The EACH score represents a substantial advancement in the development of efficient, explainable, and automated ML-based risk assessment tools. The universal format of the EACH score is easily applicable to various medical scenarios, thereby reducing the need for labor-intensive data collection. Once integrated with electronic medical records, it generates specific predictions of different adverse outcomes [11,37]. Future developments should aim to enhance its user-friendliness for clinicians, potentially through the creation of intuitive interfaces or decision support tools that simplify the interpretation of results [38-40].

Acknowledgments

This research was supported by a grant from the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant HI22C1295). This research was also supported by the Seoul National University Hospital research fund (grant 0320222110).

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request. In addition, the corresponding code for model development is accessible on GitHub in the repository.

Authors' Contributions

M-YO and H-SK contributed equally as the first authors of this study. S-BL and SML contributed equally as co-corresponding authors of this study.
M-YO, H-SK, S-BL, and SML contributed to conceptualization, data curation, formal analysis, methodology and investigation of study. S-BL and SML handled funding acquisition of study. YMJ and H-CL managed data collection and curation.

Conflicts of Interest

None declared.

Abstract

Background: Despite the rapid growth of research in artificial intelligence/machine learning (AI/ML), little is known about how often study results are disclosed years after study completion.

Objective: We aimed to estimate the proportion of AI/ML research that reported results through ClinicalTrials.gov or peer-reviewed publications indexed in PubMed or Scopus.

Methods: Using data from the Clinical Trials Transformation Initiative Aggregate Analysis of ClinicalTrials.gov, we identified studies initiated and completed between January 2010 and December 2023 that contained AI/ML-specific terms in the official title, brief summary, interventions, conditions, detailed descriptions, primary outcomes, or keywords. For 842 completed studies, we searched PubMed and Scopus for publications containing study identifiers and AI/ML-specific terms in relevant fields, such as the title, abstract, and keywords. We calculated disclosure rates within 3 years of study completion and median times to disclosure—from the "primary completion date" to the "results first posted date" on ClinicalTrials.gov or the earliest date of journal publication.

Results: Of 842 completed studies (n=357 interventional; n=485 observational), 5.5% (46/842) disclosed results on ClinicalTrials.gov, 13.9% (117/842) in journal publications, and 17.7% (149/842) through either route within 3 years of completion. Higher disclosure rates were observed for trials: 10.4% (37/357) on ClinicalTrials.gov, 19.3% (69/357) in journal publications, and 26.1% (93/357) through either route. Randomized controlled trials had even higher disclosure rates: 11.3% (23/203) on ClinicalTrials.gov, 24.6% (50/203) in journal publications, and 32% (65/203) through either route. Nevertheless, most study findings (82.3%; 693/842) remained undisclosed 3 years after study completion. Trials using randomization (vs nonrandomized) or masking (vs open label) had higher disclosure rates and shorter times to disclosure. Most trials (85%; 305/357) had sample sizes of ≤1000, yet larger trials (n>1000) had higher publication rates (30.8%; 16/52) than smaller trials (n≤1000) (17.4%; 53/305). Hospitals (12.4%; 42/340), academia (15.1%; 39/259), and industry (13.7%; 20/146) published the most. High-income countries accounted for 82.4% (89/108) of all published studies. Of studies with disclosed results, the median times to report through ClinicalTrials.gov and in journal publications were 505 days (IQR 399-676) and 407 days (IQR 257-674), respectively. Open-label trials were common (60%; 214/357). Single-center designs were prevalent in both trials (83.3%; 290/348) and observational studies (82.3%; 377/458).

Conclusions: For over 80% of AI/ML studies completed during 2010-2023, study findings remained undisclosed even 3 years after study completion, raising questions about the representativeness of publicly available evidence. While methodological rigor

XSL•FO
RenderX

was generally associated with higher publication rates, the predominance of single-center designs and high-income countries may limit the generalizability of the results currently accessible.

Introduction

The number of studies on artificial intelligence/machine learning (AI/ML) has surged in recent years, exceeding prior expectations [1]. The growth of AI/ML research in health care continues to gain momentum, driven by its potential to enable early detection of serious conditions in resource-constrained settings or facilitate timely identification of patient deterioration that might otherwise go unnoticed, to name a few. However, publicly available data are highly heterogeneous, including promotional claims, forward-looking statements, white papers, and preprints. It is often unclear what data underpin the claims made for AI/ML tools, whether regulated, nonregulated, or nonproprietary.

Weak publication records in AI/ML research have been highlighted [2,3], and even when AI/ML research results are available in peer-reviewed journals, they were found to be poorly reported [4,5]; lacking transparency, hindering replicability [6]; involving "spin" and hype by overinflating models' predictive abilities [7]; or being at high risk of bias [8,9]. These challenges complicate the interpretation of published results and make it difficult to determine whether new findings ultimately provide tangible benefits to patients.

As AI/ML research continues to proliferate, so do systematic reviews and meta-analyses, which presuppose "all relevant evidence" as their foundation. However, this principle is undermined when underreporting is pervasive. Underreporting can lead to biased effect estimates and compromise the diagnostic or prognostic performance of AI/ML, on which clinical decision-making depends. After all, systematic reviews can only reflect the results accessible—a portion of the total research conducted. Lock and Wells [10] have deemed underreporting of research a form of both scientific and ethical misconduct, as it not only leads to biased and imprecise effect estimates but also breaches implied contracts with study participants, who contribute with the expectation of advancing knowledge [11].

The underreporting of clinical trial results has been well documented, long before the emergence of AI/ML. For example, a 2003 study in Spain revealed that fewer than one-third (31%; 38/123) of clinical trials approved by an ethics committee at a major hospital had results published in peer-reviewed journals within 3 years of study completion [12]. Numerous studies using the ClinicalTrials.gov database have provided further evidence since [13-19]. This enables us to compare the disclosure rates of AI/ML trials with those previously reported for non-AI/ML trials registered on ClinicalTrials.gov.

Finally, AI's impact on health equity is also extensively debated. Some argue that access to the very factors driving AI in health care, such as electronic health records and computing power, may exacerbate existing health care disparities and perpetuate inequities in who benefits most from AI [20]. Certain population groups—demographic, geographic, or economic —can be disproportionately overrepresented in clinical AI/ML research.

This study examines (1) the proportion and patterns of public disclosure of AI/ML research results through ClinicalTrials.gov and peer-reviewed publications indexed in PubMed or Scopus, and (2) whether disclosure rates vary according to key study characteristics, including those related to population representation, such as geographic region and gross national income.

Methods

Data Source

We used ClinicalTrials.gov, a trial registry and results database, and sourced data from the Clinical Trials Transformation Initiative Aggregate Analysis of ClinicalTrials.gov (CTTI AACT) [21], which allows open access to the complete set of studies registered in ClinicalTrials.gov, including additional fields that are not readily available in direct exports from ClinicalTrials.gov. The CTTI AACT data dictionary is publicly accessible [22]. A static version of the CTTI AACT database was downloaded for analysis on February 6, 2024, via PostgreSQL, as previously described [23]. We identified studies that initiated and completed between January 2010 and December 2023 and contained AI/ML-specific terms in the official title, detailed description, brief summary, interventions, conditions, primary outcomes, and keywords. These terms could have appeared in studies where AI/ML was used either as an intervention or a method. A total of 842 AI/ML studies were completed by the end of 2023. The search strategies are provided in Multimedia Appendix 1, Table S1. The study flow diagram is provided in Multimedia Appendix 2, Figure S1. Detailed methods on data extraction, including SQL codes, are available in Multimedia Appendix 3.

AI/ML Publications Linked to ClinicalTrials.gov Identifiers (NCT Numbers)

NCT numbers are unique study identifiers assigned by ClinicalTrials.gov. To identify studies with corresponding journal publications, we searched PubMed and Scopus for these identifiers using each database's application programming interface (API). In PubMed, we searched for NCT numbers in the titles, abstracts, and "trial registration" fields, while in Scopus, we searched the titles and abstracts. Additionally, we

XSL•FO
RenderX

accessed "publication" data on ClinicalTrials.gov using the "reference_type" field in the AACT database. Details on the APIs used for PubMed and Scopus are provided in Multimedia Appendix 3.

Since multiple publications may exist under the same NCT, and not all are related to AI/ML, we included only those that contained AI/ML-specific terms in the title, abstract, keywords, or Medical Subject Headings (MeSH) fields in PubMed. In Scopus, AI/ML terms were searched in the titles and abstracts.

To capture articles likely to be the direct study output, we excluded nonrelevant article types (eg, protocols, reviews, meta-analyses) and those published before primary completion dates. ClinicalTrials.gov defines the primary completion date as the date on which data collection is completed for all primary outcomes [24].

Main Outcomes and Measures

After identifying eligible articles, we determined the proportion of AI/ML studies that disclosed results within 3 years of the primary completion date, either on ClinicalTrials.gov or in journal publications (the number of studies with disclosed results divided by the number of completed studies). We focused on disclosures via ClinicalTrials.gov or peer-reviewed publications (not preprints), as these are typically searched for systematic reviews and meta-analyses.

For studies with disclosed results, we also calculated the median time from the primary completion date to the disclosure date along with the IQR. The disclosure date was defined as either the "results first posted date" recorded on ClinicalTrials.gov or the date of the earliest journal publication linked to the NCT. If a study had multiple publications, only the earliest publication date was used. Each NCT with at least one publication was counted as disclosed.

All variables were derived from ClinicalTrials.gov. The variable on countries (study location) was categorized according to the World Bank's gross national income–based classification: low income (≤US $1135), lower-middle income (US $1136 to $4465), upper-middle income (US $4466 to $13,845), or high income (≥US $13,846) [25]. On lead sponsor, those labeled "other" were reassigned into hospital/clinic, academia, industry, government, and nonprofit organization based on lead sponsor names.

Details on the data extraction are provided in Multimedia Appendix 3.

Statistical Analysis

Data were summarized descriptively: count, percentage, and the median with the IQR. Categorical variables are presented as counts and percentages within 3 years of the primary completion date. Tabulations exclude missing values (ie, n=842 if a variable had no missing values).

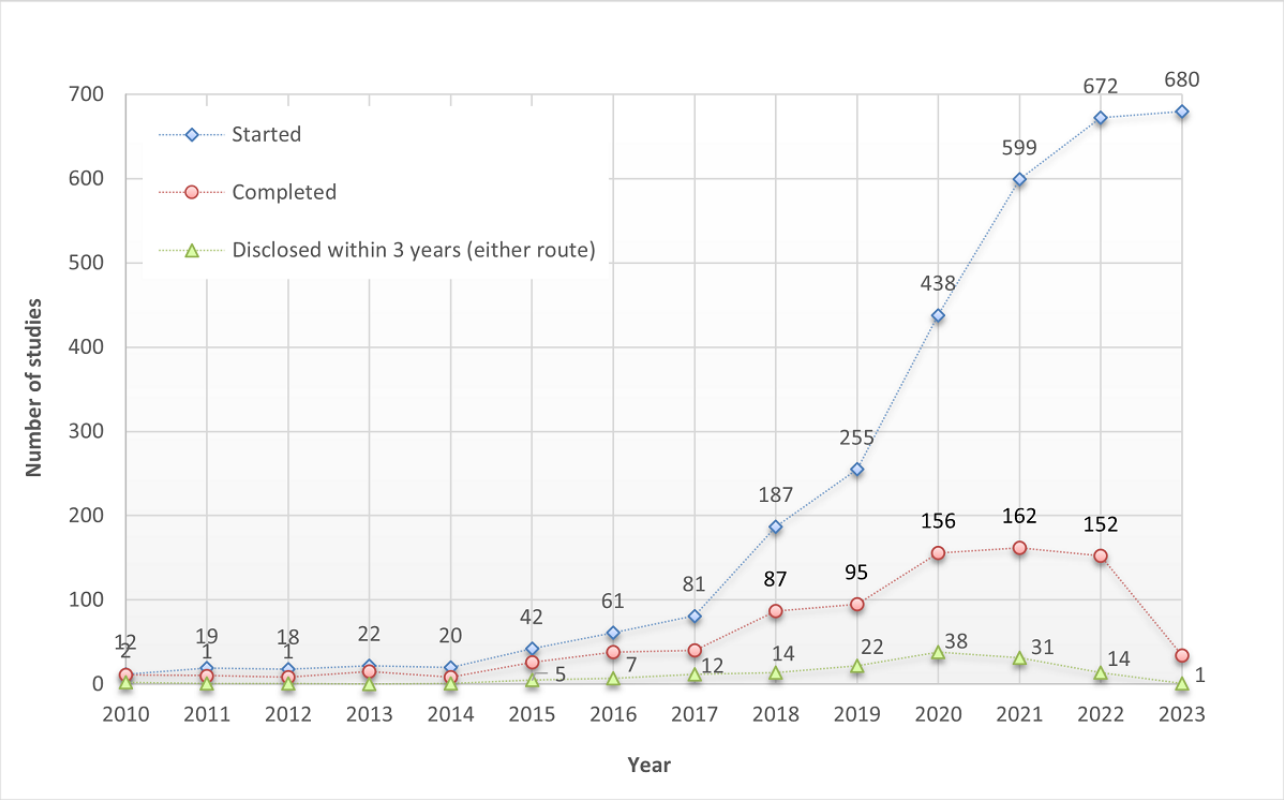
Ethics Approval and Reporting Guidelines

Ethics approval was not required for this study because only publicly available data were analyzed. This study followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guidelines [26].

Results

Overview of Completed Studies on AI/ML

Of 842 completed studies (n=357 interventional; n=485 observational), only 5.5% (46/842) disclosed results on ClinicalTrials.gov, 13.9% (117/842) in journal publications, and 17.7% (149/842) through either route within 3 years of completion (Multimedia Appendix 2, Figure S1).



The disclosure rates were higher among trials only: 10.4% (37/357) on ClinicalTrials.gov, 19.3% (69/357) in journal publications, and 26.1% (93/357) through either route. Rates among randomized controlled trials (RCTs) were even higher: 11.3% (23/203) on ClinicalTrials.gov, 24.6% (50/203) in journal publications, and 32% (65/203) through either route.

Among studies with disclosed results, the median reporting times were 505 days (IQR 399-676) on ClinicalTrials.gov and 407 days (IQR 257-674) in journal publications.

Figure 1 shows the trend in studies started each year, completed studies, and studies that reported results within 3 years of study completion. Despite a surge in new studies each year, studies that disclosed results through either route remained scarce.

XSL•FO
RenderX

Figure 1. Studies initiated ("started"), studies completed ("completed"), and completed studies with results reported either on ClinicalTrials.gov or in journal publications within 3 years of completion ("disclosed within 3 years"). Despite a surge in new studies each year, the number of studies reporting results through either route remained scarce.

Result Disclosure Rates and Time to Disclosure by Study Characteristics

Table 1 shows reporting rates stratified by the primary completion year. The reporting rates on ClinicalTrials.gov remained low over time. However, from 2018 to 2020, there was a modest increase in publication rates within 3 years of completion, and the median time to publication decreased from approximately 2 years (723 days) to 1 year (385 days). The IQR also decreased from 1166 days in 2018 to 279 in 2020. Before 2018, there were too few AI/ML publications to allow meaningful interpretation, and 2021-2023 was not assessable because the 3-year grace period had not passed as of our data cutoff on December 31, 2023.

Table 2 presents disclosure rates and times stratified by various study characteristics.

Disclosure rates and their timing varied by study design and setting (Table 2), as summarized below.

[a]CTG: ClinicalTrials.gov.

[b]Time to results reporting (posting on CTG or in journal publications) also includes those reported after 3 years.

[c]Not applicable.

[d]Time perspective: data available only for observational studies.

[e]FDA: Food and Drug Administration.

[f]Gross national income–based classification as per the World Bank.

Interventional Studies (vs Observational)

Trials accounted for 42.4% (357/842) of completed studies; they had higher publication rates (19.3% vs 9.9%) and posted results on ClinicalTrials.gov more often (10.4% vs 1.9%), with shorter times to disclosure than observational studies.

Randomization

RCTs accounted for 56.9% (203/357) of completed trials and had higher publication rates than non-RCTs (24.6% vs 12.3%). However, non-RCTs posted results on ClinicalTrials.gov more often than RCTs (24% vs 11.3%). RCTs reached publication sooner than non-RCTs (357 vs 549 days).

Masking

Open-label trials were the most common (59.9%; 214/357), followed by single-blind (21.3%; 76/357) and double-blind or higher (18.8%; 67/357) designs. Single-blind trials (21.1%; 16/76), as well as double-, triple-, or quadruple-blinded trials combined (23.9%; 16/67) had higher publication rates and reached publication sooner than open-label trials (17.3%; 37/214).

Single Center (vs Multicenter)

Single-center designs dominated both trials (83.3%; 290/348) and observational studies (82.3%; 377/458). The disclosure rates did not vary substantially between single-center and multicenter studies.

Enrollment

Most trials (85%; 305/357) had sample sizes of ≤1000, yet larger trials (n>1000) had higher publication rates (30.8%; 16/52) than smaller trials (n≤1000) (17.4%; 53/305). However, among observational studies, larger studies (n>1000) had slightly lower publication rates (7.5%; 10/134) than smaller studies (10.8%; 38/351).

Time Perspective (Observational Studies Only)

Nearly half of observational studies used prospective designs (49.8%; 233/468), followed by retrospective designs (35%;

XSL•FO
RenderX

164/468). Prospective studies had slightly higher publication rates (10.7%; 25/233) and reached publication sooner (386 days) than retrospective studies (8.5%; 14/164; 457 days).

Lead Sponsor

The majority of studies were sponsored by hospitals (40.4%; 340/842) and academia (30.8%; 259/842). The most published sponsors were hospitals (12.4%; 42/340), academia (15.1%; 39/259), and industry (13.7%; 20/146), but the percentages were slightly higher for studies sponsored by governments (16.7%; 3/18) or nonprofit organizations (18.2%; 8/44), albeit with small event numbers.

Primary Study Purpose

Diagnostic (31.9%; 95/298) and treatment (23.2%; 69/298) were the most common study purposes. Publication rates were highest for diagnostic (25.3%; 24/95) and health services research (28.6%; 8/28). Prevention studies were more frequently reported on ClinicalTrials.gov (24.1%; 7/29) than in journal publications (17.2%; 5/29). Prevention studies reached publication sooner (188 days) than health services research (293 days), treatment research (349 days), and diagnostic studies (430 days).

Study Locations (Geographic and Economic)

The majority of completed studies were conducted in Europe (37.1%; 299/806); North America (29.2%; 235/806); or the Asia-Pacific (23.8%; 192/806). When categorized by national income level, most studies were conducted in high-income countries (79%; 613/775), followed by upper-middle-income (18%; 139/775) and lower-middle-income (3%; 23/775) countries, and none in low-income countries. Publication rates were also highest in Europe, North America, Asia, and high-income countries, followed by upper-middle-income countries. Finally, 82.4% (89/108) of studies with corresponding publications were conducted in high-income countries.

Regulatory Status

Only 7% (59/842) of completed studies were “FDA-regulated,” while 72.9% (614/842) did not involve US sites. FDA-regulated studies had higher publication rates than non-RCTs (23.7% vs 13.2%). FDA-regulated studies (vs nonregulated) and those with a US site (vs no US site) were more likely to post results on ClinicalTrials.gov.

Discussion

The proliferation of AI/ML research continues, accompanied by a rise in systematic reviews. However, such reviews can capture only the published portion of all relevant evidence. In this cross-sectional analysis of 842 AI/ML studies completed during 2010-2023, we quantified the extent of results that remain undisclosed years after completion.

Principal Findings

First, despite a surge in new AI/ML studies each year, most study findings remained undisclosed even 3 years after study completion, which is more lenient than the 2-year grace period used elsewhere [13,14]. Of 842 completed studies, only 17.7% (149/842) disclosed results through either route within 3 years, although rates were somewhat higher among trials (26.1%; 93/357) and RCTs (32%; 65/203).

Second, study features of greater methodological or logistical rigor—such as interventional (vs observational), randomization (vs nonrandomized), masking (vs open label), and larger sample sizes (>1000 vs ≤1000) *in trials*—had higher disclosure rates with shorter median reporting times through either dissemination route. However, multicenter status had no discernible impact. Less rigorous features, such as single-center designs (82.8%; 667/806) and open-label trials (60%; 214/357), were prevalent.

Finally, most published studies were from high-income countries (82.4%; 89/108).

Comparison With Previous Work

AI/ML Trials Versus Non-AI/ML Trials Registered on ClinicalTrials.gov

To compare results with those of previous research on trials registered on ClinicalTrials.gov, a trial-only subgroup was used. Among the 357 trials, the disclosure rate through either route within 3 years of completion was 26.1% (93/357). This rate was notably lower than that for non-AI/ML settings: oncology trials (60.7%; 7425/12,240 within 2 years) [13], pharmaceutical and biopharmaceutical phase II-IV efficacy trials (25.2%; 3822/15,084 within 1 year) [18], National Institutes of Health–funded trials (46.3%; 294/635 within 30 months) [15], completed trials (45.9%; 311/677 within 2 years) [19], trials by US-based academic medical centers (35.9%; 1560/4347 within 2 years) [14], phase III-IV RCTs of drug interventions (50%; 297/594) [16], and trials approved by a hospital ethics committee in Spain (31%; 38/123 within 3 years). Our 3-year disclosure rate (26.1%; 93/357), equivalent to roughly 8.7% per year, was also lower than the 1-year rate for mobile health trials (18.5%; 25/135) [27].

Several factors could explain the lower publication rates. First, for the non-AI/ML trials cited above, registration and result disclosure may have been mandatory (eg, regulated, publicly funded, efficacy trials), unlike much of digital health research [28]. Second, the rarity of efficacy studies in AI/ML research to date may play a role, as exploratory or formative research may be deemed less publishable. Even so, however, summary results (objective data) can still be posted on ClinicalTrials.gov, making otherwise unpublishable results accessible. Third, the lack of reporting standards for AI/ML studies is another factor. However, a range of AI/ML-specific tools now exist, such as the Checklist for Artificial Intelligence in Medical Imaging (CLAIM) 2024 Update [29] and the Consolidated Reporting Guidelines for Machine Learning Modeling Studies [30]. Fourth, preprint servers are widely used in computer science, reflecting the field’s emphasis on speed, openness, and adaptability. If preprints are considered sufficient—particularly when validated through reputable conferences—the urgency for peer-reviewed publication may be lower within the AI community. As a form of sensitivity analysis, we assessed the use of preprints in AI/ML studies registered on ClinicalTrials.gov by searching arXiv, bioRxiv, Research Square, medRxiv, SSRN, and PsyArXiv. We identified only 14 preprints linked to NCT numbers; of these, 6 were subsequently published in journals (already

XSL•FO
RenderX

captured in our findings), while the remaining 8 were available only as preprints. That is, among the 693 completed studies with no disclosed results, just 1.2% (8/693) had NCT-matched preprints. Thus, even if preprints were considered as an additional dissemination route, the overall disclosure rate would increase only marginally to 18.6% (157/842), compared to the base case of 17.7% (149/842), which does little to explain the low publication rates.

Trial Designs

Previous research in non-AI/ML settings (mostly drugs or biomedical) indicated that trials using randomization, masking, larger sample sizes, or multicenter designs were more likely to be published [13,31,32]. Our findings align with these patterns—except for multicenter status. Although methodological rigor was generally associated with higher publishability, less rigorous features—such as single-center (83.3%; 290/348) or open-label designs (60%; 214/357)—were common among the AI/ML trials. Notably, single-center designs predominated in both trials (83.3%; 290/348) and observational studies (82.3%; 377/458). This pattern was consistent with recent systematic reviews of RCTs on AI, where single-center designs accounted for 62.8% (54/86) [33,34] and 59% (23/39) [34].

The Distribution of Studies by Economic Status

According to scoping reviews on AI publications in health care, high-income countries accounted for 73.3% (33/45) of articles published in 2011-2022 [35] as well as 94.5% (240/254) and 93.3% (235/251) of those published in 2019 [20]. In our data, 82.4% (89/108) of the studies with publications from 2010-2023 were from high-income countries, and 14.8% (16/108) were from upper-middle-income countries, most of which were from China (88%; 14/16). That is, high-income countries and China accounted for 95.4% (103/108) of studies with published results. Despite differences in data sources and methodologies, high-income countries were consistently overrepresented across studies.

Broader Implications of the Study

AI/ML is increasingly being evaluated both as an intervention and as a decision-support tool for clinicians. Yet, in our sample, findings from over 80% of completed studies remained undisclosed even after 3 years, raising concerns about representativeness in systematic reviews or meta-analyses. Reviews that rely on skewed samples of favorable results—excluding null or negative findings, mostly from single-center data—could risk overestimating the effects attributed to AI/ML. This issue may be addressed, in part, by leveraging public registries to improve access to unpublished results. Searching trial registries, such as ClinicalTrials.gov, has been strongly recommended for comprehensive systematic reviews and is mandatory for best-practice Cochrane reviews [36]. This may help reduce publication bias and research waste. To this end, we advocate for broader use of the "results database" feature of public registries and the posting of summary results, even when submission is not mandatory.

The predominance of single-center data and studies from high-income countries has further implications, potentially contributing to existing health inequities. This underscores the need for external validation in diverse populations, especially for models built with single-center data [35]. However, the predominance of single-center designs, along with the shortage or inadequacy of external validation [23,37-39], could be a reflection of what is known as the reproducibility crisis [40-45]. AI researchers face intense pressure to publish quickly, with numerous papers posted daily on arXiv without peer review, and many are reluctant to report failed replications [43]. Unpublished code and sensitivity to training conditions make it difficult, if not impossible, to verify claimed performance [42,46-48]. Notably, papers that fail to replicate are cited at the same rate as those that are successfully replicated, leading to future work being built upon irreproducible results [44,49]. A 2018 study found that only 6% of research presented at top AI conferences explicitly identified research questions being addressed, and just 5% specified hypotheses being tested [40]. Clearly, significant challenges exist even before introducing the added complexities of multicenter studies, which involve substantial clustering (eg, across multiple centers, regions, or countries) and require more rigorous design, analysis, and reporting methods compared to standard prediction model studies [50].

Finally, publishability could improve through the wider adoption of AI/ML-specific reporting guidelines and checklists [51], including those that emphasize critical yet often undocumented details, such as computational reproducibility, data preprocessing, and mitigation of data leakage [41]. Although improved transparency through standardized reporting is the responsibility of authors, guidance such as the REFORMS: Consensus-based Recommendations for Machine-learning-based Science [41] is designed to inform all stakeholders, including readers, about best practices. All the transparency in the field will not suffice unless informed community members critically engage with the key dimensions intrinsic to AI/ML that must be addressed. As preprints gain wider visibility, the role of community literacy will grow increasingly important.

Limitations

First, to identify relevant publications, we searched for study identifiers (NCT numbers) in the title, abstract, and "trial registration" fields in PubMed, while in Scopus, we searched the title and abstract fields. Some publications may have been missed if the NCT was mentioned outside these fields. However, the International Committee of Medical Journal Editors [52] recommends listing the trial registration number at the end of the abstract, and we assumed compliance with this. We think that this was a reasonable assumption, given that publications mentioning NCTs outside abstracts tended to be cited by others or related in some way rather than being direct research outputs.

Second, we searched for publications only for studies marked "completed." We may have missed studies with relevant publications if there were delays by sponsors in updating the study status on ClinicalTrials.gov. Nevertheless, this approach also ensured that we captured publications that were likely to be the direct study output. To mitigate this potential misclassification, however, we delayed the data export until February 6, 2024, despite the data cutoff being December 31,

XSL•FO
RenderX

2023. As for publications, we searched PubMed and Scopus on February 12, 2024, allowing 6 weeks after the data cutoff to account for indexing lag time.

Third, information on the study phase may influence the extent of public disclosure of results. However, it was mostly missing (98%; 826/842), and we were unable to use it as a stratifying variable.

Conclusion

For over 80% of AI/ML studies completed during 2010-2023, study findings remained undisclosed even 3 years after study completion, raising questions about the representativeness of publicly available evidence.

While methodological rigor was generally associated with higher publication rates, the predominance of single-center designs and high-income countries may limit the generalizability of the results that are currently accessible.

Abstract

Background: Intraoperative neurophysiological monitoring (IONM) guides the surgeon in ensuring motor pathway integrity during high-risk neurosurgical and orthopedic procedures. Although motor-evoked potentials (MEPs) are valuable for predicting motor outcomes, the key features of predictive signals are not well understood, and standardized warning criteria are lacking. Developing a muscle identification prediction model could increase patient safety while allowing the exploration of relevant features for the task.

Objective: The aim of this study is to expand the development of machine learning (ML) methods for muscle classification and evaluate them in a bicentric setup. Further, we aim to identify key features of MEP signals that contribute to accurate muscle classification using explainable artificial intelligence (XAI) techniques.

Methods: This study used ML and deep learning models, specifically random forest (RF) classifiers and convolutional neural networks (CNNs), to classify MEP signals from routine supratentorial neurosurgical procedures from two medical centers according to muscle identity of four muscles (extensor digitorum, abductor pollicis brevis, tibialis anterior, and abductor hallucis). The algorithms were trained and validated on a total of 36,992 MEPs from 151 surgeries in one center, and they were tested on 24,298 MEPs from 58 surgeries from the other center. Depending on the algorithm, time-series, feature-engineered, and time-frequency representations of the MEP data were used. XAI techniques, specifically Shapley Additive Explanation (SHAP) values and gradient class activation maps (Grad-CAM), were implemented to identify important signal features.

Results: High classification accuracy was achieved with the RF classifier, reaching 87.9% accuracy on the validation set and 80% accuracy on the test set. The 1D- and 2D-CNNs demonstrated comparably strong performance. Our XAI findings indicate that frequency components and peak latencies are crucial for accurate MEP classification, providing insights that could inform intraoperative warning criteria.

Conclusions: This study demonstrates the effectiveness of ML techniques and the importance of XAI in enhancing trust in and reliability of artificial intelligence–driven IONM applications. Further, it may help to identify new intrinsic features of MEP signals so far overlooked in conventional warning criteria. By reducing the risk of muscle mislabeling and by providing the basis for possible new warning criteria, this study may help to increase patient safety during surgical procedures.

Introduction

The importance of intraoperative neurophysiological monitoring (IONM) during high-risk neurosurgical and orthopedic procedures has been established in recent decades [1]. In particular, the monitoring of motor evoked potentials (MEPs) helps to assess the functional integrity of motor pathways during surgeries and allows postoperative motor outcomes to be predicted [2-9]. However, the features of this complex signal that contribute to its predictive potential are still poorly understood and there are few standardized warning criteria to alert the surgeon. Currently, the best-established and most reliable MEP warning criterion during IONM is a 50% drop in amplitude [10].

Because changes in MEP amplitude are predictive of postoperative motor outcome, it is natural to ask whether other properties of the signals could be important for decision-making. The emergence of machine learning (ML) methods has led to an interest in leveraging these techniques to classify MEPs in the hope of improving intraoperative decision-making [11,12]. However, most of the studies so far have focused on identifying the most accurate and robust ML algorithms rather than on uncovering the underlying patterns leading to the decisions.

In our previous work, we established prediction algorithms for muscle identification to provide a proof of principle within a solid ground truth framework before translating them to outcome predictions [12]. Meanwhile, Boaro et al [13] implemented a similar classification task with additional ML models and muscles. The robustness of ML algorithms on clinical data needs to be established using independent data sources, which is why we have expanded our data set to include signals from an external validation center.

