessment and preference clarification tools; facilitates informed decision-making and screening adherence; improves decision quality	Balancing the complexity of decision aids with user-friendly designs	Ensure decision aids are intuitive and support real-time interaction to enhance decision-making
Nazi [30]	SDM guided	PHRs[b]: secure messaging and PHR portal	Improved access to health information; enhances communication, patient self-reporting, and provider-patient relationships	Integration with clinical workflow, training, and support for health care professionals	Ensure PHR systems align with clinical practices, provide adequate training, and actively engage clinicians in PHR use
Wilkes et al [31]	SDM guided	EHRs[c] and decision support tools	Facilitates informed and value-concordant or personalized decisions; enhances the quality of prostate cancer screening decisions	Complexity of discussions and emotional and informational barriers	Utilize EHRs for SDM support, integrate decision aids, and adjust reimbursement to encourage SDM
Smits et al [32]	Not specific; SDM guided	Web-based information tool	Enhances patient and family engagement by providing tailored information; a comprehensive approach to developing patient-centric informational tools	Balancing diverse patient preferences and literacy levels	Follow the DoTTI[d] framework for iterative development and stakeholder engagement throughout the process
Roter 2015 [33]	SDM guided	EMR[e] and secure patient portals	Facilitates a new model of patient-physician collaboration with high transparency	Distraction of physicians by EMR use during consultations	Implement training using a practices inventory and provide patients with full access to their EMR
Lafata et al [34]	PCC[f]	EHRs, HRA[g] instruments, and patient reminder lists	Facilitates patient involvement and personalized care; EHRs for information management, HRAs for health risk assessment, and reminder lists for patient preparation	EHR use may extend visit duration and impact preventive service delivery and variability in tool effectiveness	Monitor tool impacts rigorously and tailor tool use to individual patient and practice needs to optimize outcomes

XSL•FO
RenderX

Study	Health communication model/framework	Health information technology tools used	Impact on patient empowerment/engagement	Challenges/barriers	Better practices/recommendations
Bruinessen et al [35]	SDM guided	Web-based communication tool (PatientTIME)	Enhances patient self-efficacy in clinical communication	Ensuring the intervention effectively translates into measurable confidence improvements	Continuously refine and evaluate the intervention based on patient feedback and trial results and focus on integrating practical communication strategies
Olomu et al [36]	SDM guided	Decision aids	Increases medication adherence, enhances patient satisfaction with communication and confidence in health care decisions	Ensuring consistent implementation and adaptation in varied clinical settings	Further develop and test the program to evaluate its broader applicability, effectiveness, and cost-efficiency
Lussier et al [37]	PCC	e-Learning platforms	Enhances patient engagement in communication	Ensuring patient access and familiarity with web-based tools	Integrate web-based educational tools into routine practice and encourage patients to participate as part of their care
Hakone et al [38]	SDM guided	Personalized health risk communication tool	Enhances patients' understanding of personalized risk and treatment options; improves patient decision-making capability	Balancing complexity and clarity in visual risk communication and emotional distress impact	Carefully design visual tools and narratives to meet patient needs and consider emotional states and numeracy levels
Renzi et al [39]	PCC	eHealth and self-management platform	Enhances self-management and patient empowerment in prostate cancer care with a web-based platform for patient education and management	Communication gaps postdiagnosis and postsurgery, and lack of support in self-management	Strengthen health care provider-patient communication, incorporate social support into patient care, and personalize care approaches from diagnosis through treatment
Lu and Zhang [40]	Not specific; SDM guided	Online health communities	Positive impact of physician-patient communication on compliance mediated by perceived information quality, decision-making preference, and concordance	Quality control of online health information and the gap between perceived and actual quality of information	Strengthen the management of online health information, foster open discussions and emotional connections within OHCs[h], and ensure high-quality health information and communication
Yu et al [41]	SDM guided	Online decision aid	Facilitates patient participation in decision-making, strengthens physician-patient relationships	Conflicting agendas between patients and providers and integration of new tools into routine practice	Utilize SDM and goal-setting tools to resolve conflicts and align treatment goals and ensure tools are flexible and respect professional identities
Kondylakis et al [42]	Data-driven communication	ICT[i] platforms	Enhances patient engagement and personalized cancer care management	Patient engagement, interoperability, knowledge management, and trust in technology	Increase trust and stakeholder engagement, ensure interoperability of ICT systems, and enhance knowledge management in ICT platforms

XSL•FO
RenderX

Study	Health communication model/framework	Health information technology tools used	Impact on patient empowerment/engagement	Challenges/barriers	Better practices/recommendations
Hazara et al [43]	PCC	Web-based portals	Enhances patient participation, empowerment, and self-management in their health care; web-based patient portal allowing access to EHRs and communication with health providers	Barriers to widespread portal use	Enhance portal features, learn from other portal implementations, and integrate portal use more effectively in health care delivery
Gilljam et al [44]	SDM guided; Shier's model of participation	Digital communication tools (Sisom for children)	Enhanced participation in health care; increased engagement and direct communication toward children using Sisom; children felt listened to and could express views	Lack of validation and possible variations in engagement not systematically measured	Use randomized control designs for further validation, focus on eHealth's effects on health outcomes and cost-effectiveness, and consider expanding the use of Sisom or similar tools in pediatric settings
van Velsen et al [45]	SDM guided; active and collaborative patient-physician communication	Online patient portal	The study explored the dimensions of trust that might influence patient engagement but found no direct effect on usage	Trust does not directly influence technology usage, indicating possible other factors affecting eHealth service adoption	Assess multidimensional trust factors separately to understand their influence on eHealth adoption; further research is needed to explore why trust does not directly translate to usage
Dimitri et al [46]	Not specific; SDM guided	eHealth platforms and artificial intelligence predictions	Enhanced patient and caregiver communication, improved access to educational resources, and better medical and psychological support; use of connected devices for monitoring and artificial intelligence for predicting treatment adherence	Implementation in specific clinical settings, ensuring data privacy and security, and integration into existing clinical workflows	Involve clinicians and patients in technology integration, provide robust evidence of value and utility, address data privacy concerns
Schubbe et al [47]	Not specific; SDM guided	EHRs, email, and patient portals	Improved patient involvement in decision-making, did not lengthen consultation times, and normalized in routine care	Barriers to routine integration due to clinical and organizational factors	Adapt conversation aids to fit clinical workflows, ensure flexibility in their use, and consider patient preferences and characteristics for tailored communication approaches
Kim et al [48]	PCC	Digital health communication intervention with tailored messages based on local cultures	Enhanced family communication of genetic results and decision-making	Navigating cultural and linguistic differences in genetic education across countries	Use of existing digital platforms to facilitate culturally sensitive communication and adaptation of tools rather than creating new ones
Lu and Zhang [49]	Not specific; focusing on the effectiveness of communication	eHealth and online health communities	Increased patient adherence via enhanced eHealth literacy and positive correlation between eHealth literacy and patient adherence through improved communication and information quality	Addressing gaps in the perceived and actual quality of information	Strengthen management of information quality, develop user-friendly features, and educate patients to improve eHealth literacy

XSL•FO
RenderX

Study	Health communication model/framework	Health information technology tools used	Impact on patient empowerment/engagement	Challenges/barriers	Better practices/recommendations
Schubbe et al [47]	SDM	Mobile health	Facilitates enhanced shared decision-making, reduces decisional conflict and regret, and improves communication quality	Addressing the specific needs of minority populations and integrating decision partners in the decision-making process	Use of community patient navigators to provide support during decisions, leverage mobile health for real-time data and engagement, and facilitate provider-patient-decision partner communication
Liu et al [50]	PCC	PAEHR[j] systems	Improves health self-efficacy and patient-centered communication by facilitating access to health information and communication	Lack of direct association between PAEHR portal use and health outcomes	Integrate PAEHR systems to provide PCC, enhance health self-efficacy, use portals to facilitate patient engagement in health care decisions, and ensure the accessibility of PAEHR portals to improve patient health outcomes
Yılmaz et al [51]	Enhanced patient participation communication	Health Communicator (eHealth tool)	Intended to fulfill unmet informational and psychosocial support needs; multilingual eHealth tool tailored to specific ethnic groups	Patients'/survivors' low health literacy, cultural taboos, lack of trust in health care, and perceived complexity of the tool	Ensure simplicity and ease of use in eHealth tools, involve both patients and professionals in the design process, and provide training and support for new technologies
Grynne et al [52]	Effective interpersonal communication	Digital information tool (Digi-Do)	Enhanced patient knowledge, competence, and motivation; iterative access to reliable health information, and tailored digital information tools; as well as improved preparedness before, during, and after radiation therapy	Unmet information needs, varying levels of health literacy, and reliance on non–health care professional sources	Tailor digital information tools to patient's health literacy level, provide iterative access to reliable information, and complement interpersonal communication
Orstad et al [53]	SDM	Decision aids	Enhanced information exchange needs and addressed patient/clinician relationships and decision-making process	Continuity of patient-clinician relationships, barriers to information exchange, uncertainty in decision-making, and autonomy negotiation	Comprehensive decision support interventions, communication training on scientific/existential uncertainty, and organizational changes for better continuity and dialogue time

Textbox 1. Key themes identified in the analysis.

1. Communication models and health IT functions

The integration of health IT tools within various communication models has been identified, specifically on shared decision-making and patient-centered communication. Tools such as decision aids [26], interactive health communication systems [28], and patient portals [30] have been instrumental in increasing patient participation, bridging communication gaps, and improving access to health information [29]. Additionally, tools such as EHRs and health risk assessment instruments have helped in managing health information effectively [34], ensuring that care is tailored to individual patient needs.

2. Challenges and barriers

Studies have revealed significant challenges in the integration of health IT, such as technological integration issues [30,34], resistance from health care providers due to the perceived increase in their workload [26,29], lack of personalized help [31], and a wide range of patient technology *literacy* [28,29]. *These challenges demand focused attention on design and usability improvements to promote user engagement and acceptance of health IT solutions.*

3. Better practices and recommendations

The literature suggests ongoing training and education for both patients and health care providers as essential [26,30]. It also recommends designing health IT tools that are user-friendly and adaptable to various patient needs [28,29]. Moreover, integrating these tools into clinical workflows is vital to ensure they support rather than disrupt the patient-care provider relationship [34].

Future research should conduct a detailed examination of the specific challenges and opportunities highlighted in these studies to enhance patient engagement and address potential issues. Further efforts should focus on refining health IT tools to facilitate shared decision-making and patient-centered care, ensuring that the implementation of these technologies effectively meets the diverse needs of both patients and physicians, particularly in supporting their interactions. Such targeted research is fundamental for enhancing our understanding of how health IT can effectively assist in patient-physician interactions.

Discussion

Principal Findings

The rapid expansion of this topic has generated a substantial data set, enabling us to identify 3 key themes that are essential for integration into the health communication model. In this section, we further investigate how this extensive review enhances our understanding of the critical topics and factors that influence health communication between patients and physicians in the digital era. We also explain how the trends and interactions among these key elements such as health IT, patient empowerment, trust, and patient-physician relationships are reshaping health communication. Additionally, we further elaborate on the significant role and impact of health IT as derived from our analysis. Finally, we outline potential future research opportunities, especially with technology that could further advance this field.

Primary Topics in Health Communication Models

The evolution of health communication models reflects a clear transition from physician-centered to patient-centered approaches. Earlier models primarily focused on the unidirectional flow of information from physicians to patients [54]. However, with the increasing emphasis on patient empowerment, engagement, and shared decision-making, more recent models prioritize collaboration between patients and physicians, ensuring that medical decisions are aligned with patients' values and preferences [55]. Patient-centered care and shared decision-making models have been identified in previous studies that encourage active engagement of patients, emphasizing the importance of clear, transparent, and effective communication between patients and physicians [2]. However, the integration of essential elements in health communication models was not clearly elaborated, especially in the digital age where health IT should be effectively utilized in patient-physician communication.

Our study identified 3 primary topics that should be considered to include in a refined health communication model that fits today's digital age and more collaborative, patient-centered approaches. Specifically, topic 1 underscores the prominence of the Patient-Physician Relationship and Shared Decision-Making in health communication, closely aligning with the collaborative environment and further emphasizing the importance of the patient-physician relationship. Topic 2 captures the rise of Patient Empowerment and Education Strategies. As patients are increasingly empowered to actively engage with their health information, carefully designed education strategies can help effectively bridge the knowledge gap between patients and physicians and avoid patients being misinformed [56]. Topic 3 highlights the broader Health Care Systems and Health IT Implementations that support these communication models. Existing health IT tools such as patient portals, EHRs, and online information systems facilitate patient engagement and streamline communication across the care continuum. However, the integration of these tools into communication models requires careful consideration to ensure both general applications and personalized utilizations.

Addressing these elements can better align health communication models with the evolving needs of health care systems, ensuring that patient empowerment and engagement remain central. Future research should focus on standardizing these models with the integration of these primary topics to ensure they remain flexible and relevant in a rapidly changing health care landscape.

Trend Analysis and Factor Associations in Health Communication

In our trend analysis, we not only investigated the trend of identified primary topics in topic modeling, but also explored the complex interactions among carefully selected secondary topics, including patient empowerment, health IT, patient-physician relationship, and trust.

XSL•FO
RenderX

Topic 1 (Patient-Physician Relationship and Shared Decision-Making) combined 2 themes of patient-physician relationship and shared decision-making, emphasizing the critical role of strong interpersonal relationships in shared decision-making and collaborations in health care. Notably, a peak in this topic (Figure 3, green) observed in 2021 indicates an increased focus on fostering patient-physician relationships and facilitating collaborative decision-making. This shift was likely influenced by the global health challenges and the push for more patient-centered care models [55]. The critical need for effective communication between patients and physicians emphasized the importance of involving patients more actively in their care decisions and building strong patient-physician relationships, specifically with the support of technology [57]. For instance, the expansion of remote care and digital health technologies has effectively addressed barriers such as distance, waiting times, and disparities in access to care [58], further facilitating this trend toward improved patient-physician interactions.

For topic 2 (Patient Empowerment and Education Strategies), an early and consistent upward trend has been observed in Figure 3 (orange), indicating a shift toward empowering patients with knowledge and tools to manage their health effectively. This trend aligns with broader health care movements that emphasize increased patient education and empowerment. Research has demonstrated that well-implemented education and empowerment strategies can significantly reduce hospital readmission rates and improve adherence to treatment plans [56]. Moreover, higher levels of patient activation are associated with lower health care costs and better outcomes [59]. However, the journey to effectively empower patients continues to evolve. Supporting this evolution, effective health communication between patients and physicians plays an essential role in the empowerment process [60]. Enhanced communication fundamentally supports patient empowerment by providing clearer, more accessible information, which is essential for informed decision-making. Therefore, it is crucial to develop and carefully integrate patient empowerment strategies within health communication frameworks. This integration ensures that communications not only inform but also actively engage patients, thereby enhancing their role in decision-making processes and overall care management to reach better health care outcomes.

For topic 3 (Health Care Systems and Health IT Implementations), the significant peaks observed in 2016 and 2023 correspond to critical periods of health care system reforms (Figure 3, blue), particularly those involving the integration of new technologies. The enhanced use of health IT such as EHRs and web-based communication tools facilitated improved patient involvement and personalized care [34,35,37]. The COVID-19 pandemic further accelerated the implementation of advanced digital tools such as health communicator, which were designed to meet specific patient needs, including tailored information and psychosocial support for individuals [51,52]. This reflects a field that is continually adapting, not only to technological advancements but also to the evolving needs of patients. These developments illustrate the dynamic nature of health communication research and highlight critical moments when topics such as patient empowerment, shared decision-making, and technology integration rise to prominence.