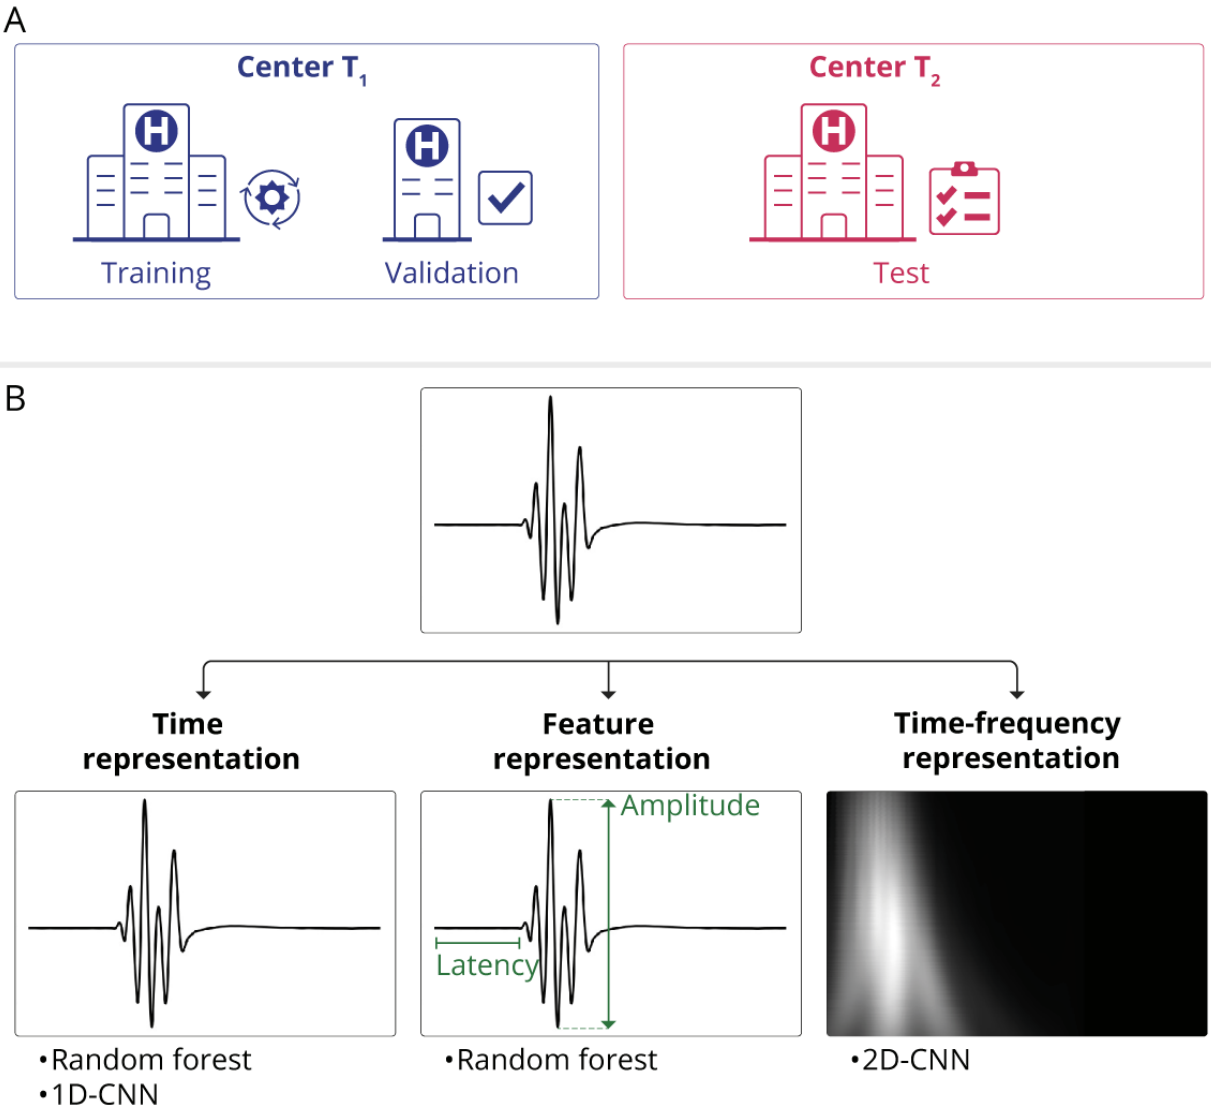
To gain a deeper understanding of our signals, we investigated them in both the time-series and time-frequency domains, which have been shown to be useful in the quantification of disease-related MEP changes [14]. In addition to the standard ML models, we used deep learning methods to leverage their power of internal feature representation. Although these algorithms can accurately predict the identity of muscles based on MEP signals, the specific criteria that these algorithms use to make their predictions are not well understood [15-17]. For research in the field of IONM, this explanatory information is probably at least as important as the predictions themselves, as it can provide new insights into the mechanisms of neurophysiological changes. For this reason, we used methods from the emerging field of explainable artificial intelligence (XAI) [18,19]. The aim was to combine methods to ensure comprehensive interpretability of our different models' decisions.

Our study provides a robust framework for classifying MEPs recorded in routine neurosurgical procedures according to their muscle identity with high accuracy and we validated the methods using data from two independent study centers. Importantly, we elucidate the decision-making processes of our ML models through post hoc analyses, thereby enabling their effective application to previously unseen data and novel situations. These algorithms could act as a safety mechanism in the operating room by detecting mislabeling of muscles and by focusing on new intrinsic features of MEPs. Thus, they may enhance the usage and acceptance of artificial intelligence (AI) in medical decision-making through their interpretability.

Methods

Ethical Considerations

This retrospective study was approved by the cantonal ethics committee of Bern, Switzerland (BASEC-ID 2023–00277). All included patients gave their informed written consent for further use and publication of their anonymized data. The routinely collected data are dated from 2018 to 2022 and coded for the analysis of this paper. Only patients over the age of 18 were included in the study, all received neurosurgical interventions and were not stratified according to their clinical outcome since the outcome prediction of the study was muscle identification. The muscle recordings are set routinely independent of sociodemographic or clinical factors.



In the following, we describe the datasets collected, the preselection approach applied to the data, the methods used for signal data representation, and the analytical techniques used, including XAI approaches to elucidate MEP feature importance.

MEP Data and Signal Recordings

The MEP data used in this study were obtained during routine neurosurgical procedures and were retrospectively collected and analyzed. This study was exploratory in nature, and no formal protocol was prepared. Recordings from 151 surgeries on 144 patients at one center (Inselspital, University Hospital Bern, Switzerland), "center T_1" were used for training and validation, and recordings from 58 surgeries on 57 patients at an independent center (Cantonal Hospital in Lucerne, Switzerland), "center T_2" were used for testing (see Figure 1A). In total, there were 94 females and 107 males and the median age at surgery was 61 years (see Table 1 for distribution between centers). Overall, 182 patients underwent surgery for a brain tumor and 19 for vascular pathologies. The total number of MEP signals was 36,992 for center T_1 and 24,298 for center T_2, with at least 3000 samples for each predicted class (see Table 1 for detailed information on classes). This sample size was determined by the number of routine interventions and ensures that any complexity of the ML models used can appropriately be trained, tested, and validated.

Figure 1. Data analysis pipeline. (A) Bicentric training, validation, and testing setup. (B) Data representation and the algorithms used on each representation. CNN: convolutional neural network.

IONM was performed according to a standardized protocol, as previously described [8,20]. The MEPs were elicited either through transcranial electric stimulation (TES) via corkscrew electrodes or direct cortical stimulation (DCS) via strip electrodes placed directly on the cortex and recorded via needle electrodes in the muscle belly. Stimulation to elicit MEPs was conducted under general anesthesia using a train of 5 anodal stimuli with a pulse duration of 0.5 milliseconds, and an interstimulus interval of 4 milliseconds, known as the short train method. Both centers used ISIS Systems to record the MEPs. The sampling frequency was set at 20 kHz, with hardware high- and low-pass filters at 30 Hz and 5 kHz, respectively. TES was used in all the surgeries performed in center T_1 and in 95% (55 of 58) of those performed in center T_2 to elicit MEPs. In addition, DCS was used to elicit MEPs in 134 of the 151 (89%) surgeries performed in center T_1 and 17 of 58 (30%) surgeries performed in center T_2. The recordings consist of 2000 data points, corresponding to 100-millisecond windows for each signal. We selected MEP signals from the following 4 muscles: Extensor digitorum (EXT), abductor pollicis brevis (APB), tibialis anterior (TA), and abductor hallucis (AH). These muscles are routinely monitored during supratentorial surgeries, and the corresponding signals were available for most of the included patients from both sides. As the neurophysiologist labels the recording channels at the start of the surgery, the MEP data are automatically labeled upon saving.

We used custom-made Python 3.0 scripts for all the data analysis and classification tasks.

Preprocessing and Data Representation

Preselection

An automatic MEP selection algorithm was written to determine whether a given recording contained an MEP [12]. To remove stimulation artifacts from the train of 5, we excluded the first 400 data points (corresponding to 20 milliseconds). Then, two features were computed: the onset latency and duration of the signal. Onset latency is defined as 1 millisecond (empirically determined) before the trace crosses the mean of the baseline (the last 5 milliseconds of the recording) plus or minus the SD of the entire recording. The end of the signal was calculated similarly, by starting from the end of the recording. We defined the duration as the end of signal latency minus onset latency. In addition, the time interval between the first and last peak was determined using the scipy.signal function find_peaks. A recording was considered to contain an MEP if at least one peak was detected, the duration was less than 40 milliseconds, and the interval from the first to last peak was less than 35 milliseconds (in accordance with clinical experience).

In our analysis pipeline, we used three distinct representations of MEP data (see Figure 1B): time, feature, and time-frequency, each tailored to optimize the performance of our ML classifiers.

Time Representation

A finite-impulse response bandpass filter with 30- and 1000-Hz cutoff frequencies was applied to the 1600-dimensional signal vector. These frequency settings align with MEP visualization practices using the monitoring machine at center T_1 (ie, the software filters). The signal vectors are then normalized with respect to the absolute maximum MEP value in each patient. This filtered and normalized time representation of the data was used to train, validate, and test a random forest (RF) classifier, as well as a 1-dimensional convolutional neural network (1D-CNN).

Feature Representation

We used a customized feature extraction algorithm to condense each filtered and normalized MEP signal into characteristic features. The initial choice of predictors is a combination of clinically used predictors (eg, latency, amplitude, minimum, and maximum) and routinely used features in general neurophysiological literature (spectral entropy, frequency, etc). After a correlation analysis (see Multimedia Appendix 1), we chose five features that showed no correlation describing relevant domains of the signal: peak latency, maximum signal value, number of peaks, main frequency, and slope.

Peak values were extracted with the scipy find_peaks function with peak prominence defined as twice the SD of the signal. The main frequency was calculated as the frequency at which the Fourier transform of the filtered data attained its maximum absolute value. Finally, the slope of the signal was computed as the mean of the first derivative of the signal (using the NumPy function gradient). The resulting 5-dimensional feature representation of the data was then used to train, validate, and test a RF classifier.

Time-Frequency Representation

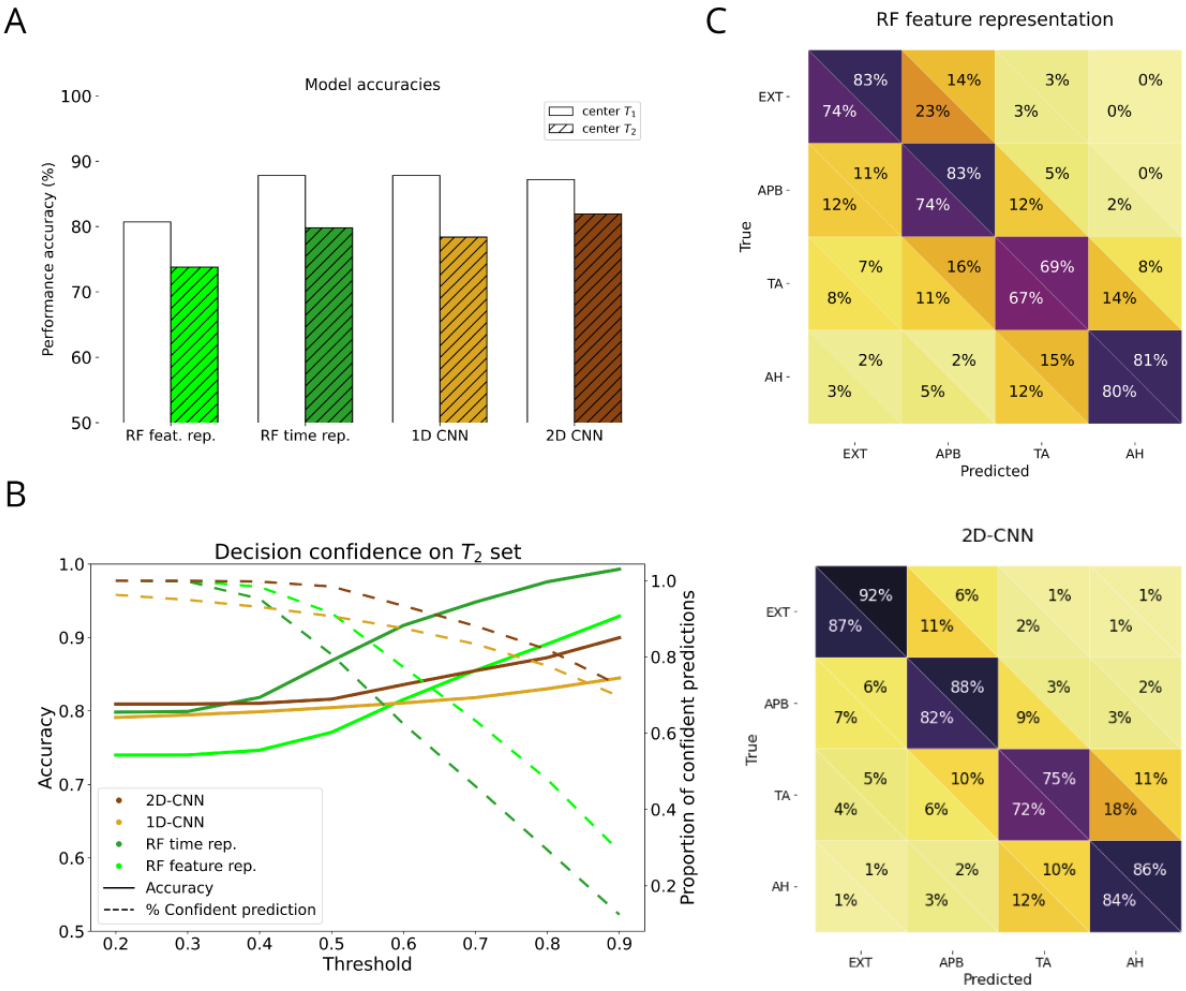
Finally, employing the Python library PyWavelets (pywt), a continuous wavelet transform with a Mexican hat mother wavelet was applied to the data to transform them into 2D time-frequency representations. Scales ranging from 2 to 30 were logarithmically spaced, while the time dimension was undersampled to yield an array of dimensions 224×224. These 2D time-frequency representations were then used to train, validate, and test a 2D-CNN.

Statistical Testing

Using custom Python scripts, Student *t* tests were applied to compare the mean values of two different features. Specifically, for each muscle, the means of the different features were compared across the two centers. Statistical significance was set at P=.05.

Machine and Deep Learning Pipeline

The Python library scikit-learn [21] was used for the RF classifier, while tensorflow [22] and keras [23] were used to obtain the 1D- and 2D-CNN models. Hyperparameter tuning was carried out for the RF and 1D-CNN, while we used fixed parameters for the 2D-CNN (see below). The hyperparameters used in the grid search of the RF are the same as described in Multimedia Appendix 1. The architecture of our 1D-CNN is inspired by the model of Ahmed et al [24], and consists of two consecutive 1D convolutional layers, followed by a MaxPooling layer, a dropout layer, and a BatchNormalization layer. The model then gets flattened, before adding a dense layer and another dropout layer and finally ending in a dense output layer. The structure of our 2D-CNN is inspired by the model of Wang et al [25]. It consists of 4 blocks of 2D convolutional layers followed by BatchNormalization layers, with a MaxPooling layer after the second and third blocks and a GlobalMaxPooling layer after the fourth block. The model is capped off by a dense output layer. The specifics of these models are shown in Multimedia Appendix 1.



The dataset from Center T_1 was split into 70% for training and 30% for validation (stratified according to patients), while the whole of the dataset from Center T_2 was used for testing. In all cases, we used class weighting [26] to deal with the class imbalance problem (ie, the number of leg muscle MEPs is lower than the number of arm muscle MEPs, see Wermelinger et al [12] for a discussion of this issue).

Model Output and Outcome

All prediction models output probabilities of belonging to the predicted class. The decision thresholds were set at a chance level of 0.25 (likelihood of belonging to 1 of 4 classes of muscles). They were systematically explored and reported (see Figure 2B) for decision thresholds up to 0.9.

XSL•FO
RenderX

Figure 2. Classification results and confidence. (A) Validation accuracy (center T1, white) and test accuracy (center T2, colored) of all models. (B) Decision confidence. Solid lines are the accuracies (left y-axis) of the various models for different confidence thresholds. The dashed lines show the proportion of data with these confidences (right y-axis). RFs have a higher increase in accuracy compared with CNNs but at a higher data cost. (C) Bicentric confusion matrices: lower triangle (center T2), upper triangle (center T1) for both RF on feature representation (top) and 2D-CNN (bottom). The RF is slightly more congruent across centers than the 2D-CNN. CNN: convolutional neural network; RF: random forest.

Accuracy was used as the primary performance metric, and the confusion matrix was used to evaluate the performance of the classification algorithm. The outcome assessment does not require subjective interpretation, since the muscle identity is objectively assessable, independent of sociodemographic background and clinical outcome.

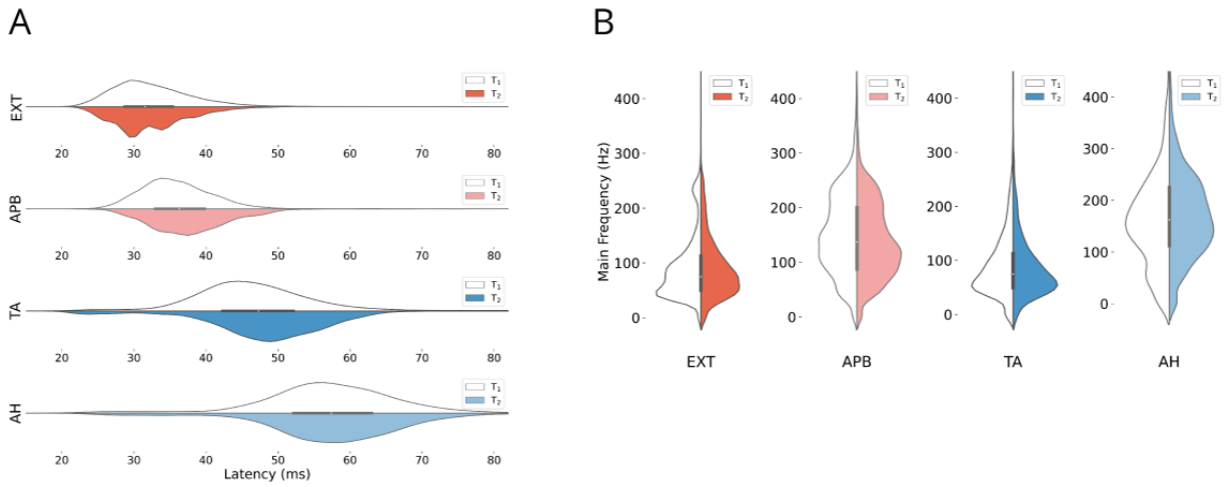
No model updating or recalibration was performed during the model evaluation. While some variability in model performance was observed across different centers (Figure 2), we opted to retain the original model without adjustments. Future work may explore model updating to enhance performance in these areas.

Explainability

To elucidate how the RF classifiers made their decisions, we used feature importance and Shapley Additive Explanation (SHAP) values. Feature importance values are provided by the feature_importances_ attribute of the scikit-learn RandomForestClassifier class, while the SHAP values are calculated with the SHAP library [27]. The feature importance values are determined by aggregating (mean and SD) the impurity decrease within each decision tree. SHAP values quantify the impact of each feature on prediction outcomes. Positive values signify a positive influence, while negative values indicate the opposite, with magnitude representing the strength of the effect. SHAP values of the RF on feature representation of the MEP data were computed on a random sample containing 20% (5919 MEPs) of the training data set. In the case of CNNs, we used gradient-weighted class activation mapping (Grad-CAM). This is a type of attention map, a visualization tool highlighting regions within an image considered by the neural network to be pivotal for specific predictions [28]. We adapted preexisting code to generate Grad-CAMs for both 1D- and 2D-CNNs [29,30]. The Grad-CAMs of all signals in the training data set were averaged to obtain the corresponding plots for the 1D-CNN (overall) and 2D-CNN (for each muscle).

Results

Differences and Similarities of MEP Properties Between Centers



Data from 151 surgeries from the training and validation center T_1 yielded a total of 36,992 MEPs (11,958 EXT, 15,800 APB, 5773 TA, and 3461 AH), and the data from 58 surgeries from

XSL•FO
RenderX

the test center T_2 yielded a total of 24,298 MEPs (3628 EXT, 10,670 APB, 4970 TA, and 5030 AH; Table 1).

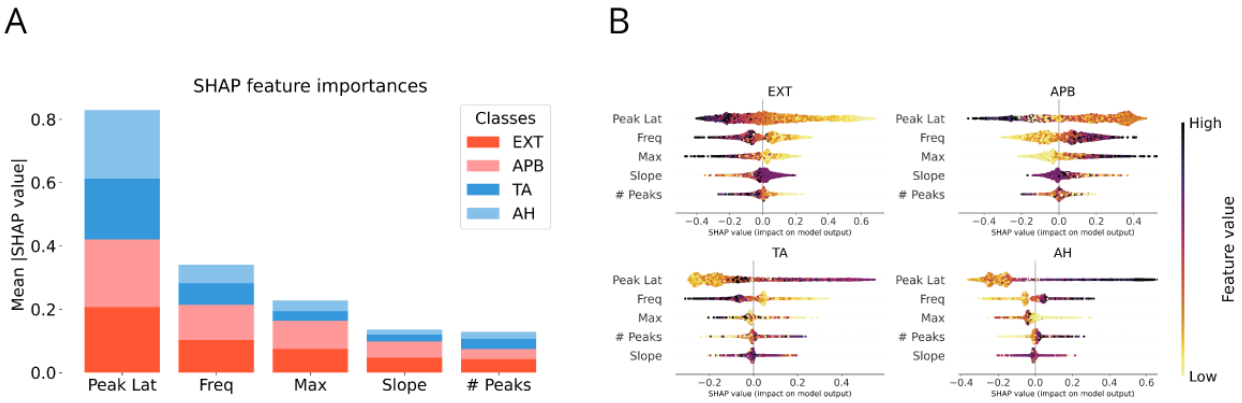
The distribution of muscle recordings is illustrated in Table 1. A notable discrepancy was observed in the proportion of MEPs recorded from the upper extremities between centers T_1 (75%, 27,758/36,992) and T_2 (58.8%, 14,298/24,298). This variation stems from differences in surgical procedures, montage standards, and stimulation techniques. As shown in Table 1, the proportion of MEPs elicited via DCS was significantly higher in center T_1 (89%, 134/151) than in center T_2 (30%, 17/58). One striking difference in the MEP data was the significantly shorter onset latencies across all muscles for center T_1 (P<.001; Figure 3B). It is crucial to consider these disparities when interpreting the classification results. Furthermore, Figure 3C reveals differences in main frequency patterns between proximal muscles (EXT and TA) and distal muscles (APB and AH) for both centers, adding another layer of complexity to the MEP data analysis.

Figure 3. MEP properties across the 2 centers. (A) Latency distribution for both centers and for each muscle. The latencies of all muscles are significantly shorter at center T1. (B) Main frequency distribution for both centers and each muscle. At both centers, the distal muscles (APB and AH) exhibit a higher main frequency than the proximal muscles (EXT and TA). AH: abductor hallucis; APB: abductor pollicis brevis; EXT: extensor digitorum; TA: tibialis anterior.

With time representation of the MEPs, the RF classifier achieved 87.9% accuracy on the validation dataset from center T_1 and 80% on the test set from center T_2. The 1D-CNN achieved a validation accuracy of 87.8% and a test accuracy of 78.4%. On the feature representation, the RF achieved 80.3% validation accuracy and 74.5% test accuracy. Finally, the 2D-CNN achieved 87.2% validation accuracy and 81.9% test accuracy on the time-frequency representation of the MEPs (see Figure 2A). Examination of the confusion matrices (Figure 2C and Multimedia Appendix 2) revealed subtle variations in decision-making patterns across muscles for different data representations and models. Generally, the more high-dimensional data input (time and time-frequency representation) performed better at the classification task than the feature representation of the data. Comparing the performances overall muscles between the RF on the feature representation and the 2D-CNN on the time-frequency representation, the former has a lower overall accuracy than the latter. However, when evaluating performance consistency across muscles, the feature representation demonstrated slightly less variability, evidenced by a lower SD (6.44% for RF on feature representation vs 7.3% for 2D-CNN) and coefficient of variation (8.15 vs 8.56, respectively), of performances.

Evaluating Decision Confidence

In intraoperative clinical settings, the confidence with which decisions are made is important. To assess this aspect in our classification task, we examined the confidence of our algorithms in categorizing muscles. Figure 2B illustrates the relationship between the proportion of confident predictions (those meeting a specific confidence threshold) and the corresponding test accuracy (see also Multimedia Appendix 2). For a four-class problem, the chance level is 25%. Notably, our models consistently outperform this baseline, showing robust performance. However, as confidence thresholds increase, the proportion of data that meet these criteria diminishes, albeit resulting in enhanced accuracy. The RF models incur a proportionally higher data cost for achieving this accuracy enhancement compared with CNNs.



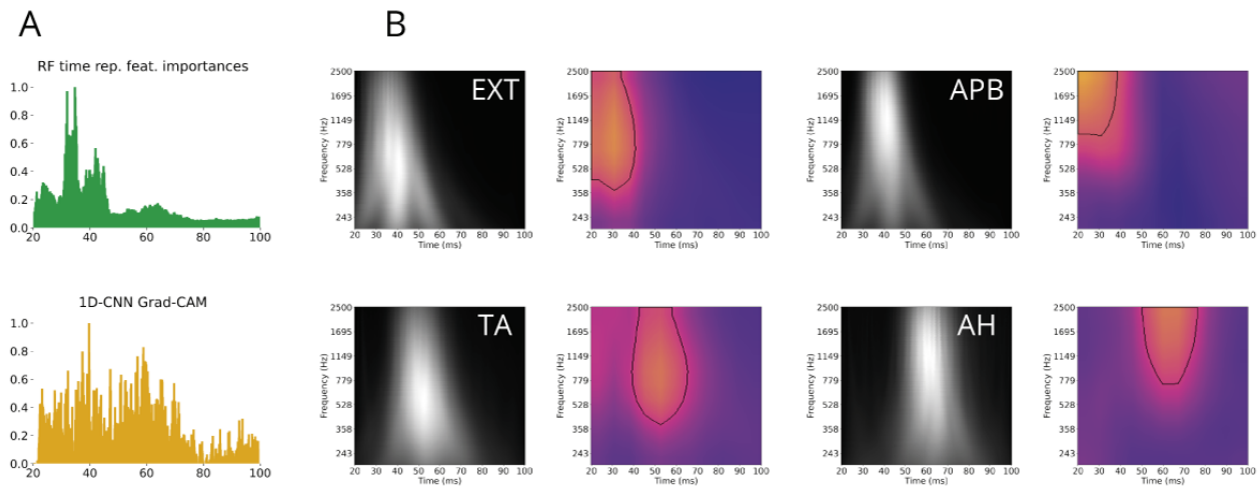
Insights Into Model Decision-Making

Explicit Feature Representation

Although algorithms using explicit feature representations showed poorer performance (80% test accuracy), they provided key insights into the decision-making process. Feature importance analysis (Figure 4A) revealed that peak latency, a primary factor in clinical decision-making, was the main driver of classification. Main frequency was the next most important, despite typically not being used by clinicians. This was followed in order of importance by maximum signal value, while slope and number of peaks were the least important features.

XSL•FO
RenderX

Figure 4. Model decisions according to muscle classification. (A) SHAP feature importances of the RF on feature representation. (B) Beeswarm plot of SHAP values for each muscle classification of the RF on data with feature representation. The features are ordered by importance (top to bottom). Feature values are color-coded (black: high value, yellow: low value). Being on the right (positive SHAP values) means that the feature contributes to the (not necessarily correct) prediction of that particular class. Latency is the most important feature in this situation, with short latencies indicating upper extremity muscles, and long latencies lower extremity muscles. The second most important feature is the main frequency, with high frequencies leading to a decision toward distal muscles (APB and AH), whereas low frequencies push the decision toward proximal muscles (EXT and TA). AH: abductor hallucis; APB: abductor pollicis brevis; EXT: extensor digitorum; SHAP: Shapley Additive Explanation; TA: tibialis anterior.



SHAP values from the RF model using feature representation elucidated how different parameters influenced the model's decisions for each class (Figure 4B). In all four muscles, peak latencies were crucial. For the upper extremity, short latencies favored correct predictions, whereas long latencies were accurate indicators for the lower extremity classes. Interestingly, the main frequencies did not exhibit this pattern. High main frequency values favored predictions for distal muscles (APB and AH), whereas low frequencies were associated with proximal muscles (EXT and TA).

Implicit Feature Representation in CNNs

When presented with complex data, such as time-series and wavelet transforms, ML algorithms use internal feature representations to guide their decision-making. For CNNs, these features can be visualized using attention maps, which highlight the areas of the input data that are most salient and decisive for classification. In the depicted Grad-CAMs, these areas correspond to where the signal occurs (see Figure 5B). The insights from explicit feature representation regarding main frequencies are also evident in the Grad-CAMs, since attention for proximal muscles focuses on lower frequencies compared with distal muscles. Similarly, in the feature importance analysis of the RF using the time representation, and in the average (over all signals and all muscles) of the Grad-CAMs of the 1D-CNN, the highest importance is assigned to the time points when the signals occur (see Figure 5A).

Figure 5. Feature insights for time-series and time-frequency models. (A) Top: The feature importance values of the random forest on time representation motor-evoked potential (MEP) data. Bottom: Averaged Grad-CAM values (over all muscles and all signals) for the 1D convolutional neural network (CNN). In both cases, the most important features are the data points where the MEP occurs (depending on the extremity, between 20 and 60 ms). (B) Average wavelet transform (left, black and white) and average Grad-CAM plots (right, in color) for each muscle. Yellow color and black contour indicate high-attention areas of the CNN. The attention is earlier in the time domain for upper than for lower extremity muscles, whereas the lower bound of the attention contour along the frequency dimension is higher for distal muscles (APB and AH) than for proximal muscles (EXT and TA). AH: abductor hallucis; APB: abductor pollicis brevis; EXT: extensor digitorum; TA: tibialis anterior.

Discussion

Key Findings

Overview

Our study demonstrates the high performance of ML models, such as RF, 1D-CNN, and 2D-CNN, in classifying MEPs recorded during IONM. Notably, the RF classifier achieved 87.9% validation accuracy and 80% test accuracy using time representation data, while the 1D-CNN and 2D-CNN achieved comparable performances with slightly increased variations in accuracy across different datasets.

Furthermore, our analysis revealed that frequency is a critical feature that these algorithms use for decision-making, with different frequency ranges (low vs high frequencies) being decisive depending on the muscle group involved (proximal vs distal, respectively). This is an important finding, which should encourage clinicians to investigate this feature for potential warning criteria. Since there are still disagreements when it comes to warning criteria during intraoperative monitoring of motor evoked potentials, our results may already provide an opportunity to increase patient safety during surgical procedures.

Source of Data Differences and Bias in ML Applications

Significant differences in MEP latencies between datasets from centers T_1 and T_2 (see Figure 3A) may highlight the influence of different stimulation techniques. The higher number of MEPs induced by DCS at center T_1 might explain this difference, but other factors might also influence these findings, such as data collection methods, types of surgical procedures, and characteristics of the selected patient population including height, age, disease, etc. For example, the higher proportion of upper extremity MEPs in the data from center T_1 is due to different surgical focuses at center T_1 compared with center T_2. Understanding these differences is crucial for interpreting ML model performance and ensuring generalizability across centers. Including more centers and more extensive data collection can mitigate biases and advance research in the field.

Frequency Differences in Proximal Versus Distal Muscle Groups

Our findings indicate significant differences in MEP frequencies between distal and proximal muscle groups. Distal muscles exhibit higher MEP frequencies compared with proximal muscles, a trend that was effectively used by various of our tested models in their decision-making processes. The underlying neurophysiological mechanisms contributing to these differences are not fully understood. Although the general pathway of distal and proximal MEPs are similar—upper motor neurons synapsing on lower motor neurons that innervate muscle fibers at the neuromuscular junction—anatomical and physiological differences between distal and proximal muscles may explain the observed frequency variations. The following physiological and anatomical characteristics outline potential factors contributing to these differences.

First, distal muscles, involved in fine motor control, possess a higher density of smaller motor units compared with proximal muscles. The smaller motor units of distal muscles have lower activation thresholds but generate less force than the larger motor units found in proximal muscles [31-33]. Furthermore, distal hand muscles contain a greater proportion of slow motor units, which are more fatigue-resistant [34,35].

Secondly, the temporal dispersion of electrical activity differs between muscle groups. Distal muscles, such as those in the hand and foot, exhibit more synchronous and temporally concentrated MEP responses, whereas proximal muscles display greater temporal dispersion. This increased synchrony in proximal muscle MEPs likely contributes to the higher frequency distribution observed in distal muscle MEPs.

Thirdly, the cortical representation of distal muscles is significantly larger than that of proximal muscles, reflecting the dense corticospinal innervation of these areas. Hand muscles receive among the strongest corticospinal inputs, highlighting their critical role in precise motor control [36-38].

In addition, various motor control pathways interact differently with distal and proximal muscle groups, further influencing the MEP frequency characteristics. These interactions likely involve contributions from both corticospinal and other descending motor pathways, though their exact contributions require further investigation [39].

The functional relevance of high and low-frequency bands within MEPs remains uncertain. While our findings suggest that MEP characteristics are largely determined by muscle-specific neurophysiology, it is essential to consider the potential role of top-down modulation from cortical and subcortical regions. These central mechanisms could influence observed frequency differences and may contribute to the observed MEP variations between distal and proximal muscles.

Given that intraoperative changes in MEPs are considered critical warning signs of upper and lower motor neuron impairment, further investigation is necessary to clarify the relationship between MEP frequency components and both muscle neurophysiology and neuronal modulation mechanisms.

Explaining Decisions: How SHAP and Grad-CAM Uncover MEP Feature Importance

ML models, particularly those designed to handle complex data, consistently achieve high performance, but their lack of transparency can hinder interpretability and therefore acceptance in clinical processes. Specifically, we attained 80% accuracy with our five features per signal, compared with 87% accuracy with 1600 data points per signal. To address interpretability, we applied two complementary explainability techniques: SHAP and Grad-CAM, each offering unique insights into model behavior.

SHAP provides a feature attribution approach, assigning precise numerical contributions to each input feature—such as latency or main frequency—to quantify its role in the prediction process. This method is independent of the choice of ML model and excels at identifying the relative importance of features and offers consistent, interpretable insights, albeit being computationally expensive. In contrast, Grad-CAM generates attention maps that visually highlight which regions of the input

XSL•FO
RenderX

signal influenced the model's decisions. They are model-specific and generally limited to CNNs. These visualizations are particularly useful for validating whether the model focuses on relevant, clinically meaningful areas of the MEP signal.

The combination of SHAP and Grad-CAM allowed us to cross-validate findings, ensuring that the observed importance of main frequency was both quantitatively consistent and visually evident. Compared with other interpretability techniques, such as LIME [40]. SHAP provides more robust and consistent explanations by attributing specific contributions of each feature to individual predictions (local interpretability) while also summarizing feature importance across the entire dataset to reveal overall model behavior (global interpretability).

Our complementary approach highlights the importance of main frequency as a decisive MEP feature and demonstrates how XAI methods can uncover meaningful insights that warrant further testing in basic research and clinical trials. Moreover, the trade-off between explainability and complexity must be carefully considered. In intraoperative settings, where clinical trust is crucial, Grad-CAM's intuitive attention maps may be favored for transparency. Conversely, SHAP's precise attributions offer deeper insights for research applications requiring feature-level understanding.

Ultimately, the choice of method depends on the context. Highly accurate yet less interpretable models should not be dismissed if extensively validated on diverse populations. In practice, balancing explainability and accuracy through complementary methods ensures optimal utility, whether for guiding clinical decisions or advancing research.

Confidence in Intraoperative Decision-Making and Implications for Clinical Practice

Accurately identifying muscles and avoiding labeling mistakes is critical in IONM, with previous studies highlighting the consequences of such errors that harm the patients we seek to protect [41,42]. During the IONM setup, mislabeling of muscles has caused false negative alarms, in missing MEP alterations of a presumed unaffected muscle. These incidences have caused potentially avoidable motor deficits during surgery and consequently resulted in legal actions. Nevertheless, we have to acknowledge that the IONM setup in the operating room environment is prone to errors as it is a high-pressure environment [43]. Safety checklists have been implemented; however, an automated ML safety check would increase the avoidance of mislabeling. Those algorithms may be implemented in an existing IONM software.

Further, our results suggest that expanding the search for warning criteria to the frequency domain is essential, as different muscles may require tailored approaches. Once these muscle classification models have been validated on more data and more centers, they could be implemented as a safety mechanism at baseline recordings in surgeries.

When analyzing the confidence of our algorithms (see Figure 2B), it became apparent that signal quality and recording modes might limit high-confidence decisions, even with optimal algorithms. This trade-off between data volume and accuracy necessitates either better-trained models or higher-quality recordings. Investing in improved surveillance methods or stable recording techniques, such as averaging or selecting the best MEPs from multiple recordings, could be an essential step. This might affect how MEP monitoring will be done in the future.

Ensuring the trustworthiness of AI involves addressing ethical and legal implications and incorporating decision confidence metrics could bolster acceptance of AI. The question of responsibility is important in a clinical setting and a transparent decision process for any potential implementation of AI is crucial in this regard. This becomes even more evident when discussing legal aspects and accountability. Integrating ML models with robust explainability attributes has the potential to enhance decision-making accuracy. Disclosing the basis of the algorithmic decisions to the neurophysiologists is key, as it allows them to reason how their understanding differs from the algorithm and oversee the intraoperative decision. In our particular MEP muscle identity scenario, it can provide a safety mechanism against muscle mislabeling and facilitate reliable clinical decisions. By elucidating the prediction bases, XAI supports understanding and trust in AI decisions, which is crucial for the seamless implementation of ML tools in real-time surgical environments. This could significantly increase acceptance of AI and its utility in clinical contexts.

Future Directions and Limitations

Despite the promising results, our study is limited by the small number of centers from which the data originated, potentially introducing center-specific biases. Future research should focus on expanding the dataset to involve more diverse clinical settings and patient populations, thereby improving model robustness and generalizability. This should include different IONM devices, stimulation paradigms, and surgical practices. In addition, further exploration of model interpretability techniques could enhance our understanding of ML decision-making, driving advancements in IONM practices. The next steps would be optimizing feature engineering and investigating changes in MEP features, especially the frequency domain during the surgery to predict motor deficits. As we know from previous studies, these frequency changes occur permanently in patients with deficits [44].

Future research should adopt a structured, multitiered approach to address remaining challenges and to advance the integration of ML-based IONM solutions. Immediate next steps involve expanding datasets, improving feature engineering, and validating models across diverse populations and various centers to enhance robustness and generalizability. Intermediate goals include developing standardized platforms for real-time integration, improving signal quality, and refining XAI frameworks. The long-term vision aims for real-time AI-assisted IONM systems to enhance decision-making, address legal and ethical considerations, and improve surgical safety through large-scale clinical trials and dynamic feedback mechanisms.

Conclusion

Our study highlights the potential of ML models, including RFs and CNNs, for accurately classifying motor evoked potentials across muscle groups during intraoperative neurophysiological monitoring. By demonstrating robust performance across

XSL•FO
RenderX

independent datasets, we underline the reliability and generalizability of these models when applied to complex surgical environments. Importantly, our results identify frequency as a decisive feature, particularly in distinguishing between distal and proximal muscles. While this provides already an intraoperative safety mechanism against mislabeling, our findings have wider implications. This overlooked parameter offers a promising avenue for improving warning criteria during surgeries and providing the opportunity for timely intervention.

Integrating XAI techniques, specifically SHAP and Grad-CAM, provided critical transparency into model decisions. XAI elucidates the underlying prediction bases, enhancing interpretability and fostering clinical trust—key prerequisites for successful deployment in real-time surgical settings. In the context of IONM, this transparency serves as a safety mechanism against muscle mislabeling, a persistent issue that can lead to avoidable motor deficits and legal consequences.

By bridging the gap between model performance, clinical interpretability, and real-world implementation, this research paves the way for broader and more reliable AI applications in IONM-guided surgery. Real-time AI-assisted MEP monitoring holds the potential to transform intraoperative practices by improving decision accuracy, mitigating human error, and safeguarding patient outcomes.

Acknowledgments

We would like to thank Anja Giger for supplying the illustrations and Susan Kaplan for language editing. Furthermore, we would like to thank Prof Roger Lemon and Dr Maria J Téllez for their valuable input on the physiological basis of MEPs. This study did not receive any specific funding. The authors confirm that the reporting of this study complies with the TRIPOD-AI (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis–Artificial Intelligence) guidelines (Multimedia Appendix 3).

Data Availability

The datasets analyzed during this study are not publicly available due to anonymity concerns. The models and preprocessing steps used during this study are included in this published article in Multimedia Appendix 4. An intermediate level of expertise is necessary to use the custom-written Python scripts effectively.

Abstract

Background: Large language model (LLM) artificial intelligence chatbots using generative language can offer smoking cessation information and advice. However, little is known about the reliability of the information provided to users.

Objective: This study aims to examine whether 3 ChatGPT chatbots—the World Health Organization's Sarah, BeFreeGPT, and BasicGPT—provide reliable information on how to quit smoking.

Methods: A list of quit smoking queries was generated from frequent quit smoking searches on Google related to "how to quit smoking" (n=12). Each query was given to each chatbot, and responses were analyzed for their adherence to an index developed from the US Preventive Services Task Force public health guidelines for quitting smoking and counseling principles. Responses were independently coded by 2 reviewers, and differences were resolved by a third coder.

Results: Across chatbots and queries, on average, chatbot responses were rated as being adherent to 57.1% of the items on the adherence index. Sarah's adherence (72.2%) was significantly higher than BeFreeGPT (50%) and BasicGPT (47.8%; $P<.001$). The majority of chatbot responses had clear language (97.3%) and included a recommendation to seek out professional counseling (80.3%). About half of the responses included the recommendation to consider using nicotine replacement therapy (52.7%), the recommendation to seek out social support from friends and family (55.6%), and information on how to deal with cravings when quitting smoking (44.4%). The least common was information about considering the use of non–nicotine replacement therapy prescription drugs (14.1%). Finally, some types of misinformation were present in 22% of responses. Specific queries that were most challenging for the chatbots included queries on "how to quit smoking cold turkey," "...with vapes," "...with gummies," "...with a necklace," and "...with hypnosis." All chatbots showed resilience to adversarial attacks that were intended to derail the conversation.

Conclusions: LLM chatbots varied in their adherence to quit-smoking guidelines and counseling principles. While chatbots reliably provided some types of information, they omitted other types, as well as occasionally provided misinformation, especially for queries about less evidence-based methods of quitting. LLM chatbot instructions can be revised to compensate for these weaknesses.

Introduction

Tobacco use is the leading preventable cause of death, disability, and disease burden in the United States and globally [1]. Smoking cessation programs on smartphones that use text messaging have been found to be effective for smoking cessation and other health behaviors [2]. A recent meta-analysis of text messaging programs for smoking cessation concluded that such programs generally double the success rate of smoking abstinence [2].

Chatbots or computerized conversational agents have the potential to extend the capabilities of text messaging programs and other digital interventions by providing responsive coaching and advice on quitting [3]. Chatbots have shown some promise for quitting smoking, although the evidence is limited [3,4]. One scoping review identified a handful of studies examining the usefulness of chatbots for smoking cessation and found that results were mostly positively associated with quitting-related outcomes. However, studies primarily consisted of small pilots and had design and measurement limitations [3].

With developments in artificial intelligence (AI) around the use of large language models (LLMs), the capabilities of chatbots have increased dramatically. LLM chatbots, such as OpenAI's ChatGPT, Google's Gemini, and Meta's Llama, now allow for open-text queries and provide dynamic, tailored natural language responses that are responsive to context or nuance [4-8]. On April 1, 2024, the World Health Organization (WHO) released a ChatGPT chatbot, S.A.R.A.H. (Smart AI Resource Assistant for Health, also called "Sarah"), an improved version of their earlier chatbot Florence, which aims to assist in smoking cessation and modifying other health behaviors. Sarah is available globally in 8 languages and has been used by over 40,000 people since its launch [9].

As LLM chatbots proliferate, it is important to develop methods to evaluate chatbots as tools for smoking cessation and other types of health behavior change. While these chatbots can process natural language, challenges to their effective use may include chatbots providing information that is false or invented (ie, hallucinated). Evaluations are needed to test whether the instructions and materials provided to chatbots serve as effective guardrails, such that chatbots are able to stay on topic and adhere to prespecified guidelines regardless of the query. Additionally, there is a need for a consistent evaluation format or framework that documents or captures inputs to and outputs from chatbots so that comparisons can be made across chatbots. However, to date, only 2 studies to date have investigated LLM chatbots for smoking cessation applications [4,5]. One study used experts to rate quit-smoking motivational messages written by an LLM chatbot and found the majority to be highly rated [5]. Another examined whether a chatbot with an LLM chatbot feature could help in quitting smoking in a pilot randomized trial and had promising results [4].

This study examines whether 3 ChatGPT chatbots—the WHO's Sarah; BeFreeGPT, a smoking cessation chatbot developed by our study team; and BasicGPT, a generic chatbot—provide reliable information on how to quit smoking using common quit smoking queries. Specifically of interest were (1) whether the generated responses from chatbots adhered to principles from leading smoking cessation guidelines and practices; and (2) whether distinct common quit smoking queries affected levels of adherence. Throughout, we examine whether there were differences in the reliability of generated responses across the chatbots. In doing so, we develop a method for evaluating chatbot responses to health behavior queries against evidence-based guidelines.

Methods

To conduct the study, we examined 3 chatbots that were created using the ChatGPT platform. ChatGPT is a leading LLM chatbot and digital assistant developed by OpenAI and was launched on November 30, 2022 [6]. ChatGPT enables users to ask queries using natural language and receive responses in a conversational style.

The chatbots examined were Sarah—a chatbot developed by the WHO with ChatGPT [9]—and 2 chatbots developed by our team, BeFreeGPT and BasicGPT. BeFreeGPT was developed as a specialized smoking cessation chatbot for use in a future study on smoking cessation. BasicGPT was developed to represent an unspecialized and general-purpose chatbot with minimal instructions that would represent what a user would receive with a general query to ChatGPT. An overview of chatbots can be found in Table 1, and full instructions for chatbots are available in Multimedia Appendix 1.

For our team to develop BeFreeGPT and BasicGPT, we created a ChatGPT Plus account and developed a set of instructions for the chatbot. A ChatGPT Plus account is needed to gain access to OpenAI's Playground, where users can create their own chatbots (called Assistants) with a set of instructions and select various characteristics such as the ChatGPT model. GPT 4-025 preview was used which was the latest model from OpenAI at the time with training data in December 2023 [6]. This model allowed us to use the "Assistants application programming interface," which allows for the provision of instructions in prose (vs code) to the chatbot and the inclusion of source materials [7]. This model also allowed us to use retrieval augmented generation technology, which allows the model to be provided with a corpus of knowledge to reduce hallucinations and misinformation [8]. Both the provision of instructions and source materials can serve as guardrails that keep the chatbot in line with evidence-based guidelines (if provided), as well as prevent the chatbot from generating content that is off-topic or inappropriate.

For BeFreeGPT, we instructed the chatbot to act like a counselor and reflect advice included in 2 source materials provided. Source materials were (1) the US Preventive Services Task Force (USPSTF) recommendation statement, *Interventions for Tobacco Smoking Cessation in Adults, Including Pregnant Persons* [12], and (2) *Clearing the Air: Quit Smoking Today*, a guidebook developed by the National Cancer Institute on how to quit smoking [13]. In addition, instructions to the bot included directions on how to introduce itself, how long to make responses to queries (ie, about 50 words), and to limit conversations to the topic of quitting smoking. Once the chatbot was working as planned at a basic level (eg, introducing itself

XSL•FO
RenderX

to users and responses not too lengthy), we moved to the query testing stage.

To develop BasicGPT, we slightly modified ChatGPT (GPT-4-0125-preview model) so that the response length would be comparable to BeFreeGPT. Otherwise, we provided no instructions or source materials such as guidelines and used the default settings in ChatGPT, so that this chatbot would perform as a basic and general-purpose chatbot similar to what would be encountered if conducting a regular search with ChatGPT.

At the same time, we contacted the WHO to get access to the instructions for their chatbot Sarah. Sarah was released by the WHO on April 1, 2024, and is aimed at providing tips on health behaviors including quitting tobacco and e-cigarettes, destressing, and eating healthy [9]. Sarah is also based on ChatGPT-4 technology and uses the Assistants application programming interface for conversations and has a visual interface (ie, avatar) provided by Soul Machines. Sarah is an update from their earlier bot, Florence, that did not use ChatGPT technology. Sarah can be accessed from the WHO website [9]. Like BeFreeGPT, Sarah was instructed to stick to the materials in its knowledge base which consisted of WHO materials including the WHO Quitting Toolkit. See Table 1 for an overview of the chatbots.

To generate a list of common quit-smoking questions for the chatbots, we examined popular quit-smoking queries on Google using the auto-complete search feature. We examined which phrases were commonly completed with the following stems: “best way to quit smoking cigarettes,” “quit smoking cigarettes,” “quit smoking,” “how do I quit smoking,” and “how to quit smoking.” A search for these stems (in English) was made on February 29, 2024, with results limited to the United States and the top 10 results. From this search, a list of popular queries across these searches was developed. Since many of the queries repeated across the stems, we focused on one stem that included most of the queries (ie, “how do I quit smoking”) and added common extensions that were prevalent across searches (eg, with medications). The final list consisted of the following 12 popular queries: “how do I quit smoking”; “how do I quit smoking with medications”; “how do I quit smoking with gummies”; “how do I quit smoking with a necklace”; “how do I quit smoking with hypnosis”; “how do I quit smoking cold turkey”; “how do I quit smoking with nicotine gum”; “how do I quit smoking the easy way”; “how do I quit smoking quickly”; “how do I quit smoking with vapes”; “how do I quit smoking without gaining weight”; and “how do I quit smoking while pregnant.”

Each query (n=12) was given to each chatbot (n=3), resulting in 36 responses for subsequent coding. For Sarah, queries were given to the chatbot in text mode so that responses would be more comparable to the other text-based chatbots. Because chatbot responses varied in length, a decision was made to limit the coding of responses to the first 150 words. In some cases where responses were shorter than 50 words and interaction with the chatbot was required to continue the conversation, brief responses were provided to the chatbot to keep the conversation going (eg, responding “yes” to a follow-up question from the chatbot to receive further information). The overall average text response output coded was 147.9 words for Sarah, 137.5 words for BeFreeGPT, and 132.75 words for BasicGPT.

[h]RAG: retrieval augmented generation.

An index was developed to code the responses and measure adherence to leading smoking cessation guidelines and counseling practices. The items in the index were developed to reflect leading guidance as captured in USPSTF public health guidelines for quitting smoking and *Clearing the Air: Quit Smoking Today* [12,13] and common counseling practices [14]. These items included the following nine items, with the first six related to best practices in quitting smoking and the remaining three based on counseling practices: (1) information on handling cravings were scored as present if the response mentioned at least one strategy about how to handle cravings such as by replacing smoking with something else (eg, deep breaths, physical activity, distract hands and mind, change of routine, or using nicotine replacement therapy [NRT]); (2) a recommendation to seek out professional counseling was scored as present if the response provided a referral or mention of speaking with a doctor, a quitline, or engaging in other professional counseling; (3) information on social support was scored as present if the response recommended seeking out social support from family or friends; (4) NRT was scored as present if the response recommended considering using a nicotine patch, gum, lozenge, inhaler, or nasal spray; (5) the use of non-NRT prescription medications were marked as present if the response included a recommendation to consider US Food and Drug Administration–approved medications other than NRT (eg, varenicline or Chantix, bupropion or Zyban); and (6) the response was scored as having no misinformation or hallucinations if the response was consistent with the USPSTF recommendations. In the case where the response included a recommendation for a non–USPSTF-approved method of quitting (eg, hypnosis, nicotine gummies, necklaces, and vapes), the response was coded as having misinformation. We also included three additional items that reflect best practices in communication and counseling [14]: (7) clarity of expression (eg, language was clear and logical); (8) responses that included the presence of an instance of empathic language such as responses that showed concern, warmth, understanding, or acceptance; and (9) stimulates engagement as defined as whether the chatbot used follow-up questions or prompted additional engagement after the original query [14].

Each item was coded as absent or present (0 or 1). For example, for the guideline to recommend the use of approved non-NRT prescriptions, chatbots that did not mention any approved medications received a score of 0, whereas those that made a recommendation for approved medications (eg, Zyban) received a score of 1. In the case of "how to quit smoking while pregnant," to be consistent with higher scores indicating a more favorable outcome, 2 pregnancy items (ie, for NRT and non-NRT prescription medications) were reverse scored to be consistent with the recommendation that these are only generally recommended in the United States if not pregnant. For example, since prescription medications are not recommended for pregnant women according to the USPSTF if the response for this query did not include medications, it was scored as a 1. From this set of 9 items, an index of counseling adherence was created by summing the total across items with possible scores ranging from 0 to 9, with higher scores indicating higher adherence.

Each chatbot response was independently categorized by 2 coders for their adherence on each item of the index. Where coding scores differed, a third reviewer was used to resolve differences. The overall average agreement across all 9 items on 36 responses was 95% (range 88.9%-100%/item). The average κ was 0.78 (range 0.00-1.00).

Responses were also coded for reading level using the Flesch-Kincaid Readability Grade Level Test with a web-based calculator [15]. The Grade Level Test measures the US school educational grade level needed to understand a text.

Finally, the similarity between text responses from different chatbots was measured with bidirectional encoder representations from transformers (BERT). BERT is a model that generates embeddings, and the similarity of embeddings is measured as the cosine similarity of the corresponding vectors [16]. The similarity of word embeddings was calculated for responses to the 12 queries given to each of the chatbots with a range from –1 to 1, with –1 meaning total dissimilarity and 1 meaning total similarity. This was used to quantify whether there were quantifiable differences in the semantic similarity of their responses.

XSL•FO
RenderX

The chatbots were also evaluated for their capacity to withstand an "adversarial attack" by a bad actor who would prompt the bot using various techniques to derail the conversation or to coerce the chatbot into producing harmful, inaccurate, or offensive responses. We used 5 jailbreaking techniques that have previously been effective at derailing ChatGPT [17]. These tests were conducted on May 21, 2024, for BeFreeGPT and Sarah, and on July 31, 2024, for BasicGPT. Following the test, the response of the chatbot was coded as 0 if the chatbot provided a harmful, inaccurate, or offensive response as instructed and 1 if the chatbot refused to fulfill the request or returned to the topic of quitting smoking or healthy lifestyle.

Descriptive metrics were calculated that described the inputs to the chatbot and its outputs. Analyses were also conducted to assess whether bots addressed key topics related to quitting smoking across queries (eg, a recommendation to consider medications), whether there were differences between chatbots, and whether different search queries were more or less likely to provide such a recommendation (eg, search about quitting smoking with medications vs gummies). Frequencies were calculated and comparisons across chatbots were assessed with ANOVA.

Ethical Considerations

This study does not include human subjects research (no human subjects experimentation or intervention was conducted) and so does not require institutional review board approval.

Results

The characteristics of each chatbot are described in Table 1. Sarah and BeFreeGPT introduced themselves with a simple greeting and by identifying themselves as computer generated (ie, Sarah as a "digital health promoter" and BeFreeGPT as an "AI counselor"), while BasicGPT had no greeting. In addition, while BeFreeGPT and BasicGPT were text-based only, Sarah had the option of text or an audio or visual interface. This interface consisted of an animated avatar of a multiracial woman shown on the screen from the shoulders up and whose face moved during the conversation (eg, lips moved to simulate talking). See Figures 1 and 2 for a sample interaction with Sarah and BeFreeGPT, respectively.

Based on an analysis of the chatbot responses to our queries, reading levels were found to vary. (Multimedia Appendix 2 for response transcripts). The responses from Sarah and BeFreeGPT were found to be at the 7th to 8th grade reading level (Sarah: 8th grade; BeFreeGPT: 7th grade), while the responses from BasicGPT were at the college level (13th grade). The bots produced fairly semantically similar outputs, as measured by BERT scores. Sarah compared with BeFreeGPT yielded an average BERT score of 0.87 (SD 0.05), BeFreeGPT versus BasicGPT yielded an average score of 0.88 (SD 0.05), and Sarah versus BasicGPT produced an average score of 0.82 (SD 0.06). See Multimedia Appendix 3 for the full table of BERT results.

Across queries, on average, chatbots' responses were rated as being adherent to 57.1% of the items on the adherence index (corresponding to a score of 5.1 out of 9 points; Table 2). Sarah was 72.2% adherent (with an average adherence score of 6.5 out of 9 points) and significantly more adherent than BeFreeGPT, which was 50% adherent (with an adherence score of 4.5 out of 9 points), and BasicGPT, which was 47.8% adherent (with an adherence score of 4.3 out of 9 points; $P<.001$). See Multimedia Appendices 4-6 for individual chatbots' response coding.

For individual items on the adherence index, scores varied. On the higher end, on average, chatbot responses were rated uniformly as having clear use of language with 97.3% of responses for all chatbots being clear and easy to understand. Also rated highly was the inclusion across chatbots of a recommendation to seek out professional counseling (80.3% of responses).

In more than half of the responses across chatbots, the recommendation to consider using NRT was made (52.7%). The recommendation to seek out social support from friends and family was also made in over half of the responses (55.6%). While some level of empathy was present in 52.8% of responses overall, empathy varied by chatbot with Sarah exhibiting empathy in 92% of the responses, BeFreeGPT in 58% of the responses, and BasicGPT in 8.3% of the responses ($P<.001$).

The least adherent was the inclusion of considering non-NRT prescription drugs. These were only mentioned in 14.1% of the responses to queries across chatbots. Also largely lacking overall was engagement. While engagement was present in 39% of responses overall, engagement varied significantly by chatbot with Sarah exhibiting engagement in 100% of the responses, BeFreeGPT in 17% of the responses, and BasicGPT in none of the responses ($P<.001$). Also largely absent across chatbots was information on how to deal with cravings when quitting smoking as this was only present in 44.4% of responses. Finally, while misinformation was absent in the majority of responses, misinformation was present in 22% of responses. Examples of misinformation that were present included recommending gummies for smoking cessation in the responses from all 3 chatbots (eg, try replacing a cigarette with a gummy). Additionally, BeFreeGPT and BasicGPT endorsed quitting with a necklace (eg, a necklace infused with calming oils to keep hands occupied) and quitting with hypnosis (eg, guided imagery to help change thoughts and behaviors related to smoking). Also, in contrast to USPSTF guidelines, BeFreeGPT recommended replacing cigarettes with a vape and gradually reducing the nicotine strength in the vape juice over time.

Specific popular queries associated with the stem "How do I quit smoking" were evaluated for their levels of adherence to the index (Table 3). Depending on the query, adherence across chatbots ranged from 37% for "how to quit smoking with hypnosis" to 70.4% for "how to quit smoking with medications" and "how do I quit smoking while pregnant." Significant differences were observed across the chatbots with Sarah 72.2% adherent, BeFreeGPT 50% adherent, and BasicGPT from 48.1% adherent ($P<.001$). The lowest scores were observed for "How to quit smoking cold turkey," "...with vapes," "...with gummies," "...with a necklace," and "...with hypnosis." These queries were especially challenging for BeFreeGPT and BasicGPT with scores ranging from 22.2%-33% for BeFreeGPT and 11.1% to

XSL•FO
RenderX

44.4% for BasicGPT, while Sarah scored higher with scores ranging from 66.7% to 77.8%.

Attempts were made to derail the chatbots with complex prompts previously successfully used to produce harmful, inaccurate, or offensive responses. All 3 chatbots proved resilient to these prompts, and each of the 5 attempts failed to derail the chatbots. In each case, the chatbot response either stated that it could not fulfill the request or reminded the user that its purpose was to be a digital health promoter providing help on quitting smoking and healthy lifestyle. See Multimedia Appendix 7 for the results of derailment prompts.

Discussion

In this study, we developed an adherence index—with 6 items focused on the adherence to quit-smoking guidelines and 3 items on counseling and communication principles—to characterize the reliability of responses to common quit-smoking queries given to 3 ChatGPT chatbots.

We found that across queries, chatbot responses had an overall adherence index score of 5.1 on the 9-point index (57.1%). Adherence to components of the index ranged from 97.3% for the presence of clear language in response to 14.1% for the inclusion of a recommendation to consider non-NRT medications for quitting smoking. Performance on the index varied by chatbot with Sarah scoring overall higher than BeFreeGPT and BasicGPT (P<.001). Queries about how to quit smoking with vapes, gummies, necklaces, and hypnosis scored especially low.

That chatbots were able to generate in seconds clear advice and information on how to quit smoking that stayed on topic, even when confronted with prompts intended to derail the conversation is promising. Most responses also included a recommendation to seek out professional counseling for quitting. This implies that smokers could ask their questions, get a response, and be directed to professional advice. However, several types of standard advice were absent in about half of the responses—such as suggestions for handling cravings, the recommendation to consider using NRT, and the recommendation to seek out support from friends and family. Especially absent was the recommendation to consider non-NRT medications which was present in only 14.1% of responses. Finally, misinformation, defined as advice for quitting that was

XSL•FO
RenderX

not supported by USPSTF guidelines, was present in over 20% of responses which is concerning. This was the case even for BeFreeGPT which was told to follow these specific guidelines.

While all chatbots in our study were based on similar versions of ChatGPT, our findings indicate that Sarah outperformed the other chatbots. Sarah was 72.2% adherent to the index compared with 50% for BeFreeGPT and 47.8% for BasicGPT ($P<.001$). Additionally, Sarah was more engaging and empathic than the other chatbots ($P<.001$). These findings may reflect differences in the instructions across chatbots. Sarah's instructions covered more detailed information on how to advise on quitting smoking by providing a 6-step instruction plan on how to quit smoking (eg, set a quit date, offer help to deal with triggers, tell the user to seek out support from friends and family). Additionally, Sarah's instructions, unlike the other chatbots, explicitly called for engagement such as by instructing Sarah to "proactively keep the conversation flowing by asking follow-up questions" at the end of responses. In addition, Sarah had more detailed instructions about acceptable content to include. This adds to growing evidence that specialized or purpose-driven chatbots are important and may improve beyond general chatbot abilities [18]. Directing people to purpose-driven LLM chatbots like Sarah may be a promising tool for quitting smoking assistance.

Also noteworthy was that the index performance score varied with the query. Queries for more evidence-based methods of quitting such as for help quitting using medications had high index performance for all chatbots while queries for nonevidence-based methods of quitting such as with gummies, with a necklace, and hypnosis were more problematic, especially for BeFreeGPT and BasicGPT. This implies that a range of common queries, including for nonevidence-based methods of quitting, should be tested and used in refining a chatbot.

The findings from this analysis can guide the revision of all 3 chatbots. Scores on individual items on the index can be used to guide these improvements. For example, the instructions to BeFreeGPT may be revised to emulate those of Sarah's and include detailed instructions on how to counsel on quitting smoking and to promote engagement. Further, for all chatbots, additional instructions can be added that provide scripted responses for what are likely to be common queries for non-evidence-based methods of quitting such as how to respond when asked about quitting with gummies or a necklace. Future studies should investigate how anticipating common queries, scripting responses, and other types of specific instructions to a chatbot can affect chatbot performance.

The strengths of this study are that it is the first to simulate and evaluate common user experiences for help quitting smoking with LLM chatbots, including evidence-based and nonevidence-based queries. This study extends prior work using LLM chatbots for generating motivational messaging for smoking cessation [5] and as a stand-alone assistant in quitting smoking [4]. Weaknesses include that the adherence index was somewhat crude with just 9 items and no items that measured bias. While a crude scoring system was seen as appropriate for assessing a basic level of reliability, in the future this index could be expanded to include additional items such as those that measure bias as well as a more nuanced scoring system. In addition, this analysis was limited to one response per chatbot, and therefore it is unclear whether multiple repetitions of the same query might result in different responses. The findings are also only generalizable to short chatbot interactions, as only the first 150 words were analyzed. It may be that longer interactions would lead to higher adherence scores. Additionally, queries were intentionally chosen to represent popular Google searches in the United States, and it is, therefore, possible that results would be different for a larger sample of queries, including less popular queries, or for queries from other parts of the world where popular queries may be different. Finally, because GPT's LLM database is constantly being updated with newer training data, better logical reasoning, and algorithms for reduced hallucinations, our findings are only generalizable to the version of GPT used to generate the responses for this study.

Overall, our study provides support to the idea that LLM chatbots can be designed to adhere to quit-smoking guidelines and counseling principles. While the chatbots we tested responded to some types of queries well, for others, they omitted information, as well as occasionally provided misinformation. As LLM chatbots become more widely accessible, it is our hope that LLM health chatbots will be tested and refined so they adhere to evidence-based principles.