Additional analyses involved refined secondary terms that helped us to investigate the detailed associations between specific terms that represented the core idea of the primary topics. This targeted selection process was crucial for accurately mapping the evolution of specific themes within health communication over the study period, enabling us to uncover nuanced trends and associations that might be unnoticed in a broader topic modeling analysis.

The top 2 strongest intersections we explored emphasize the critical role of the patient-physician relationship in health communication, particularly as patients take more control in the context of patient-centered care [61]. The integration of patient empowerment within the intersections highlights the necessity of bridging the knowledge gap for patients, enabling them to engage more actively in their health care decisions. Additionally, the third most prominent intersection, involving health IT, further underscores the growing role of technology in empowering patients and facilitating effective communication. Although the topic of trust appeared less frequently in association with other secondary terms, its close connections with each term were consistently identified. These individual connections emphasize the multifaceted role that trust plays in health communication, demanding further investigation. Specifically, trust acts as a foundational element in promoting better treatment adherence and fostering stronger patient-physician relationships [62]. Moreover, trust in health IT is equally vital, influencing patients' willingness to adopt and engage with digital health solutions, thereby enhancing the overall effectiveness of health communication [45,63].

The Role of Health IT in Health Communication Models

In our in-depth synthesis and analysis (shown in Table 2), many communication-related technologies are not under any specific communication model, but only guided by the idea of shared decision-making or facilitating patients' participation. Previous studies suggested that while shared decision-making is widely endorsed, many implementations lack a structured model that consistently leads to effective communication outcomes [64,65]. Similarly, patient-centered communication, despite its widespread advocacy as a concept that should lead to more satisfactory health care processes and outcomes, often remains theoretical rather than practical in its application [66]. Despite these challenges in the implementation of shared decision-making and patient-centered communication, the setting began to change significantly with technological advancements. By 2016, significant advancements in health care were driven by the adoption of digital solutions, addressing key shortcomings of traditional communication methods, such as inefficiency in data management, limited patient access, and fragmented communication [30,67]. Health IT, particularly through web-based interventions, began to enhance the structural foundation and accessibility of health care communications. Specifically, the integration of EHRs with patient portals has matured significantly, enhancing communication channels between patients and health care providers [34,68]. Additionally,

XSL•FO
RenderX

the implementation of web-based communication tools, decision aids, and online learning platforms has significantly advanced patient education, engagement, and effective communication with physicians [34-37]. These technologies provide essential continuity in patient care and enhance direct interactions between health care providers and patients, fundamentally altering the efficiency and effectiveness of health care delivery. By 2021, the COVID-19 pandemic had further catalyzed design improvements and validations for the application of health IT. The development of digital health, such as conversational aids, emerged as a notable advancement during this period. These tools, essential in a time of increased remote interactions due to social distancing measures, are designed to enhance patient engagement and support shared decision-making processes [46,47]. They aim to provide personalized, accessible information that patients can easily navigate and understand, filling a critical gap as in-person health care interactions become less frequent [45,48,51]. This pandemic emphasized the importance of reliable, accessible health communication technologies, driving innovations that could meet the new health care demands efficiently and effectively.

Building on the significant progress made in health IT, the evolution of health communication has been deeply intertwined with technological advancements across multiple dimensions. These advancements include facilitating interactions between patients and physicians, managing health care data, enhancing education, and improving overall health care delivery [68]. However, despite these advances, challenges and barriers persist in integrating human interactions with health IT systems. Notably, aspects such as the patient-physician relationship and trust building remain underexplored, despite being crucial for optimizing the effectiveness of health communication [39-42]. Addressing these gaps is essential to ensure that health IT supports not only the operational but also the interpersonal aspects of health care delivery, paving the way for more comprehensive and effective communication strategies.

Future Outlook: Artificial Intelligence in Health Communication

AI is transforming patient-physician communication by facilitating more personalized, efficient, and informed interactions through advanced data analysis and real-time information processing. AI is also increasingly being utilized to support or inform health care diagnoses and decisions [69,70]. Emerging AI tools, such as ChatGPT and other generative AI systems, analyze vast amounts of written material to generate coherent, contextually relevant text that closely resembles human writing styles. The use of AI before patient-physician interactions can significantly reshape the traditional dynamics of knowledge and power. Traditionally, physicians, with years of training and experience, have held professional knowledge, guiding the flow and outcomes of health care discussions. However, AI technologies—particularly those offering instant access to vast medical information—empower patients with a form of “pocket expertise.” This access enables patients to approach consultations with a preliminary understanding of potential diagnoses, treatments, and even novel therapies. Such information can help level the playing field, fostering a more collaborative relationship. However, it may also introduce tension or conflict between patients and health care professionals. While AI can rapidly process and synthesize information, it can also produce incorrect or misleading conclusions [71]. The technology’s interpretations are only as reliable as the data and algorithms driving them, which may lack the nuanced or contextual understanding of a health care professional.

This revolution in patient-physician communication through AI has the potential to transform interaction dynamics, offering both opportunities and challenges that warrant further exploration. Future studies should investigate AI’s potential to enhance personalized medical knowledge and its implications for health care decision-making, while carefully addressing the limitations of these technologies.

Limitations

The analysis of associations and trends in our study offers valuable insights into the dynamics of health communication influenced by health IT, patient empowerment, and patient-physician relationships, as well as the interactions among these key factors. However, it is important to emphasize that these associations should not be interpreted as direct causal relationships. Our analysis primarily identifies correlations that suggest potential interactions between these variables, providing a foundation for future hypotheses and more in-depth research tailored to specific situations and conditions. The identification of these patterns is essential for developing a more nuanced understanding of how various factors contribute to the effectiveness of health communication. This understanding can then inform subsequent experimental studies aimed at verifying causality and uncovering the underlying mechanisms at play.

Our review focused broadly on the general interactions between patients and physicians across diverse health care settings. As a result, specific demographic variables—such as different diseases, age groups, and racial backgrounds—were not extensively differentiated in our analysis. This broad approach aligns with our goal of identifying overarching trends and commonalities in health communication. However, it is acknowledged that health communication dynamics can vary significantly across different patient groups, shaped by unique needs and contexts related to specific health conditions, age-related preferences, and cultural or racial backgrounds. Future research could benefit from stratifying these variables to gain more detailed insights and develop communication strategies that are better tailored to the specific characteristics and needs of diverse patient populations.

Finally, this paper presents several important findings, such as the interactions between key terms identified in our trend analysis. However, the depth of synthesis regarding these intersections remains limited. Our synthesis primarily focuses on elucidating the role of health IT in health communication, highlighting its significant applications across diverse health care contexts. While the study offers a broad overview, outlining relevant terms and setting the stage for future research, it leaves room for more focused investigations. Subsequent studies are encouraged to investigate each finding in greater detail, further exploring the complex dynamics at play and refining our

XSL•FO
RenderX

understanding of these critical intersections in health communication.

Conclusions

This review extensively explored the key factors influencing health communication between patients and physicians in the digital age. Our analysis identified 3 main topics central to the field: the Patient-Physician Relationship and Shared Decision-Making, Patient Empowerment and Education Strategies, and Health Care Systems and Health IT Implementations. These topics serve as foundational elements for refining health communication models that foster effective interactions between patients and physicians. Additionally, this review highlighted significant interactions between health IT and key aspects of health communication, particularly patient-physician relationships, patient empowerment, and trust. The COVID-19 pandemic accelerated the adoption of digital health technologies such as telehealth, patient portals, and decision aids, all of which have demonstrated great potential in enhancing these interactions. Finally, the synthesis of health IT's role in health communication reveals its transformative impact on patient empowerment and engagement, while also highlighting significant challenges related to integration, usability, and user acceptance. These findings emphasize the need for continuous refinement of health IT tools to better support patient-centered care and informed decision-making within health communication. Future research should focus on developing models that integrate health IT and foster trust-based relationships between patients and physicians. Investigating how emerging technologies, such as AI, can enhance these models will also be crucial. Such efforts are essential for realizing the full potential of health IT in improving health care outcomes through effective communication between patients and physicians.

Abstract

Background: Electronic health record (EHR) systems have undergone substantial evolution over the past 25 years, transitioning from rudimentary digital repositories to sophisticated tools that are integral to modern health care delivery. These systems have the potential to increase efficiency and improve patient care. However, for these systems to reach their potential, we need to understand how the process of EHR implementation works.

Objective: This scoping review aimed to examine the implementation process of EHRs from 1999 to 2024 and to articulate process-focused recommendations for future EHR implementations that build on this history of EHR research.

Methods: We conducted a scoping literature review following a systematic methodological framework. A total of 5 databases were selected from the disciplines of medicine and business: EBSCO, PubMed, Embase, IEEE Explore, and Scopus. The search included studies published from 1999 to 2024 that addressed the process of implementing an EHR. Keywords included “EHR,” “EHRS,” “Electronic Health Record*,” “EMR,” “EMRS,” “Electronic Medical Record*,” “implemen*,” and “process.” The findings were reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. The selected literature was thematically coded using NVivo qualitative analysis software, with the results reported qualitatively.

Results: This review included 90 studies that described the process of EHR implementation in different settings. The studies identified key elements, such as the role of the government and vendors, the importance of communication and relationships, the provision of training and support, and the implementation approach and cost. Four process-related categories emerged from these results: compliance processes, collaboration processes, competence-development processes, and process costs.

Conclusions: Although EHRs hold immense promise in improving patient care, enhancing research capabilities, and optimizing health care efficiency, there is a pressing need to examine the actual implementation process to understand how to approach implementation. Our findings offer 7 process-focused recommendations for EHR implementation formed from analysis of the selected literature.

KEYWORDS

electronic health record system; EHR; electronic medical record; EMR; scoping review; process; implementation

Introduction

Background

Over the past 25 years, electronic health record (EHR) systems have undergone remarkable development, becoming an important element of modern health care [1]. Since their inception in the late 20th century, EHRs have advanced substantially, propelled by both technological innovations and critical policy reforms [2]. Key legislation, such as the Health Information Technology for Economic and Clinical Health (HITECH) Act of 2009, was instrumental in accelerating the

XSL•FO
RenderX

widespread adoption of EHRs, solidifying their role in enhancing health care delivery. Today, EHRs are indispensable for improving patient safety, improving operational efficiency, and ensuring that vital patient information is securely stored and easily accessible across health care settings [3].

Research to date has examined some of the key pre-implementation indicators of EHR adoption and success. Studies have revealed how certain organizational characteristics are likely to predict success, such as the size of the organization [4,5] and where it is located [6,7]. Other research has provided important details on postimplementation evaluations by users. These evaluations may include an increase or a decrease in the difficulty of tasks for the physician [8], the impact on patient care [9], and effects on privacy and security [10].

There is an extensive body of literature reviews published over the past 2 decades that explore the success factors and challenges associated with EHR implementation [11-20]. This has substantially and importantly improved our understanding of those factors that must be considered when planning EHR implementation. Fennelly et al [20], for example, identified 15 interlinked organizational, human, and technological factors that affect successful EHR implementation across primary, secondary, and long-term care settings. Our study built on this body of work by returning to the source literature with a process focus—digging beneath the success factors and challenges to examine the underpinning processes of EHR implementation. A process focus allows us to examine the connections between the factors already identified, unveiling new aspects, such as flow, activity, and temporality [21]. We, therefore, foregrounded and synthesized those papers that center on this vital process of *implementing* an EHR rather than delving into the technical intricacies of EHR technology itself.

Defining an EHR

The World Health Organization defines the EHR as "a longitudinal record of patient health information generated by one or more encounters in any care delivery setting" [22]. These records may include details such as demographics, progress notes, vital signs, medications, immunizations, lab results, and radiology reports, which all provide a comprehensive view of a patient's health. Similarly, the Centers for Medicare and Medicaid Services (CMS) emphasizes that EHRs play a crucial role in helping health care providers maintain accurate and up-to-date patient data over time, ensuring that key clinical and administrative information is easily accessible and securely shared among authorized users [23].

Electronic medical records (EMRs), in contrast, are records created by practitioners for specific encounters, examples of which may be hospital visits or the use of facilities within ambulatory environments. Finally, a personal health record (PHR) is data controlled by the patient through the use of an electronic application that they are able to provide to their health practitioners. PHRs support patient-centered health care by making medical records and other relevant information accessible to patients, assisting patients in health self-management [24]. We focused exclusively on EHRs rather than EMRs or PHRs. The scope of EHRs is generally larger than that of EMRs or PHRs. They require a broad range of data types and need to be able to connect these across systems, whereas EMRs are generally confined to an individual practice [25], limiting their scope, and PHRs are generally subject to personal management [26]. This makes them less complex, and therefore less interesting from a research perspective, than EHRs. EHRs require higher levels of interoperability, regulatory challenges, stakeholder involvement, and cost and time investment than EMRs or PHRs, making them the ideal focus of this research.

Although the terms "EHR" and "EMR" are conceptually distinct, they are often used interchangeably in the literature. We recognize that the definitions we used for EHRs and EMRs in our review are not universally observed, and the terminology used in the literature and in practice often reflects the contexts in which these systems are implemented rather than the strict definitional boundaries placed upon them. In instances where studies, such as Felt-Lisk et al [27], have examined systems referred to as EHRs but may have operationally aligned with our definition of EMRs, we opted for a more inclusive approach. This definitional ambiguity may mean that some of our recommendations may equally apply to systems labeled as EMRs rather than EHRs. Addressing this overlap is essential for advancing a more unified understanding of electronic records in health care; however, it was not the purpose of this research.

Implementation Process

Rather than the broader issue of EHR adoption, which relates to the widespread acceptance and use of the technology across health care settings, our focus was on implementation as the practical, often complex, process of integrating EHR technology into health care environments. Adoption is the "phase of investigation, research, consideration and decision making in order to introduce a new innovation into the organization" [28,29]. Implementation is the "phase of internal strategy formation, project definition and activities in which an adopted application is introduced within the organization, with the aim of removing reservations and stimulating the optimum use of the application" [29]. Although adoption can occur both prior to and after implementation, these terms describe separate, distinct actions. We discussed EHRs in terms of the process of implementation, as defined by Bouwman et al [29].

Study Focus

This scoping review examined the EHR implementation process over the past 25 years. The paper presented a qualitative thematic analysis of 90 relevant academic papers describing the EHR implementation process. Our review of 25 years' worth of EHR implementation processes ultimately offers some advice and hope for more effective EHR implementations and those policies that support them.

Methods

Overview

A scoping review was conducted according to the 5-stage framework by Arksey and O'Malley [30]. Results were reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist (Multimedia Appendix 1).

XSL•FO
RenderX

Stage 1: Identifying the Research Question

Our research question was as follows: What have we learned about the process of implementing EHRs over the past 25 years?

Stage 2: Identifying Relevant Studies

A systematic literature search was conducted across 5 databases to identify all relevant literature: EBSCO, PubMed, EMBASE, IEEE Explore, and Scopus. The following specific keywords were used in the search strategy: (EHR OR EHRS OR Electronic Health Record* OR EMR OR EMRS OR Electronic Medical Record*) AND implemen* AND process (all in abstract). Detailed search strategies are provided in Multimedia Appendix 2. The research period was from January 1999 to August 2024 in line with the focus of this special issue looking at the past 25 years. We chose to include the word "process" in our search string, in addition to variations of the word "implement" in order to refine our results to include discussions focused on the process of implementing EHRs rather than those centered on the outcomes of EHR implementation. We also chose to search for the term "electronic medical records," in addition to EHRs in the initial stage, even though the focus of our paper was on EHRs. This inclusion of EMRs in the initial search allowed us to account for discrepancies in the language used when discussing EHRs. This initial inclusion in our search criteria also meant we were able to manually exclude EMR studies that were purely discussions of EMRs and manually include EMR studies that also discussed EHRs or possessed the same functionalities of an EHR. This broadening of our search terms meant that our analysis of the literature was more thorough. We chose only empirical studies because we sought evidence of specific experiences of EHR implementation processes.