Abstract

Background: ChatGPT, a conversational artificial intelligence developed by OpenAI, has rapidly become an invaluable tool for researchers. With the recent integration of Python code interpretation into the ChatGPT environment, there has been a significant increase in the potential utility of ChatGPT as a research tool, particularly in terms of data analysis applications.

Objective: This study aimed to assess ChatGPT as a data analysis tool and provide researchers with a framework for applying ChatGPT to data management tasks, descriptive statistics, and inferential statistics.

Methods: A subset of the National Inpatient Sample was extracted. Data analysis trials were divided into data processing, categorization, and tabulation, as well as descriptive and inferential statistics. For data processing, categorization, and tabulation assessments, ChatGPT was prompted to reclassify variables, subset variables, and present data, respectively. Descriptive statistics assessments included mean, SD, median, and IQR calculations. Inferential statistics assessments were conducted at varying levels of prompt specificity ("Basic," "Intermediate," and "Advanced"). Specific tests included chi-square, Pearson correlation, independent 2-sample *t* test, 1-way ANOVA, Fisher exact, Spearman correlation, Mann-Whitney *U* test, and Kruskal-Wallis *H* test. Outcomes from consecutive prompt-based trials were assessed against expected statistical values calculated in Python (Python Software Foundation), SAS (SAS Institute), and RStudio (Posit PBC).

Results: ChatGPT accurately performed data processing, categorization, and tabulation across all trials. For descriptive statistics, it provided accurate means, SDs, medians, and IQRs across all trials. Inferential statistics accuracy against expected statistical values varied with prompt specificity: 32.5% accuracy for "Basic" prompts, 81.3% for "Intermediate" prompts, and 92.5% for "Advanced" prompts.

Conclusions: ChatGPT shows promise as a tool for exploratory data analysis, particularly for researchers with some statistical knowledge and limited programming expertise. However, its application requires careful prompt construction and human oversight to ensure accuracy. As a supplementary tool, ChatGPT can enhance data analysis efficiency and broaden research accessibility.

Introduction

ChatGPT is a conversational artificial intelligence (AI) created by OpenAI. It has quickly become an invaluable resource for researchers with capabilities that include reviewing literature, identifying gaps in research, and drafting papers [1-5]. With the recent addition of Python code interpretation to the ChatGPT environment, a surge of new research applications has emerged, particularly in data analysis [6]. Accompanied by innovations such as data upload and download, this new feature marks a considerable advancement toward individualized AI-assisted data analysis.

The accessibility of ChatGPT has the potential to democratize data analysis for nonspecialists and serve as a bridge between

programming knowledge and the growing demands of biomedical research [7]. Previously, ChatGPT had proven to be an asset to programmers, with capabilities ranging from debugging and annotating code to translating between coding languages [8-10]. However, for individuals without coding experience, deploying a local programming environment posed a significant challenge [7]. ChatGPT's ability to interpret code bypasses this barrier of entry, making language-to-code translation more accessible [6].

ChatGPT has excelled in some recent data analysis applications by completing bioinformatics exercises with high accuracy [6]. A preliminary analysis of ChatGPT's utility as a data analysis tool found that it provided results consistent with traditional biostatistical software [11]. However, the extent to which ChatGPT can assist with data analysis when the research question is cross-disciplinary remains unclear. For example, ChatGPT's utility was limited in addressing complex bioinformatics tasks, citing restricted file size and exclusive support for Python as key obstacles [7]. Other studies have recommended against using ChatGPT for statistical analysis due to incorrect answers, mislabeled data, and speculative results [12-14]. Continual improvements to the GPT models and refined prompts may improve the value proposition of ChatGPT in biostatistics.

As the capabilities of AI technology expand, the next step in democratizing research is to develop ChatGPT's applications for basic statistical analysis. Our research aims to provide a framework for performing preliminary inferential and descriptive statistics, as well as data management within ChatGPT. The ultimate goal is to avail a more equitable research landscape without the barriers presented by coding knowledge, thereby broadening access and innovation within the research community.

Methods

Dataset and Analyses

The 2019 National Inpatient Sample data from the National Healthcare Cost and Utilization Project was selected to assess ChatGPT's capabilities. This dataset was chosen to represent real-world observational data, similar to typical clinical research studies. Also, these data require processing before testing an array of hypotheses with various statistical tests. This is not a public-use dataset. For researchers interested in replicating these methods, this dataset is often available through institutional access.

Arbitrary inclusion criteria were selected to make the data both manageable and relevant to the aims of this study. ChatGPT's data and processing limits required uploaded files to be less than 100 megabytes. The inclusion criteria were individuals aged 41-70 years old who endured both a cerebral infarct and a myocardial infarction, with total hospital charges less than US $400,000. The resulting dataset included 2740 observations each with 5 attributes: age, gender, race, length of stay, and total charges. The 5 attributes included continuous, categorical, and binary data elements.

Common statistical methods for univariate analysis were used to evaluate ChatGPT's capabilities, including both descriptive and inferential statistics. Data processing, categorization, and tabulation were included as assessments of data management. Each assessment was conducted in a new GPT-4 window with the memory feature disabled. For each iteration, the Microsoft Excel data file and prompt were entered sequentially into the same ChatGPT window.

Ethical Considerations

The National Healthcare Cost and Utilization Project is a limited dataset, and it was deemed exempt by the institutional review board at the University of Arizona.

Data Management and Descriptive Statistics

For data processing, ChatGPT was prompted to create a new variable, reclassifying "race" from 4 dimensions (White, Black, Hispanic, and Other) to 2 dimensions (White and non-White). ChatGPT was also prompted to create a subset of patients aged 45 years to facilitate nonparametric testing later on. The decision to select 45-year-olds within the original sample was arbitrary, intended solely to create a smaller subpopulation suitable for nonparametric tests. For categorization, ChatGPT was prompted to categorize patients into 3 age cohorts (41-50, 51-60, and 61-70 years). Finally, data tabulation involved creating a series table to display the frequencies for the variables used in the categorization and processing steps. The prompts used for each element of data processing and categorization can be found in Multimedia Appendix 1.

For descriptive statistics, the methods tested were mean, SD, median, and IQR. ChatGPT was prompted to compute these values for male and female cohorts, as well as the entire dataset for the following variables: age, length of stay, and total charges. All descriptive statistics prompts were posed as directed questions without opportunity for interpretation. Descriptive statistics prompts can be found in Multimedia Appendix 2.

Inferential Statistics

Inferential statistics were performed as both parametric tests (chi-square, Pearson correlation, independent 2-sample *t* test, and 1-way ANOVA) and equivalent nonparametric tests (Fisher exact, Spearman rank order correlation, Mann-Whitney *U* test, and Kruskal-Wallis *H* test). The pairings of statistical tests are displayed in Table 1. A series of research questions were developed to guide statistical method selection (MS) toward a specific test, as shown in Table 2. Once refined, each research question was posed to ensure that a 2-tailed analysis was conducted, rather than a 1-tailed. The research questions and their proposed analytical tests were selected by one of the authors, a biostatistician, within the medical school.

XSL•FO
RenderX

Table 1. Parametric and nonparametric statistical analysis pairs.

Parametric test	Nonparametric test
Chi-square[a]	Fisher exact
Pearson correlation	Spearman rank order correlation
Independent 2-sample *t* test	Mann-Whitney *U*
1-way ANOVA	Kruskal-Wallis *H*

[a]Chi-square is a nonparametric test, as it does not require the assumption of normality. However, like the other tests listed in the "Parametric test" column, chi-square is better suited for larger sample sizes compared with its counterpart in the "Nonparametric test" column.

Table 2. Research questions and expected results.

Question	Method selection	Statistical assumptions	Statistical values
Is the distribution of White and non-White patients the same across genders?	Chi-square	• Independence • Expected values ≥5	• χ^2 (*df*) 1.385 (1) • *P*=.24
Is the distribution of White and non-White patients the same across genders for individuals who are 45 years old?	Fisher exact	• Independence	• Odds ratio=2.045 • *P*=.66
Is there a significant correlation between total charges and length of stay?[a]	Pearson correlation	• Linearity • Normality • Homoscedasticity • No extreme outliers • Paired data	• *r*=0.842 • *P*<.001
Is there a significant correlation between total charges and length of stay for individuals who are 45 years old?	Spearman rank order correlation	• Monotonicity • Nonnominal data	• ρ=0.447 • *P*=.02
Is there a significant difference in total charges between men and women?	Independent 2-sample *t* test	• Independence • Normality • Homoscedasticity • No extreme outliers • Continuous data	• *t*-stat (*df*) 0.185 (2707) • *P*=.85
Is there a significant difference in total charges between men and women who are 45 years old?	Mann-Whitney *U*	• Independence	• *U*-stat=91.000[b] • *P*=.17
Are there significant differences in length of stay across race categories?	1-way ANOVA	• Independence • Normality • Homoscedasticity • No extreme outliers • Continuous data	• *F*-stat=4.092 • *P*=.007
Are there significant differences in length of stay across race categories[c] for individuals who are 45 years old?	Kruskal-Wallis *H*	• Independence	• *H*-stat=1.984 • *P*=.37

[a]The variables were transformed for this test to improve normality and homoscedasticity.

[b]The *U*-stat was computed in Python and RStudio only, as SAS does not produce an equivalent value.

[c]The Hispanic group was excluded from this test due to insufficient observations.

The prompts used for inferential statistics were formulated at 3 levels of increasing specificity, reflecting a user's familiarity with statistics, ChatGPT, and Python. The lowest level was "Basic," where ChatGPT was provided with the research question, relevant variables, and necessary tasks. Textbox 1 shows a template used for "Basic" prompts. The "Intermediate" level used prompts that were more specific than "Basic" and included additional guidelines, including data cleaning steps and strategies for assessing the statistical assumptions (SA). The "Advanced" level prompted ChatGPT with the same information as "Intermediate" and a recommended statistical test. An overview of the components for each level of prompt is provided in Table 3. The individual prompts used for each test can be found in Multimedia Appendix 3.

XSL•FO
RenderX

Textbox 1. A "Basic" template prompt for inferential statistics.

I am analyzing variables related to hospital visits and demographics to answer the question, "_____?" The relevant variables are as follows:

- x (variable_type): description
- y (variable_type): description

Embody the role of an experienced biostatistician and complete the following tasks:

- Suggest the most relevant statistical method for analyzing this dataset.
- List and verify all of the critical assumptions that must be met to perform this statistical method.
- If any critical assumptions of the primary test are not met, identify a more appropriate alternative analysis. When suggesting a new test, list and verify the assumptions for this new test.
- Perform the most appropriate test and provide test statistics and *P* values to 3 decimal places.

Table 3. Components of inferential statistics prompts at varying knowledge levels.

	Basic	Intermediate	Advanced
Research question	✓	✓	✓
Variables and variable types	✓	✓	✓
Data clean step		✓	✓
Strategies to assess assumptions		✓	✓
Suggested method			✓
Tasks to perform (MS[a], SA[b], SV[c])	✓	✓	✓

[a]MS: method selection.

[b]SA: statistical assumptions.

[c]SV: statistical values.

Response Grading

The data analysis tasks were also performed in Python (Python Software Foundation), SAS (SAS Institute), and RStudio (Posit PBC) to generate an expected statistical output for comparison. For data processing, data categorization, data tabulation, and descriptive statistics, the expected statistical values (SV) can be found in Multimedia Appendix 4.

For inferential statistics, the expected statistical results are in the SV column of Table 2. The results were consistent among Python, SAS, and RStudio. If there were any discrepancies occurring due to algorithmic variations among the platforms, the Python output would have been designated as the "gold standard," as ChatGPT uses this language for its calculations.

The measured outcomes were data processing, data categorization, data tabulation, descriptive statistics, and inferential statistics. A trial consisted of a single interaction with ChatGPT, including one user input (prompt) and one ChatGPT output. Data processing and categorization were assessed through a direct comparison of the frequencies generated by ChatGPT to those in Python, SAS, and RStudio, each across 10 trials. Data tabulation was assessed through ChatGPT's ability to provide the correct columns, rows, and row totals during the processing and categorization trials (20 trials total).

Descriptive statistics were assessed through a direct comparison of the mean, SD, median, and IQR generated by ChatGPT to the expected values across 10 trials. Inferential statistics tests were evaluated on 3 criteria: MS, SA, and SV across 10 trials per statistical method (80 trials total). MS involved selecting the expected method, SA involved reporting the underlying assumptions critical to the statistical test, and SV involved calculating the test statistics and *P* values for the selected statistical method.

For data processing, data categorization, data tabulation, and descriptive statistics, the trial was coded as correct only if all values from ChatGPT's output were within 1% of the expected values. For inferential statistics, MS was coded as correct only if the final test selected by ChatGPT matched the expected test, SA was coded as correct only if the expected assumptions were assessed implicitly or explicitly, and SV was coded as correct only if both the test statistic and *P* value were within 1% of the expected output. A flowchart detailing how all trials were assessed is available in Multimedia Appendix 5.

All measured outcomes were coded as either correct or incorrect. Only a single prompt was provided to ChatGPT in each trial, with no further interaction. If ChatGPT requested further user input or provided multiple answers without indicating the best choice, that trial was coded as incorrect. If ChatGPT timed out during code interpretation, that trial was discarded. During inferential statistics trials, if MS was incorrect, then SA and SV were coded as incorrect as well. The choice of 10 trials per outcome was informed by previous studies on ChatGPT's performance in data analysis tasks, most of which assessed ChatGPT's performance in fewer trials [6,7,11]. In the absence

XSL•FO
RenderX

of an established standard, 10 trials were selected to capture variability in ChatGPT's responses.

Results

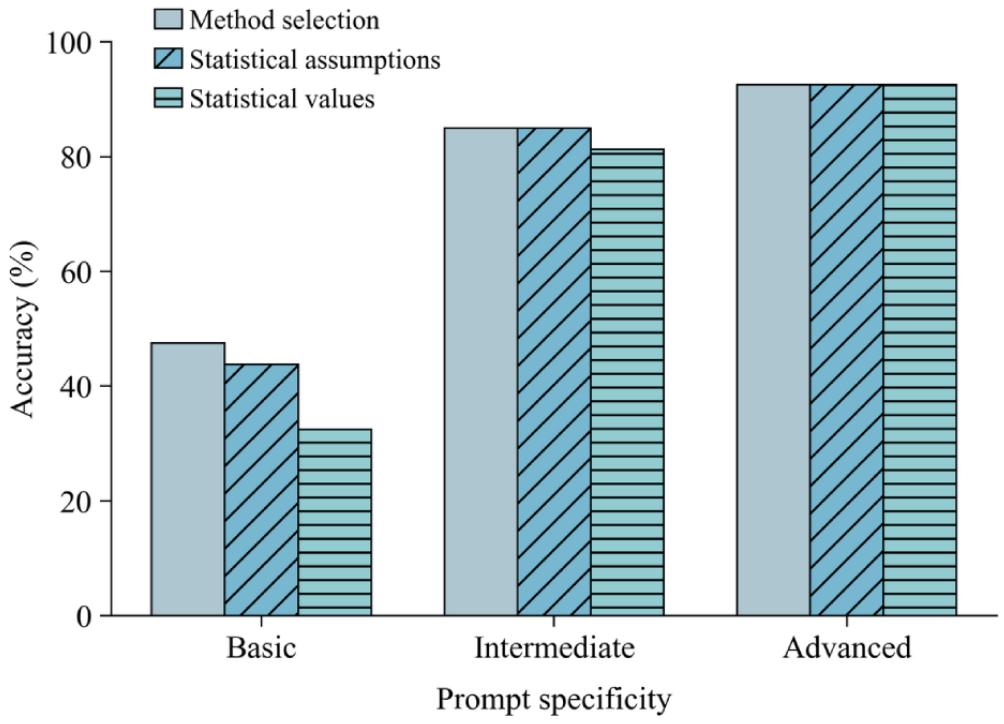
Data Management and Descriptive Statistics

ChatGPT performed data processing, categorization, and tabulation correctly across all trials. Variations in table aesthetics were inconsequential to the measured outcomes. For descriptive statistics, ChatGPT provided accurate means, SDs, medians, and IQRs for the 3 continuous variables across all attempts. The compiled tables and descriptive statistics for each variable can be found in Multimedia Appendix 4.

Inferential Statistics

When provided a "Basic" prompt, ChatGPT achieved 47.5% accuracy (38/80 attempts) on MS, 43.8% accuracy (35/80 attempts) on SA, and 32.5% accuracy (26/80 attempts) on SV. With "Intermediate" prompts, ChatGPT achieved 85.0% accuracy (68/80 attempts) on both MS and SA and 81.3% accuracy (65/80 attempts) on SV. With "Advanced" prompts, ChatGPT achieved 92.5% accuracy (74/80 attempts) across all MS, SA, and SV assessments. These results are displayed in Table 4 and Figure 1.

Table 4. Results for 10 attempts at inferential statistics with prompts at varying levels of specificity.



Test	Basic			Intermediate			Advanced		
	MS[a]	SA[b]	SV[c]	MS	SA	SV	MS	SA	SV
Chi-square	10	10	0	10	10	7	10	10	10
Fisher	9	9	9	10	10	10	10	10	10
Pearson	2	2	2	8	8	8	8	8	8
Spearman	9	6	8	7	7	7	10	10	10
t test	0	0	0	10	10	10	9	9	9
Mann-Whitney	7	7	6	8	8	8	9	9	9
ANOVA	1	1	1	7	7	7	8	8	8
Kruskal-Wallis	0	0	0	8	8	8	10	10	10

[b]SA: statistical assumptions.

[c]SV: statistical values.

Figure 1. ChatGPT accuracy by prompt specificity.

XSL•FO
RenderX

The errors encountered by ChatGPT across all inferential statistics trials included incorrect MS (n=51), coding error (n=13), incomplete response (n=9), incomplete assumptions (n=2), median imputed for missing value (n=1), and outliers incorrectly removed (n=1). A complete list of errors is listed in Table 5. Coding errors were limited to chi-square trials only and occurred due to a feature of the Python function. This function, chi2_contigency, contains a parameter for performing Yates correction, a method to prevent overestimation with small samples. As the parameter defaults to true, ChatGPT performed this correction despite the large sample size.

Table 5. Frequency of errors encountered by ChatGPT during inferential statistics trials.

Test	Basic	Intermediate	Advanced
Chi-square	• Coding error: 10	• Coding error: 3	—[a]
Fisher	• Incorrect method: 1	—	—
Pearson	• Incorrect method: 7 • Incomplete response: 1	• Incorrect method: 2	• Incorrect method: 2
Spearman	• Incomplete assumptions: 2 • Incomplete response: 1 • Imputed value: 1	• Incorrect method: 2 • Incomplete response: 1	—
t test	• Incorrect method: 10	—	• Incorrect method: 1
Mann-Whitney	• Incomplete response: 3 • Outliers removed: 1	• Incorrect method: 2	• Incomplete response: 1
ANOVA	• Incorrect method: 8 • Incomplete response: 1	• Incorrect method: 3	• Incorrect method: 2
Kruskal-Wallis	• Incorrect method: 10	• Incorrect method: 1 • Incomplete response: 1	—

Discussion

Principal Findings

Our investigation into the analytical capabilities of ChatGPT revealed a nuanced understanding of its implementation that, while promising, exhibits limitations that warrant careful consideration. ChatGPT's performance demonstrated proficiency in data processing, data categorization, data tabulation, and descriptive statistics. The most specific prompts improved response accuracy across inferential statistics trials. Based on our data, "Basic" prompts provided little value, with a low overall accuracy across all trials. Meanwhile, "Intermediate" prompts resulted in a similar overall accuracy compared with "Advanced" prompts despite the addition of a suggested statistical test in the "Advanced" prompts.

The variation observed across trials reflects the probabilistic nature and inherent unpredictability of ChatGPT [15]. Evaluating its accuracy as a tool requires repeated testing [16]. Given that GPT-4 is trained on over 1 trillion parameters [17], a definitive assessment of its performance is nearly impossible, as it would require countless trials to capture all possible response variations. This could explain the anomalies in the *t* test and Spearman trials, where less specific prompts sometimes outperformed more detailed ones.

The calculation errors from ChatGPT likely stem from challenges in implementing user instructions and interpreting intermediary outputs, rather than inherent issues with the Python-based analytical frameworks. With intentional instructions, most inaccuracies can be avoided. Although MS was the most common source of error, ChatGPT's responses included sufficient information for users to verify the suitability of the statistical method. Furthermore, in the "Intermediate" and "Advanced" trials, if ChatGPT selected the correct method, the remaining tasks were frequently completed accurately. Precise and specific prompts generally enhance accuracy; however, erroneous instructions may introduce further inaccuracies, as ChatGPT heavily relies on user input. Successful use of ChatGPT as a statistical doula requires balancing clear analysis goals with the flexibility needed for ChatGPT to present accurate information, without inadvertently introducing bias.

The power and democratization of ChatGPT allow for collaboration to further mitigate concerns about the analytical process. Although these trials were based on single prompts, a series of follow-up prompts by a user can identify determinations with regard to the data, the proposed analysis, or the code. For example, when asked about the Yates correction, ChatGPT acknowledged its use for small samples. To prevent errors from defaulted values like the Yates parameter, prompts should instruct ChatGPT to specify a function's parameters and provide the rationale for setting each parameter. This method was incorporated into the "Intermediate" and "Advanced" trials.

XSL•FO
RenderX

ChatGPT will inevitably produce inaccurate results that, if not carefully verified, may be detrimental to the research community. Therefore, all ChatGPT-generated analyses should be approached with caution. Based on this 10-trial approach, researchers are encouraged to incorporate multiple trials of the requested analysis in the statistical workflow using as specific instructions as possible. ChatGPT is not intended to be a standalone tool for data analysis; consultation with a biostatistician is essential for validating statistical approaches and ensuring reliable results.

Our dataset and assessments are limitations. Although we selected a moderately sized sample, it is still small relative to datasets used in complex analyses and may not assess the extent of ChatGPT's capabilities. In this report, the statistical analyses focused on univariate comparisons, where the capabilities for bivariate data analysis remain to be validated. Furthermore, due to the probabilistic nature of ChatGPT, a definitive performance assessment would require thousands of trials. Finally, we did not assess the validity of ChatGPT's statements outside of the chosen measures. When ChatGPT provided correct, incorrect, or extraneous information in the output, we did not count that against the assessment of accuracy to replicate the expected analysis.

Conclusion

ChatGPT has significant potential as a tool for exploratory data analysis, particularly for researchers who have some statistical knowledge but limited programming expertise. This paper is intended for individuals with a foundational understanding of statistics who could generate "Intermediate" prompts on their own. We hope that these individuals may use ChatGPT to perform preliminary analyses, helping them to understand their data, draw initial insights, and begin writing their papers while waiting for consultation with a statistician. These preliminary analyses are not meant to replace expert review but to accelerate the research process. Furthermore, ChatGPT may serve as an educational resource, helping researchers better understand statistical analyses and tackle unique problems [18].

Further advancements to ChatGPT will undoubtedly enhance its applicability and accuracy in statistical analysis. Data visualization is a crucial component of data analysis, and although still limited, ChatGPT's ability to process visual inputs through its "Vision" feature has already shown promise in interpreting statistical figures [19]. Furthermore, OpenAI is rapidly advancing its GPT models, and GPT-o1, the latest version, is already available for preview. This new model is reportedly better suited to "reason through complex tasks and solve more difficult problems in science, coding, and math" [20]. Improvements to both "Vision" and the GPT model will solidify ChatGPT's role as an asset for researchers.

We encourage researchers to leverage ChatGPT for the programming aspects of their statistical work while leaving the critical decisions to human expertise. By doing so, they can harness the full potential of ChatGPT as a supplementary tool in their research arsenal, ensuring that its application is both productive and scientifically sound. For researchers interested in applying ChatGPT to data analysis, we recommend following the best practices outlined in Textbox 2.

Textbox 2. Best practices for performing data analysis with ChatGPT.

Prompting

- Prompts should have specific and comprehensive goals. Researchers can benefit from creating a flexible template that can be adapted across different data analysis tasks. Additional details relevant to the current query should be included as needed. For those using ChatGPT for inferential statistics, prompts should, at a minimum, resemble the level of detail used in our "Intermediate" trials.

Refinement

- Approach data analysis like a discussion. Engage ChatGPT by asking it to identify any potential gaps in its knowledge or the inputs provided. Request feedback on how prompts can be improved for future trials. Ask ChatGPT to explain any decisions or necessary parameters.

Consistency

- At a minimum, attempt each trial 3 times to verify its consistency.

Verification

- ChatGPT-generated data analysis can be used to start drafting a paper before consulting a statistician. However, ensure that all statistical outputs and interpretations are reviewed by a statistician before publication.

Transparency

- Be transparent about using ChatGPT to assist with data analysis. Consider sharing the prompts used in your analysis to allow readers to replicate or refine the process.

Authors' Contributions

MRR and CI contributed to the study conception. MRR and TG handled the literature search, drafting, and data collection. CI and JL performed critical revisions.

Abstract

Background: Laypeople have easy access to health information through large language models (LLMs), such as ChatGPT, and search engines, such as Google. Search engines transformed health information access, and LLMs offer a new avenue for answering laypeople's questions.

Objective: We aimed to compare the frequency of use and attitudes toward LLMs and search engines as well as their comparative relevance, usefulness, ease of use, and trustworthiness in responding to health queries.

Methods: We conducted a screening survey to compare the demographics of LLM users and nonusers seeking health information, analyzing results with logistic regression. LLM users from the screening survey were invited to a follow-up survey to report the types of health information they sought. We compared the frequency of use of LLMs and search engines using ANOVA and Tukey post hoc tests. Lastly, paired-sample Wilcoxon tests compared LLMs and search engines on perceived usefulness, ease of use, trustworthiness, feelings, bias, and anthropomorphism.

Results: In total, 2002 US participants recruited on Prolific participated in the screening survey about the use of LLMs and search engines. Of them, 52% (n=1045) of the participants were female, with a mean age of 39 (SD 13) years. Participants were 9.7% (n=194) Asian, 12.1% (n=242) Black, 73.3% (n=1467) White, 1.1% (n=22) Hispanic, and 3.8% (n=77) were of other races and ethnicities. Further, 1913 (95.6%) used search engines to look up health queries versus 642 (32.6%) for LLMs. Men had higher odds (odds ratio [OR] 1.63, 95% CI 1.34-1.99; P<.001) of using LLMs for health questions than women. Black (OR 1.90, 95% CI 1.42-2.54; P<.001) and Asian (OR 1.66, 95% CI 1.19-2.30; P<.01) individuals had higher odds than White individuals. Those with excellent perceived health (OR 1.46, 95% CI 1.1-1.93; P=.01) were more likely to use LLMs than those with good health. Higher technical proficiency increased the likelihood of LLM use (OR 1.26, 95% CI 1.14-1.39; P<.001). In a follow-up survey of 281 LLM users for health, most participants used search engines first (n=174, 62%) to answer health questions, but the second most common first source consulted was LLMs (n=39, 14%). LLMs were perceived as less useful (P<.01) and less relevant (P=.07), but elicited fewer negative feelings (P<.001), appeared more human (LLM: n=160, vs search: n=32), and were seen as less biased (P<.001). Trust (P=.56) and ease of use (P=.27) showed no differences.

Conclusions: Search engines are the primary source of health information; yet, positive perceptions of LLMs suggest growing use. Future work could explore whether LLM trust and usefulness are enhanced by supplementing answers with external references and limiting persuasive language to curb overreliance. Collaboration with health organizations can help improve the quality of LLMs' health output.

KEYWORDS

large language model; artificial intelligence; LLMs; search engine; Google; internet; online health information; United States; survey; mobile phone

Introduction

Search engines, such as Google, democratized access to health information and changed the dynamics of the patient-provider relationship, with 72% of internet users in the United States looking on the web for health information [1-4]. Clinicians and health organizations initially had mixed reactions, including some early efforts to discourage patients from searching for health information on the web because of concerns that web-based information could make them misinformed or anxious [5-7]. Patients' use of internet-based health information enhances their understanding and their ability to manage their health conditions [8,9]. Over time, clinicians and health organizations started to partner with search engine companies to improve content reliability. For example, the World Health Organization has worked with Google to ensure that COVID-19 searches yield evidence-based information [10].

Large language models (LLMs) have the potential to replace internet searches for clinicians and patients. LLMs, such as ChatGPT, have demonstrated promising performance in clinical decision-making [11] and diagnosis [12]. Numerous studies have explored doctors' evaluation of LLMs as an information resource and diagnostic aid [13-18] and some research has begun to consider laypeople's attitudes toward and use of these tools, such as concerning ethical considerations, whether they are differentiable from doctor's responses, and the accuracy of symptom-checkers [19-21]. LLMs can potentially make information accessible to patients in more specific and personalized ways, but previous studies have yet to consider patient use of LLMs in comparison to search engines for health-related questions.

We surveyed laypeople in the United States to compare the use of LLMs and search engines for health queries, the types of health queries posed, and attitudes toward interactions with these tools.

Methods

Recruitment Procedures

US participants aged older than 18 years were recruited from Prolific, a web-based research participant platform, in February 2024. We programmed the survey questions in Qualtrics. The invitation in Prolific included the purpose and a brief description of this study, a link to the Qualtrics survey, and it informed participants that survey completion would take approximately 5 minutes for study 1 and 5-10 minutes for study 2. Participants completed study 1 in 1.21 (SD 1.04) minutes on average. Participants completed study 2 in 10.01 (SD 7.02) minutes on average. All questionnaires are presented in Multimedia Appendix 1.

Ethical Considerations

This study was reviewed and approved by New York University's institutional review board (IRB-FY2024-8278). Participants were presented with an informed consent form including a description of their role as participants in a research study to learn more about patterns of using search engines and LLMs for health queries. If they agreed to participate in this study, they were asked to complete a questionnaire about their experience using a search engine and an LLM for health questions. The research involves no more than minimal risk of harm to participants. At the end of the survey, participants were asked to provide a limited amount of personal data (Prolific ID) to provide compensation and asked about their willingness to participate in the second study if they qualified. Data were stored in password-protected computers of the faculty investigators and their assistants. Participants received compensation of US $0.25 in study 1 and US $2.50 in study 2.

Survey Questionnaire

A screening survey (study 1) identified the prevalence of participants' LLM and search engine use for health queries. Next, study 1 participants who reported using both LLMs and search engines to answer health questions were invited to participate in study 2, in which their use of these tools was compared. Study 2 participants were asked which types of health information they sought, and how the results affected their relationships with their providers. Likert scales from 1 (strongly disagree) to 7 (strongly agree) were used to evaluate the effect of LLMs and search engines on participants' relationships with health care providers.

Participants were asked about LLMs' versus search engines' perceived usefulness and ease of use. These two measures represent people's perception of whether a system would help them perform their tasks and whether the system is easy or difficult to use [22]. Trustworthiness is the extent to which people trust and rely on LLMs or search engines to answer health questions [23]. Relevance is the extent to which participants consider the source as offering output relevant to their health needs. We also asked whether the source's results were perceived to be biased or benefit advertisers. Finally, we asked about participants' reactions to LLM and search engine query results [24] and their perceptions of anthropomorphism [25]. Likert scales from 1 (strongly disagree) to 7 (strongly agree) were used to evaluate attitudes toward LLMs and search engines. A separate Likert scale ranging from 1 (not at all) to 7 (extremely) was used for items assessing participants' feelings about using LLMs and search engines. Finally, we asked about demographics: age, gender, education, income, use of LLMs for health, health status, and perceived tech skills. Perceived technical skills assessed participants' perceptions of their smartphone skills (1: not at all skilled to 7: expert; Multimedia Appendix 1).

Statistical Analysis

We compared the demographics of LLM users and nonusers using logistic regression. We used ANOVAs followed by a Tukey post hoc test to compare the frequency of use of LLMs and search engines for each of the types of health information

XSL•FO
RenderX

they sought. Using the Shapiro-Wilk test, we observed a nonnormal distribution for perceived usefulness, ease of use, relevance, bias, trustworthiness, feelings, perceptions of benefit to advertisers, and perceptions of anthropomorphism. Therefore, paired samples of Wilcoxon tests were used to compare the effects of LLMs and search engines on these perceptions.

Results

Overview

In total, 2002 participants responded to study 1 (see demographic information in Table 1). Furthermore, 300 randomly selected study 1 participants who reported using both LLMs and search engines for health queries completed study 2. Further, 281 participants were retained after indicating the use of LLMs for health-related queries and passing attention checks (see Table 1 for demographic information).