Inclusion Criteria

Studies meeting the following inclusion criteria were included: (1) published from January 1999 to August 2024, (2) peer reviewed, (3) journal papers, (4) published in English, and (5) mentioned the implementation process of EHRs.

Exclusion Criteria

Studies meeting the following criteria were excluded: (1) focused purely on the aftermath of implementation; (2) did not discuss the implementation process; (3) did not clearly report methods; (4) nonempirical; (5) not published in a peer-reviewed journal; (6) letters to the editor, editorials, or essays; (7) gray literature and review papers; and (8) discussed single-location EMRs.

Stage 3: Study Selection

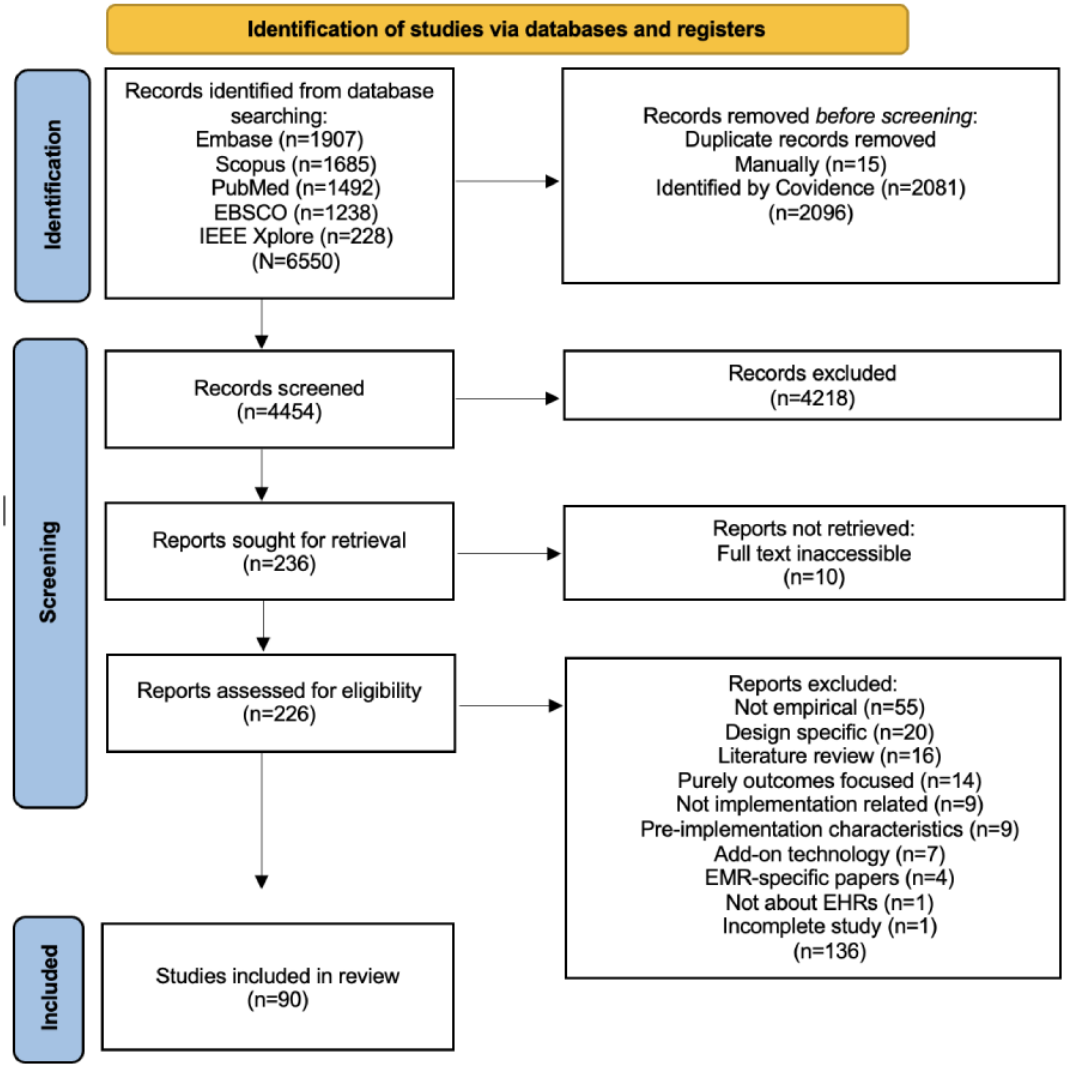
All citations were uploaded to Covidence, a web-based research tool used by researchers to collaborate and organize citations in systematic reviews. Duplicates were removed automatically by the software and manually by both authors. Both authors screened all 4454 remaining papers by title and abstract and 226 papers by full text. Both authors also reviewed any disagreements before proceeding to the next stage of screening. This was done at each stage of screening to ensure consistency between decisions. Any disagreements were resolved by both authors discussing the eligibility of the paper in relation to the research focus and the agreed-upon inclusion and exclusion criteria until reaching consensus.

Stage 4: Charting the Data

Data were extracted by the first author using Microsoft Excel, including the following details: author(s)/publication year, country of origin, aim(s)/purpose, study design, type of organization, study population/sample size, record type, and methods.

Stage 5: Collating, Summarizing, and Reporting Results

After reviewing all full texts of the eligible studies, the first author loaded the remaining 90 full texts into NVivo, a qualitative data analysis software program. This software was used to manually organize the texts and facilitate the thematic coding of the data. All 90 full texts were then thematically coded by the first author. The second author thematically coded a subset of 10 (11.1%) full texts. Both authors then met to discuss any differences in coding decisions. This was carried out to ensure intercoder reliability.



Results

Sample Characteristics

The paper-screening process is illustrated in detail in Figure 1, while the distribution of the selected studies by year of publication is shown in Figure 2. Among the 90 papers, some discussed more than 1 country in their study. This included 37 (41.1%) studies conducted in the United States, 11 (12.2%) in England, 6 (6.7%) in Australia, 5 (5.6%) in Germany, 5 (5.6%) in Denmark, 3 (3.3%) in the Netherlands, 3 (3.3%) in Italy, 3 (3.3%) in Canada, 3 (3.3%) in Norway, 2 (2.2%) in Singapore, 2 (2.2%) in Kenya, 2 (2.2%) in the United Kingdom, and the remaining countries mentioned in only 1 (1.1%) study each. The majority of studies (n=59, 65.6%) were qualitative, while the remainder (n=19, 21.1%) were quantitative or used mixed methods (n=12, 13.3%). The selected papers begin in 1999 with 1 publication. Examining these figures showed initial inactivity on the topic, followed by steady growth starting in 2008 and peaking in 2017, with a slight decline in recent years. The peak years from 2014 to 2017 suggest a strong research interest during this time. Recently, from 2019 to 2024, there seemed to be a stabilization in research output, with around 4 publications annually. The main characteristics of the included studies are presented in Multimedia Appendix 3.

Figure 2. Distribution of the selected papers by year of publication.

During the thematic coding process, sections of text within each paper were allocated to specific codes rather than entire papers being allocated to one code. As a result, multiple different codes may have appeared in one paper, as can be seen in the coding distribution table (Table 1). The full coding structure is provided in Multimedia Appendix 4.

Table 1. Coding distribution across studies (N=90).

The Implementation Process

Overview

The 90 studies provide a broad overview of the process of EHR implementation over the past 25 years.

A process-based view considers time as a key element. EHR implementation is described by Boonstra et al [34] as a complex and time consuming process, and by Hernández-Ávila et al [48] as a gradual and often slow process. The main benefits of EHRs are likely to accrue in the long term, so it is important to envision them as long-term change management endeavors [96]. These long-term benefits may never be realized, however, where short-term time pressures jeopardize implementation. This may arise where there is limited time available to adapt the system to local conditions [98] or where the pace of implementation is being dictated by other ongoing projects [49]. Deadlines imposed by external actors may also result in implementation timelines being rushed. For example, political considerations

XSL•FO
RenderX

may frame procurement arrangements [52], or vendors might enforce tight deadlines [73]. Diffusion processes require good planning and consume both time and resources [110]. Time looms large in our reviewed studies, justifying our process focus. There is a constant pressure of time in relation to the implementation [38], but the reality is that pre-existing day-to-day pressures may limit the pace of implementation [27].

Four central process-related categories emerged from the thematic review: (1) compliance processes featured indirectly through references to the important role of the government, policy, regulations, and vendors; (2) collaboration processes centered on the work of managing these implementations through communication and relationships; (3) competence-building processes included discussions of training and support; and (4) process costs drew attention to areas of cost.

Compliance Processes in EHR Implementation

Our review suggested that compliance processes in EHR implementation center around the government, policy, regulations, and vendors. The literature referenced government-related processes in 29 (32.2%) papers. There were discussions of policy-related processes in 21 (23.3%) papers. Regulation-related processes were considered in 10 (11.1%) papers, and vendor-related processes were referenced throughout 20 (22.2%) papers.

Government-Related Compliance Processes

EHR implementation problems often arise at the national level rather than at regional or health service–specific levels. This is a result of the increased complexity of national implementation [38]. Nationwide implementation requires a huge change from stakeholders [42]. In a national project, practitioners operating in public and private domains require different engagement strategies to secure their buy-in [51]. A national strategy is, therefore, needed for a national EHR implementation process [110]. National EHRs require adaptation with clinician practices nationwide to ensure workflow processes are consistent [91]. Further recommendations from the literature include changing from a top-down implementation model to increased involvement of local organizations in decision-making [35]. Planners need to ensure potentially unclear areas are clarified with program management and that clinicians are informed and consulted [51]. National-level implementation is not just simple system installation; it is discovering ideas from private institutions and using them to drive best practices across the system nationwide [49]. Bottom-up implementation is, however, time-consuming and may hinder future collaborations [94], whereas the top-down nature of some projects contributes to a lack of organizational and user involvement in decision-making [52].

The role of the government in initiating and maintaining momentum around EHR implementation processes came through strongly from our review. Government leadership is considered a strategic advantage when the goal is the sustained enforcement of EHR initiatives [31]. Mature EHR systems benefit from being well integrated into the national health-planning documents of the government [39], while national reimbursement policies can increase EHR dissemination [49]. To maintain momentum, government commitment must be both strong and continued and accompanied by political support [36]. eHealth experts are, therefore, generally in favor of a strong central solution for political regulation problems [62]. It is, however, not just the national government that matters. Support from the local government also plays a crucial role in terms of finances, provision of resources, and technical support [41]. Indeed, implementation processes suffer where they lack sufficient coordination with the local government [41]. However, strong national or local government policies mandating the use of specific eHealth solutions may support EHR implementation processes [41]. Excessive regulation may also hinder the long-term sustainability of EHR initiatives [31].

Changes in the government may lead to having to modify an overall implementation process [35]. Shifts in the government strategy affect the power dynamics between national branches of large IT companies compared to national information and communication technology companies [55]. A change in the government also has the potential to result in uncertainty about the future of national programs [52,58]. It is, therefore, advisable for system evaluators to form close relationships with policy makers [35]. Alternatively, if there is a lack of a government-level information policy at the time of design and development, the sustainability of the EHR implementation is endangered [48].

The Role of Vendors

Governments are not, however, the only organizational actors who can manage or lead EHR compliance processes. Vendor organizations that have strong centralized administrative and medical structures are drivers of organizational policies and processes that are crucial to compliance [64]. Indeed, in some instances, large private vendors may enter a market specifically to provide unified access to health care data [49]. It is the process of compliance of large technology companies with uniform national standards and rules that enables EHR implementation in this instance [55,60].

Vendor recommendations influence software choice processes [69]. EHR implementors cannot simply buy from the same vendor as their existing financial system and assume turnkey, seamless interoperability [71]. There are often limitations to existing vendor-based EHRs when compared with in-house systems, including autonomy of practice decisions at each hospital [70]. These limitations are also seen in difficult-to-assess EHR usability as a result of restrictive vendor license agreements [59].

EHR vendors are generally at least partly responsible for the amount of training received by users [69] and sometimes also responsible for providing technical support [27]. Indeed, vendors may use the provision of ongoing technical support as a form of training [77]. Both peer and technical support may be issued from these vendors, which can help end-users optimize their use of the EHRs and solve issues [67]. Even large vendors may need to consider EHR adaptations for small practices as part of the sale of the EHR, ensuring that a person within the practice conducts training and adapts it to the specific needs of the practice rather than relying on training by IT specialists [53].

Collaboration Processes in EHR Implementation

Collaboration in the literature includes communication and relationships throughout the management of the implementation process. Communication was mentioned in 40 (44.4%) papers. Relationships were discussed in 30 (33.3%) papers.

Collaboration among team members is important [60], as is communicating clear expectations and guidelines [61]. Consistent, reliable communication fosters trust [83], and well-articulated visions are important for the management of expectations [74]. Strong communication practices are an enabler of successful implementation outcomes [84]. However, a lack of communication during planning can cause issues [49].

Collaborating facilitates successful EHR implementation [95]. Cuccinello et al [36] illustrate this in their study of a vendor's collaborative relationship with a health care department in Italy. Relationships with vendors build confidence within the organization and ensure strong external support [60]. Where, however, communication breaks down, it can jeopardize implementation processes [41]. Relationships between contractors and suppliers may become more impersonal and distant as a result [34]. Direct and close channels of communication between the implementer hospitals and software suppliers are, therefore, essential from the outset [89]. Kiepek and Sengstack [84] suggest an open and transparent relationship with external support from vendors, beginning with initial negotiations.

Competence-Building Processes in EHR Implementation

Competence building in the literature includes training and technical support. The literature referenced training in 44 (48.9%) papers. Support was discussed in 35 (38.9%) of the selected papers.

Training is necessary for successful EHR implementation [95]. This training should provide practitioners with the skills necessary to operate the system, as well as the confidence to help them adapt to the new system [98]. Sufficient training for practitioners is associated with improved well-being [100] and has a positive and substantial influence on perceived ease of use [67]. Hiring experts can help, for example, in providing technical support both during the implementation and afterward [110], and hiring clinical informaticists can help support EHR implementation and sustainment [86].

Issues surrounding training and implementation processes are numerous. These include a lack of resources for EHR training [70], the need to train medical personnel [38], a lack of training for smaller entities [38], ensuring sufficient time for staff training [41], providers and patients not receiving adequate support and training [63], and a lack of appropriately specific training [102]. The need for sufficient trained personnel is felt across all stages of an implementation process [39]. Staff that are not trained to interact with an EHR can hinder implementation [31,42]. Recommendations to enhance EHR training include ensuring that it occurs pre- and postimplementation on a continued cycle [86]. Decreased support is an additional issue [70], whether that be in relation to practitioner support [43] or in determining the right type of IT support for successful implementation [97].