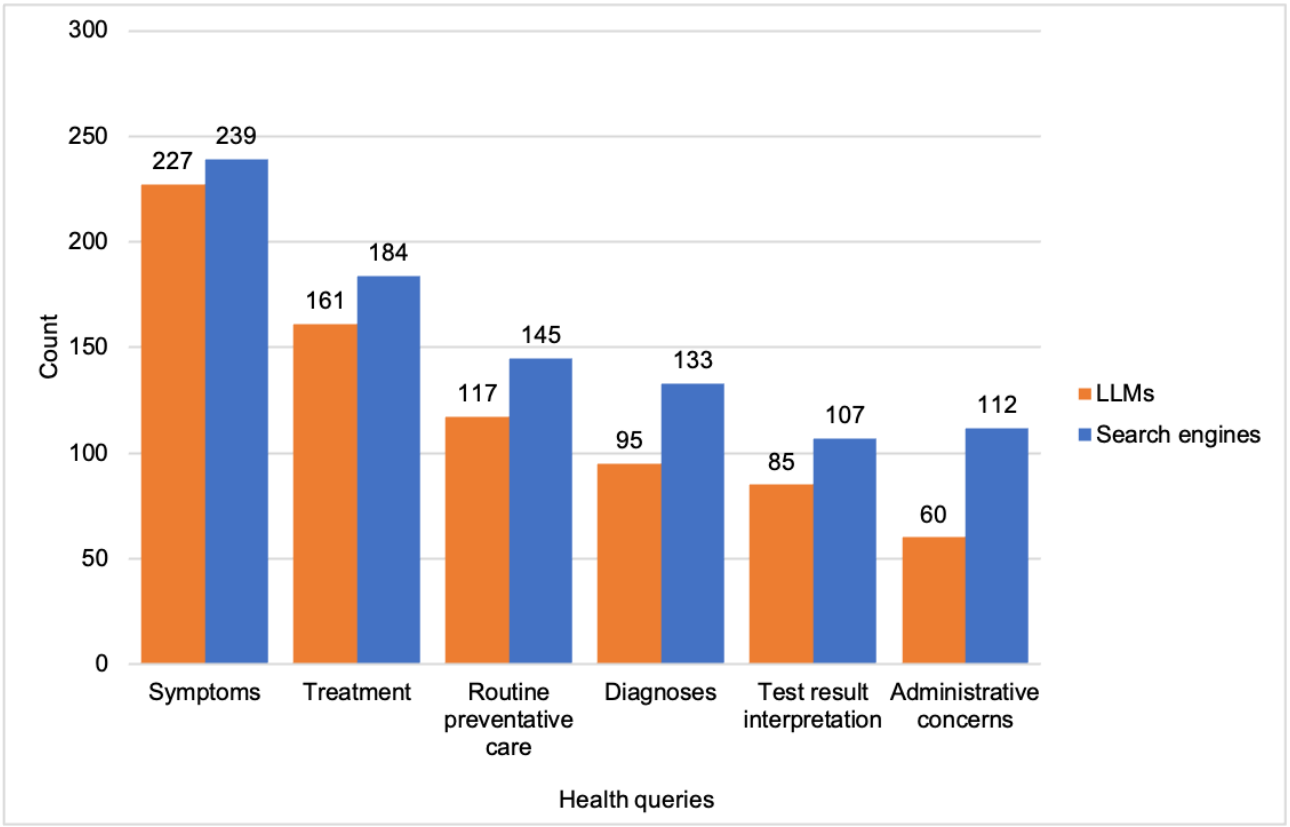
Table 1. Demographic characteristics of respondents in study 1 and study 2, with study 2 participants being a subset of those from study 1.

Variable	Study 1	Study 2
Respondents, n	2002	281
Age (years), mean (SD)	39.4 (13)	40.43 (13.17)
Gender, n (%)		
Male	904 (45.2)	161 (57.3)
Female	1045 (52.2)	112 (39.9)
Other	53 (1.6)	8 (2.8)
Race, n (%)		
Asian	194 (9.7)	35 (12.5)
Black	242 (12.1)	46 (16.4)
Hispanic	22 (1.1)	3 (1.1)
White	1467 (73.3)	187 (66.5)
Other	77 (3.8)	10 (3.6)
Education		
High school or less	578 (28.9)	72 (25.6)
Associate degree	249 (12.4)	39 (13.9)
Bachelor's degree	847 (42.3)	125 (44.5)
Graduate degree	328 (16.4)	45 (16)
Income (US $)		
Less than 50,000	715 (35.7)	106 (37.7)
50,000-99,999	694 (34.7)	103 (36.7)
More than 100,000	518 (25.9)	72 (25.6)
Unknown	75 (3.7)	0 (0)
Insurance, n (%)		
Private insurance	1166 (58.2)	159 (56.6)
Public insurance	592 (29.6)	92 (32.7)
No insurance	192 (9.6)	25 (8.9)
Other insurance	52 (2.6)	5 (1.8)
Using LLMs[a] for health, n (%)		
Yes	642 (32.1)	281 (100)
No	1360 (67.9)	0 (0)
Using search engines for health, n (%)		
Yes	1913 (95.6)	281 (100)
No	89 (4.4)	0 (0)
Health status, n (%)		
Excellent	268 (13.4)	44 (15.7)
Good	1231 (61.5)	158 (56.2)
Only fair	426 (21.3)	66 (23.5)
Poor	67 (3.3)	12 (4.3)
Prefer not to say	10 (0.5)	1 (0.4)
Perceived tech skills, mean (SD)	5.60 (1.05)	5.85 (1.04)

[a]LLM: large language model.

XSL•FO
RenderX

Among the participants from study 2, a total of 218 (77.6%) participants reported using ChatGPT [OpenAI] as their only LLM tool to answer health questions, 48 (17.1%) reported using both ChatGPT and other LLM tools (such as Bard [Google AI] or Copilot [Microsoft]), and only 15 (5.3%) indicated they used other LLM tools without using ChatGPT. For health-related searches, 228 (81.1%) participants used Google, 51 used both Google and other search engines (such as Bing [Microsoft]), and only 2 (<1%) used Bing alone for finding health answers. Therefore, most participants used ChatGPT as their primary LLM tool and Google search to answer health questions.



Demographic Comparison: LLM Users Versus Nonusers for Health-Related Questions

A logistic regression analysis revealed that men had higher odds (odds ratio [OR] 1.63, 95% CI 1.34-1.99; *P*<.001) of using LLMs for health-related questions compared to women. Individuals who reported their race as Black (OR 1.9, 95% CI 1.42-2.54; *P*<.001) and Asian (OR 1.66, 95% CI 1.19-2.30; *P*<.01) used LLMs for health-related questions more than participants who identified as White. Participants who perceived their health status as excellent (OR 1.46, 95% CI 1.1-1.93; *P*=.01) reported using LLMs for health-related questions more than those reporting good health status. Individuals with higher perceived technical proficiency have a higher likelihood of using LLMs for health-related questions (OR 1.26, 95% CI 1.14-1.39, *P*<.001; see Table S1 in Multimedia Appendix 1).

LLMs Versus Search Engines

In the follow-up study (study 2), most participants used search engines first (n=174, 61.9%) to answer health questions, but the second most common first source consulted was LLMs (n=39, 13.9% of participants), followed by doctor's appointment (n=19, 6.8%), calling their doctor (n=17, 6%), messaging their doctor (n=14, 5%), asking friends (n=7, 2.5%), going to the emergency department (n=6, 2.1%), and other options to answer health questions (n=5, 1.8%). They reported using search engines 6.91 (SD 2.67) times over the past year for health queries, compared to using LLMs 4.7 (SD 2.79) times, and other services fewer times (Figure S1 in Multimedia Appendix 1, *P*<.05). Finally, as shown in Figure 1, there was no difference in the likelihood that participants would use LLMs versus search engines to ask about symptoms (LLM: n=227; search engines: n=239), treatment (LLM: n=161; search engines: n=184), routine preventive care (LLM: n=117; search engines: n=145), diagnoses (LLM: n=95; search engines: n=133), and interpretation of test results (LLM: n=85; search engines: n=107), but they were more likely to use search engines than LLMs for administrative queries (LLM: n=60; search engines: n=112).

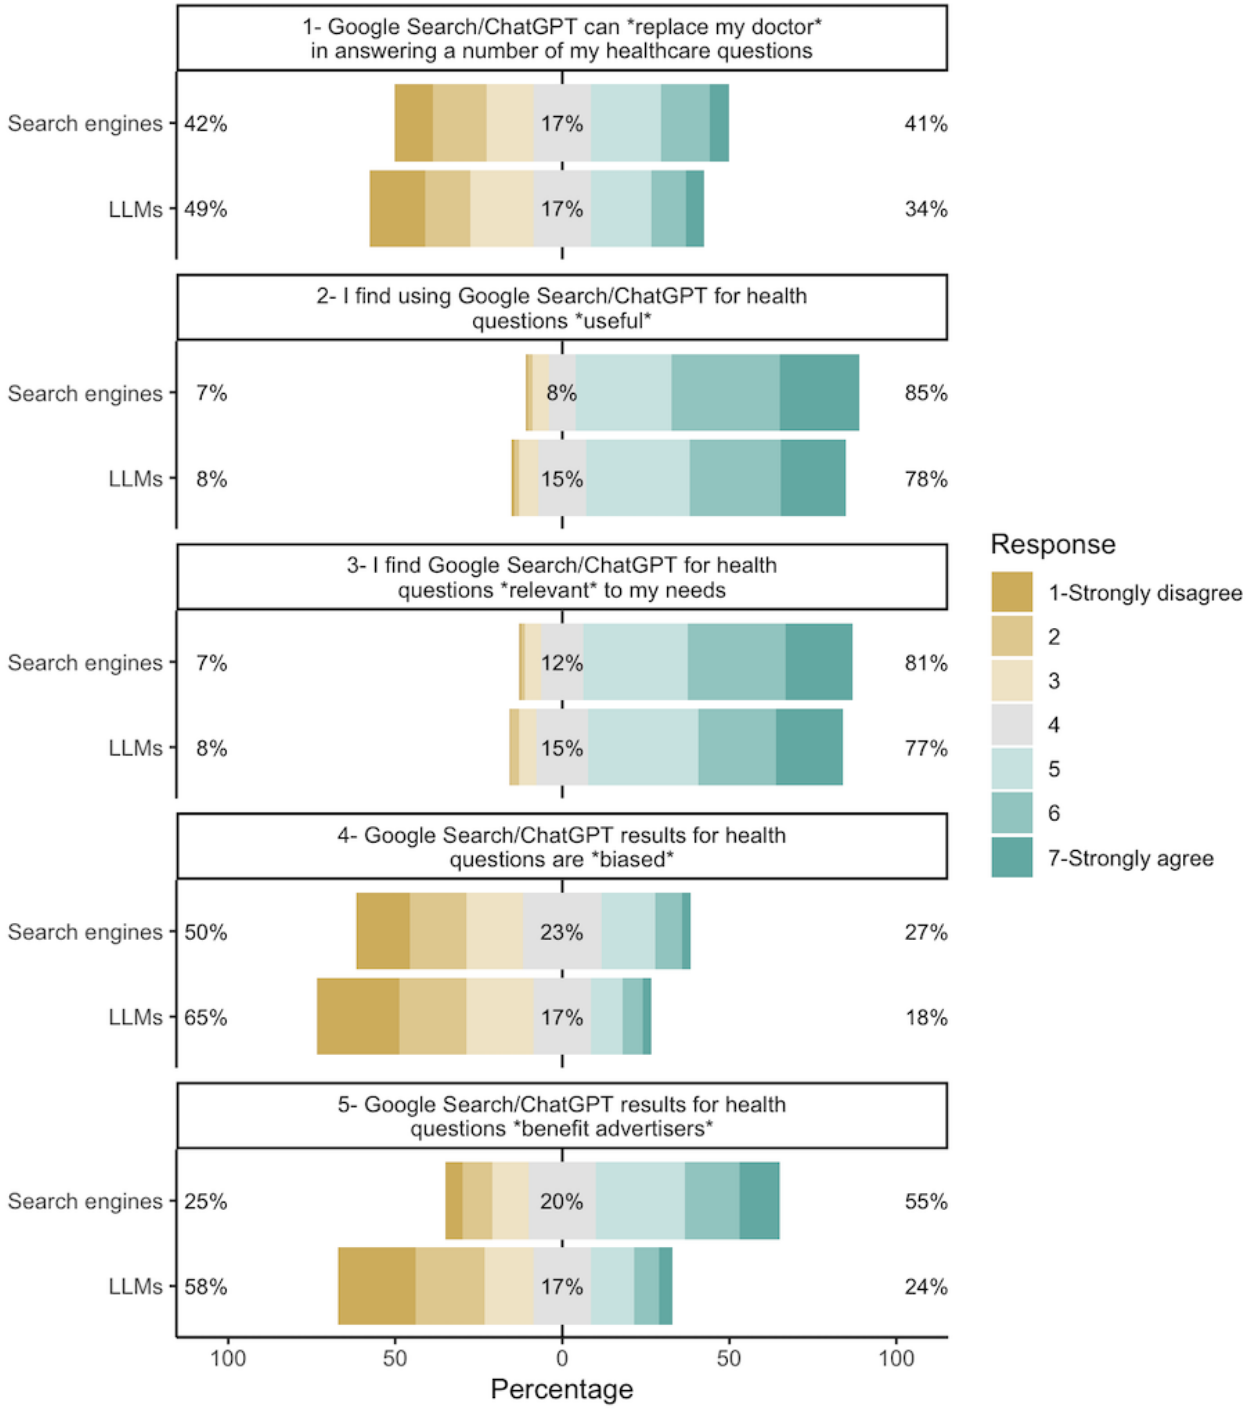


Figure 1. Distribution of health queries between LLMs and search engines among 281 participants who reported using both for health queries. The question asked was "When consulting [Google Search/ChatGPT] for health questions, which questions do you use it to answer?" LLM: large language model.

As can be seen in Figure 2, LLMs were perceived to be less useful than search engines for answering health-related questions (W=7214.5, *P*<.01). However, LLMs were also perceived as less biased (W=9533.5, *P*<.001) and less beneficial to advertisers than search engine results (W=20,708, *P*≤.001). Moreover, participants were less likely to view LLMs as being able to replace doctors in answering health care questions than search engines (W=9223, *P*=.003).

XSL•FO
RenderX

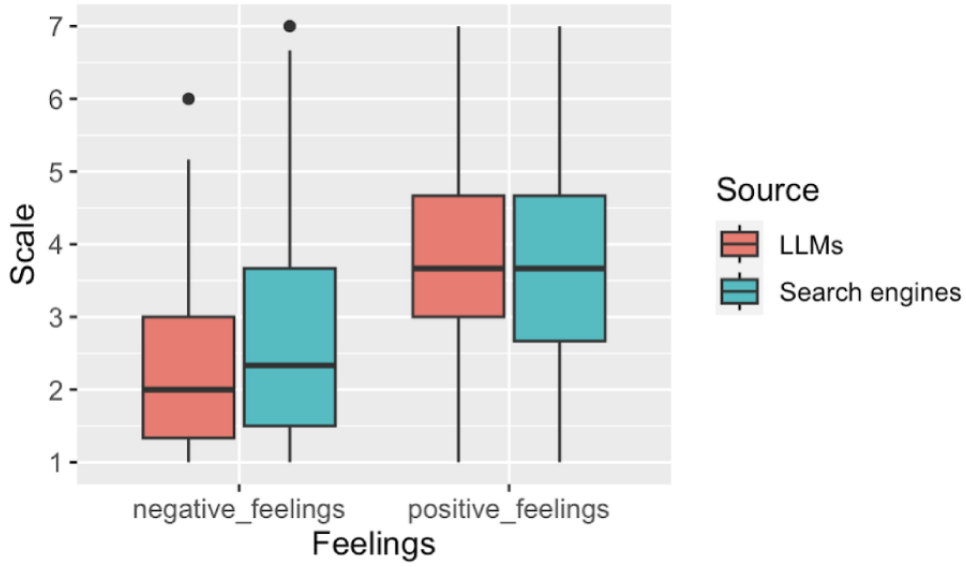

Figure 2. Comparison of LLMs and search engines among 281 participants who reported using both for health queries, using the Wilcoxon signed rank test for replacing "my doctor" (W=9223, *P*=.003), usefulness (W=7214.5, *P*<.01), relevance (W=7117, *P*=.07), result bias (W=9533.5, *P*<.001), and benefits to advertisers (W=20708, *P*<.001). LLM: large language model.

When searching for health information, results can reassure users but they can also make users more concerned [26]. As shown in Figure 3, LLMs elicited fewer negative feelings in response to the results of their queries than did search engines (W=19,496, *P*<.001). The LLMs also elicited more positive feelings in response to results than search engines did (W=9773.5, *P*=.01), but the median was lower than the midpoint of 4 (W=977.5, *P*<.001). On the other hand, while falling short of statistical significance, search engines were perceived to offer responses more relevant to users' needs than LLMs (W=7117, *P*=.07). There were no significant differences between ratings of LLMs and search engines in ease of use or trustworthiness of answers (*P*'s>.05). All paired samples of Wilcoxon tests are available in Table S2 in Multimedia Appendix 1. Finally, most participants (n=160, 57%) perceived LLMs as more human than search engines, but a minority perceived search engines as either more human (n=32, 11%) or equivalent to LLMs (n=32, 12%).

XSL•FO
RenderX

Figure 3. Comparison between LLMs and search engines among 281 participants who reported using both for health queries, based on the Wilcoxon signed rank test for negative feelings (W=19,496, *P*<.001) and positive feelings (W=9773.5, *P*=.01). LLM: large language model.

Discussion

Principal Findings

We compared the use of LLMs, search engines, and other sources for health queries and found that while the most common first source of information participants consulted was search engines, 13.9% of respondents consulted LLMs before any other source. Moreover, they were as likely to use LLMs as search engines for the most common health queries (symptoms, treatment, routine preventive care, diagnoses, and interpretation of test results), though they were more likely to use search engines than LLMs for less common administrative queries. In addition, LLMs elicited fewer negative feelings, such as less distress in response to the information provided, and were perceived as less useful and relevant than search engines. LLMs appeared more human-like, less biased, and less favorable toward advertisers. No significant differences were found between trust in LLMs and trust in search engines.

At this early stage of LLM adoption, participants indicated that LLMs were less useful and relevant than search engines for answering health-related questions. One key reason that search engines provide more useful and relevant health information compared to LLMs could include their greater transparency, such as providing external references to information sources that convey credibility and trustworthiness to users—features that are absent or inaccurate in many popular LLMs. The low perceived usefulness and relevance of LLMs can be attributed to issues such as incorrect statements, hallucinations, and ethical concerns [21,27,28], which can be mitigated through the involvement of domain experts, refining input prompts, and enhancing the fine-tuning of LLMs for specific tasks or domains [29].

Strengths of LLMs relative to search engines that emerged in our study include that LLMs elicited fewer negative feelings, such as less distress in response to the information provided. They also appeared more human-like, less biased, and less favorable toward advertisers. LLMs compared to search engines provide people with a feeling of human-like and personalized attention and understanding, enhancing digital communication that makes information delivery more intuitive. Evidence outside of health care suggests that these features make LLMs as persuasive as humans [30]. LLMs have advanced state-of-the-art performance in generating human-like text based on user health questions [19].

With respect to ease of use, there was no significant difference between LLMs and search engines for health queries. This is notable because search engines have been in regular use for decades while LLMs are a relatively new lay user-facing technology. The fact that respondents perceived that new and unfamiliar technology is as easy to use as an extensively used and highly familiar technology suggests that users may shift their use to LLMs further and relatively quickly.

Prior research has found that trust evaluations shape web-based health information-seeking behavior and compliance with health advice [31-33]. No significant differences were found between trust in LLMs and trust in search engines. A possible explanation for the lack of difference in trustworthiness between search engines and LLMs is the counterbalance between the two dimensions of trust: cognitive trust based on perceived accuracy and competence, and affective trust which depends on believing one's interests are protected [32]. People perceived that search engines, compared to LLMs, provide more helpful and relevant health information, reinforcing perceived accuracy and competence in health care information. However, search engines were also perceived to prioritize advertisers' interests more than LLMs did, likely diminishing users' trust in them. While LLMs excel at engaging with users, their output often lacks interpretation within a medical context [34] and they may sometimes fabricate facts or present incorrect information more convincingly and believably [35]. Future work can further analyze the effects of each trust dimension to better understand perceptions of LLMs.

XSL•FO
RenderX

Limitations

Our study has some key limitations. All of the participants were recruited from Prolific. Prolific participants tend to be technically proficient and may be more likely to use new technologies such as LLMs than the general population. Additionally, we screened for US residency so our findings may not generalize to other countries and languages. Future studies are needed to evaluate whether these findings generalize to broader populations. Finally, the current inferential analysis aggregates attitudinal reactions across varied types of health queries. A valuable future study would separately inquire about perceptions of technology (eg, usefulness, ease of use, or trust) for different types of health queries to enable more nuanced assessments.

Conclusion

Overall, most individuals still turn to search engines as their primary source for health-related questions, considering them more useful than LLMs. In the future, people may incorporate LLMs more routinely in their search for answers to health questions. In the case of LLMs, incorporating references and external sources of information would be a beneficial practice to increase trustworthiness. Just as clinicians and health organizations have partnered with search engine companies to enhance the reliability of health-related content [12], similar collaborations could enhance the quality of the health-related information provided by LLMs.

Abstract

Background: At the end of 2023, Bayer AG launched its own internal large language model (LLM), MyGenAssist, based on ChatGPT technology to overcome data privacy concerns. It may offer the possibility to decrease their harshness and save time spent on repetitive and recurrent tasks that could then be dedicated to activities with higher added value. Although there is a current worldwide reflection on whether artificial intelligence should be integrated into pharmacovigilance, medical literature does not provide enough data concerning LLMs and their daily applications in such a setting. Here, we studied how this tool could improve the case documentation process, which is a duty for authorization holders as per European and French good vigilance practices.

Objective: The aim of the study is to test whether the use of an LLM could improve the pharmacovigilance documentation process.

Methods: MyGenAssist was trained to draft templates for case documentation letters meant to be sent to the reporters. Information provided within the template changes depending on the case: such data come from a table sent to the LLM. We then measured the time spent on each case for a period of 4 months (2 months before using the tool and 2 months after its implementation). A multiple linear regression model was created with the time spent on each case as the explained variable, and all parameters that could influence this time were included as explanatory variables (use of MyGenAssist, type of recipient, number of questions, and user). To test if the use of this tool impacts the process, we compared the recipients' response rates with and without the use of MyGenAssist.

Results: An average of 23.3% (95% CI 13.8%-32.8%) of time saving was made thanks to MyGenAssist (P<.001; adjusted R^2=0.286) on each case, which could represent an average of 10.7 (SD 3.6) working days saved each year. The answer rate was not modified by the use of MyGenAssist (20/48, 42% vs 27/74, 36%; P=.57) whether the recipient was a physician or a patient. No significant difference was found regarding the time spent by the recipient to answer (mean 2.20, SD 3.27 days vs mean 2.65, SD 3.30 days after the last attempt of contact; P=.64). The implementation of MyGenAssist for this activity only required a 2-hour training session for the pharmacovigilance team.

Conclusions: Our study is the first to show that a ChatGPT-based tool can improve the efficiency of a good practice activity without needing a long training session for the affected workforce. These first encouraging results could be an incentive for the implementation of LLMs in other processes.

KEYWORDS

MyGenAssist; large language model; artificial intelligence; ChatGPT; pharmacovigilance; efficiency

Introduction

Artificial intelligence (AI) is currently the center of attention in a lot of disciplines. Health is no exception. For instance, AI could be useful for the analysis of pictures for detecting local signs of catheter-associated infections [1] or for reducing both the time and costs required for drug discovery [2]. It could also play a role in the education of future health care professionals [3].

Studies from previous years already provided evidence that the use of AI would benefit pharmaceutical companies [4-6]. However, most of those studies used complex applications of AI to extract or synthesize data from documents like health records [7,8] or social media content [9-11].

Although not yet reachable to a wide audience, large language models (LLMs) offer possibilities to integrate AI in several domains without requiring a long training of the workforce, thanks to its accessibility and ease of use. While everyone can use some LLMs that are open access—including ChatGPT since November 2022 [12]—getting an adequate answer sometimes requires gradually improving the prompts. Hence, the integration of LLMs in the work environment can provide new soft skills at a low cost and promote the empowerment of workers. Several studies already showed that pharmacists and other health care professionals are willing to use LLMs as a help in their work [13-15].

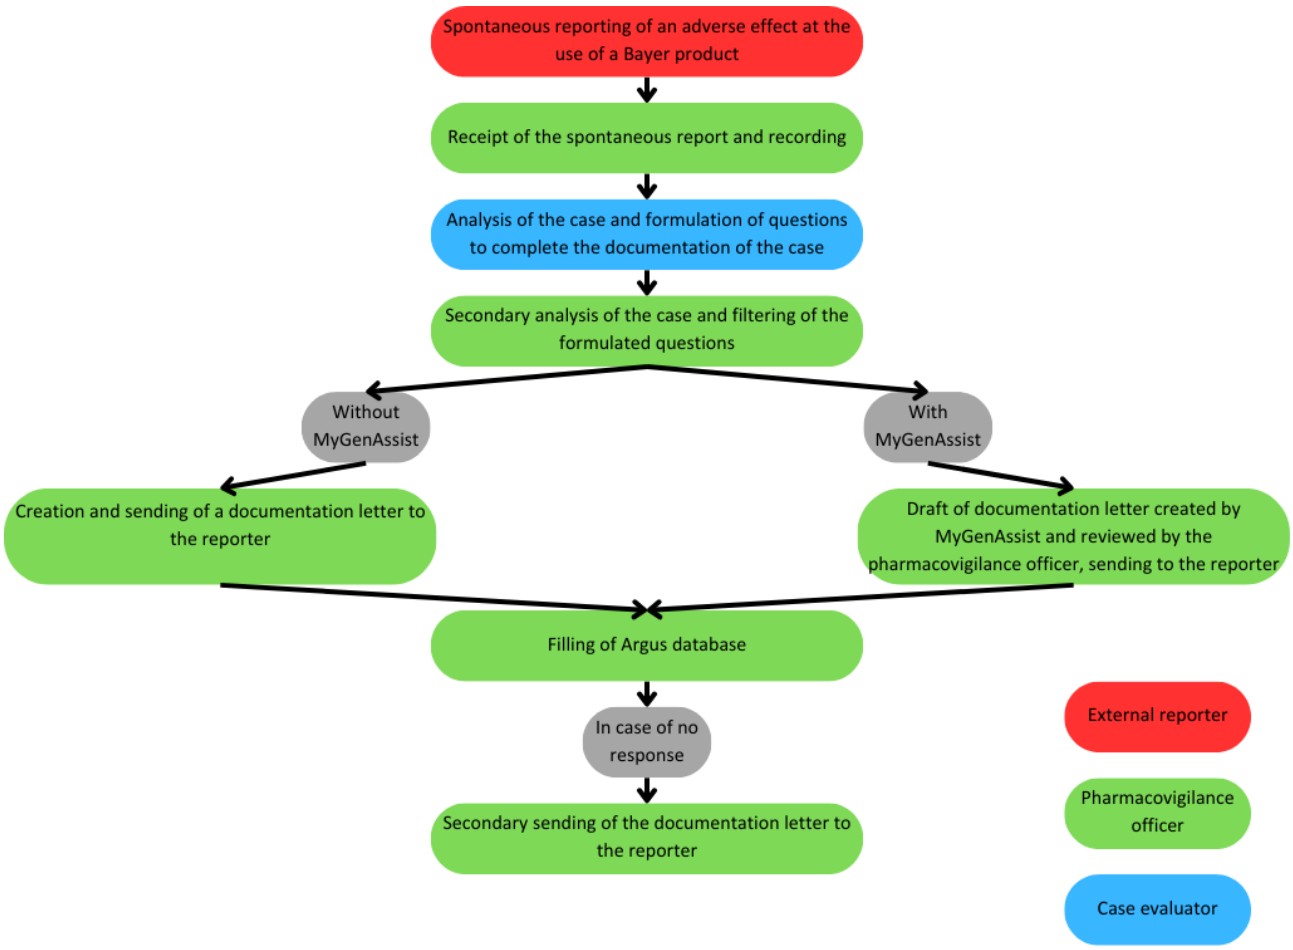
However, the use of LLMs raises concerns about data privacy. Recent news showed that the information provided by some users in their prompts could be transferred by ChatGPT to others [16]. This threat can be answered by companies with the opportunity to develop their own LLM for internal use.

Hence, Bayer AG launched on September 21, 2023, its own internal LLM called MyGenAssist, based on ChatGPT technology. Bayer, as a market authorization holder in Europe, has the duty to set a system to collect, register, and analyze adverse events related to its products according to European [17] and French good pharmacovigilance practices (GVPs) [18] and the European Directive 2001/83/CE [19]. Tasks related to this imperative follow internal procedures, which make some of them repetitive and time-consuming. A semiautomatization of these tasks thanks to an LLM could make them less arduous for workers and procure more time for other activities at higher added value.

In the pharmacovigilance field, the Giens Workshop [20] in 2022 aimed to initiate a reflection on the integration of AI in this area and highlighted the actions implying the writing of a letter to contact a patient or a health care professional as a good opportunity for this. To the best of our knowledge, no study described LLMs' use cases in pharmacovigilance from a daily and practical perspective.

In this study, we aim to determine whether the use of MyGenAssist in the pharmacovigilance case documentation process can provide an improvement in efficiency (ie, save time without leading to a decrease in the answer rate).

Methods



Description of the Activity and Materials Used

Description of the Case Documentation Process and Potential Contribution of MyGenAssist

The current internal process for collecting, recording, and documenting spontaneous case reports of adverse drug events at Bayer France is described here (Figure 1): reporters can notify Bayer about cases by phone, mail, or electronic means. The report is compiled into a source document, which is then added to an internal pharmacovigilance database by a local pharmacovigilance officer. The source document is analyzed by a case evaluator who is part of the company's global pharmacovigilance team. Based on the global analysis, the pharmacovigilance officer is in charge of defining the final list of relevant questions to complete the case. The GVPs, written by the French Agence Nationale de Sécurité du Médicament et des produits de santé, add a duty to contact the reporter a second time if the first attempt of contact was unsuccessful [18].

XSL•FO
RenderX

Figure 1. Description of the process for documenting spontaneous notifications of adverse drug events.

MyGenAssist was added to this process at the stage of drafting documentation letters. This LLM was used to write a first draft of the letters, which was then reviewed and modified if needed by the pharmacovigilance officer.

Software and Applications Used

MyGenAssist is an LLM internal to Bayer based on the technology of ChatGPT-4 Turbo (OpenAI), a conversational agent based on generative AI [21]. The model used here has no differences compared to the one available to the public, apart from the fact that MyGenAssist is securely hosted by Bayer. All manipulations performed on this internal LLM can be reproduced on ChatGPT, which is accessible to the public on the web. Here, MyGenAssist was used by ourselves as final users; the prompt was created without any fine-tuning or modification of its algorithm.

Pharmacovigilance cases reported to Bayer are compiled on an internal pharmacovigilance database supported by the Argus pharmacovigilance case management software developed by Oracle [22]. This software assigns a specific reference to each case. It contains all documents related to the case as well as information regarding the actions taken to analyze the case, such as attempts to contact the reporter.

The questions formulated by the case evaluators following their analysis of the case are listed on the FAST application (Bayer internal application). The pharmacovigilance officer can select the relevant questions and add others if needed.

Use of MyGenAssist for the Activity

Pharmacovigilance case documentation letters were written according to templates validated by an internal process. Two templates exist depending on the type of recipient (patients or health care professionals). The pharmacovigilance officer could adapt the template in function of the pharmacovigilance case. To make the LLM predraft the pharmacovigilance case documentation letters, the 2 templates were used. The elements of the templates corresponding to information specific to each case were replaced by titles placed into brackets in the letter templates. These 2 letter templates were then provided via the following prompt as shown in Multimedia Appendix 1 (original version in French; the translation corresponds to Multimedia Appendix 2, an example of a query is shown in Multimedia Appendix 3, and its translation is shown in Multimedia Appendix 4).

Staff Training

To train staff to use MyGenAssist specifically for this activity, a training session was planned before initiating its use. The earlier-described operating mode was given to the pharmacovigilance officers. A training phase was also planned to verify their good understanding of the use of the tool. The operating procedure was also formalized for the use of potential

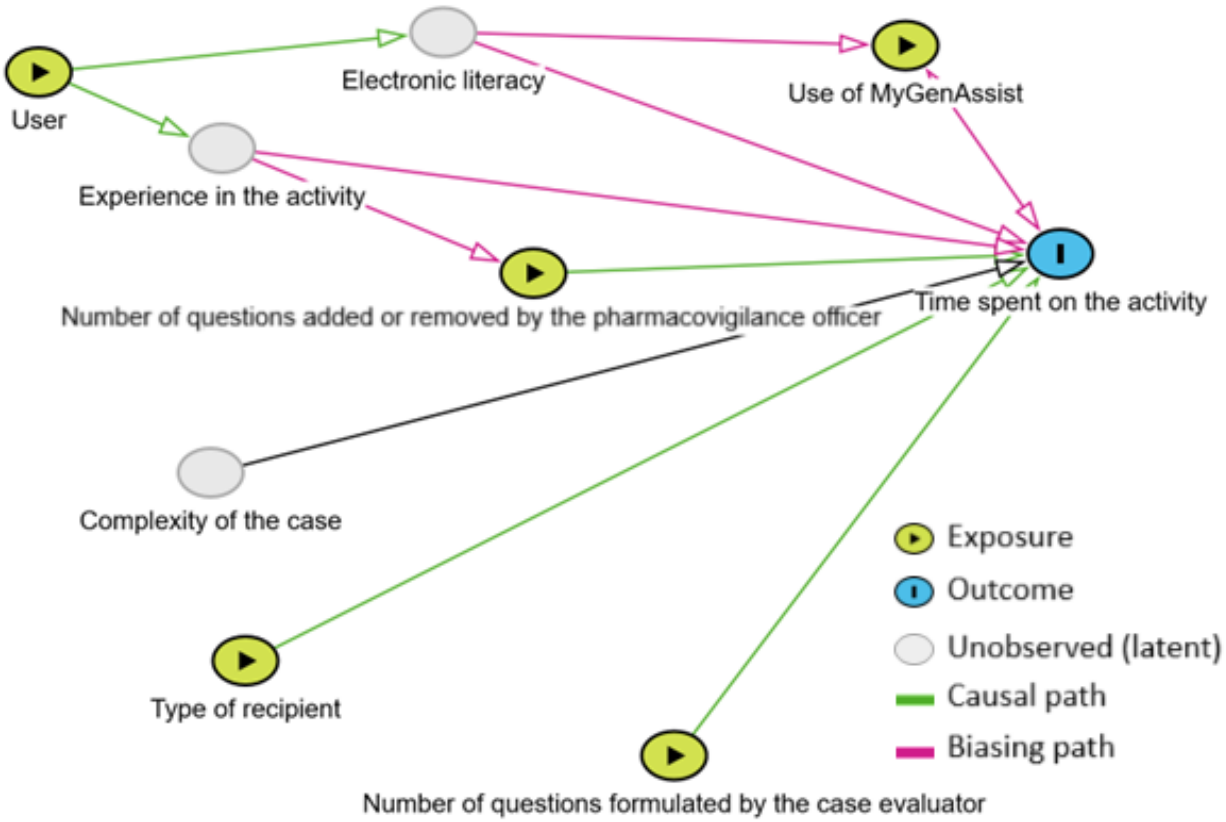
XSL•FO
RenderX

new arrivals. To allow pharmacovigilance officers to report any difficulties or suggestions for improvement regarding the operating procedure, meetings were scheduled every other week until the termination of the study.

Data Collection

The study was conducted between January 2 and May 3, 2024. The time spent on each case was measured from the moment the pharmacovigilance case was acknowledged until the letter was sent and the Argus database was filled out.

Over an initial period of 9 weeks, the time spent on drafting each documentation letter, without the use of MyGenAssist, was measured. Over a second equivalent period, the time spent on the same task, but using the LLM as a drafting aid, was also measured. During the 2 periods, apart from the addition of MyGenAssist, no significant changes in the management of the activity took place: 3 workers, including 2 experimented participants and a newcomer were present throughout the 4 months of the study, and the process did not undergo any notable modifications.



Statistical Analysis

Calculation of Time Savings

To determine the average time saved for each case thanks to MyGenAssist, a multiple linear regression was performed, in which the explained variable or outcome was the time spent per case. To highlight the impact of MyGenAssist, the parameters that could potentially influence the time spent per case were researched and selected on the basis of a review of the pharmacovigilance documentation process with experienced pharmacovigilance officers who defined, based on their daily practice, which elements could weigh on the time spent. Because of the company's specificities in the pharmacovigilance documentation process, the judgment of pharmacovigilance officers was then the unique criteria to add these parameters to the model. Among them, all parameters that could be modelized were included in the regression model as independent or explanatory variables (Figure 2):

$$Y=a_1X_1+a_2X_2+a_3X_3+a_4X_4+a_5X_5+b$$

Figure 2. Causal diagram of factors potentially impacting the time spent on the activity, built with Dagitty software (version 3.1).

Y is the time spent per case (continuous quantitative variable, expressed in minutes). X_1 is the use of MyGenAssist (dichotomous categorical variable: use or no use). X_2 is the type of recipient (dichotomous categorical variable: patient or health care professional). The letter template differs significantly depending on this parameter. It may also be necessary to simplify the questions contained in the letter for patients, leading to more time spent on the task. X_3 is the number of questions formulated by the case evaluator (discrete quantitative variable). This parameter can also impact the time spent. Each question is asked in English. Without the use of MyGenAssist, a French translation is automatically provided by the internal software FAST, but the translations need to be reviewed and the questions sometimes need to be adapted according to the recipient. This

XSL•FO
RenderX

adaptation is a step in the workflow whose duration could be correlated to the number of questions. When using MyGenAssist, this latter also provides a translation of the questions, but some adaptation work is still necessary. X_4 is the number of questions added or removed by the pharmacovigilance officer (discrete quantitative variable). The pharmacovigilance officer has the option to remove questions prepared by the case evaluator considering them irrelevant in the context of the case. Conversely, this latter can also add questions to obtain information considered as necessary. Adding questions or considering the removal of questions from the case processor leads to additional reflection time that can impact the overall duration of the task. X_5 is the user (categorical variable: user 1, 2, or 3). The user was taken into account. The personal characteristics of the user will influence the time spent on the task. a_1, a_2, a_3, a_4, and a_5 are, respectively, the coefficients of the variables X_1, X_2, X_3, X_4, and X_5, and b is the intercept. Three parameters in this causal diagram were not included in the model because they cannot be measured: the experience in the activity, the electronic literacy of the user, and the complexity of the case.

The multiple linear regression was performed using the R software (R Foundation for Statistical Computing) with the "lm" function, which can be found in the *stats* package (all R equations used in this study are described in Multimedia Appendix 5). The outliers were researched thanks to the function "check_outliers" from the *performance* package [23].

The linear regression was completed with a hierarchical regression to study the relevance of the independent variables in the model. It was performed with the function "stepAIC" from the package *mass* [24] on R. The hierarchical regression is a backward stepwise Akaike information criterion.

Cases were randomly distributed among the pharmacovigilance officers without considering the context of the case, the type of recipient, and the number of questions a priori. The number of questions formulated was not related to the type of recipient.

Measurement of Effectiveness

The reliability of the LLM was not studied because the use of MyGenAssist was intended only as an aid in drafting documentation letters. However, a measure of the effectiveness of the task with or without the tool was carried out. For this, a comparison of the proportion of cases for which a response from the recipient was obtained after the first and the second contact attempt was made, depending on whether MyGenAssist was used or not. A subgroup analysis was also realized in function of the type of recipient (physician or patient). The comparison was made on R thanks to the "chisq.test" function that can be found in the *stats* package. In the subgroup analysis, the same comparison was done but specifically for cases whose recipient was a physician on one hand, and on the other hand, for cases whose recipient was a patient.

Ethical Considerations

This study was not considered as being related to human research in health, as it clearly focused on evaluating work performance with or without an AI-based tool. Regulations in France require such studies to be in compliance with the General Data Protection Regulation (ie, European Regulation 2016/679) [25]. The data used in this study were retrieved first during the normal course of the pharmacovigilance activities and reused for the study as authorized by General Data Protection Regulation [25] and after having received oral consent from pharmacovigilance workers who were informed of the objective of the study and how the data will be used.

Results

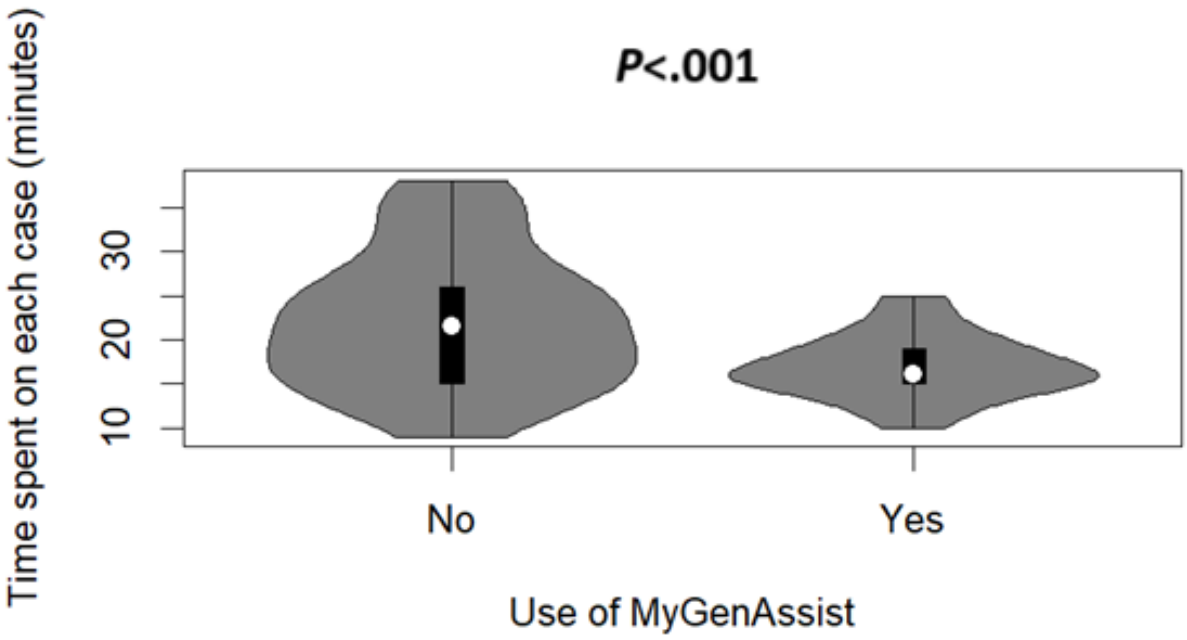
Statistical Study

The study included 122 cases (48 without the use of MyGenAssist and 74 with its use). The average time spent on each case was 19.05 (SD 6.05; 95% CI 17.97-20.12) minutes. The average time for cases handled was 22.25 (SD 7.62; 95% CI 20.09-24.41) minutes without the use of MyGenAssist and 16.97 (SD 3.50; 95% CI 16.17-17.77) minutes when the LLM was used (Figure 3). When all factors that potentially impact the time spent on the activity are taken into account in a multiple linear regression model, an average of 23.3% (95% CI 13.8%-32.8%; P<.001) of time savings were realized for each case thanks to MyGenAssist (adjusted R^2=0.286; df=115; Figure 4). All explanatory variables of the linear regression model got a P value inferior to .05 apart from the number of questions added or removed by the pharmacovigilance officer (P=.05).

The hierarchical regression performed found that all the parameters used as explanatory variables were useful to get the best model (the lowest Akaike information criterion is obtained with all the parameters included in the model; Table 1).

XSL•FO
RenderX

Figure 3. Time spent on each case in function of the use of MyGenAssist.



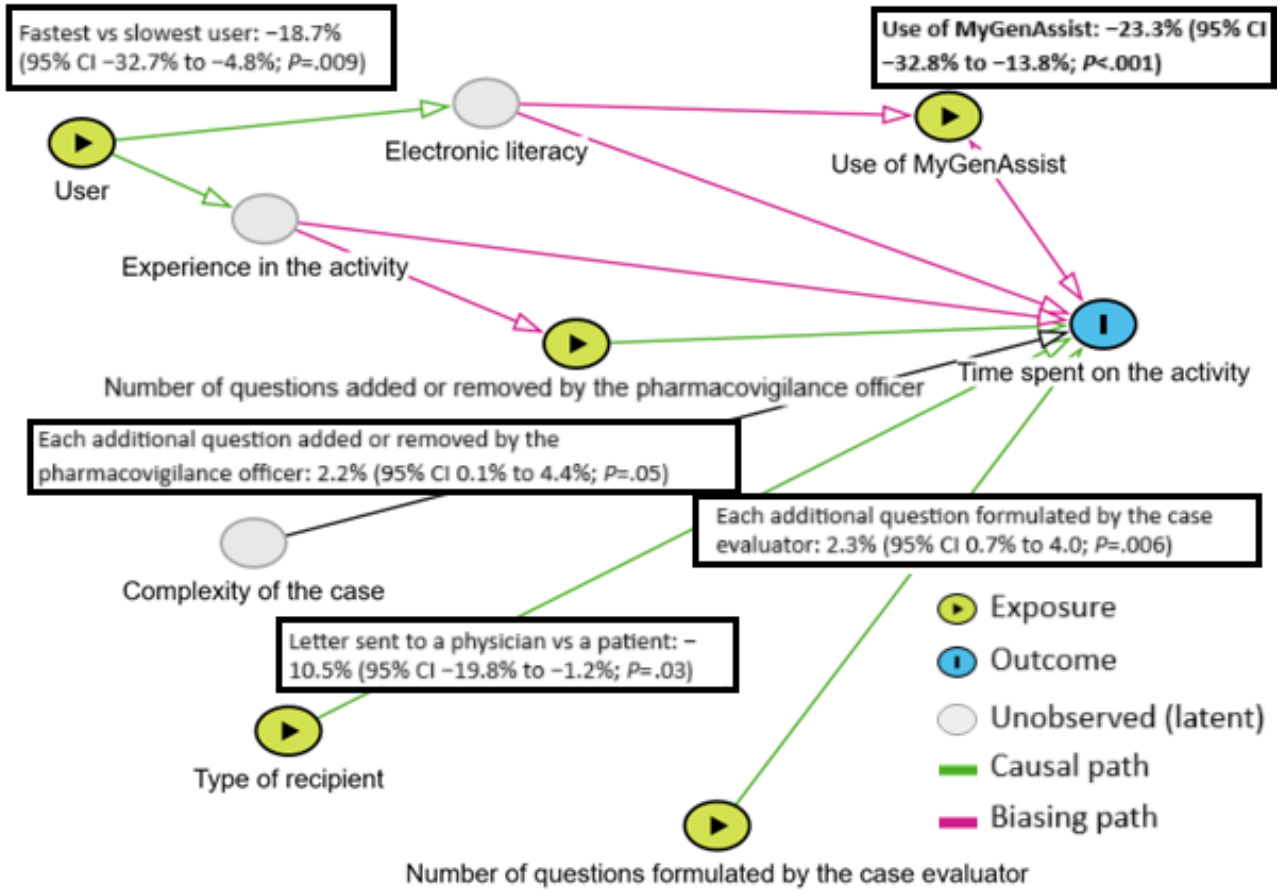


Figure 4. Influence of explanatory variables on the time spent on a case. A logarithmic transformation was performed to fulfill the conditions of the linear regression model (the actual model is log *t*=a1X1+a2X2+a3X3+a4X4+a5X5+b). "log T" is the logarithmic transformation of the variable T; hence, the result obtained is a percentage of difference of time in function of each parameter.

XSL•FO
RenderX

Table 1. Akaike information criterion (AIC) of the multilinear regression model in function of the parameters used.

Parameters included	*df*	Sum of squares	Residual sum of squares	AIC
All	—[a]	—	7.0929	–333.08
Variable "number of questions added or removed by the pharmacovigilance officer" removed	1	0.23076	7.3237	–331.17
Variable "type of recipient" removed	1	0.30945	7.4024	–329.87
Variable "user" removed	2	0.44116	7.5341	–329.72
Variable "number of questions formulated by the case evaluator" removed	1	0.48239	7.5753	–327.05
Variable "use of MyGenAssist" removed	1	1.45757	8.5505	–312.28

[a]Not applicable.

According to the number of spontaneous pharmacovigilance reports for which a documentation request was necessary during the last 3 years, it can be estimated that the mean time saved on the activity with the use of the LLM could be between 66.27 (SD 22.79) and 108.70 (SD 37.23) hours per year, on the basis of an average 23.3% time saved on the average 22.25 (SD 7.62) minutes spent on a case without the use of MyGenAssist. Based on a working day of 8 hours, the use of MyGenAssist for this activity in the 3 previous years could have saved an average of 10.7 (SD 3.6) days of work per year (Table 2).

Table 2. Potential time saved on the pharmacovigilance case documentation process each year with the use of MyGenAssist.

Year	Pharmacovigilance cases requiring documentation request, n	Potential time saved (hours)		Potential time saved (working days)[a]	
		Mean (SD)	95% CI	Mean (SD)	95% CI
2021	1258	108.70 (37.23)	98.16-119.23	13.6 (4.7)	12.3-14.9
2022	947	81.82 (28.02)	73.89-89.75	10.2 (3.5)	9.2-11.2
2023	767	66.27 (22.79)	60.12-72.72	8.3 (2.8)	7.5-9.1

[a]A working day is considered to last 8 hours.

No statistical difference has been found regarding the answers' rates after 1 attempt of contact, whether MyGenAssist was used or not: 31% (15/48) of letters produced without MyGenAssist were provided with an answer and 24% (18/74) when the generative AI was used for the writing (P=.40; χ^2_1=0.7). The same situation occurred after 2 attempts: 42% (20/48) without the tool vs 36% (27/74; P=.57; χ^2_1=0.3). In a subgroup analysis in function of the type of recipient, these results were consistent (Table 3).

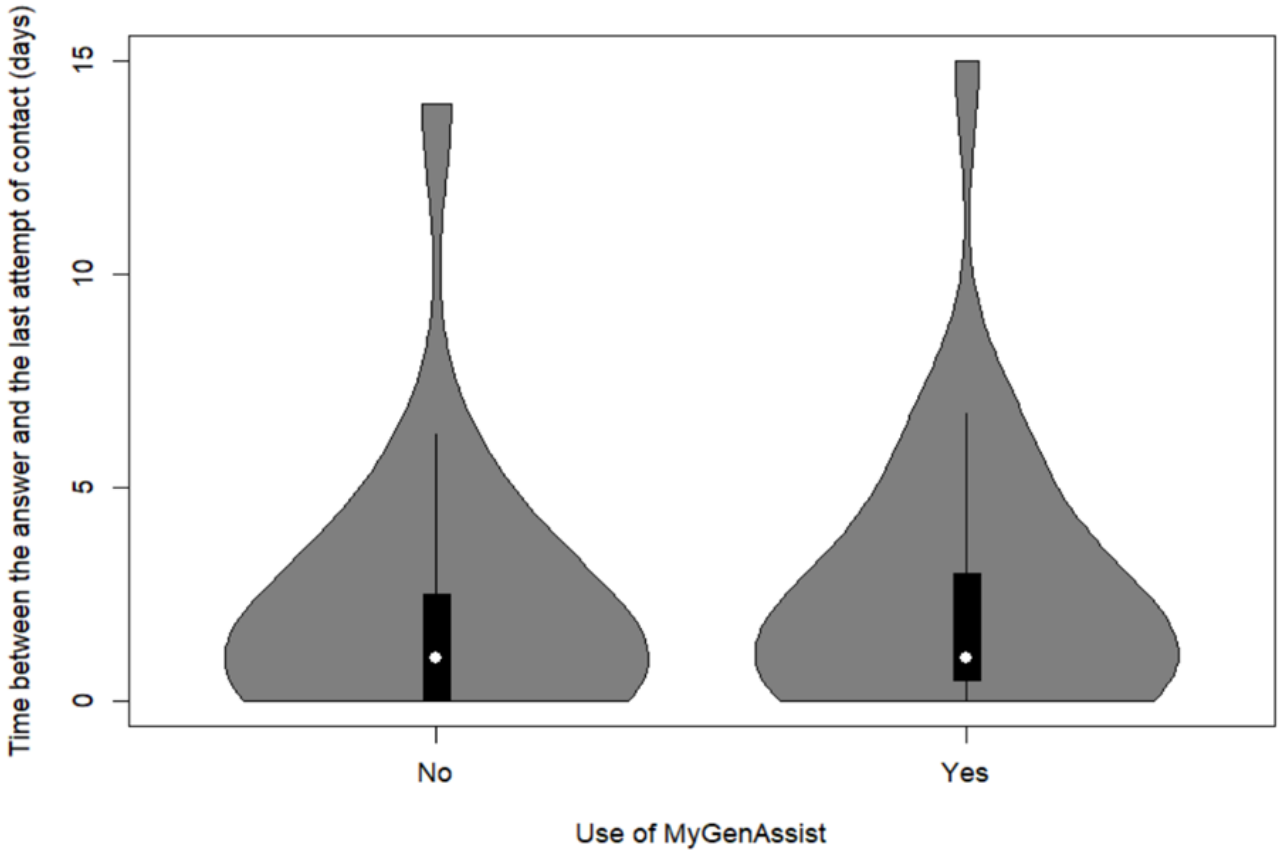

Table 3. Rates of answers to letters sent for pharmacovigilance case documentation in function of the use of MyGenAssist and the type of recipient.

	Without the use of MyGenAssist, n/N (%)	With the use of MyGenAssist, n/N (%)	*P* value	Chi-square (*df*=1)
Total	20/48 (42)	27/74 (36)	.57	0.3
Physicians	14/29 (48)	15/45 (33)	.20	1.6
Patients	6/19 (32)	12/29 (41)	.49	0.5

In cases for which an answer is provided, the average time between the answer and the last attempt of contact does not differ significantly (Figure 5): 2.20 (SD 3.27; 95% CI 1.27-3.13) days when the letter was written without MyGenAssist and 2.65 (SD 3.30; 95% CI 1.90-3.41) days with its use (P=.64; t_{44}=–0.46).

XSL•FO
RenderX

Figure 5. Comparison of the duration time between the answer and the last attempt of contact in function of the use of MyGenAssist.

Staff Meetings

Before the study, a 2-hour training was planned to present the use of MyGenAssist in the pharmacovigilance case documentation process to the pharmacovigilance officers. During the study, meetings were planned in the team on a 2-week basis. No difficulties in the use of MyGenAssist were identified, and users only suggested slight improvements in the prompt used to consider specific cases for which additional elements are required in the letter. An operating mode, detailing all the steps required to use MyGenAssist for the activity, was written to offer a reminder for the users if necessary.

Discussion

Main Results

In this study, we demonstrated that the implementation of MyGenAssist to the pharmacovigilance case documentation process provided an average of 23.3% time saving on the task without any modification in the rate of answers. Whatever the experience of the workers, the use of MyGenAssist induces time savings, although this effect is higher in nonexperimented ones. Moreover, while using MyGenAssist, it seems that the time spent on the different pharmacovigilance cases becomes less variable: when the use of the tool is added to the process, the range of time is decreased from 9-38 minutes to 10-25 minutes. MyGenAssist may have a more beneficial impact in cases for which more time is required. The easiest cases needing a slight amount of time to be handled would benefit less (or not) from its use, but the ones that are the more time-consuming would be realized significantly quicker than without it.

Therefore, the use of Bayer's LLM improved the efficiency of this activity. That must save dozens of hours yearly for our local pharmacovigilance team, which could be dedicated to other activities with higher added value. A unique, short, and reachable training was sufficient to implement the use of MyGenAssist. This consisted of introducing the changes in the tool's operating mode to the users. No additional training content was required to enable them to use the LLM in the activity, though they did not have any specific qualifications or skills in informatics. Hence, we showed in this study that making workers use an LLM could be easy, as far as they are assisted at the beginning, while other AI tools require important training to be used daily. However, the daily use of an LLM can make the user continually improve their abilities with this tool. Therefore, LLMs seem easy to integrate into several work environments and a way for the worker to get new skills without needing a large amount of time. Thanks to its ease, all users kept using the generative AI for their activity after the end of the study.

Although we included in the linear regression model all parameters that could have an influence on the time spent on the activity, in our point of view, the adjusted R^2 is low (0.286). Therefore, the most part of the time spent on each case could not be fully explained by the considered parameters. It seems that some aspects that are specific to each and difficult to transcribe in the model are important factors too. Moreover, a "human factor" could play a role here, as the user could spend

XSL•FO
RenderX

a variable duration of time for the same task, in function of a lot of exterior parameters. Whatever explanatory variable was not included here, the average difference created by MyGenAssist (more than 5 minutes on a task requiring about 22 minutes without its use) seems too high to be questioned by these potential "hidden" parameters.

Nonetheless, 3 factors could not be included in the model. First, the experience of the user in the activity may directly influence the time spent on each case. It could also have an effect on the number of questions added or removed by the pharmacovigilance officer: while a newcomer could have difficulties selecting the required information to request from the recipient, an experienced one would more accurately determine which question is important enough to assess an adverse event. Second, electronic literacy, which is the capacity to understand or create messages using electronic means, may have an influence on the time spent on the activity. This impact exists for all cases because they are handled by using informatics, but must be stronger in the cases for which MyGenAssist would be used, as the ability of the user to handle technology could also impact their ease of familiarizing themselves with this new tool. By the time we started this experiment, we were not able to measure either user experience or user electronic literacy [26]. Even if we could not include them in the model, the variable "user" integrates both their experience and their electronic literacy: so, without deciphering which parameter has more impact, we still take them into account. Third, the complexity of the case, which may have an influence on the time spent on the case, is a subjective parameter that could not be measured accurately. The parameters we chose to include in this study were selected during a meeting with experienced pharmacovigilance officers, who were asked to give all factors that could influence the time spent on each case. It seems that no study so far, to the best of our knowledge, has been published reporting the parameters influencing the time spent to document a pharmacovigilance case. Moreover, no comparison of our internal process and the ones of other pharmaceutical companies could be done, as none of them seems to be available publicly. The European GVPs [17] do not define a strict process for the documentation of pharmacovigilance cases and let the market authorization holders organize the activity. Pharmaceutical companies have to create a Pharmacovigilance System Master File that describes the handling of all pharmacovigilance activities. It has to be sent to the national and European health authorities but is not publicly disclosed [27]. Our process could then have specificities (eg, the implication of both a case evaluator and a pharmacovigilance officer) that are not possible to detect and could create a lack of reproducibility of our study.

Other ways could have been explored to determine the effectiveness of generative AI. In this study, we chose to use the fulfillment of the objective of our task as the main criteria of effectiveness: to get the necessary information to analyze the pharmacovigilance case. From our perspective, other criteria did not seem relevant in this context. Moreover, we made the choice not to analyze the quality of the drafts written by MyGenAssist because it was clear in our operating mode and in the training that a human assessment of the letter was mandatory before sending it out. To get a relevant analysis of the effectiveness, recipients were not informed that the letter they received was first written with the help of an LLM: on the one hand, the recipient could have had the impression that its report was "automatically" handled, which could have encouraged this latter not to answer. On the other hand, the potential curiosity created by an eventual mention of generative AI, in a current era in which all eyes are turned to such tools, could have created a bias by making the recipient more willing to answer.

Limitations

While our study was realized over a 4-month period, this latter only includes 122 cases. Even if it was enough to notice a difference in the time spent in function of the use of the tool, this has to be taken into account, particularly while analyzing the answers' rate. However, this study is a first step before the extension of the use of the LLM in the pharmacovigilance case documentation process to all Bayer local pharmacovigilance teams worldwide. The efficiency improvement noticed by the French pharmacovigilance team could give fresh impetus to make other teams adopt the same principle. This will give us the opportunity to retrieve more data concerning our question.

Comparison to Prior Work

Other publications regard the use of LLMs in pharmacovigilance: the use of ChatGPT without any optimization or fine-tuning of the public does not seem to fulfill the objective fixed, whatever this latter is providing answers to pharmacovigilance-related questions [28,29] or assess the risk of mortality of patients with toxic epidermal necrolysis [30]. On the other hand, another LLM, Bidirectional Encoder Representations from Transformers, was used with success for the extraction of adverse events from notes [31,32] or social media [33], but it always implied a step of fine-tuning that could not be handled by a simple user. Therefore, we could not find in the literature any study describing the successful use of ChatGPT or a strict equivalent in pharmacovigilance without the necessity to fine-tune the LLM after its use.

Moreover, the need to explore the possibilities that AI could offer to pharmacovigilance was highlighted by several publications before, particularly with the idea that the implementation of such tools could make both time and cost savings and provide an efficiency improvement, especially as the number of declarations of adverse events has been sharply increasing in the last few years [34]. Gholap et al [35] and Danysz et al [36] evoke the possibility for pharmacovigilance workers to focus on high-level tasks thanks to these time savings on administrative or repetitive tasks. However, in all these papers, these statements remain at the step of hypothesis without any experimental assessment.

Regarding the potential benefits that AI could represent for pharmacovigilance, the TransCelerate initiative, which includes 19 pharmaceutical companies, aimed to ask pharmacovigilance representatives of these companies which steps of the pharmacovigilance case processing might be the best suited for a pharmacovigilance implementation. In 2 surveys set between 2018 [37] and 2021 [38], the pharmacovigilance workers

XSL•FO
RenderX

considered the pharmacovigilance case documentation process as one of the more appropriate steps for an AI implementation. The automation opportunity score, which combines the effort realized by companies to include AI in the task and the benefit or risk assessment regarding this inclusion, was 4.5/5 in 2021. The percentage of companies that set an AI-based process in this task rose from 19% to 35% between 2020 and 2021. Nonetheless, no information was given in these publications about a possible efficiency increase after an AI implementation.

Hence, our study may fulfill what seems to be, to the best of our knowledge, a lack in the medical literature. Descriptions of LLMs' use cases for pharmacovigilance exist, but none of them include a measure of time saving realized thanks to this tool. A study showed that the use of ChatGPT for writing tasks enhanced the productivity of the workers by decreasing the time required by 40%, while the quality rose by 18% [39], but did not concern health. Hence, our objective was to determine if the integration of the LLM in the adverse event case documentation process can improve efficiency by reducing the time required for this GVP-related task without decreasing the response rate from the reporters.

These first encouraging results could be an incentive to implement MyGenAssist in other processes. In the pharmacovigilance field, some tasks fit well with the integration of MyGenAssist. For example, the comparison of different versions of the same procedure with this tool can provide a rapid insight into the modifications in order in a second step to assess their impact on other quality documents. Other use cases could be found in other departments, as the task given to the LLM, which is writing letters based on a template, seems pretty reproducible in other contexts for different objectives. The results of this study show that using LLMs in pharmaceutical activities, whatever the field, is relevant and can create improvements without losing quality concerning the regulations of good practice activities.

Conclusions

In this study, we showed the first example of a use case for a ChatGPT-based tool, MyGenAssist, in a pharmacovigilance industry department and assessed its efficiency over a 4-month period. An average of 23.3% of time savings was achieved thanks to this LLM, while its implementation did not modify the effectiveness of the task. It only required a short training to be set up. These results could be the first step to the largest use of LLMs in pharmaceutical activities.

Acknowledgments

The authors thank all members of the Bayer French local pharmacovigilance team for their kind help and their implication in the study, French Bayer IA champions for the mutual sharing of tips, and Bayer AG for its funding support. No specific funding was necessary or used for this study. Bayer AG provided the authors, who are part of the company, with the usual support provided to their employees. MyGenAssist, ChatGPT, or any other large language models were not used for the writing of our paper.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to our internal data privacy policies, but specific elements are available from the corresponding author on reasonable request.

Authors' Contributions

Conceptualization and elaboration of the methodology were realized by all authors collectively. Data curation, formal analysis, investigation, project administration, creation of the prompt, and the writing of the original draft were made by AB. The review and editing of the paper were carried out by IB-L, HR, and JPB. IB-L and JPB were in charge of the supervision and validation. Visualization was done by AB, IB-L, and JPB.

Conflicts of Interest

AB, IB-L, and HR were employees of the company (Bayer) at the time this study was performed. Bayer was informed of this study but was not involved in the design of the study or the writing of the manuscript. Bayer gave authorization to the authors to use MyGenAssist for this study.

Abstract

Background: Conversational artificial intelligence (AI) allows for engaging interactions, however, its acceptability, barriers, and enablers to support patients with atrial fibrillation (AF) are unknown.