Process Costs in EHR Implementation

Cost considerations were shown to be an important part of the implementation process, with 41 (45.6%) papers making reference to cost. Adoption of appropriate processes is crucial regarding system development time and budget [42]. As such, successful implementation should have sustainable funding that aligns with a national strategy for eHealth [41]. Determining costs and measures of success is a vital part of project management, especially in pre-implementation [108]. The role of monetary incentives in this stage of the process is also an enabler [36]. One of the challenges of a national project is that funding sources depend largely on the government [31]. Implementing a system on a national scale is an extremely complex activity [52]. It is difficult to manage, costly to maintain, and hard to sustain [89]. Financially, the most serious obstacle in implementing EHRs is the cost of electrification [38]. Further customization also leads to increased maintenance costs [60]. The high upfront cost of EHRs for small practices is a major factor limiting their use [27]. Most hospitals report substantial financial challenges in EHR implementation and use, including EHR and broadband implementation costs and the limited availability of grants and loans to support EHR implementation and use [113]. A lack of capital resources can hinder the EHR implementation process [43]. Other issues include inadequate capital for investment and maintenance costs [110], large-scale procurement being undertaken to save costs [52], attempts to implement EHRs halting due to financial issues [54], and the high costs of implementing a system [97].

Discussion

Principal Findings

This scoping review revealed 4 main areas for consideration in the EHR implementation process. These areas are compliance, collaboration, competence, and costs. Specific issues recurred in each area throughout the literature: the role of the government and the role of vendors in compliance processes, the importance of communication and relationships to facilitate collaboration processes, training and support to build competence; and the cost of financing throughout the implementation process. Many of the 19 interventions identified by Boonstra et al [13], and the 15 factors identified by Fennelly et al [20] pertaining to successful or effective implementation strategies featured within our findings. Rather than replicate the reviews of Fennelly et al [20] or Boonstra et al [13], however, we built on these to provide a focused exploration of the implementation process to complement the broader insights that these reviews offer. We built on these works to offer practical recommendations for use in the implementation process.

Our study and research question focused on the *process* of implementation of EHRs. The process of implementation deserves attention, especially when we consider that the implementation process influences implementation outcomes. Put differently, it is not just what system we implement, nor the recognition of challenges or facilitators, but also the process by which we navigate and manage these over time that ultimately decides how successful an EHR might be. There is, therefore, a need to understand how to approach these implementation

XSL•FO
RenderX

processes in a way that is informed by previous implementations and the appropriate literature. To address this, we provide recommendations produced from our synthesis of the selected literature reviewed in this paper. Organizing our findings into compliance processes, collaboration processes, competence processes, and process costs allowed us to provide distinct actionable recommendations for stakeholders. Our recommendations emphasize implementation priorities in a way that facilitates targeted interventions. Our recommendations not only reaffirm established principles found in reviews, such as those by Boonstra et al [13] and Fennelly et al [20], but also provide a modernized roadmap for undertaking the implementation process.

Seven Process-Based Recommendations for EHR Implementation

The literature consistently demonstrates the value of both the government and vendors in ensuring sustained EHR compliance processes, while highlighting some dangers. We drew from this some recommendations for successful compliance processes. The first recommendation is to *maintain close and ongoing government/implementor relationships to balance user, government, and organizational requirements in the short and longer terms.* There is a need for the central government to work with hospitals and local governments to ensure EHRs satisfy the requirements of users [49]. Government planners have the power to exert more influence on public health care providers than private providers [51]. Liaising with organizations and policy makers to inform strategic decisions and policy making is important [35]. As part of this, it is necessary for evaluators of EHRs to form close relationships with policy makers [35]. The second recommendation is to *rebalance vendor/implementor relationships to ensure small-site customization and training that will drive sustained compliance.* The role of the vendor is notable, with numerous best-practice sites viewing their vendor as an active partner in the implementation and compliance process [76]. Designating key contact people to act as liaisons may help foster this relationship from the beginning. Fostering open, regular communication between vendors and implementers can also be done through regular meetings.

The literature clearly highlights the importance of collaboration processes across teams, as well as multistakeholder communication, in ensuring sustained support for EHR implementation. Breakdown of communication and relationships is damaging to implementation processes. We built on these findings to suggest some collaboration processes that support EHR implementation. Our third recommendation, therefore, is to *cultivate varied sources of support across stakeholder groups*. Strong and continued commitment and support at the highest level facilitate and support collaboration processes [36]. The types of support needed vary to include political support [36], practitioner support [108], and social support [109]. Supporting the interest in EHRs is an important behavior linked to successful EHR implementation [95]. Indeed, issues may arise where there is inadequate patient and broader community engagement around EHR implementation [88]. The fourth recommendation is to *pay particular attention to communication and collaboration in the implementation-planning phase of EHR implementation, including the development of cross-functional teams, the appointment of "opinion leaders'" and realistic envisioning of postimplementation challenges and benefits*. Effective communication processes are critical in an organization when implementing an EHR [70], especially during the implementation-planning phase [76]. Stakeholders working toward change also need a close collaborative working environment [65]. Forming cross-functional teams [60] and enlisting the collaborative effort of physicians, hospital administrators, IT specialists, and state officials are integral to the process of design and development [48]. Appointing "opinion leaders" to hear concerns of practitioners makes audiences more receptive to implementation [45]. Crafting communication campaigns that balance potential expected benefits with realistic expectations of the challenges faced may be an issue [59]. Anticipating the challenges that will be faced during implementation can cause these issues, as each implementation occurs in a unique environment.

The studies clearly show the importance of competence-building processes, such as training and technical support provision during the implementation process. We drew from this to suggest competence-building processes that will positively contribute to the EHR implementation process. The fifth recommendation is to *ensure that staff are adequately trained to use the systems and for planners to consider the timing of this training when organizing wider implementation processes.* Implementation processes depend on training the staff who will be using the system [77]. Ongoing training and optimization are necessary [103], as well as curricula for EHR training [104]. Training processes must be ongoing, embedded in workflows, and flexible so that they can be tailored to the diverse needs of users [89]. In terms of timing, training should be conducted close to the time of actual implementation of new technology [54], with the most successful training session conducted within a few weeks of the system going live [76]. Some authors recommend that staff be required to complete training by the end of the preparatory phase to retain their access to the EHR [94]. Others suggest sending staff to training classes customized by job role, with trainers on-site for 1-2 weeks after the system goes live [64]. The time it takes practitioners to chart should be addressed early on in training [53], and training focusing on how the EHR will work should be replaced with a focus on how the EHR can be adapted to the practitioners [53]. Vadillo et al [54] stress the importance of providing proper training in basic computer functions, with training conducted in the classroom with an instructor rather than one to one. Recommendations also suggest that senior management provide practice leaders with IT training and have them visit an EHR-based practice [97]. The sixth recommendation is to *assess what support will be needed at each stage of the implementation and ensure that this support is put in place for an appropriate amount of time*. Support is critical during the go-live period [76]. Carayon et al [69] suggest having support staff present from the EHR vendor on the day the EHR goes live and having an expert user present at the clinic for the following weeks as a useful support to implementation processes. The availability of "super users" who offer support at go-live time is also noted as appropriate [60] and particularly useful when considering user support as a higher priority than initial user training [39]. Other notable forms of support are vendor support [60] and industry support

XSL•FO
RenderX

[42]. Informal support (provided via Facebook, involving both vendors and peer-to-peer support) is also noted to be effective and efficient [74]. Support throughout the planning and implementation period ensures clarity of roles, strong communication practices, and a successful outcome [84].

Finally, the literature clearly demonstrates the integral role of cost throughout implementation. We drew from this discussion of cost in the literature to provide our concluding recommendation. The seventh recommendation is to *promote an understanding of the system as a long-term investment*. Some of the literature promotes the development process of a solid government reimbursement plan [49]. However, more central to our recommendation is deRiel et al's study [39]. The authors discuss the importance of understanding the system, its value, and the total cost of ownership so that investments are not seen as one-time expenses but ongoing investments. Other authors suggest that the process of choosing an EHR system should center on its potential for improving clinical care rather than achieving cost savings [96]. Inadequate practitioner consultation processes [46], delays [58], and tendering processes all increase the cost of the overall process [34].

Our findings illustrate that successful implementation processes benefit from meticulous planning [76]. Our recommended processes for addressing compliance, collaboration, competence, and costs within the wider EHR implementation process aim to provide the materials for informed "meticulous *process* planning" to occur. Examining EHR implementation purely from a pre- versus postimplementation perspective of outcomes may blind both researchers and practitioners to the importance of the intervening implementation processes. Our review connects previously established barriers and facilitators with a time-and-action focus to offer additional insights into the process of implementation.

Limitations

Several limitations should be considered in this scoping review. This study focused on EHRs and did not consider the implementation processes of other eHealth systems, which may benefit from future analysis. Our findings also highlight the need for improved standardization in the terminology surrounding electronic records in health care to better differentiate between EHRs and EMRs in both research and practice. This improved clarity would allow for greater comparability across studies and guide more tailored implementation processes. The included studies tended toward the United States and Europe, centering our analysis in the Global North. The search strategy included studies from 1999 onward. The resulting studies selected were mostly from 2007 onward. It is unlikely that this date limitation largely impacted the selected studies; however. it is possible that due to the date limitation, this scoping review may have missed interesting studies conducted prior to 1999. Finally, our specific search terms, chosen with the intention of focusing the literature on the implementation process, may mean that the literature describing the same event but not using those specific search terms was not retrieved. Additionally, shifts in the language and naming of systems in health care mean that this study may apply to systems discussed under a name other than "EHRs," which have not been retrieved during the search strategy of this research. As such, we did not retrieve or include any studies discussing EHRs under the recently emerging term of "digital health records."

Conclusion

Completed implementation of EHRs is integral to improving health care delivery. The findings from this scoping review offer important insights into the complexities of the actual process of implementation and its subprocesses. Our review identified 3 key processes (compliance, collaboration, and competence building), as well as considering overall process costs. In doing so, we offered a new time- and action-based perspective on EHR implementation. Compliance processes reference the role of the government, policy, regulation, and vendors in shaping the implementation process. Collaboration processes promote the need for strong communication and the building of relationships across all stakeholders involved in the implementation process. Competence-building processes focus on ensuring that users are provided with the resources to be able to operate an EHR, centering around the importance of the timing of training and support. Finally, our discussion of process cost illustrates the importance of a time-focused financial approach during the implementation process.

We proposed 7 strategies in this review, which all provide a structured approach to navigating the different areas of implementation. Future research should focus on deepening our understanding of how these outlined strategies change and operate at different stages of the implementation process. This scoping review contributes to the intersection of management and health care research. We hope that the review results and recommended strategies provided will inform areas for future research and help develop future implementation processes.

Abstract

Background: Trajectory modeling is a long-standing challenge in the application of computational methods to health care. In the age of big data, traditional statistical and machine learning methods do not achieve satisfactory results as they often fail to capture the complex underlying distributions of multimodal health data and long-term dependencies throughout medical histories. Recent advances in generative artificial intelligence (AI) have provided powerful tools to represent complex distributions and patterns with minimal underlying assumptions, with major impact in fields such as finance and environmental sciences, prompting researchers to apply these methods for disease modeling in health care.

Objective: While AI methods have proven powerful, their application in clinical practice remains limited due to their highly complex nature. The proliferation of AI algorithms also poses a significant challenge for nondevelopers to track and incorporate these advances into clinical research and application. In this paper, we introduce basic concepts in generative AI and discuss current algorithms and how they can be applied to health care for practitioners with little background in computer science.

Methods: We surveyed peer-reviewed papers on generative AI models with specific applications to time-series health data. Our search included single- and multimodal generative AI models that operated over structured and unstructured data, physiological waveforms, medical imaging, and multi-omics data. We introduce current generative AI methods, review their applications, and discuss their limitations and future directions in each data modality.

Results: We followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines and reviewed 155 articles on generative AI applications to time-series health care data across modalities. Furthermore, we offer a systematic framework for clinicians to easily identify suitable AI methods for their data and task at hand.

Conclusions: We reviewed and critiqued existing applications of generative AI to time-series health data with the aim of bridging the gap between computational methods and clinical application. We also identified the shortcomings of existing approaches and highlighted recent advances in generative AI that represent promising directions for health care modeling.