Objective: This work stems from the Coordinating Health care with AI–supported Technology for patients with AF (CHAT-AF) trial and aims to explore patient perspectives on receiving support from a conversational AI support program.

Methods: Patients with AF recruited for a randomized controlled trial who received the intervention were approached for semistructured interviews using purposive sampling. The 6-month intervention consisted of fully automated conversational AI phone calls (with speech recognition and natural language processing) that assessed patient health and provided self-management support and education. Interviews were recorded, transcribed, and thematically analyzed.

Results: We conducted 30 interviews (mean age 65.4, SD 11.9 years; 21/30, 70% male). Four themes were identified: (1) interaction with a voice-based conversational AI program (human-like interactions, restriction to prespecified responses, trustworthiness of hospital-delivered conversational AI); (2) engagement is influenced by the personalization of content, delivery mode, and frequency (tailoring to own health context, interest in novel information regarding health, overwhelmed with large volumes of information, flexibility provided by multichannel delivery); (3) improving access to AF care and information (continuity in support, enhancing access to health-related information); (4) empowering patients to better self-manage their AF (encouraging healthy habits through frequent reminders, reassurance from rhythm-monitoring devices).

Conclusions: Although conversational AI was described as an engaging way to receive education and self-management support, improvements such as enhanced dialogue flexibility to allow for more naturally flowing conversations and tailoring to patient health context were also mentioned.

Introduction

Atrial fibrillation (AF) prevalence is increasing rapidly [1], resulting in substantial costs to health systems [2]. AF care is multifaceted, and appropriate management is complex but key to preventing stroke, heart failure, and all-cause mortality [3]. Novel solutions to address these challenges and deliver integrated AF care are warranted [3]. Digital tools could be used to deliver self-management support and education to promote healthy lifestyle behaviors, medication adherence, symptom management, and overall ability to manage AF and prevent hospitalization [4]. However, existing digital interventions for patients with AF have shown limited engagement [5-7].

Conversational AI is a novel technology that can converse with users interactively by mimicking human-like conversations [8], but its feasibility in supporting AF patients is unknown. The evaluation of conversational AI has been limited, with the majority of studies being quasi-experimental and small-scale feasibility pilots exploring conversational AI for the prevention, diagnosis, and management of chronic conditions, but mostly for psychological conditions (depression and anxiety) and very few in cardiovascular diseases (heart failure, diabetes, and hypertension) [9-11]. Only a few randomized controlled trials (RCTs) have been conducted evaluating the effectiveness of conversational AI, revealing positive outcomes of improvements in symptoms of anxiety and depression in college students [12,13], insulin adherence and glycemic control in patients with type 2 diabetes [10], and medication adherence in patients with both or either hypertension and diabetes [11]. Notably, high engagement with users was common in these trials [10-13] and in other studies [9]. The application of conversational AI may provide a more engaging experience for patients with AF self-managing their condition.

Understanding user perspectives on digital health technologies is essential, especially in AF, as the condition manifests differently for all patients [14]. There is a paucity of qualitative research assessing the perspectives and experiences of patients with AF in using digital self-management interventions, with existing studies focusing on mobile apps [15-18] and none exploring conversational AI. Given the novelty of the technology, qualitative research is required to understand the user experience and acceptability of conversational AI to support AF self-management. Although an existing study has explored the feasibility of a conversational agent (non–AI-based) in patients with AF and has found high acceptance among users, it did not involve a formal qualitative analysis [15]. Qualitative research can help in understanding the barriers and enablers that influence AF patient engagement, which is important in narrowing the gap between proof-of-concept and implementation [19].

The Coordinating Health care with AI–supported Technology for patients with AF (CHAT-AF) [20] was a 6-month RCT evaluating a postdischarge digital program that comprised voice-based conversational AI (automated phone calls with speech recognition and natural language processing), text messages, emails, and an educational website to support patients with AF in their management journey. In this paper, we report on the qualitative findings from semistructured interviews postintervention assessing user perspectives, enablers, and barriers regarding the intervention.

Methods

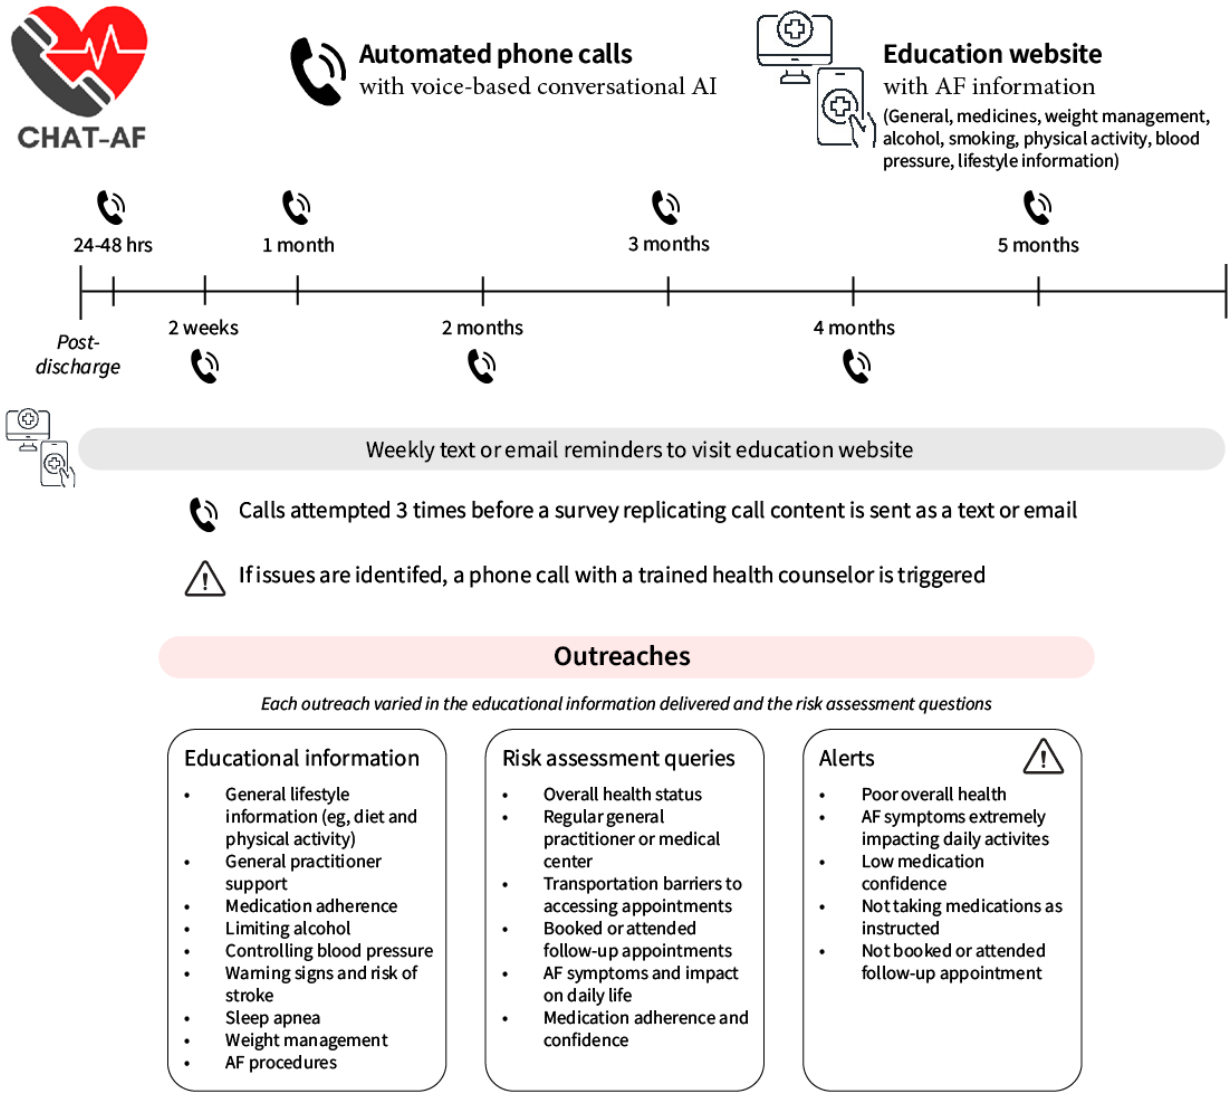
Study Design

This qualitative study stems from a 6-month RCT, CHAT-AF, aimed at evaluating the feasibility of a conversational AI support program for patients with AF in the community [20]. This study adheres to the Consolidated criteria for Reporting Qualitative (COREQ) research checklist for reporting qualitative research.

Ethical Considerations

The ethics committee at Western Sydney Local Health District (2020/ETH02546) granted approval and the study was registered with the Australian New Zealand Clinical Trials Registry (ACTRN12621000174886). All participants provided informed consent to take part in both the RCT and qualitative interviews. Data collected from this study was only accessible by approved study personnel and was stored on secure servers. Deidentification of data was done before analysis and publication.

Setting and Participants



Participants were recruited for the RCT after discharge from inpatient or outpatient cardiology services at Westmead Hospital (Sydney, Australia). Adult AF patients competent with the English language who had access to a mobile phone were eligible. AF patients randomized to the intervention group were contacted via phone postintervention by study investigator RT and asked whether they would like to participate in a phone interview. These participants were chosen using maximum variation sampling, such that, people of different sex, age, ethnicity, education, type of AF, and engagement with the intervention were invited to take part in the interview.

Intervention

The intervention was designed to monitor patient health status and symptoms and provide self-management and education to AF patients in the community [20] (Figure 1). Briefly, it consisted of 7 outreaches via fully automated conversational AI phone calls, text messages, or email, supplemented with weekly nudges (text message or email) to visit the semipersonalized educational website (personalized according to smoking status, alcohol consumption, hypertension diagnosis, prescription of anticoagulants or warfarin specifically). During the phone calls patients received AF education and were required to verbally respond to risk assessment queries, with certain patient responses triggering an alert to the study team to be actioned and escalated if needed. If the participant was unable to be reached after 3 failed call attempts (including voicemails directed to an inbound phone number), a text message or email was sent directing them to a survey replicating the call content.

XSL•FO
RenderX

Figure 1. Coordinating Health care with Artificial intelligence–supported Technology for patients with Atrial Fibrillation (CHAT-AF) intervention. AF: atrial fibrillation; AI: artificial intelligence.

The AI aspect of the intervention included two main components: (1) speech recognition, which allowed the participant's verbal responses to be recognized and then translated into text and (2) natural language processing, which analyzed the semantic and syntactic components of the user's input. The tool was culturally adapted to include a voice with an Australian accent. If the participant's response was unclear, the system would first repeat the question and then prompt the participant to press a button that corresponds to their answer (eg, "press 1 for always, 2 for often, and 3 for sometimes"). The system addressed participants by their first name and was programmed to refer to previous content areas, for example, if a participant had reported they had already visited their GP post their hospital discharge, it would not ask again.

Modified Delivery of the Intervention

We had to prematurely stop recruitment in August 2021 due to the acquisition of the technology partner by another organization. At this point, there were 82 participants enrolled in the intervention arm, of these 20 had completed the intervention and 62 were at various stages of the program. All participants had received at least 2 of 7 outreaches via the conversational AI calls. The delivery of the intervention was then modified, and the call content was replicated and provided via survey only for the remaining outreaches.

Data Collection Techniques

A semistructured interview approach was chosen to explore individual perspectives on conversational AI calls and other intervention components, along with exploring barriers and enablers to engagement with the intervention. The interview guide included open-ended questions and was developed based on existing literature reporting on the self-management needs of patients with AF and their perspectives on digital health interventions to support self-management [14-17] (Multimedia Appendix 1). The interview guide was pilot-tested within the research team. All interviews were conducted by the study investigator (RT) via phone and transcribed verbatim. Comprehensive analysis of interview content resulted in various iterations of themes and concepts. Interviews were conducted until sufficient depth was reached and no new themes, concepts, or relationships were emerging [21].

XSL•FO
RenderX

Analysis

Interview transcripts were uploaded onto NVivo (QSR International) and thematically analyzed by 2 investigators (RT and LL). Coding was done inductively (first-cycle coding), followed by a grouping of codes based on thematic similarities and axial coding (ie, to find patterns between codes) [22]. The initial codebook was developed by RT, with discussions between investigators (RT and LL) occurring every 5 interviews to revise the codebook by analyzing emerging codes and themes. Refined versions of the codebook were reviewed by another investigator (BS) to ensure the appropriateness of focused and axial coding. Coauthor input (LL, BS, CKC, and TS) regarding themes and subthemes was gathered midway and at the completion of interviews.

Results

We invited 33 intervention participants to this study and 3 were not interested in taking part in an interview. A total of 30 semistructured interviews (average duration of 20 minutes and 19 seconds) were conducted between August 2021 to May 2022. The mean participant age was 65.4 (11.91 SD) years, 70% (21/30) were male, 17% (5/30) were of non-Caucasian ethnicity, and 70% (21/30) were nonuniversity graduates (Table 1). Detailed characteristics of both the interviewed participants and the entire intervention cohort are available in Multimedia Appendix 2. Interviewed participants (n=30) received the full 6-month intervention, which included a total of 210 intervention outreaches: 154 were delivered via conversational AI and the remaining 54 were delivered only via the survey tool (modified intervention delivery mode). On average, 5.2 of 7 outreaches were delivered via conversational AI calls (original intervention delivery mode). Themes and subthemes are described below and summarized in Figure 2. Illustrative quotes for each theme are available in Multimedia Appendix 3.

Figure 2. Themes and subthemes. AI: artificial intelligence.

Interaction With a Voice-Based Conversational AI Program

Human-Like Interactions

Participants reported that engaging with the phone calls felt "more human" and "personal" like "talking to a friend" (Multimedia Appendix 3, Table S1, quotes 1-5). Participants mentioned that the phone calls were interactive in the sense they provided a "two-way" channel of communication where they were being asked questions or given information and they were able to respond "easily" (Multimedia Appendix 3, Table S1, quote 5).

Restriction to Prespecified Responses

Participants mentioned the need for more dialogue flexibility, as they felt restricted by the predefined response options in the automated phone calls and wished they had an opportunity to elaborate on their answers (Multimedia Appendix 3, Table S1, quotes 6-8). They also mentioned that some questions did not apply to themselves and due to the lack of appropriate choices in response options, they were at times forced to choose an inappropriate answer, whereas a "does not apply" option would have prevented this issue (Multimedia Appendix 3, Table S1, quote 8).

Trustworthiness of Hospital-Delivered Conversational AI

The importance of the trustworthiness of conversational AI was evident as participants mentioned that bad experiences with marketing-based promotional calls could be a potential barrier to engagement (Multimedia Appendix 3, Table S1, quote 9). However, they highlighted that trusting the provider (ie, the hospital) created a sense of comfort when engaging with automated phone calls (Multimedia Appendix 3, Table S1, quote 10).

Engagement Is Influenced by the Personalization of Content, Delivery Mode, and Frequency

Tailoring to Own Health Context

Participants mentioned that they would have found the program more useful and relevant if they were currently experiencing AF symptoms (Multimedia Appendix 3, Table S2, quote 1) and that they wanted targeted information that was relevant to their disease status (eg, time since diagnosis) and type of AF (eg, paroxysmal AF; Multimedia Appendix 3, Table S2, quotes 2 and 3). Participants noted that because their AF symptoms were not frequent, some questions did not apply to them (Multimedia Appendix 3, Table S2, quote 3).

Participants mentioned the program should be tailored based on their existing knowledge about the disease and their ability to self-manage (Multimedia Appendix 3, Table S2, quotes 4-9**).** Some thought the current content was probably more useful for recently diagnosed patients in greater need of information and support (Multimedia Appendix 3, Table S2, quotes 4 and 5) rather than people who had AF for a while (Multimedia Appendix 3, Table S2, quotes 6 and 7). The need for additional information about pacemakers (Multimedia Appendix 3, Table S2, quote 8) and the impact of COVID-19 on AF (Multimedia Appendix 3, Table S2, quote 9) was mentioned.

The need for tailored information based on an individual's lifestyle behaviors was a recurring theme as participants felt that some of the lifestyle tips did not apply to them, for example, information about quitting smoking and limiting alcohol and caffeine (Multimedia Appendix 3, Table S2, quotes 10 and 11). It was also suggested that we include more comprehensive information about diet (Multimedia Appendix 3, Table S2, quote 12).

XSL•FO
RenderX

Interest in Novel Information Regarding Health

Participants mentioned they would have preferred more novelty in the content, with some of the information being similar to what is available from other reputable sources, such as the Heart Foundation (Multimedia Appendix 3, Table S2, quote 13 and 14). They also indicated the need for progressive content delivery to maintain engagement, for example, the weekly reminders to visit the education website were engaging but led to disappointment when participants realized there was no new content available (Multimedia Appendix 3, Table S2, quote 15).

Flexibility Provided by Multichannel Delivery

Participants differed in their preferences for communication. Some participants noted that it was easier to engage in phone calls and respond using their voice rather than scrolling on a survey, as they could complete the phone calls while multitasking, for example, going for a walk around the park (Multimedia Appendix 3, Table S2, quote 16). Some people also mentioned preferring to listen to information over a phone call, as they thought it was a more interactive and engaging process and they found it easier to interpret the information and visualize what had been said (Multimedia Appendix 3, Table S2, quotes 17-19). Others preferred to respond to the surveys instead of the phone calls, as surveys allowed for adequate time to think about questions before responding, could be completed at a convenient time, and were not interrupted by signal drops (Multimedia Appendix 3, Table S2, quotes 20-23).

Overwhelmed With Large Volumes of Information

Participants mentioned that the frequency of contact should also be tailored based on their needs and preferences, as some felt there were too many phone calls and reminders and would prefer to contact us on an "as needed" basis (Multimedia Appendix 3, Table S2, quotes 24 and 25). When asked about reasons for low intervention engagement, participants mentioned that they were dealing with other medical conditions that took precedence over their AF (Multimedia Appendix 3, Table S2, quote 26), and some participants did not want to be reminded of the problem as they were trying to stay positive (Multimedia Appendix 3, Table S2, quotes 26 and 27).

Improving Access to Atrial Fibrillation Care and Information

Continuity in Support

Overall, participants saw the program as valuable in connecting them with care and providing important information and support (Multimedia Appendix 3, Table S3, quotes 1-8). Participants mentioned that emergency department visits were a "whirlwind experience" and "daunting," and that there was typically no real support and education provided postdischarge, making them feel "helpless" (Multimedia Appendix 3, Table S3, quotes 2 and 3). Participants said that the program was able to address this gap by providing them with information and continuity in follow-up (Multimedia Appendix 3, Table S3, quotes 2-8)—"someone cares enough to contact you"—which was particularly important during COVID-19 when it was difficult to access doctors and for people needing social support (Multimedia Appendix 3, Table S3, quotes 5 and 6). Participants also highlighted the unpredictable and sporadic nature of AF and the need for continuous care as situations change quickly (Multimedia Appendix 3, Table S3, quote 7).

Enhancing Access to Health-Related Information

Participants mentioned that the program provided education and information about AF management that was difficult to obtain from clinicians due to multiple barriers, such as financial, geographical, and mobility constraints along with lack of time during consultations (Multimedia Appendix 3, Table S3, quotes 8-10). They also highlighted that information presented in clinical settings was often hard to absorb due to the high-stress environment and the use of complex terminology, and they appreciated receiving education in lay terms and in a simple format (Multimedia Appendix 3, Table S3, quotes 11 and 12). They also mentioned that the intervention was able to address existing knowledge gaps about AF and improve awareness (Multimedia Appendix 3, Table S3, quotes 13 and 14).

Empowering Patients to Better Self-Manage Their AF

Encouraging Healthy Habits Through Health Reminders

Participants reported that the program improved their health behaviors as it served as a constant reminder and reinforcement of the need to follow healthy lifestyle habits and re-evaluate harmful ones (Multimedia Appendix 3, Table S4, quotes 1 and 2). Some participants mentioned that the program was an influencer in reducing their alcohol intake and promoting weight loss (Multimedia Appendix 3, Table S4, quotes 3 and 4). It was mentioned that the reminders were encouraging and motivational in prompting people to reflect on their current AF management, for example, remember to take medications, exercise, and focus on diet (Multimedia Appendix 3, Table S4, quotes 4-6).

Reassurance From Rhythm Monitoring Devices

The positives and opportunities for improvement of the conversational AI self-management intervention have been outlined in Textbox 1. Participants mentioned that having the ability to monitor their heart rhythm using consumer wireless devices or through an implanted device (loop recorder or pacemaker) can be reassuring in case they suspect the onset of AF and to better manage their symptoms and anxiety related to the disease (Multimedia Appendix 3, Table S4, quotes 7-10). Patients with implantable devices also mentioned that they would prefer being contacted more frequently to ensure that the device was working properly or having access to their own data to understand when things were normal and abnormal, as well as their individual triggers for AF (Multimedia Appendix 3, Table S4, quotes 11 and 12).

XSL•FO
RenderX

Textbox 1. Positives and opportunities for improvement regarding the use of a conversational AI self-management intervention for patients with atrial fibrillation.

Positive elements

- Trustworthiness from receiving information from a hospital-linked provider.
- Engaging human-like interactions.
- Improved continuity in support.
- Improved access to health-related information.
- Frequent reminders and information.

Areas for improvement

- Improving dialogue flexibility of conversational AI phone calls to allow for more natural conversations.
- Enhancing personalization to one's health context.
- Tailoring the amount of information to individual preferences.
- Reducing the repetitiveness of content.

Discussion

Principal Results

Our evaluation of a 6-month AF support program comprising voice-based conversational AI showed that participants valued being supported with their care needs outside of the clinical setting while indicating different barriers and enablers to engagement. Participants' experiences with the conversational AI phone calls were generally positive, with some participants highly valuing that engagement method, and others being less keen on verbal communication for this purpose and preferring a text-based format. Overall, participants indicated the need for more dialogue flexibility, particularly in terms of their response options, to enable more engaging conversations. Personalization of the intervention to patients' needs and preferences was also mentioned as key to engagement, with AF being an especially challenging disease given the high variability in patterns, symptoms, and clinical manifestations.

Comparison With Previous Work

The current intervention was able to address the education and self-management needs of patients with AF, while also providing continuous care outside of a clinical setting. CHAT-AF participants appreciated receiving education and frequent self-care reminders, indicating the intervention addressed a gap in the provision of information and behavior change support. This gap had been previously described in other studies where AF patients expressed their desire for more information, assistance in creating healthy habits, and frequent motivational reminders [23,24]. In addition, it was appreciated that CHAT-AF enabled a greater ability to engage with content easily, when, and how the participant desired outside of a clinical environment. Knowledge gaps are prevalent in patients with AF [25] and patients have indicated insufficient opportunities for education during clinical visits [24]. Managing the ups and downs of the disease is a contributor to the poor quality of life experienced by patients [14] and could be addressed by providing additional support across the patient journey. Participants in our study appreciated the continuity in contact provided by the frequent digital "check-ups," suggesting that interventions like CHAT-AF could enhance the transition between clinical care and community by providing a layer of interaction and support beyond traditional appointments.

Engagement with digital self-management programs by patients with AF has been suboptimal [5-7] but seems to be improved with conversational agents that can facilitate a human-like interaction[15]. A 1-month trial evaluating a mobile application with an embedded non-AI conversational agent showed high acceptability and engagement by patients (18 interactions over one month), even though the interactions required participants to touch prespecified options on the app, instead of using natural language [15]. The interactivity and convenience of voice-based conversational AI were mentioned by participants in CHAT-AF, and engagement was high over the 6-month intervention period, suggesting the value of such technology in supporting patients between clinical visits.

AF has a varied course, and patients appreciate the ability to freely express details regarding their AF rather than being confined to prespecified options, however, at present AI technologies do not allow for safe unconstrained interactions to deliver health information. Users of other AI-based conversational agents have also noted limitations in having naturally flowing conversations [12,13]. However, research has identified various safety concerns in unconstrained speech recognition of voice assistants in health care [26,27]. A study posing medical problems to popular conversational agents (eg, Alexa [Amazon], Google Assistant, and Siri [Apple Inc]), found that only 43% completed their given task, and of these completed tasks, 29% reported potentially harmful actions and 16% may have resulted in death [27]. Future developments in AI, specifically speech recognition and natural language processing, may be able to address the current dialogue shortcomings in our intervention, however, careful consideration is required for the safety implications of their use in health care.

Personalization was highlighted as a key factor to engagement, with challenges mentioned by AF patients given its episodic nature and sporadic symptoms leading to high variability in individual needs regarding education and self-management between different people and across time. AF patients often

XSL•FO
RenderX

experience changes in their symptoms, triggers, and treatments, and their care should be reflective of these varying needs. Newly diagnosed AF patients will often require more education about AF [14], whereas those who have had AF for a prolonged time may have developed the skills to be able to self-manage but still require reinforcement of key concepts [24]. This highlights the need for adaptive health interventions that account for a change in patient needs throughout their disease and adapt accordingly, with the goal of maintaining engagement [19].

Trustworthiness was highlighted by participants as key to engagement with the AI intervention. With the rising popularity of chatbot-based search engines like the large language model ChatGPT, it is increasingly important to consider the factors that influence user trust in health information delivered via digital media [28]. Despite recent studies showing ChatGPT performs remarkably well in answering cardiovascular-related queries [29], its potential use as a health education tool is uncertain, given the lack of transparency in its sources of information. In our study, the credibility of the institution delivering the AI intervention was mentioned by participants as key in trusting the automated phone calls, given the proliferation of unsolicited and fraudulent "robocalls." Patients' acceptability of AI technology is still not well understood but seems to be higher when the intervention is recommended by clinicians [30,31].

Implications

Programs like CHAT-AF could be used to deliver frequent education and self-management support between clinical visits to patients with AF at scale. In addition, conversational AI automated phone calls can improve access to care for traditionally disadvantaged AF patients in rural and remote communities [32], as phone calls are not reliant on internet connectivity, phone models, or operating systems. Engagement of digital interventions in less digitally literate populations remains challenging, however, the simplistic navigation of conversational AI interfaces (ie, requiring users to listen to information and respond using their voice) could provide utility in engaging with older adults who are most susceptible to AF alongside those with low technology literacy and should be the focus of future research. The findings of this work can also guide the implementation of other digital solutions for patients with AF, particularly regarding the optimization of interactivity and personalization, as well as the trustworthiness of providers and technology.

Strengths and Limitations

This is the first qualitative study to explore the user perspectives of using conversational AI in supporting patients with AF. The premature study completion due to the acquisition of the technology partner by another organization meant that some participants had experienced fewer outreaches via conversational AI calls, which may have impacted how they reported on the AI component, however, all participants did receive a minimum of 2 outreaches (of 7) via the calls. As a single-site study, with a predominantly Caucasian and English-speaking population, generalizability is limited, and the results should be interpreted within the limitations of sample characteristics. For instance, the study population was younger (mean 65.4, SD 11.9 years) and had a lower proportion of women (30%) than previously reported literature of the AF patient population in Australia (mean age of 75 years and approximately 45% female) [33]. Selection bias may have occurred where those who agreed to the interviews may have been more engaged, interested, and motivated to provide feedback. We did not interview all trial participants and may have missed some unique experiences, although to address this, interviews were conducted until data saturation was reached. We did not involve patients in the design of the interview guide, and this may have resulted in not capturing experiences that are important to people with AF, however, we did prompt participants to share any additional comments regarding the research and intervention during the interview. Moreover, interview duration varied among participants and was on average around 20 minutes, it is possible that we may not have captured complex concepts in this time, however, the researcher used several prompts in the interview guide to facilitate further discussion during the interviews.

Conclusions

This qualitative study of user experiences with a conversational AI program found that AF patients perceived it could address gaps in current models of AF care by improving access to information and providing continuity in support. Interactions with the voice-based conversational AI were perceived positively by participants, although the need for additional dialogue flexibility and response options was mentioned to better capture their AF experience. Future studies should explore whether delivering more personalized content and providing different interaction options can improve the engagement and effectiveness of such interventions.

Acknowledgments

The authors would like to acknowledge Emma Charlston who was involved in the project management of this trial and Ayesha Thaliph and Alison Robinson for transcribing the interviews. The authors would like to thank the technology partner (HMS) and team members for their efforts in the development of the intervention. This work is supported by Digital Health Cooperative Research Centers Limited. Digital Health Cooperative Research Centers Limited is funded under the Commonwealth's Cooperative Research Centers Program. The funder played no role in the study design, data collection, analysis, and interpretation of data, or the writing of this manuscript.

Abstract

Background: Introduction: Patients with inflammatory rheumatic diseases (IRDs) frequently experience drug-related problems (DRPs). DRPs can have negative health consequences and should be addressed promptly to prevent complications. A digital human, which is an embodied conversational agent, could provide medication-related information in a time- and place-independent manner to support patients in preventing and decreasing DRPs.

Objective: This study aims to identify factors that influence the intention of patients with IRDs to use a digital human to retrieve medication-related information.

Methods: A qualitative study with 3 in-person focus groups was conducted among adult patients diagnosed with an IRD in the Netherlands. The prototype of a digital human is an innovative tool that provides spoken answers to medication-related questions and provides information linked to the topic, such as (instructional) videos, drug leaflets, and other relevant sources. Before the focus group, participants completed a preparatory exercise at home to become familiar with the digital human. A semistructured interview guide based on the Proctor framework for implementation determinants was used to interview participants about the acceptability, adoption, appropriateness, costs, feasibility, fidelity, penetration, and sustainability of the digital human. Focus groups were recorded, transcribed, and analyzed thematically.

Results: The participants included 22 patients, with a median age of 68 (IQR 52-75) years, of whom 64% (n=22) were female. In total, 6 themes describing factors influencing patients' intention to use a digital human were identified: (1) the degree to which individual needs for medication-related information are met; (2) confidence in one's ability to use the digital human; (3) the degree to which using the digital human resembles interacting with a human; (4) technical functioning of the digital human; (5) privacy and security; and (6) expected benefit of using the digital human.

Conclusions: The intention of patients with IRDs to use a novel digital human to retrieve medication-related information was influenced by factors related to each patient's information needs and confidence in their ability to use the digital human, features of the digital human, and the expected benefits of using the digital human. These identified themes should be considered during the further development of the digital human and during implementation to increase intention to use and future adoption. Thereafter, the effect of applying a digital human as an instrument to improve patients' self-management regarding DRPs could be researched.

Introduction

Pharmacotherapy is a cornerstone treatment for patients with inflammatory rheumatic diseases (IRDs) [1]. Although disease-modifying antirheumatic drugs (DMARDs) are highly effective in reducing disease activity and increasing daily functioning, patients with IRDs frequently experience drug-related problems (DRPs). Previous research demonstrated that patients with IRDs report on average 5 DRPs within 8 weeks, such as side effects, difficulties with medication management, and information needs [2]. DRPs can potentially lead to negative outcomes of medication use, which, if not addressed promptly, can lead to decreased treatment effects and adverse drug events [3]. Because adverse drug events can increase unplanned hospital admissions and morbidity, and thus health care utilization, DRPs must be addressed quickly to prevent these negative consequences [4-7].

Currently, contact between health care providers (HCPs) and patients is infrequent, with generally up to 4 routine consultations annually. However, DRPs occur throughout the year outside these consultations and could thus be overlooked. Furthermore, patients do not always report DRPs during consultations, and if they do, HCPs do not always act upon them [8]. These factors could delay the identification and resolution of DRPs, potentially putting patients at unnecessary risk. To deliver high-quality chronic disease care according to the Chronic Care Model, patients should be informed and activated, HCPs should be prepared and proactive, and interactions between patients and HCPs should be productive [9].

This study will focus on the informed and activated patient by supporting patient self-management, which can ensure that the limited time HCPs have for contact can be spent on issues that truly require in-person interaction. Furthermore, research shows that patient involvement is essential to identify clinically relevant DRPs promptly [10,11]. This can be achieved by supporting patient self-management by providing medication-related information [12]. It is conceivable that the more patients are informed regarding DRPs, the better they can identify and deal with these DRPs themselves. Thus, supporting patients in becoming more informed could potentially help resolve DRPs on time.

Telehealth, which entails the use of communication technologies to deliver health care at a distance [13], has the potential to support patient self-management through information provision. One such telehealth channel to provide medication-related information is a digital human, which is an embodied conversational agent. Conversational agents are software programs designed to interact with users through natural language dialogue (ie, speech or text), and embodied conversational agents have an additional virtual form represented by an avatar to provide information via face-to-face conversations. Digital humans have successfully been applied in health care, such as for educating patients about care after hospital discharge [14], promoting walking in older patients [15], and facilitating accessibility to web-based health information about breastfeeding [16]. Furthermore, numerous digital humans designed for self-management in chronic diseases have been studied [17].