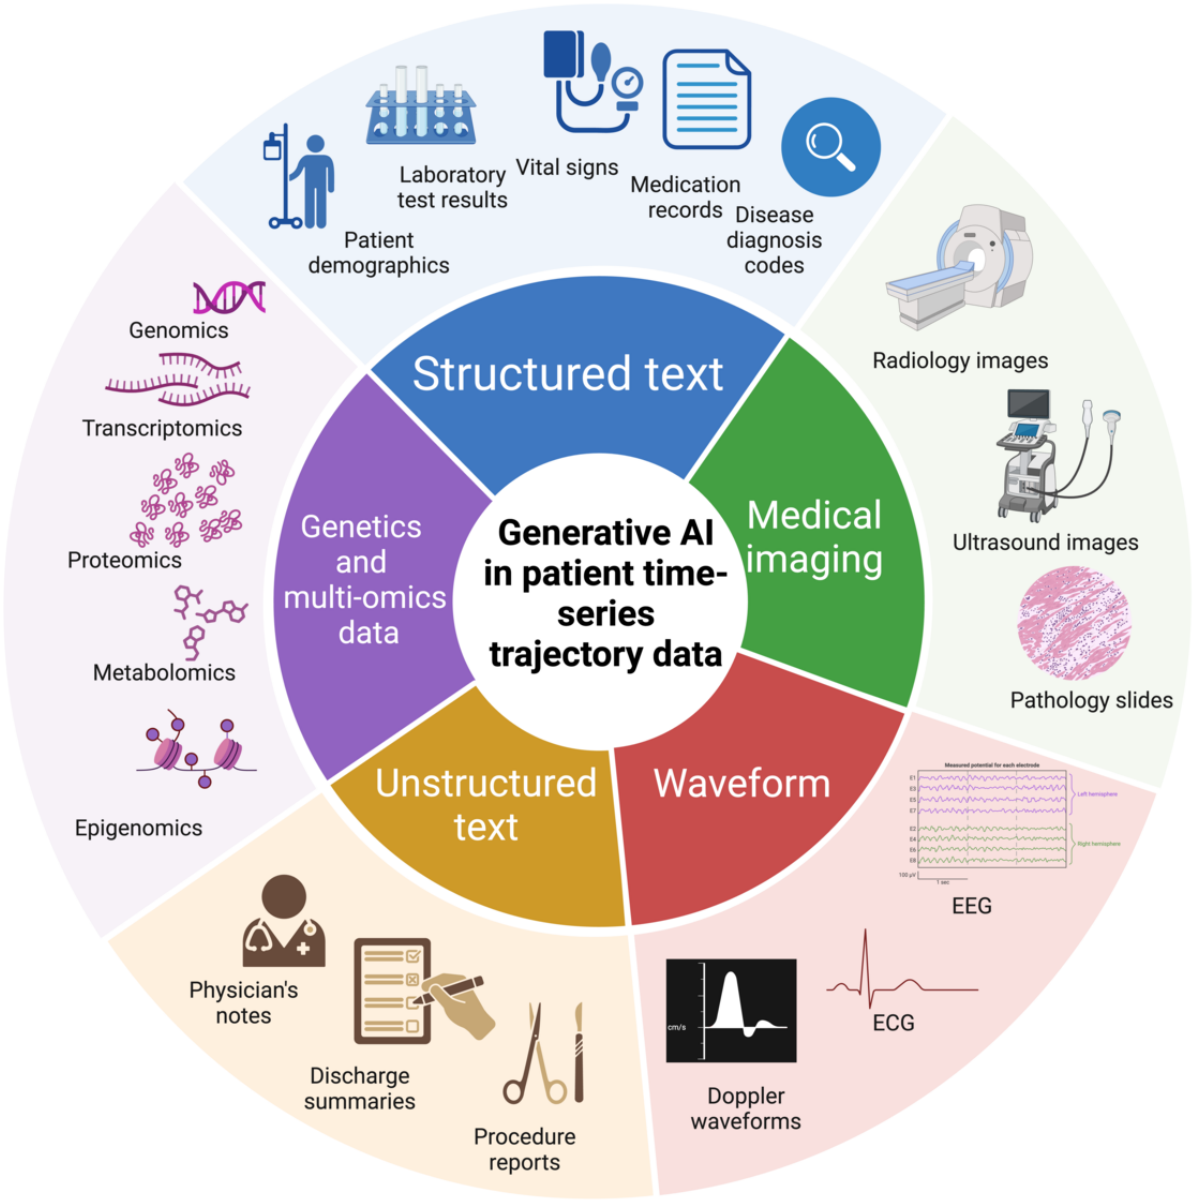
Introduction

Background



Generative artificial intelligence (GenAI) is a family of artificial intelligence (AI) models that can generate synthetic content ranging across text, images, audio, and video. Well-known GenAI tools such as ChatGPT [1] and DALL-E [1] have revolutionized the way in which people view AI [2]. On the other hand, data analysis in health care has entered a new era as large amounts of electronic health records (EHRs) are generated daily. Among these data, biomedical time series have been of particular interest to researchers in tasks including tracking patient trajectories [3] and treatment estimations [4]. Compared to cross-sectional data, which represent 1 time point, time series provide more information on development over time. There are 2 main types of time-series data: real-time and longitudinal data. While real-time data usually span a shorter period (minutes or days) and have more consistent time-point entries, longitudinal data are recorded over the magnitude of months or years with various sampling frequencies and number of entries. Compared to traditional time-series data in finance and climate science, biomedical time series face unique challenges in modeling, including missingness and sampling rate [5]. Therefore, traditional methods such as foundation models (FMs) that work well on high-frequency time series are not guaranteed to work well on biomedical data. In the age of big data, GenAI models have begun to outperform traditional statistical and machine learning (ML) methods in various tasks [6]. On the other hand, GenAI for health care faces unique challenges, including data privacy, transparency of the decision process, and other ethical issues that must be addressed. Nonetheless, these tools have the potential to improve disease modeling accuracy, tailor treatment plans across a heterogeneous population, and assist clinicians in making clinical decisions.

In this paper, we aim to provide a comprehensive review of GenAI applications to biomedical time-series data and a technical overview for clinicians who wish to work with AI tools but are unsure of where to begin. We survey GenAI applications to time-series health care data and its ability to improve patient care and the diagnosis process while considering the challenges and showcasing real-world uses that highlight its importance in the field. For the selection process, we followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews; Multimedia Appendix 1) guidelines and searched in PubMed and Google Scholar for conference and workshop papers using the following keywords: “generative AI (GenAI),” “health care,” “time series,” “longitudinal,” “electronic health records (EHR),” “electronic medical records (EMR),” and “genetics.” From the initial search, we applied the following inclusion criteria—being peer reviewed, published after 2000, and focusing on time-series or longitudinal data—ultimately yielding 155 studies as of April 2024. The detailed selection process is described in the Related Works section.

We organized the review by data modality, including structured and unstructured text, imaging, waveform, and multi-omics data, and illustrate possible data sources in each modality for GenAI application in Figure 1. For each modality, we discuss preprocessing, applications, model selection, and challenges and future directions. In the Model Selection sections, we help guide how to choose the appropriate models for this type of data for clinicians who are interested in incorporating GenAI into their practice. We organize the workflow for choosing an appropriate model for the data and computational resources at hand. We have organized the paper as follows: (1) overview of the algorithms and techniques introduced in the review; (2) structured data; (3) unstructured data; (4) medical imaging; (5) physiological waveforms; (6) genetics and multi-omics data; and (7) ethical considerations, challenges, and future directions.

Related Works

Our electronic search retrieved 20,978 study records: 20,003 (95.35%) from Google Scholar and 975 (4.65%) from PubMed, as shown in Figure 2. After title and abstract screening and removing duplicates, 3.24% (680/20,978) of these articles were retained for full-text review. Of these 680 articles, 533 (78.4%) were excluded, leaving 147 (21.6%) studies after the primary screening. A total of 8 more articles were added through secondary screening, resulting in a total of 155 articles included in our scoping review.

Our search for existing reviews on GenAI for disease trajectory modeling returned 39 entries broadly covering the use of AI in health care (Multimedia Appendix 2) in Google Scholar, Scopus, and PubMed. From a review of these works, although we observed an increasing number of AI-related review papers in the biomedical setting in recent years (Multimedia Appendix 3), there remained a gap in reviewing GenAI approaches working with time-series data specifically, prompting the need for our paper.

Algorithm and Technique Overview

Overview

Despite a shared nomenclature, it is important to differentiate between modern AI and the field of AI. The general study of AI encompasses the class of ML methods, which includes the subset of deep learning (DL) methods (also thought of as modern AI). Previous ML approaches have been mostly *discriminative* such that, given a set of input predictors, they learn a strategy (decision boundary) to fit or separate data points. On the other hand, DL models can be discriminative or generative based on the choice of the objective function. Therefore, they are not inherently generative or discriminative and are the building blocks of modern AI models, although they have typically been developed and demonstrated in the discriminative setting. Finally, GenAI methods belong to the class of *generative* ML methods and capture the underlying data generation process. By learning the distribution domain of the data, these models can synthesize hypothetical data points that are statistically indistinguishable from the originals. For discriminative tasks, GenAI models are often combined with downstream models, which can be simply rule based or more complex. In this section, we introduce a set of traditional, ML, DL, and GenAI models that are referenced later in the paper and list existing models used in time-series forecasting in Figure 3, as well as showing a timeline for when these models were first introduced in Figure 4 and a comparison among these methods using common metrics in Table 1.

Traditional Statistical Models

In this section, we introduce several statistical models commonly used as benchmarks in modeling time-series data. One of the most basic yet effective methods is the Naive2 model, which makes a prediction by using the value from the most recent observation or from a similar period in the past. In the class of autoregressive methods, the autoregressive moving average model [7] predicts the outcome value at a given time point using both a linear combination of multiple past observations and a linear combination of past error terms in the regression model. As an extension of the autoregressive moving average, the autoregressive integrated moving average (ARIMA) model [8] accounts for seasonal or periodical changes in the data. One of the most widely used methods is the Prophet model by Meta [9], which uses an additive model that accounts for yearly, weekly, and daily seasonality and holidays. Finally, the exponential smoothing (ETS) model [10] uses a weighted combination of multiple past observations in which the decay of the weights is exponentially distributed. While these methods have limited performance with highly complex data, they remain a popular choice due to their simplicity and transparency in the decision-making process.

DL Models

DL models are the combination of an architecture (ie, the structure) and an objective (ie, the loss function). In this section, we introduce the canonical DL architectures that are the foundation of different GenAI settings but are not GenAI models themselves.

Convolutional Neural Networks

Convolutional neural networks (CNNs) [11] are a type of DL neural network architecture that is particularly well suited for processing and analyzing image data. CNNs are good at recognizing patterns in small areas and work well for short-term connections due to their ability to perform convolutions step by step over time [12]. CNNs can be used for univariate time-series forecasting, in which the trend can be viewed as a 2D graph. In addition, researchers have explored different CNN architectures for time-series forecasting, such as temporal convolutional networks [13] that are tailored for sequence-to-sequence modeling tasks, leveraging the strengths of CNNs while addressing the challenges of working with sequential data.

Recurrent Neural Networks

Recurrent neural networks (RNNs) [14] are one of the earliest DL frameworks that are designed to capture sequential dependencies and patterns across time steps. RNNs have an internal or hidden state that captures information from previous time steps and influences the processing of subsequent inputs. During training, sequential data are fed into the network one step at a time. The network processes each input along with its corresponding hidden state, updating the hidden state based on the current input and the previous hidden state. This process is repeated for each time step in the sequence, allowing the network to capture temporal dependencies and learn patterns in the data. The architecture of RNNs consists of multiple recurrent layers, each containing recurrent units. There are 2 main types of units: long short-term memory (LSTM) cells and gated recurrent units (GRUs). These units are responsible for capturing temporal dependencies and encoding information from previous time steps. Due to their training on sequential data and the leveraging of their recurrent structure, RNNs have performed strongly against traditional DL networks in modeling complex patterns in time-series data [15,16]. However, RNNs can be time-consuming as inputs are processed sequentially and do not model long-range dependencies well as the information diminishes over time.

Transformers

Transformers [17] are the foundation of many state-of-the-art generative models, including ChatGPT. Unlike RNNs, which

XSL•FO
RenderX

process data sequentially and can be computationally expensive, transformers rely on a mechanism called self-attention [17] to capture dependencies simultaneously and over long ranges. They consist of an encoder-decoder architecture in which the encoder processes the input sequence and the decoder generates the output sequence. During training, the input is embedded into a high-dimensional space, and the encoder applies a self-attention mechanism to capture relationships between different parts of the input sequence in the embedding space. Self-attention allows each position in the sequence to attend to all other positions, enabling the model to learn contextual representations efficiently. These representations are then passed through feedforward neural networks within each layer to further process the information. The decoder, on the other hand, predicts the output sequence step by step based on the encoder's contextualized representations and previous outputs. Transformer models typically include multiple layers of encoder and decoder blocks, each containing self-attention mechanisms and feedforward neural networks. In the age of large data, transformers are one of the most powerful models to capture complex relationships in sequential data. One example is in the field of natural language processing (NLP), where Bidirectional Encoder Representations From Transformers (BERT) [18] and generative pretrained transformer architecture have become state of the art, achieving the best performance across many NLP benchmarks [19,20].

GenAI Models

Generative Adversarial Networks

A generative adversarial network (GAN) [21] is a generative vision model that consists of 2 parts: the generator that creates fake data and the discriminator that critiques them. The generator's goal is to produce realistic outputs from random noise that resemble realistic images. On the other hand, the discriminator's role is to differentiate between real data and the data generated by the generator. Through this back-and-forth process of creation and critique, GANs improve over time, producing increasingly realistic results. GANs are one of the earliest image generation models that have shown great success in generating synthetic images [22] and have been used extensively for the generation of new datasets and domain transfer in medical imaging [23,24]. However, training GANs can be challenging due to issues such as the limited type of data produced and instability during training.

Variational Autoencoders

Autoencoders are a class of neural network that learn a low-dimensional representation of high-dimensional structured data [25]. Autoencoders consist of 2 parts: an encoder that projects high-dimensional data into a latent space with lower dimensions and a decoder that learns to map a point in the latent space back to its high-dimensional representation. However, the latent distribution of a vanilla autoencoder is unknown, making inference difficult and prompting the need for variational autoencoders (VAEs). VAE models [26] make further assumptions about the sample generation process that allow us to model an approximation of the distribution of the latent space, usually a Gaussian distribution with a mean and variance estimated by the model. Unlike other image generation models, VAEs provide a latent space that can be estimated efficiently and used for further modeling. As with many medical applications, conditional variables offer additional information and can improve parameter estimation. A natural extension to the VAE is the conditional VAE, which includes additional conditional variables [27].

Diffusion Models

Denoising diffusion probabilistic models (DDPMs) [28] are a class of vision models that generate a new image by removing noise gradually from a pure noise input. The model learns to denoise data by understanding the probabilistic relationships between noisy and clean data points, making it particularly effective in scenarios in which data are corrupted by noise. During training, DDPMs simulate a diffusion process in which noise is gradually added to the data and then iteratively remove this noise to reconstruct the original signal. At each step, the noisy observation is generated by adding a small amount of noise to the previous observation. The diffusion process is typically modeled using an autoregressive process in which the next observation is conditioned on the previous observation and noise.

FMs for Medicine

FMs [29] are ML models capable of performing various generative tasks after being trained on extremely large and typically unlabeled datasets [30]. In the past few years, FMs have received significant attention given their impressive range of capabilities across multiple domains. FMs trained on EHRs have shown the ability to predict the risk of 30-day readmission [31], select future treatments [32], and diagnose rare diseases [33]. These models encode the patient features, such as procedures, diagnosis, medications, and laboratory values, into embeddings that represent the patient's entire medical history. There are 2 broad categories of FMs built from electronic medical record data: clinical language models (CLaMs) and FMs for electronic medical records (FEMRs). CLaMs are a subtype of large language models that specialize on clinical or biomedical text—CLaMs are primarily trained on and output clinical or biomedical text. On the other hand, FEMRs are trained on the entire timeline of events in a patient's medical history. Given a patient's electronic medical record as input, an FEMR will output not clinical text but rather a machine-understandable representation for that patient. This representation, also referred to as a patient embedding, is typically a fixed-length, high-dimensional vector that condenses large amounts of patient information.

Although most of the CLaMs are freely accessible on the web, the best-performing models are trained on private datasets—EHR-BERT [34]; University of California, San Francisco–BERT [35]; and GatorTron [36]. Researchers developed the BERT for Biomedical Text Mining [37] and PubMedBERT [38] transformer models using biomedical literature from PubMed. NVIDIA developed the BioMegatron models in the biomedical domain with different sizes from 345 million to 1.2 billion parameters using a more expansive set of PubMed-derived free text [39]. Other large transformer models include ClinicalBERT [40], which has 110 million parameters

XSL•FO
RenderX

and was trained using 0.5 billion words from the publicly available dataset.

Structured Text Data

Overview

In an effort to improve patient safety and reduce medical costs, >500,000 physicians and almost 6000 hospitals in the United States are expected to have operating EHRs and health IT systems [41] and charts [42] as of 2015. As a result, big data in health care in the United States have grown rapidly in recent years, with a massive database of electronic patient data. Among these, unstructured text data, also referred to as tabular data, are the most recorded and used time series, including numeric (eg, laboratory measurements and vital signs) and categorical (demographics, medications, and diagnostic codes) features. We note here that tabular data encompass a wide range of data, and we focus only on time series in this review.

Preprocessing

Among time-series structured data, vital signs and laboratory results are the most common sources. These are typically represented in one of two ways: (1) as one 2D matrix in which each row is an encounter or patient and each feature can be represented across time as multiple columns, such as *heart_rate_time1* and *heart_rate_time2*; and (2) as stacked 2D matrices in which each matrix contains columns of all features at 1 time point. Depending on the recorded values, feature values can be either numerical or categorical. During preprocessing, the number of time points can be determined by the mean or median number of entries available across patients. The interval between each point can be absolute or relative time depending on whether the cohort has a large variability in terms of hospital stay time. With a large variability, a set number of time points can correspond to the relative time such that all patients have the same number of points but the intervals do not match up in absolute time. For uncommon measures such as certain laboratory tests, there may be large missingness within the cohort, which is further discussed in the next section. Finally, feature engineering can be performed through either a manual selection or feature selection algorithms [43,44].

Applications

In this section, we introduce existing work on GenAI application in 3 main categories: data augmentation and imputation, disease classification and prediction, and counterfactual estimation.

Data Augmentation and Imputation

EHR datasets often face the problem of missing or unavailable data, which is especially common in laboratory data as not every patient in the cohort will receive the same tests. In addition, incomplete documentation or patient privacy concerns could also limit access to the complete dataset. Naive approaches such as filling missing data with 0 or forward filling in time add noise to the dataset at the cost of performance, prompting the need for better methods. Generative models impute missing values by learning underlying patterns of the trajectory, resulting in an overall smoother trajectory. Another challenge arises when the prevalence of certain rare diseases is so low that it is impossible for models to learn the pattern. In this case, generative models are used to generate synthetic patient records that mimic real-world data distributions. This can help in augmenting limited datasets and improving the robustness of predictive models trained on scarce data. The general approach of data imputation will start with an RNN model with LSTM layers [45-50] or GRU layers [51]. In more advanced approaches, researchers can modify the architecture parameters based on the dataset size or augment the model with additional pieces. In the work by Zaman and Du [52], the authors combined the GRU with ordinary differential equations to model irregularly sampled data and impute the entire time series. ImputeRNN [45] is a method that imputes data with consideration of medical bias by applying a mask during training. One can also combine DL methods, where a VAE is used first to find a data representation, which is then passed to an RNN for imputation [53]. For filling in missing data, it may be favorable to consider both previous and later observations. Bidirectional Recurrent Imputation for Time Series [54] imputes the missing data bidirectionally using an RNN graph. While RNN is the most common method in the space, GANs have also become a popular choice. In a few studies (4/155, 2.6%), time-series data were treated as an “image” on which a GAN was trained to fill in the missing “gaps” [55-58].

Disease Classification and Prediction

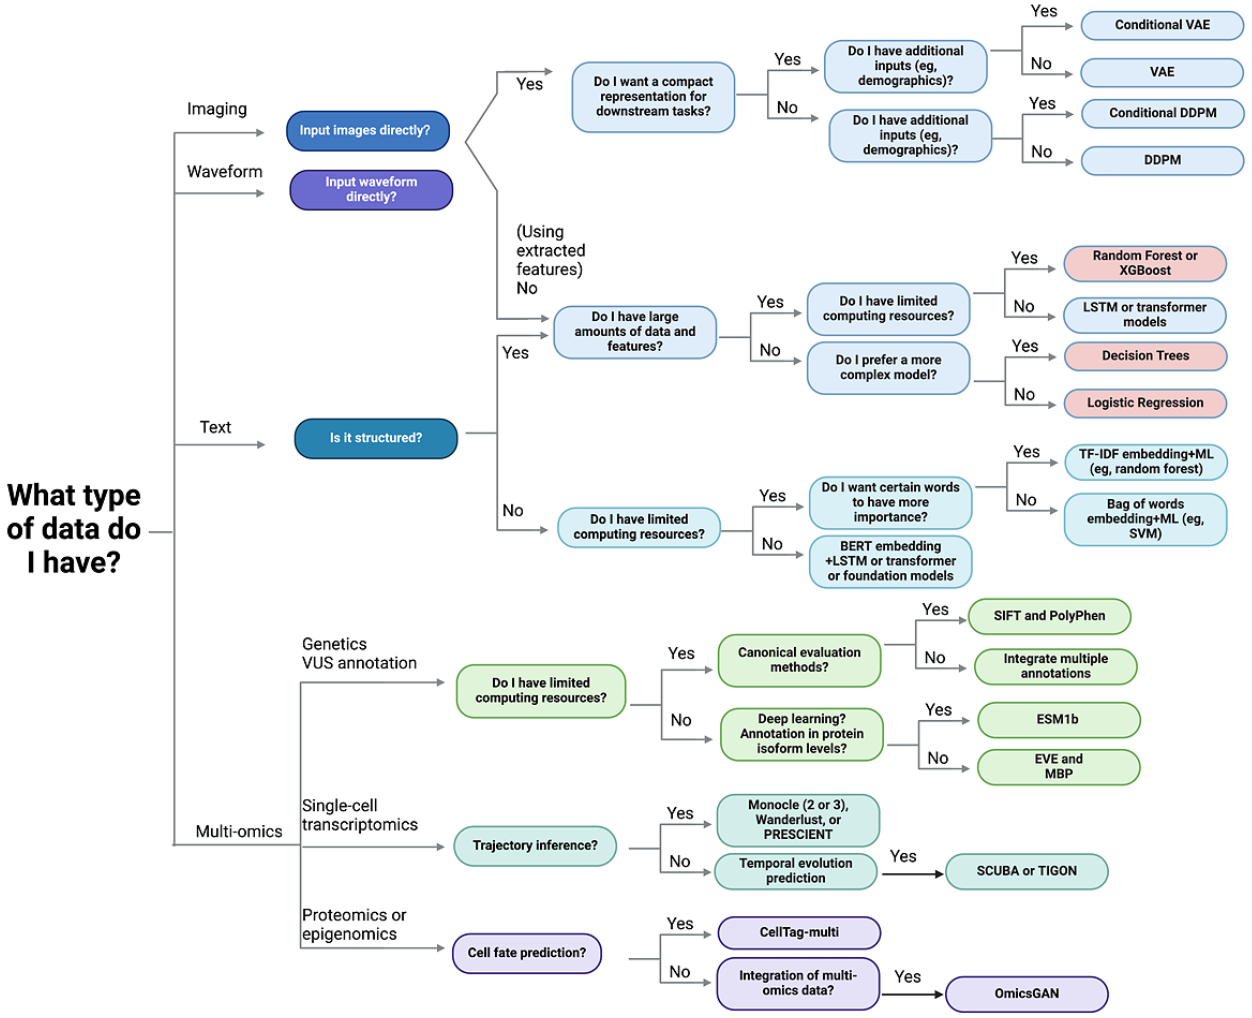
The most common goal in modeling disease trajectory is disease prediction and classification. Generative models can learn temporal dependencies within these sequences and generate realistic patient trajectories over time, enabling downstream predictive modeling of disease progression or treatment outcomes. There are several types of predictions that can be made: a binary classification of whether an event will occur (eg, mortality or sepsis), a probability prediction of an event occurring at some point, or a time at which an event occurs (survival analysis). Due to time-series data’s nature of unfixed length and frequency, many ways are proposed to handle such data. In earlier approaches, time points in time-series data are treated as separate entries with no relation to each other and passed through a fully connected neural network to predict the disease of interest. However, this approach ignores temporal information that can be crucial in future predictions. One of the most common ways of handling input with variable length is to first convert the input into a fixed-length representation, which is then passed through a network. In the study by Guo et al [59], measures such as BMI, smoking status, and cholesterol level were first converted to an embedding of fixed size and then passed through an RNN with LSTM layers to predict cardiac dysrhythmias. In another study [60], time-series data including laboratory results and vital signs were divided into 5 relative time points in reference to the duration of the hospital stay (eg, if the hospital stay for 1 patient is 4 hours, the times are admission, 1 hour into admission, 2 hours into admission, and so on) to fix the input length and predict mortality in patients with heart failure.

In many studies (19/155, 12.3%), once the embedding choice was made, the subsequent model of choice was similar. In these studies, RNN models were used to predict methicillin-resistant *Staphylococcus aureus* positivity [61], mortality [51,62-64],

XSL•FO
RenderX

readmission [65-68], next diagnosis [69-72], length of stay [73,74], hypertension [75,76], treatment response [77], and survival analysis [78]. Furthermore, the general-use prediction models in several studies (4/155, 2.6%) [32,79-81] all used an RNN model to predict clinical events based on time-series data. Extending from a single prediction point, the work by Pham et al [81] used LSTM to model irregularly timed time-series data and predict multistep future trajectories on diabetes and mental health cohorts. In recent years, researchers have also turned to transformer models for prediction tasks [82-84] as they capture more long-range dependencies and provide more interpretability of model weights than RNNs. In the work by Sheikhalishahi et al [85], self-attention was used to measure each feature's relevance to each other and also each time point's relevance within each feature to predict delirium in critical care, and another study [86] used similar mechanisms to predict the mortality risk of patients with cardiac issues. Transformers have also been useful in making multi-point predictions. The Transformer for Electronic Health Records is one of the earlier models using transformers to predict clinical events and can predict up to 300 events simultaneously [87]. The Dual Event Time Transformer for Electronic Health Records is a general-purpose transformer-based method that takes in time-series features [88]. In addition to RNN and transformers, a deep diffusion model can also be used to learn complex representations of disease networks that can be used for downstream prediction tasks [89].

Counterfactual Estimation



Counterfactual estimations aim to track the "what-if" trajectory—what would a patient's trajectories look like if they were not given any medication or treatment. To estimate a trajectory that is never observed, one must take into account both observed and hidden confounding variables, which is challenging in causal inference models. AI models offer the advantage of making no previous assumptions about the relationship between variables, learning purely from the data. However, this does not tackle the issue of the hidden variable, which is still an active problem in the field. Most commonly, RNNs were used to estimate treatment outcomes and, therefore, provide counterfactual estimation in several studies (4/155, 2.6%) [77,89-91]. Depending on the task and data at hand, modifications can be made to the basic RNN to achieve better results. In the work by Wang et al [92], a 2-layer bidirectional LSTM model was used for survival estimation. Similarly, the work by Li et al [93] combined RNN with g-computation, a causal inference method, to estimate treatment effects. A combination of reinforcement learning and RNN was also used to predict counterfactual evaluation in a study on public intervention for COVID-19 [94]. In addition to RNN models, autoencoders have been used to discriminate patient characteristics from treatment for counterfactual estimation [95].

Model Selection

As they are most abundant and easiest to access, unstructured text data are a good place to start for clinicians who want to explore GenAI tools. In Figure 5, we present a flowchart to help guide the process of choosing the right model for the data and task at hand. The flowchart is organized in the same way as the sections in this paper, where different colors refer to different data modalities for easier visualization. In addition to the statistical methods mentioned previously, there are also a number of ML models, including logistic regression, decision tree, random forest, and Extreme Gradient Boosting (colored red in Figure 5). While we do not discuss these methods in this review, there are review papers that describe them in detail [96-98]. If the dataset is quite small, a traditional autoregressive or a simple ML method would work better as more complex models require more data. However, if the dataset is large, DL models would perform better as the relationship between features is more complex and tends to be nonlinear. Commonly, the model of choice will be RNN or transformer based, which also have the most literature available. Once one has chosen a base model, they can start with a published framework and modify certain parameters based on their goal. If the model is quite simple and only consists of linear layers, one may also consider changing part of the structure to newer architectures, such as attention layers, or chaining 2 models together to improve performance.

Challenges and Future Directions

As ML and DL methods, including GenAI, continue to grow with an increasing amount of available data, many comparisons have been made between AI methods and traditional statistical methods. Cerqueira et al [99] compared ML methods in time-series forecasting (rule based, random forest, and Gaussian process regression) to statistical methods (ARIMA, Naive2, and ETS) using datasets with varying sample sizes up to 1000 and showed that ML methods outperformed statistical methods when the sample size was relatively large. Makridakis et al [100] jointly evaluated the accuracy of DL methods and statistical methods (Naive2, ARIMA, ETS, and ensemble methods) using the 1045 M3 dataset and showed that, among the nonensemble approaches, the statistical methods on average yielded better performance than DL methods for short-range prediction with regard to symmetric mean absolute percentage error and mean absolute scaled error, whereas the DL methods performed better in general for medium- and long-range predictions. The DL ensemble method using a combination of the 4 DL methods consistently outperformed the nonensemble methods in the study by Bonnheim et al [101]. However, in a practical setting, AI methods face the biggest challenge of low transparency due to their black-box nature. Interpretability has been an active area of research, and many techniques and tools have been proposed to understand the decision-making process of such models. Feature importance analysis tools such as Shapley Additive Explanations [102] and Local Interpretable Model-Agnostic Estimations [103] estimate feature contribution to reveal top features that are important to the decision. These tools may help shed light on how the model predicts the outcome, which is extremely important in the field of health care. A second challenge that AI methods face is the trade-off between generalization and performance as an exceptionally good performance of a model on one dataset may be caused by overfitting. As patient distributions can differ widely between hospitals and areas, the model's robustness must be measured before deploying it in practice. Nonetheless, GenAI has shown great potential in clinical support, such as early warning systems or care assistance tools. Future GenAI tools that tackle these challenges will become paramount in health care.

XSL•FO
RenderX

Unstructured Text Data

Overview

Unstructured data include a wide range of clinical narratives, such as progress notes, radiology reports, patient correspondence, and discharge summaries, comprising 80% of EHRs [104]. The loosely structured nature of typed text (also known as "free text") is effective in day-to-day clinical workflows but presents a major challenge for automating EHR-based registries. The unstructured data may contain key patient information missing in structured data, extra information complementing structured data, or even data that may contradict information presented in structured data. As such, the overall goal of modeling using unstructured data is to assist disease prediction using structured data by adding critical missing information. The complexities of unstructured data, along with the fact that existing text-mining tools and NLP applications have limited accuracy in extracting information from free text, have prompted some registries to ask for a manual chart review of individual patients before final inclusion in the registry. Unstructured data limit the application of automated computational phenotyping methods and increase the likelihood of low data quality (eg, missing data) when data are extracted from structured EHR data only [105,106].

Preprocessing

Information retrieval from unstructured data is challenging because the information can often be of low quality and contain missing values. Commonly used data preprocessing techniques for unstructured data include data collection, data cleaning, tokenization, stemming, and the removal of stop words [107,108]. Tokenization refers to segregating, for example, words and punctuation marks in the input document as tokens and computing their frequency. Stemming is the process of identifying the roots of words, typically by removing the suffix. Stop word removal consists of removing infrequent words to reduce the dimensionality of the dataset. Once the key components of the dataset are extracted, they can be used for downstream applications such as the identification of risk factors and individuals at high risk of a particular disease.

Applications

As the application of large language models to health care time-series data is still a developing area of research, in this section, we discuss static time applications of these models. We will discuss potential research directions for time-series unstructured text based on progress in other fields such as climate and finance in the Challenges and Future Directions section. Both traditional NLP and FMs can be used to perform clinical NLP tasks such as clinical concept extraction (or named entity recognition), medical relation extraction, semantic textual similarity, natural language inference, medical question answering, and medical report summarization. The domain of medical report summarization is a popular area of research, with numerous papers published on the use of NLP and FMs to summarize medical reports, health care records, and medical dialogues [109]. A radiology report is a medical document that contains the details of an imaging examination (such as x-rays and magnetic resonance imaging [MRI]). A radiology report consists of three components: (1) the Background section, which contains the medical history of the patient; (2) the Findings section, which discusses the crucial observations and findings of the radiology examination; and (3) the Impression section, which is a short summary of the findings section. The Impression section is usually written by medical professionals, which is a time-consuming process. The only aim of radiology report summarization is to automate the generation of this Impression section. Several attention-based and FM-based models have been developed to improve the quality of summarization [110].

Medical dialogue summarization corresponds to the automatic generation of coherent summaries that capture medically relevant context from dialogues between patients and health care providers. Medical dialogue summarization can help medical providers keep a record of patient encounters and also provide the necessary context of a patient's medical history during patient handoffs between providers. Existing studies have used techniques from computational linguistics [111], NLP (Pegasus [112]), pretrained language models, and low-shot learning to collect labeled data and perform medical dialogue summarization.

Medical question answering refers to developing a technique that automatically analyzes thousands of articles to generate a short text, ideally in less than a few seconds, to answer questions posed by physicians [113]. Such a technique provides a practical alternative that allows physicians to efficiently seek information at the point of patient care. Several question-and-answer systems have been developed using NLP [114] and FMs (generalist medical AI and MedLM).

Model Selection

FMs hold great potential to assist clinicians in a wide range of health care problems. However, clinicians should be aware of the risks associated with the use of these models and potential data leaks. They should also select which models to use based on the computational resources available to them, as shown in Figure 5, as the training of these models is becoming increasingly expensive (Table 1).