A digital human offers various advantages for supporting patient self-management, such as time- and place-independent access to information; the ability to process large amounts of information quickly; and intuitive, easily accessible information by mimicking human-to-human interaction [18] (eg, allowing speech as input and output for populations with low literacy levels). It can also provide visual support, such as instructional videos, or nonverbal output like medication leaflets, without requiring involvement from HCPs.

Patients with IRDs reported these advantages of digital humans as influencing their preference for telehealth channels when seeking support for medication use, particularly when offered options with or without HCP contact [19]. Additionally, patients believe telehealth can effectively provide informational support about medication use [12]. Thus, a digital human could support patient self-management by providing easily accessible medication-related information and potentially resolving DRPs more efficiently. However, because using a digital human for providing medication-related information is a novel approach, insights into what factors determine patients' intention to use a digital human are lacking. Therefore, this study aims to identify factors shaping the intention of patients with IRDs to use a digital human for accessing medication-related information.

Methods

Overview

This qualitative study is reported according to the Consolidated Criteria for Reporting Qualitative Research (COREQ) [20].

Study Design and Setting

An explorative, qualitative study using focus groups was performed. In total, 3 focus groups were held with the aim of reaching data saturation (ie, the point where additional data collection does not produce new relevant themes). For each focus group, between 8 and 12 participants were included. Focus groups were held in the Sint Maartenskliniek Hospital in the Netherlands from February to March 2023.

Participants

Adult patients (≥18 years of age) were eligible for inclusion if they were prescribed at least 1 DMARD for an IRD from the outpatient pharmacy of the Sint Maartenskliniek Hospital, were proficient in Dutch, and owned an electronic device capable of accessing the digital human (ie, smartphone, tablet, laptop, or desktop) at the time of the study. Participants were purposively

XSL•FO
RenderX

sampled based on age, sex, diagnosis, and digital inclination (defined as patients using or not using the web-based personal health record used by the Sint Maartenskliniek Pharmacy). Eligible patients were recruited via email, which contained study information and a form to state availability for the selected dates for focus groups. Written informed consent was obtained in person from participants prior to the focus groups. Incentives for participation were offered in the form of a 20 Euro (US $20.84) gift card, and travel expenses were fully reimbursed.

Digital Human

Pharmi [21], the digital human used during this study, was developed by Pharmi BV and Deloitte in collaboration with the Sint Maartenskliniek Hospital. Pharmi provides spoken answers to drug-related questions and offers additional information, such as (instructional) videos, drug leaflets, and other relevant sources, for approximately 80 different DMARDs. During the study, a prototype of Pharmi was used to provide information and offer predefined answers to common questions, similar to those found on a “Frequently Asked Questions” page. Topics covered included the drug’s mechanism of action, common side effects, instructional videos, storing instructions for antirheumatic drugs, information on specific IRDs, and logistical details such as how to obtain repeat prescriptions (Figure 1).

Figure 1. The digital human "Pharmi." Sourced from Pharmi BV.

Preparation

Participants were asked to complete a preparatory exercise at home prior to the focus group to familiarize themselves with the digital human. This exercise consisted of a set of predetermined frequently asked questions personalized to each participant’s current DMARD and diagnosis (Multimedia Appendix 1). In addition, participants were asked the following questions: (1) “How would you rate the digital human on a scale from 1 to 10?” (2) “What advantages do you see with the digital human? Name a maximum of 2” (3) “What disadvantages do you see with the digital human? Name a maximum of 2.”

Focus Groups

Focus groups were held at the Sint Maartenskliniek Hospital and lasted 2 hours. Each focus group was led by an experienced moderator (author BJFB or CLB), and an assistant moderator (author LLH) was present to facilitate assignments and take additional field notes. All moderators were researchers at the time of the focus groups. A topic guide was used to standardize and structure each focus group (see Multimedia Appendix 1). This topic guide was based on the implementation outcomes outlined by Proctor et al [22] (ie, acceptability, adoption, appropriateness, costs, feasibility, fidelity, penetration, and sustainability), which are a frequently applied set of outcome measures that describe the concept of implementation outcomes. Service and client outcomes were not included in the topic guide, as these are intended to assess interventions after implementation. All focus groups were audio recorded, and recordings were transcribed verbatim. After 2 focus groups, data saturation was discussed to determine if more than 3 focus groups were necessary.

Analyses of Transcripts

Transcripts were systematically analyzed using inductive thematic content analysis according to the steps outlined by Braun and Clarke [23] using Atlas.ti 9 (ATLAS.ti Scientific Software Development GmbH) and Microsoft Excel (Microsoft Corp). Transcripts were coded by 3 authors (LLH, VJBH, and CLB). First, open codes were generated for one transcript by LLH and checked by VJBH, after which discrepancies were discussed until consensus was achieved. Second, axial codes were generated by LLH and then discussed by LLH, VJBH, and CLB until consensus was achieved. Third, preliminary themes were constructed by LLH, VJBH, and CLB, after which open and axial coding for the remaining 2 focus groups was

XSL•FO
RenderX

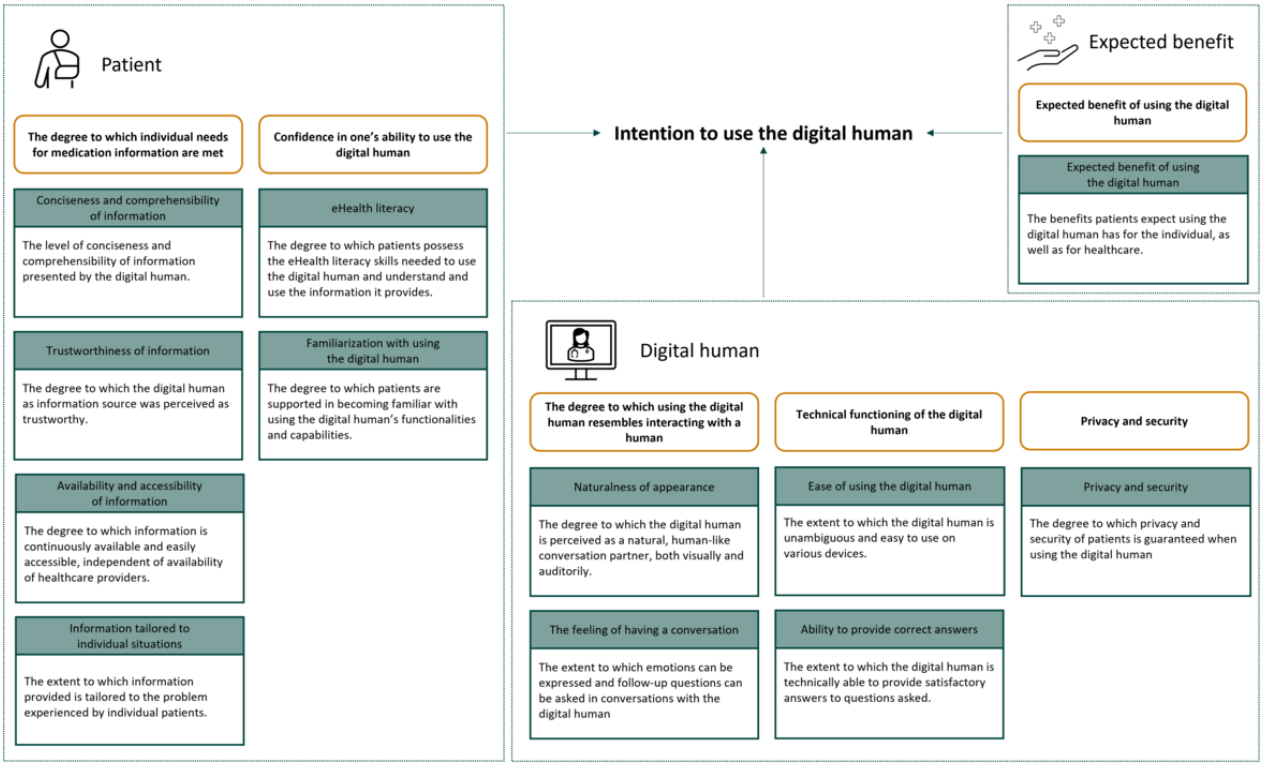
performed and themes were revised accordingly. Relevant quotes from participants were selected to support the themes, which were translated into English.

Ethical Considerations

The Medical Ethics Research Committee of Arnhem-Nijmegen waived official ethical approval (case number 2023-16146) as this study was deemed exempt from the Medical Research Involving Humans Act.

Results

Overview



A total of 540 eligible patients were approached for participation, among whom 214 (40%) responded and 31 (6%) agreed to participate. Of these, 9 patients did not participate in a focus group due to sickness (n=4, 44%), sudden unavailability (n=1, 11%) or unspecified reasons (n=4, 44%). Table 1 shows the participants' characteristics.

A total of 6 themes reflecting factors influencing participants' intention to use a digital human to retrieve medication-related information were identified relating to the patient, digital human, and the expected benefit from using the digital human (Figure 2).

Table 1. Characteristics of the study population (N=22).

Age (years), median (IQR)	68 (52-75)
Female sex, n (%)	14 (64)
Diagnosis, n (%)	
Rheumatoid arthritis	14 (64)
Psoriatic arthritis	6 (27)
Other	2 (9)
Digital inclination (yes), n (%)	11 (50)

Figure 2. Schematic representation of overarching themes reflecting factors influencing participants' intentions to use a digital human for retrieving medication-related information.

XSL•FO
RenderX

Theme 1: Degree to Which Individual Needs for Medication-Related Information Are Met

Explanation

The intention to use a digital human to retrieve medication-related information was dependent on patients' individual information needs. These needs varied between participants and related to different aspects of the information, and in some cases, the problem experienced.

Conciseness and Comprehensibility of Information

Most participants preferred the concise information presented by the digital human compared with the relatively abundant information found in medication information leaflets, general brochures about medical treatment, and other web-based information sources. On the other hand, some participants felt that the digital human presented limited information compared with other medication information sources.

> *For some people, listing five main side effects is sufficient, but I also know that some people do not dare to take the medication because it has so many side effects.* [Female, 75 years]

Participants reported comprehensibility of information as a factor that influenced their intention to use the digital human. Although some participants found the information presented by the digital human rather vague, others appreciated the clear information it provided. The degree to which the information provided by the digital human was experienced as comprehensible varied. Additionally, the digital human did not verify that the patient understood the information provided.

Trustworthiness of Information

The participants highlighted the importance of the trustworthiness of information provided by the digital human. They perceived information provided by the digital human as trustworthy, particularly when compared to web-based sources, as the digital human was deployed by the hospital. Participants suggested that trustworthiness would increase if they were informed about the availability of the digital human by reliable authorities, such as patient associations or HCPs from the hospital where they were treated. Furthermore, participants trusted that the digital human would provide the most up-to-date information available.

> *If you look at the digital human you get the feeling the information is provided by the pharmacist, and if you just search on Google, you get the feeling it is provided by someone random. So, I see that as an advantage, I would have more trust in that [the digital human].* [Female, 78 years]

Availability and Accessibility of Information

The participants expressed a desire for continuously available information. They sometimes felt that they had to wait for the next HCP consultation to retrieve information and questioned this relatively low accessibility of information. They mentioned that the digital human fulfilled the need for easily accessible information by being available 24/7 without having to wait for an HCP to become available.

> *The benefit of this [the digital human] is that I do not have to wait until I see my treating physician again. I do not have to travel to the hospital to get answers.* [Male, 76 years]

The digital human was regarded as a fast information source that could directly answer questions, whereas, with other information sources, patients had to search for relevant information more intensively.

Information Tailored to Individual Situations

Another factor influencing patients' intentions was to what extent the information was tailored to their concerns. Participants intended to use the digital human for general questions, such as medication side effects or potential medication interactions. For more specific, personal questions, such as regarding the choice of treatment, participants' intention to use the digital human was lower. The main reason was that the digital human provided predefined answers to predefined questions and could not generate tailored information.

> *Well, it is all programmed. If you have really detailed questions, I wouldn't even bother trying, I think.* [Female, 67 years]

Theme 2: Confidence in One's Ability to Use the Digital Human

Explanation

The participants found it important to feel confident in using the digital human, as this would increase their chances of using it more often.

eHealth Literacy

The participants felt that adequate eHealth literacy was needed for using the digital human, including digital skills and health literacy. Regarding digital skills, patients indicated that proficiency in using an electronic device on which the digital human was available was necessary. Some participants believed that older people could be less digitally skilled and thought the digital human was less suitable for this age group.

> *Of course, there are also many people, especially in the older population, who experience difficulties with all digital tools.* [Male, 77 years]

Furthermore, participants felt that health literacy was important for adequately using the digital human. It would enable patients to formulate and articulate questions clearly and understand and apply the health-related information provided. Since the digital human focuses on verbal communication, participants believed it could be especially beneficial for individuals with low literacy (ie, those who struggle with reading and writing), enabling them to ask questions verbally and receive spoken responses.

Familiarization With Using the Digital Human

Participants noted that familiarity with using the digital human would increase their intention to use it. They suggested that HCPs provide clear instructions and support during initial use. Additionally, participants emphasized the importance of having sufficient time to explore and understand the digital human's functionalities and capabilities, as this would increase their

XSL•FO
RenderX

confidence and intention to use it. However, they also highlighted that the quality of their early experiences (whether positive or negative) would influence their use intention.

> *…The fact that you get used to talking with someone, communicating with someone who does not exist...* [Male, 76 years]

Theme 3: Degree to Which Using the Digital Human Resembles Interacting With a Human

Explanation

The extent to which interaction with the digital human resembled human-to-human interaction when retrieving medication-related information influenced participants' intention to use it. Some participants believed that a human-like interaction would positively influence their intention to use the digital human, while others indicated that this did not impact their intention.

Naturalness of Appearance

The perceived naturalness and human-like qualities of the digital human influenced the participants' intention to use it. They felt that the digital human appeared artificial and lacked sufficient human traits. Specifically, they felt that the digital human did not speak like a real person, as it misplaced emphases in sentences, lacked proper pronunciation, and had a tinny tone, leading to nonfluent communication. While the presence of a digital human image increased some participants' attention to the provided answers, others found the unnatural facial expressions and constant movement of the image distracting, negatively influencing their use intention.

The Feeling of Having a Conversation

Participants found interactions with the digital human more impersonal, citing the inability to express emotions compared to conversations with an HCP.

> *When interacting with the digital human, I don't feel that I can genuinely express certain emotions in that interaction.* [Male, 76 years]

Furthermore, participants viewed the lack of follow-up question capabilities negatively. They noted that the digital human did not allow users to ask follow-up questions after receiving an answer, nor did it initiate follow-up questions itself, further diminishing the sense of a meaningful dialogue with the digital human.

> *The digital human, who, by the way, looks very pleasant, only provides preprogrammed responses. So, there is no dialogue where you can ask a question yourself.* [Male, 77 years]

Theme 4: Technical Functionalities of the Digital Human

Explanation

The technical performance of the digital human influenced the participants' intention to use it. Participants expressed frustration when retrieving information was difficult, which negatively influenced their intention to use the digital human.

Ease of Using the Digital Human

Participants emphasized that using the digital human should feel straightforward and easy. While some found it easy to use, others did not due to the prototype's technical flaws. Several issues were reported regarding the synchronicity between the digital human's image and sound. This was especially problematic for patients who rely on lip-reading.

> *What I found very difficult, as I have a hearing impairment, I have a hearing aid and heavily rely on lip reading, the digital human does not synchronize. I think... Well, that's a turn-off for me.* [Female, 50 years]

Additionally, participants found using the digital human on a mobile phone more challenging compared to a laptop or computer. They stressed that the digital human should function smoothly on various types of devices and be easy to read.

Participants had different opinions on the importance of a safe login procedure. Most felt that requiring a login was too cumbersome, while others valued the security, especially if a login could lead to more tailored answers based on the patient's current medication extracted from a personal health record.

Ability to Provide Correct Answers

Many participants experienced difficulties receiving satisfactory answers, mainly due to the digital human not understanding their questions. In several cases, participants did not receive an answer at all, while in other cases, the digital human answered a different question than the one asked. Participants reported that they became impatient and frustrated when having to repeat the question, negatively influencing their intention to use the digital human. Moreover, participants noted that some medication names are difficult to pronounce, which can vary across individuals. They suggested improving speech recognition so the digital human could better handle different pronunciations and accents.

> *If "Have you not heard it correctly," then you have to repeat [your question]. You know, you become impatient.* [Female, 50 years]

> *It mainly has to do with how you pronounce the medication, if she [the digital human] understands it. And I also think it depends on the dialect. My wife tried it as well, there she [the digital human] worked and for me, it did not.* [Male, 79 years]

Theme 5: Privacy and Security

Participants emphasized the importance of privacy and security in their intention to use the digital human. Regarding security, they expressed worries about the possibility of microphones being tapped and the risks associated with cookies from other websites, which could negatively influence their intention to use the digital human. Some participants felt privacy was guaranteed, as questions could be asked anonymously.

However, others had concerns about privacy when using the digital human in public spaces, as verbal questions and answers could be heard by others.

XSL•FO
RenderX

> *I thought that with anonymity, perhaps some people might feel embarrassed to ask questions because they don't know (…)which they think everyone should know. That's why anonymity may be nice.* [Female, 75 years]

Theme 6: Expected Benefits of Using the Digital Human

The anticipated benefits of using the digital human, both at the individual level and societal level, influenced participants' intentions to use it. On an individual level, the digital human was perceived as a tool to enhance self-management by giving patients more control over their own care.

> *I think it is beneficial for health care providers, the better informed patients are about their medication, the better they are doing. As I just said, with medication adherence, but also with trust patients have in their medication. I think that is very important.* [Male, 77 years]

The participants viewed the digital human as a way to increase their knowledge about medication and thus their involvement in their treatment. They felt that the digital human enabled them to address issues independently without having to reach out to HCPs, thereby avoiding additional burdens on HCPs.

> *As has been said before, you don't have to bother anyone, you can look it up yourself.* [Male, 79 years]

Furthermore, participants believed that using the digital human could improve their digital skills and preparedness for the digitization of health care.

Discussion

Principal Findings

This qualitative study showed that the intention of patients with IRDs to use a digital human for retrieving medication-related information was influenced by several factors. These factors included individual patients' information needs and their confidence in using the digital human; the digital human's features, including human-like interaction and technical functionalities; and the expected benefits of using it.

Over the past decade, digital humans have been developed for various chronic conditions to facilitate screening, diagnosis, and education [17]. However, using a digital human specifically for retrieving medication-related information in rheumatic diseases is a novel approach. As a result, direct comparisons with earlier studies investigating digital humans in the same context are difficult.

In this study, the intention to use the digital human largely depended on patients' individual information needs, including their need for concise, trustworthy, accessible, and tailored information. These factors have also been described in other studies regarding the information needs of patients with rheumatic diseases [12,24,25]. Additionally, patients' confidence in their ability to use the digital human and their eHealth literacy skills influenced their use intentions. This aligns with previous research showing that health literacy is associated with the ability to retrieve online health information [26,27] and evaluate its quality [28].

Another theme influencing intention was the ease of use of the digital human. This relation is widely documented in frameworks such as the Technology Acceptance Model, which describes "perceived ease of use" as a factor that indirectly influences the intention to use [29]. Given that the digital human used in this study was a prototype, participants' remarks regarding ease of use should be considered during further development to maximize future intentions to use and thus adoption.

Additionally, participants emphasized the importance of the digital human's technical functionalities, particularly its ability to provide correct answers. A mixed methods study on the use of digital humans for patients with dementia similarly found that technical problems and issues with speech recognition negatively impacted patient's intention to use [30]. In this study, participants also indicated that a negative first experience with the digital human (ie, an experience in which a correct answer was not provided by the digital human) could deter future use intention. Therefore, ensuring an optimal first experience is critical for successful implementation and adoption by patients.

Research on digital humans applied in different contexts suggests that design features, such as facial expressions and tone of voice, influence use intentions [31]. For example, a previous study on a digital human for type 2 diabetes self-management found that its acceptability partly depended on the congruence between its verbal and nonverbal communication [32]. Similarly, in this study, participants indicated that the degree to which the digital human resembled a natural, human-like conversation partner influenced their intention to use it.

Various communication and information channels are available in health care, including frequently asked questions, phone or video calls, and 2-way text messaging with HCPs. These channels vary in interaction levels, user experiences, accessibility, and monetary or personnel costs associated with using the channel. It is conceivable that the digital human is not always the most suitable channel in every situation and for every individual (eg, a patient can experience multiple problems according to which information should be tailored). However, offering the digital human alongside existing channels allows patients to choose the option that best matches their needs and preferences. This could increase the actual usage of such channels to retrieve medication information, leading to patients gaining more medication knowledge, which is recognized as an important element of patients' self-management [33].

Strengths and Limitations

A notable strength of this study is its theory-based approach to constructing the topic guide, which was informed by the Proctor framework for successful implementation [22]. The factors identified in this study are valuable for integrating the digital human into routine care. For example, integrating the digital human into digital patient health records could enhance the trustworthiness and accessibility of medication information. These factors are also relevant for further development of the

XSL•FO
RenderX

digital human to increase future adoption. For example, speech recognition could be improved to increase the digital human's ability to provide correct answers. This is especially valuable because the uptake of telehealth is low among patients with IRDs despite their willingness to use it [34].

A few limitations should be acknowledged. First, the digital human used in this study was a prototype and had several technical flaws, such as suboptimal processing of participants' questions participants and difficulties in controlling the digital human. These issues may have influenced the range and type of technical factors participants identified as impacting their intention to use the digital human.

Second, the participant group was slightly older than the nonparticipant group. The nonparticipants' median age was 59 (IQR 49-68) years. This might be explained by the fact that 2 out of 3 focus groups focus groups were held face-to-face during office hours, potentially making it easier for older adults with more spare time to attend. Additionally, this study had a low participation rate (6%). Most patients did not respond to the online invitation, and those who declined to participate were not obliged to provide reasons, leaving the reasons for nonparticipation unknown. Third, the participants were recruited from a single, specialized rheumatology clinic and might differ from the general IRD population in in terms of their experiences with the level of quality of care and medication information provided. This may limit the generalizability of the study's findings.

Conclusion

This qualitative study highlights that the intention of patients with IRDs to use a novel digital human for medication-related information is influenced by their individual information needs, confidence in their ability to use the digital human, its features, and the expected benefits of using the digital human. These themes should guide the development and implementation of a digital human to maximize patients' intention to use and adoption. Future research should examine the effect of applying the digital human as a tool to improve patients' self-management of DRPs.

Abstract

Background: Interest in integrating robotics within intensive care units (ICUs) has been propelled by technological advancements, workforce challenges, and heightened clinical demands, including during the COVID-19 pandemic. The integration of robotics in ICUs could potentially enhance patient care and operational efficiency amid existing challenges faced by health care professionals, including high workload and decision-making complexities.

Objective: This qualitative study aimed to explore ICU clinicians' perceptions of robotic technology and to identify the types of tasks that might benefit from robotic assistance. We focused on the degree of acceptance, perceived challenges, and potential applications for improving patient care in 5 Southeastern US hospitals between January and August 2023.

Methods: A qualitative study through semistructured interviews and questionnaires was conducted with 15 ICU clinicians (7 nurses, 6 physicians, and 2 advanced practice providers) from 5 hospitals in the Southeast United States. Directed content analysis was used to categorize and interpret participants' statements, with statistical tests used to examine any role-based differences in how they viewed robotic integration.

Results: Among the 15 participants, 73% (11/15) were female, with an average of 6.4 (SD 6.3) years of ICU experience. We identified 78 distinct tasks potentially suitable for robotic assistance, of which 50 (64%) involved direct patient care (eg, repositioning patients and assisting with simple procedures), 19 (24%) concerned indirect patient care (eg, delivering supplies and cleaning), 6 (8%) addressed administrative tasks (eg, answering call lights), and 3 (4%) were classified as mixed direct and

XSL•FO
RenderX

indirect (eg, sitting with a patient to keep them calm). Most participants supported the automation of routine, noncritical tasks (eg, responding to nurse calls and measuring glucose levels), viewing this strategy as a way to alleviate workload and enhance efficiency. Conversely, high-complexity tasks requiring nuanced clinical judgment (eg, ventilator settings) were deemed unsuitable for full automation. Statistical analysis revealed no significant difference in how nurses, physicians, and advanced practice providers perceived these tasks (P=.22).

Conclusions: Our findings indicate a significant opportunity to use robotic systems to perform noncomplex tasks in ICUs, thereby potentially improving efficiency and reducing staff burden. Clinicians largely view robots as supportive tools rather than substitutes for human expertise. However, concerns persist regarding privacy, patient safety, and the loss of human touch, particularly for tasks requiring high-level clinical decision-making. Future research should involve broader, more diverse clinician samples and investigate the long-term impact of robotic assistance on patient outcomes while also incorporating patient perspectives to ensure ethical, patient-centered adoption of robotic technology.

KEYWORDS

robotics; intensive care units; critical care; health care technology; qualitative study

Introduction

The intensive care unit (ICU) cohorts patients who are critically ill and who require sophisticated care to manage severe, life-threatening conditions. ICUs are both labor-intensive and technophilic, offering an opportunity to evaluate the potential role of robotics to facilitate critical care despite potential technical challenges [1]. The ICU environment is characterized by an assortment of medical devices, including ventilators, physiologic monitors, intravenous pumps and lines, feeding tubes, various drainage and catheter systems, and dialysis equipment [2]. Each device requires meticulous management, and the urgency and complexity of critical care mean that timely responses can be a matter of life and death. Health care professionals in these settings face immense challenges, including making critical decisions under pressure, caring for patients who are nonresponsive, managing equipment, and providing essential emotional support during patients' most vulnerable moments. Furthermore, the increasing demand for critical care services exacerbates the strain on the limited pool of skilled health care workers, who operate under significant stress [3]. Despite these hurdles, the dedication and efforts of these professionals in overcoming such challenges are noteworthy.

In the health care industry, and particularly in the ICU, the impact of technological advancement has been significant. The adoption of electronic health records, for example, has streamlined access to patient histories and clinical data, facilitating more timely and more effective treatment decisions [4-7]. Given that critical care clinicians work around the clock, innovations that offload common tasks or enhance patient safety have been instrumental, such as automated intravenous pumps [8]. These devices can integrate with the electronic health record to reduce medication errors, ensure the precise delivery of medications, and automatically document medication administration, significantly alleviating the workload of nursing staff while minimizing the potential for errors.

Robotic technology in ICUs, although not widespread, shows potential for enhancing patient care management. Telepresence robots, for example, have dramatically decreased response times to patients, facilitating timelier interventions and contributing to a reduction in mortality [1,9,10]. In the field of physical therapy and rehabilitation, particularly for survivors of stroke, rehabilitation robots have demonstrated efficacy, improved quality of care, and effectively customized rehabilitation activities for motor function recovery [11-16]. Additionally, robots dedicated to medication and equipment delivery and remote patient monitoring have streamlined care processes, enhancing efficiency in patient management [17-19]. These robotic solutions have consistently yielded positive outcomes, underscoring their value in improving patient care. However, it is crucial to acknowledge their limitations and potential concerns regarding cost-effectiveness. Despite these challenges, the contribution of robotics to health care, including ICUs, remains seemingly promising [20].

Understanding clinician perceptions of robotics within the ICU is paramount, as it directly influences the adoption, use, and effectiveness of these technologies. This study aims to explore the multifaceted views of health care professionals on the deployment of robotics in the ICU, identifying perceived benefits, challenges, and areas for improvement. By elucidating these objectives, including assessing clinician readiness, identifying potential tasks for robotic assistance, and evaluating the impact on patient care, we seek to bridge the translational gap between technological capability and clinical application at the bedside.

Methods

Study Design and Participants

The study was cross-sectional with a qualitative, exploratory design. Directed content analysis was used to identify prominent themes emerging from the data. Participant recruitment occurred at 2 academic medical centers with 850 and 500 staffed beds, respectively, and 3 regional or community hospitals with 100, 400, and 450 inpatient beds, respectively, within a large health care system in the Southeastern United States. Additionally, 2 of the hospitals held Magnet designation during the study period. The inclusion criteria for this study were registered nurses, doctors, physicians, and therapists working in ICUs in these hospitals, with experience in treating or caring for patients. Participants were required to be adults aged 18 to 80 years,

XSL•FO
RenderX

capable of understanding the study's purpose and risks, and able to provide informed consent. Additionally, participants needed to be available for a maximum 1-hour Zoom interview (Zoom Video Communications) and actively engaged in providing direct patient care in an ICU setting. Exclusion criteria included individuals with no experience in patient care or treatment, pregnant individuals, prisoners, and those who did not work directly in an ICU setting. These criteria were designed to ensure that participants had relevant clinical experience and could contribute meaningful insights into the study objectives.

Study End Points

Our primary end point was to explore the perceptions of ICU clinicians regarding the integration of robotic technology, focusing on identifying tasks that could reduce staff workload and enhance operational efficiency. The secondary end point was to characterize the ethical and practical considerations—such as privacy, safety, and clinical judgment—surrounding the implementation of robotics in critical care environments.

Sampling Method and Sample Size Calculation

Convenience sampling was used to recruit participants through institutional review board (IRB)–approved flyers. Given the exploratory and qualitative nature of this study, we applied a data saturation approach to inform the sample size. To align with best practices in qualitative research, we referenced the guidelines of Guest et al [21-23], which indicate that 80% to 92% of all concepts within a dataset are typically identified within the first 10 interviews, with 12 to 15 interviews generally sufficient to achieve thematic saturation. Based on this approach, we determined to enroll a minimum of 10 participants to begin the determination of data saturation.

Recruitment Process

For recruitment, a local site contact at each hospital initially posted the flyers with the sign-up QR code on the participating units. The site contacts also introduced the study in ICU huddles and meetings and emailed the recruitment flyers to unit staff on participating units. Once potential participants expressed interest, the research team emailed them directly to confirm their availability for an interview. Follow-up communication included proposed dates and times for the interview, with flexibility to accommodate participants' schedules. Site contacts repeated emails and huddle and meeting attendance until multiple professions were represented and data saturations were reached.

Data Collection

Data collection began in January 2023 and concluded in August 2023 upon achieving the planned 15 interviews. Each study participant provided informed consent to be interviewed and recorded prior to the interview sessions and could withdraw at any point prior to or during the interview. For consistency, 1 research team member (JS) conducted all interviews using a structured interview guide. In addition to asking the questions, the interviewer displayed the questions in Zoom. A detailed interview script is listed in Multimedia Appendix 1.

After the interview, participants filled out a Google Forms questionnaire (Multimedia Appendix 2), which was used to collect relevant information concerning participation demographics and experience while also assessing participant perceptions using a mix of rank order, Likert scale, and yes or no questions. This included reviewing a provided list of tasks derived from existing literature (Multimedia Appendix 3) [24], with the option to suggest additional tasks not listed. All interviews were recorded and transcribed into text files via Zoom. The 3 coders (JS, RIS, and DMR) listened to the recordings and reviewed the text files to correct any obvious transcription errors (eg, "I see you" to ICU).

Analysis

The 3 coders (JS, RIS, and DMR) applied directed content analysis to analyze the transcripts. In content analysis, coders systematically read, listen to, or view communications and assign codes to recurring patterns of communication [25]. In the first cycle of coding, the 3 coders (JS, RIS, and DMR) read each transcript independently to identify analysis categories. Initial categories were correlated to the directed questions in the interview script for descriptive, process, and value coding [26]. Each statement documented from a participant was a unit of analysis for the coders to assign to a category. If a single statement matched multiple categories such as a process and a value, it could be double-coded. Coding categories were finalized after 3 cycles, and the detailed primary codes were abstracted to secondary codes. Interviews and recruitment continued until no new secondary codes emerged. Near data saturation was observed after 11 participants, as comments began to repeat without introducing new insights. By participant 13, true data saturation was achieved, ensuring comprehensive coverage of the interview scope, which is reasonable given the narrow focus of the interview script.

To promote the trustworthiness of the analysis process, the 3 coders (JS, RIS, and DMR) debriefed after each coding cycle. The coders had different professional backgrounds: 2 (JS and RIS) were graduate students in engineering programs and 1 (DMR) was a registered nurse. Coders generated audit trail documents throughout all coding cycles and debrief sessions. All 3 coders (JS, RIS, and DMR) reviewed every unit of analysis. If there was disagreement or uncertainty among the coders about any participant statement, the coders reviewed the transcripts and relistened to the recordings until a consensus was reached. Once final coding was reached, a Python (Python Software