Challenges and Future Directions

Compared to traditional ML models, FMs have a significantly higher computational cost, requiring massive datasets and graphics processing unit specifications for training. While they achieve high predictive accuracy [115], these models are composed of millions to billions of parameters and have poor interpretability and high latency and runtime. While these costs can be lowered over multiple downstream applications, their value may take longer to realize than that a smaller model developed for a single high-value task [30]. In addition, data privacy and security are significant concerns with FMs as they may leak protected health information through model weights or prompt injection attacks [116]. As the cost of computing decreases and the amount of data increases, FMs may become easier to train and more accessible. One active area of research is testing FMs' potential in multimodality input, in which FMs are trained and evaluated on multimodal datasets, such as both text and images. These models can be used to generate

XSL•FO
RenderX

personalized treatment plans based on the patient history as well as develop early warning systems for individuals at high risk. These advancements would transform how health care professionals interact with patient data, making health care more predictive, personalized, and precise.

Medical Imaging

Overview

Medical imaging refers to 2D or 3D images obtained from radiology procedures such as MRI and computed tomography (CT). GenAI has been applied to a wide set of problems in medical imaging to solve issues of scarcity, heterogeneity between datasets, and low resolution quality, among others. There are 3 main classes of generative vision methods: GANs, VAEs, and DDPMs. Each of these classes has been applied to medical imaging. Among all applications, medical image series input has been used mostly in data generation, anomaly detection and classification, and image segmentation and registration tasks.

Preprocessing

There are several steps in preparing a medical imaging dataset as the quality varies largely depending on location, time, and cohort [117]. First, a denoising technique is applied to remove as much nuisance noise as possible. After denoising, data interpolation can be conducted for certain images such as CT scans to ensure the same spacing across all images. In the case of MRI images, bias field correction may be performed to adjust image intensity. Third, image registration is performed to align all images with a common template to avoid unnecessary incoherency among images, such as rotation. Finally, images can be standardized or normalized to improve algorithm efficiency. Depending on computational resources, the image may also be downsampled to a lower resolution or split into patches to reduce computational cost. Publicly available datasets such as those of the Alzheimer's Disease Neuroimaging Initiative [118] and Open Access Series of Imaging Studies [119] do not need much preprocessing as they have been carefully curated. However, image registration is recommended to align all patients with a common template of choice if multiple datasets are combined. The medical images are usually represented as 2D matrices or 3D vectors of the pixels or voxels.

Applications

Data Generation

Similarly to tabular data, data generation has been used to combat the problem of data scarcity. For longitudinal medical image series, GANs, VAEs, and DDPMs have all been used to generate synthetic images. In the work by Hamghalam and Simpson [120], a recurrent conditional GAN was used to generate sequential image data conditioned on past variables. Diffusion-based models have also been applied to impute longitudinal CT and MRI images [121]. Finally, predicting and generating aging brain images using only the input of age and disease state is an example of applying autoencoders with contractions on the latent space [122].

Anomaly Detection and Classification

The most common application to longitudinal images is anomaly detection and disease progression prediction. For clinical diagnosis, GenAI-based anomaly detection tools have been developed in which the model identifies deviations in 1 image from the rest of the population, aiding in the detection of diseases or abnormalities. For medical image series, previous scans are used as inputs or conditional variables to predict the next image. Many approaches in this space are a variation of GANs as they were introduced earlier than VAEs and DDPMs. Gaussian-Poisson GAN uses stacked GANs to predict tumor growth from longitudinal MRI [123]. The multi-Pareto GAN makes longitudinal prediction of infant MRI using multi-contrast perceptual adversarial learning [124]. In the low-dimensional GAN [125], disease progression images are predicted using missing MRI in the input. In the study by Devika et al [126], the authors trained a GAN to predict autism spectrum disorder given longitudinal structural MRI scans. More recently, VAEs have been applied extensively as they offer a latent space to work with. In general, researchers start with a vanilla VAE and apply slight modifications to fit their data modality and goal to detect and predict diseases, including multiple sclerosis [127], Alzheimer disease (AD) [128-131], tau biomarker detection for AD [132], glaucoma [133], and lung cancer [134]. There has also been an increase in works published using multi-modality data, such as imaging data and tabular or genetics data. In the work by Kmetzsch et al [135], the authors trained a VAE model to predict disease progression score based on longitudinal images and micro-RNA data input. When dealing with multimodal inputs, a combination of DL models dealing with each modality may also be advantageous. The work by Sauty and Durrleman [136] combined VAE with a linear mixed-effects model to learn a Riemann progression model that can be applied to general disease trajectory estimation. Another study combined an autoencoder framework with attention units in a transformer to predict final ischemic stroke lesions from MRI [137]. In the study by Zhang et al [138], a spatiotemporal convolutional LSTM was learned to combine imaging and nonimaging data to predict tumor growth images. Conditional SliceGen is a method that takes an arbitrary axial slice in the abdominal region as a condition and estimates a vertebral-level slice [139].

Image Segmentation and Registration Tasks

Another common task in medical imaging is image segmentation and registration. We note here that, while image segmentation and registration tasks are different concepts, the underlying models applied to solve the problems are largely the same. In the work by Zhang et al [140], an encoder-decoder structure model was used for contrastive learning for image segmentation. Extending from autoencoders, a conditional VAE has also been used to produce cardiac image segmentation conditioned on predefined anatomical criteria [141]. We note here that, while work in this area using time-series input is scarce, the underlying model and training process remain the same for single time input models [142-147]. Furthermore, many of the methods mentioned previously for anomaly detection can also be applied to registration and segmentation tasks during training.

XSL•FO
RenderX

Model Selection

Although there are many tasks associated with imaging data input, the underlying model architecture remains largely the same for prediction, synthesis, registration, or even domain transfer tasks. For anyone using time-series or longitudinal images for any task, choosing 1 of the 3 families of vision methods following the workflow in Figure 5 is a good place to start. One may also refer to Table 1 to compare the models' strengths and weaknesses. GANs are an earlier framework that remains powerful today, especially with synthetic generation, but are more complicated to implement as they have a generator and a discriminator. On the other hand, VAEs offer a latent space that can be used to downstream linear models such as mixed-effects models to control for variables such as age, but its generation quality may not be as ideal as that of GANs or DDPMs. Finally, diffusion models have been largely applied in recent years due to their simple architecture compared to that of the other 2 and low memory requirements but offer very little interpretability on the generation process. For clinicians with limited computing resources, 3D images may be too large to fit onto graphics processing units, and in many cases, the images can be split into smaller patches to reduce memory footprint [148]. Finally, there are publicly available general-purpose vision models that can be downloaded as a starting point, which can be further trained and fine-tuned for the specific task at hand.

Challenges and Future Directions

With computer vision models' success in recent years, there is a lot of potential in their applications to medical imaging. In recent years, diffusion models have shown great promise in generating images that are comparable to those generated by state-of-the-art GAN methods. Furthermore, GenAI methods that support video generation can potentially be adapted for medical imaging [149-153]. However, some issues that are present in current vision models also extend to medical imaging, such as illogical generations that do not comply with physical laws [119]. Therefore, clinicians should take the generations with a grain of salt when applying them to downstream tasks. The advent of vision models has been revolutionary in the study of medical images as previous methods must first transform the images into numeric representations, such as thickness and mean intensity. These representations are then fed into linear models for tasks such as classification and segmentation. To work with raw image inputs, linear models of estimation such as principal component analysis or single-value decomposition are often used. However, these generations often have poor resolution or fail to adequately capture variability. In contrast, modern neural network approaches (eg, CNN) *jointly* learn the optimal feature extraction strategy together with the downstream task. Thus, GenAI algorithms are able to consider highly nonlinear and nuanced interactions between inputs that better capture the underlying distribution of the data. While GenAI faces the challenge of transparency, interpretability methods such as Gradient-Weighted Class Activation Mapping [154] have shown convincing results. Another challenge of GenAI in medical imaging is the computational resources required to support such a model, which will become cheaper and easier to acquire as hardware technology becomes more efficient.

Physiological Waveforms

Overview

Waveform data capture the change of one or multiple physical quantities over time and can be viewed as either univariate or multivariate time-series data. Examples of medical waveform data include single-lead electrocardiograms (ECGs) or photoplethysmograms, which can be represented as univariate time series. Multi-channel technologies such as electroencephalograms (EEGs) are typically represented as multivariate time series. Although waveforms are considered to be closer to structured time-series tabular data, DL methods applied to structured data often face technical limitations when applied to waveforms as the sampling frequency is much higher. As such, GenAI methods applied to waveforms often resemble speech processing [155] or vision-based models adapted for 1D input signals.

Preprocessing

Physiological waveforms are often recorded over a short period with low missingness but face the problem of noise and signal artifacts. Therefore, waveform preprocessing aims to remove as much nonphysiological noise and artifacts as possible while preserving the actual signal. This is typically accomplished by applying digital filters designed to address nonbiological signals, drifts, and spikes [155]. Depending on the signal, specific filters have also been developed and shown strong performance, such as the Wiener filter for ECGs [156]. After filtering, the waveform is usually normalized for efficiency and resampled to a common frequency.

Applications

GenAI models have gained increasing popularity among medical waveform data. Major tasks using GenAI models for this type of data include synthesis and imputation and anomaly detection.

Synthesis and Imputation

GenAI-based approaches can augment existing data and generate synthetic data to support downstream algorithms, allowing for more applications when the amount of real medical waveform data is limited. For this task, GANs have been used extensively [156-161], along with diffusion models [162]. In their work, Elazab et al [123] made modifications to the improved Wasserstein GANs and generated single-channel EEG signals. Zhu et al [163] constructed a GAN with bidirectional LSTM and CNN to synthesize single-beat ECGs and demonstrated that the model performed consistently better than benchmark architectures with regard to the quality of the signals. In another work, To et al [127] reconstructed high–sampling sensitivity EEG signals with improvements in reconstruction and classification results.

Anomaly Detection

While little work has been done on anomaly detection directly, GAN-based approaches have been explored to detect cardiac abnormalities [164-166] and seizures [167,168]. Diffusion-based models have also been used for anomaly detection with ECGs and EEGs. Xiao et al [169] adopted a denoising diffusion-based imputation method with conditional weight-incremental

XSL•FO
RenderX

diffusion to improve data generation quality and ECG anomaly detection stability. Wang et al [170] designed a diffusion-based framework with a reverse diffusion data augmentation module to learn more generalized features for major depressive disorder detection using EEGs.

Model Selection

In general, waveform data are best trained using vision models such as VAE and DDPM as the time series can be viewed as a 1D image. Therefore, the workflow to choose an appropriate model for waveform data is similar to that for imaging data. As GANs are often more complex but do not significantly outperform other vision models, they are being replaced with VAEs and DDPMs [171,172].

Challenges and Future Directions

As GenAI models are only beginning to be applied to waveform data, there are many directions to pursue. One of these is cross-modality imputation, where, given an EEG, a GenAI model can be trained to generate the corresponding functional MRI or vice versa. Another area of study is to convert EEG signals to natural language by combining vision models with a language model [173]. As previous studies have focused on modeling a single type of waveform data in isolation, one natural direction is to use more data sources, for example, EEGs with text data or ECGs with medication data, as they are often informative about one another in tasks such as imputation [174] and forecasting [175].

Genetics and Multi-Omics Data

Multi-omics data encompass genomics, transcriptomics, proteomics, epigenomics, and metabolomics, offering a detailed picture of biological activities at various molecular layers. One of the most successful applications of AI in genetics is in trajectory modeling using multi-omics data, which focuses on how biological systems such as cell development, diseases, or reactions to treatments change over time.

Preprocessing

Multi-omics data comprise multiple-sequencing data types and various features. To efficiently preprocess the data, different methods are used for each type of data. DNA sequences are represented as strings of adenine, thymine, guanine, and cytosine nucleotides, which can be transformed into a numerical matrix in which each nucleotide is represented as a binary vector. For transcriptomics, expression data are often represented as a matrix of continuous numeric values in which each row corresponds to a sample or a cell and each column corresponds to a gene or transcript. Proteomics data are similarly structured but represent peptide abundances or protein expression levels, and epigenomics data such as methylation status are typically captured as binary values or continuous levels indicating methylation at specific sites. Depending on the goal, different omics data can be combined to uncover time-related trends and critical factors that influence those biological shifts.

Applications

Identifying Pathogenic Mutations

Identifying pathogenic mutations is pivotal for unraveling the genetic underpinnings of diseases. The task of variant effect prediction, which seeks to determine the phenotypic implications of genetic variations, stands as a cornerstone challenge in human genetics. Traditional approaches leveraging statistical methods alongside evolutionary conservation scores such as Sorting Intolerant From Tolerant and phyloP have made strides in classifying variants of uncertain significance (VUSs) [176,177]. Despite these advancements, accurately differentiating between variants that disrupt protein function and those with neutral effects remains a daunting challenge. The persistence of many missense variants within the gray area of VUSs significantly hampers the diagnostic utility of exome sequencing in clinical settings. To effectively address the challenge of categorizing mutations, particularly those classified as VUSs, ML techniques have been increasingly applied. Among the array of ML methodologies, random forest, gradient-boosting models, and support vector machines are often used for training complex genetic datasets to decipher VUSs [178,179]. However, the high dimensionality of genomic information and the intricate interactions between genetic variants often exceed the capacity of traditional ML techniques, leading to potential overfitting and a lack of generalizability to unseen data. DL methods, including CNNs and RNNs, offer a promising solution for addressing the challenges of modeling complex, nonlinear relationships in high-dimensional biological data. These methods significantly diminish the need for manual feature engineering by efficiently learning from raw data. Among the DL models developed for predicting VUSs are Evolutionary Scale Modeling 1b (ESM1b), Evolutionary Model of Variant Effect, MetaRNN, masked bidirectional prediction, PrimateAI, and deleterious annotation of genetic variants using neural networks. ESM1b is particularly noteworthy for its innovative use of a protein language model developed by Meta AI [180-185]. ESM1b has demonstrated exceptional capability in classifying approximately 150,000 ClinVar and Human Gene Mutation Database variants and annotating approximately 2 million variants as damaging in specific protein isoforms, a feat not previously achieved with ML-based methods. This focus on isoform-specific annotations underlines the critical importance of considering all protein isoforms in variant effect predictions, marking a significant advancement with which ESM1b contributes to genetic research.

Trajectory Modeling

Time-series transcriptomics and proteomics data have been used widely to study trajectories in biological processes and disease development. Among them, single-cell transcriptomics data have been used to reveal cellular dynamics via pseudotime inference models, including Monocle (versions 2 and 3), Wanderlust, scVelo, single-cell clustering using bifurcation analysis, partition-based graph abstraction, and Trajectory Inference With Growth via Optimal Transport and Neural Network [154]. Monocle uses single-cell variations to sequence cells in pseudotime, depicting their progression through biological processes such as differentiation based on gene expression. Monocle version 2 [186] uses reversed graph

XSL•FO
RenderX

embedding with a minimum spanning tree algorithm for pseudotime reconstruction, whereas Monocle version 3 [187] enhances this with principal graph learning for refined trajectory inference. Wanderlust adjusts each cell's trajectory position using weighted averages from the shortest-path distances of randomly chosen waypoints until convergence, thereby producing an average trajectory. scVelo [188], a likelihood-based dynamic model, estimates RNA velocity to derive dynamic insights from RNA sequencing data, analyzing gene-level transcriptional dynamics by determining gene-specific transcription, splicing, and degradation rates, which is suitable for both transient states and systems with varying subpopulation kinetics. Single-cell clustering using bifurcation analysis [189] forecasts the temporal evolution of gene expression in single cells using theories of nonlinear dynamics and stochastic differential equations, aiding in the comprehension of gene expression dynamics. Partition-based graph abstraction [190] merges clustering and trajectory inference in single-cell RNA sequencing data, creating a graph to depict cell relationships based on gene expression and enhance understanding of cellular transitions. Finally, Trajectory Inference With Growth via Optimal Transport and Neural Network [191] uses dynamic unbalanced optimal transport based on the Wasserstein-Fisher-Rao distance to integrate temporal datasets, which provides a framework for connecting temporal measurements and predicting novel dynamics. In addition, expression data can be used to study responses to infectious diseases. Huang et al [192] analyzed time-series expression data from human volunteers infected with influenza. They identified distinct temporal patterns of gene expression that could discriminate between asymptomatic and symptomatic infections. Similar approaches have been used to study the response to various treatments, such as interferon-β therapy in patients with multiple sclerosis [193].

On the other hand, single-cell proteomics approaches such as mass cytometry (cytometry by time of flight) have revolutionized our ability to understand complex cellular processes at an unprecedented resolution. Palii et al [194] used single-cell proteomics to define the temporal hierarchy of human erythropoiesis. The analysis revealed a timely ordered appearance and disappearance of transient cell populations or stages that accumulate at various positions along the erythroid trajectory, with cells undergoing gradual transitions between these stages. In the fields of proteomics, epigenomics, and metabolomics, CellTag-multi [195], a method for single-cell lineage tracing across single-cell RNA sequencing and single-cell assay for transposase-accessible chromatin sequencing assays, mapped transcriptional and epigenomic states of progenitor cells, significantly improving cell fate prediction. In addition, linear mixed models have been used to quantify temporal changes in metabolite concentrations, offering insights into the dynamics of the metabolic system [196,197].

Model Selection

GenAI has shown great promise in analyzing multi-omics data for disease progression analysis. By using techniques such as omicsGAN, which uses GANs, and graph-linked unified embedding and MultiVI, which use VAEs, GenAI facilitates the integration and compression of multi-omics data from diverse sources into a unified representation [198-200]. This aids in a more comprehensive analysis of the data. In addition, tools such as Potential Energy Underlying Single-Cell Gradients apply generative modeling to map out potential landscapes from time-series single-cell transcriptomics data, making it possible to generate trajectories for unseen data points [201]. This opens up avenues for hypothesizing about biological perturbations and pathways of disease progression. Moreover, GenAI proves instrumental in identifying distinct disease subtypes and stratifying patients based on their multi-omics profiles. For example, gene-guided weakly supervised clustering via GANs uses a GAN to generate imaging features from brain MRIs and single nucleotide polymorphisms to explore conditions such as AD and hypertension [202], whereas the Trained GAN Discriminator model stratifies patients with breast cancer into high- versus low-risk categories based on their transcriptome profiles [203]. For clinicians interested in working with multi-omics data, we outline a procedure for finding the best tool in Figure 5 based on their specific needs, such as resource availability and the type of data analysis required, including genetics, single-cell transcriptomics, and proteomics or epigenomics.

Challenges and Future Directions

Analyzing and modeling multi-omics data in time-series contexts presents challenges in addressing missing data across different biomolecule types, which complicates the integration of datasets obtained through various omics technologies. In addition, the complexity of biological interactions can lead to analytical difficulties when dealing with high-dimensional data. The integration of multi-omics data is becoming increasingly important in the pursuit of future progress. This approach uses various biological data layers—genomics, transcriptomics, proteomics, and metabolomics—to enhance the understanding of genetic interactions and disease mechanisms.

Discussion

Data Ownership and Privacy

Overview

While GenAI software has proven powerful in understanding and predicting disease trajectories across modalities, its implementation in the clinic remains difficult due to challenges including ethical considerations [204] and other regulatory and technical challenges. Regulations such as HIPAA (Health Insurance Portability and Accountability Act) and the General Data Protection Regulation protect personal health information, but the evolving nature of GenAI complicates compliance, especially regarding AI-generated synthetic data and indirect identification risks [205-207]. This rapid advancement outpaces regulatory updates, causing uncertainty among health care providers and AI developers about legal responsibilities and best practices [208-210]. Technically, health care time-series forecasting struggles with short data lengths and significant temporal changes as discussed in previous sections, making model training and parameter estimation difficult [211,212].

Data ownership and privacy in health care GenAI are critical issues involving rights and responsibilities over data control,

XSL•FO
RenderX

use, and dissemination [213]. This includes patient records, genetic information, and AI-generated datasets. Ambiguities in ownership, particularly with AI-generated synthetic data, complicate matters. This raises questions about who owns the data—the AI developer, health care providers, or patients [214]. Current regulations enforce data minimization, purpose limitation, and consent to protect patients' privacy rights [215]. However, GenAI models require extensive patient data for training, leading to the risk of reidentification of anonymized data through advanced algorithms [216]. Ensuring that raw patient data remain protected is crucial to prevent unauthorized access [217,218].

Security

AI models in health care should be deployed with the highest standard of data security as breaches of sensitive patient information can be disastrous. In 2023, >500 data breaches affected >112 million individuals [219]. Cyberattacks such as phishing and malware are common, but prompt injection attacks in GenAI models are emerging threats [220]. Effective countermeasures such as prompt filtering and human-in-the-loop systems are essential despite potentially compromising model performance [221-224].

Bias

The deployment of GenAI in health care can also result in inadvertently embedded societal biases, leading to discriminatory outcomes [225]. Biases in training data can result in disparities in treatment across different patient groups [226]. Addressing these biases requires comprehensive strategies throughout AI development to ensure fairness and equity [227-231].

Clinical Safety and Reliability

Ensuring clinical safety and reliability is vital for the trustworthiness of health care GenAI. AI models can produce inconsistent or erroneous outputs, particularly in complex medical scenarios, due to issues such as hallucinations [232,233]. In health care, such errors are unacceptable and can lead to harmful consequences, which require rigorous scrutiny and validation. Moreover, AI models, particularly DL models, often lack transparency and explainability, posing challenges in health care [234]. Enhancing transparency and explainability through techniques such as feature importance scores and decision trees is crucial for gaining trust and ensuring comprehensible AI decisions [235-237]. Regulatory and ethical frameworks must evolve to support these efforts [238].

Conclusions

While there remain many challenges to deploy reliable GenAI methods in real practice, including technical, regulatory, and ethical issues, these models can have huge impacts that could benefit patients, practitioners, and administrators. As such, collaboration among policy makers, legal experts, AI developers, and health care providers is crucial in overcoming these issues. In this paper, we introduced concepts basic to DL and GenAI to those unfamiliar with the field, reviewed existing work on GenAI application to time-series health data, and offered suggestions to clinicians who are interested in applying such tools to their field. We hope that this review bridges the gap and promotes better collaboration between technical and applied disciplines to develop better methods that are suitable and robust in a practical setting.

News and Perspective

The Controversial Push for New Brain and Neurorights

Simon Spichak

(J Med Internet Res 2025;27:e72270) doi:10.2196/72270

In August 2023, the Supreme Court of Chile issued a unanimous decision ordering the US-based brain-computer interface company Emotiv to erase the brain data it had collected on a former Chilean Senator [1].

The results of the court case were reported as a landmark decision for "neurorights"—enacting the country's recent constitutional provision to protect people's brain data and mental privacy from being sold or manipulated by neurotechnology. Rafael Yuste, a codirector of Columbia University's Neurotechnology Center and cofounder of the Neurorights Foundation, took part in crafting the provision.

The Neurorights Foundation is instrumental in the push for new human rights and legislation to protect people's brains from neurotechnology.

Rafael Yuste delivering a lecture in Chile.

However, these efforts have proven controversial among scientists, legal scholars, and advocacy groups [2-4]. Yuste told JMIR Publications (JMIR) that some of the criticism is "poorly informed" and that neurorights are not adequately covered by existing rights or data privacy legislation. He added that some of the critics may receive funding from the industry.

(The experts who spoke with JMIR disclosed that they had not received funding from neurotechnology companies.)

J Carlos Lara Gálvez, executive director of Derechos Digitales, a nonprofit organization based in Chile that advocates for digital rights across Latin America, told JMIR that legal experts in the country are split on the neurorights provision, with some skeptical that "such legal and constitutional changes are needed at all."

Danielle Zaror Miralles, a law and technology professor at the University of Chile Law School, explained to JMIR that the constitutional provisions are based on the colonial idea that "there were no legal protections" for brain data in Chile before this legislation.

Why are some researchers advocating for "neurorights"?

Neurotechnology encompasses any device that can directly read, measure, or manipulate brain data. Some invasive forms of neurotechnology, like deep brain stimulation (DBS), are implanted directly into the brain to treat the symptoms of Parkinson disease, depression, obsessive-compulsive disorder, and other diseases [5].

These forms of neurotechnology are regulated as medical devices, while consumer-facing devices are largely unregulated in countries like the United States.

"I became very concerned with this [neurorights] through our own experiments with mice," Yuste told JMIR. "About a decade ago, we were able to decode the activity of the visual cortex and manipulate it selectively using laser-based technology."

While invasive brain implants or "mind-reading" devices aren't hitting the consumer market anytime soon, many noninvasive consumer electronics—like Muse or Emotiv—are already on the market. These devices measure electroencephalographic (EEG) brain data to help measure and potentially improve sleep and mental health. Researchers are also developing "mind-controlled" drones using consumer-grade EEG headsets [6]. In 2023, Apple also received approval on its patent for AirPod-like earbuds with built-in electrodes that could theoretically measure and collect EEGs [7].

Marcello Ienca, a professor who studies the ethics of artificial intelligence (AI) and neuroscience at the Technical University of Munich and the Swiss Federal Institute of Technology Lausanne, also believes this raises new problems. "The potential for intervening into brain function, either by recording activity from the brain, or for writing into the brain using neurostimulation techniques, opens challenges that are substantial from a human rights perspective, and that can be well understood as human rights challenges," he told JMIR.

In response to the development of this technology, Yuste and other experts believe that new "neurorights" relating to brain data are needed [8,9].

1. **The right to mental privacy.** To prevent neural activity from being deciphered without consent.
2. **The right to mental identity.** To protect against technology altering the self, consciousness, or personality.
3. **The right to free will.** To prevent neurotechnology from tampering with decision-making abilities.
4. **Fair access to mental augmentation.**
5. **Protection from bias embedded in neurotechnology algorithms.**

Other experts are more skeptical of neurorights. "While there is rough consensus on the potential risks of certain technologies that interact with the human body or the brain, there is no consensus on the notion that those risks are certain or well-defined, that those risks are current and actual instead of potential and speculative," Gálvez said. "Some of the most publicly visible support comes accompanied by highly exaggerated claims about the capabilities of these technologies."

XSL•FO
RenderX

Gálvez is concerned that the debate on neurorights displaces attention and discussion from other fundamental rights and data protection regulations.

Danielle Zaror Miralles, law and technology professor at the University of Chile Law School.

So, are new human rights needed to protect the brain?

The Neurorights Foundation analyzed seven existing international human rights treaties and determined that they included insufficient protections for brain data, concluding that amendments or new rights were needed to protect brain data [10].

Nita Farahany, a legal scholar and bioscience professor at Duke University who wrote *The Battle for Your Brain*, also thinks that new rights are needed. She argues for a broader approach through the lens of "cognitive liberty," which would protect self-determination, freedom of thought, and mental privacy. Farahany told JMIR that cognitive liberty could provide broad protections against technologies that can predict cognitive states, even if they don't directly measure neural data.

"If the biometric data is being used to make inferences about a person's mental state, it deserves a higher level of protection," she said.

Ienca told JMIR that he's agnostic about the right approach to protecting these rights—whether reinterpreting existing rights or introducing new ones.

Several legal experts told JMIR they don't think this new framework is needed.

Susie Alegre, a human rights lawyer, author of the book *Freedom to Think*, and a senior fellow at the Center for International Governance Innovation, told JMIR that adding new rights or amending existing ones doesn't make sense. "The big problem is that when you say we need new rights, then you are firstly saying the rights we have don't cover this, and therefore, it's a kind of a free pass," she said. "Fundamentally, I don't understand advocating for new rights without testing the boundaries of existing rights in court."

Jan Cristoph Bublitz, associate junior professor of criminal law at the University of Hamburg, also argued against the proposal for neurorights in a 2022 paper in the journal *Neuroethics* [11]. "The proposal tends to promote rights inflationism, is tainted by neuroexceptionalism and neuroessentialism, and lacks grounding in relevant scholarship," he argued.

In 2022, the UN Human Rights Council asked its Advisory Committee to study the issue [12].

Liz Throssell, a spokesperson from the UN Human Rights Office, said that the existing human rights framework does address the issues related to privacy and autonomy. Throssell told JMIR that there may be emerging issues outside the scope of legislation, but these will require further discussion.

"But the bottom line is that huge and potentially very consequential work needs to be done now in ensuring existing human rights standards are applied," Throssel said, explaining that adding or amending human rights takes a lot of time. "What is important is that we focus on implementing the human rights standards we have at our disposal."

Legislating neurorights around the world

The Neurorights Foundation recently surveyed 30 user agreements from direct-to-consumer neurotechnology companies. Clicking "I agree" on 29 of these agreements would give the neurotechnology company any rights to the data, which would allow them to sell it to a third party. Yuste called these user agreements "predatory."

"There are no rules; the company is taking everything," he said. "That's why we're working with many countries and international organizations to protect brain data." Ultimately, he believes that brain data should be protected as stringently as medical data.

Following the constitutional provisions in Chile, which Yuste and the Neurorights Foundation helped influence, other countries like Uruguay, Brazil, and Mexico have all either proposed or pushed through constitutional amendments that would provide similar protections.

However, experts, including Miralles, say these provisions are unnecessary as the constitutional protections in Latin America sufficiently encompass brain data and can restrict the use of medical neurotechnologies because of how the law is written [4].

Miralles and Pablo Contreras, a law professor at the Central University of Chile, argued that the neurorights provision was irrelevant to the Emotiv case, arguing that the company deleted the data in conjunction with existing data protection laws [13]. "Most constitutions on the continent recognize the right to privacy, and almost all countries have laws on personal data protection inspired by the GDPR," she said. "Needless to say, the entire hypothesis of this legislation is based on a science fiction fantasy idea."

Gálvez told JMIR that there were concerns the constitutional provision led to "altering the functions of public health authorities and the application of data protection law, introducing confusion to the legal landscape."

Meanwhile, in the United States, the Neurorights Foundation also worked alongside the Colorado Medical Society to sponsor bill HB24-1058 to protect brain activity and brain data.

Other states have enacted broader laws to protect other types of biometric data that technology companies collect. Illinois's

XSL•FO
RenderX

Biometric Information Privacy Act, for example, requires private entities collecting biometric data to inform people about what kind of data is being collected, how it's stored, and how it's used.

"I think that's a good start, but I would go further than it does," Farahany said, adding that cognitive biometric data should, for example, be kept on the device where it is collected and not sent to an external company.

In the European Union, Alegre explained that there are already laws and regulations protecting people's data from exploitation, but the problem involves enforcing and regulating these rules, adding that "the biggest problem is it's very hard to take a tech company to court."

JMIR News & Perspectives articles are written by journalists. They are not peer-reviewed but rigorously fact-checked. We invite freelance journalists to pitch us original ideas.
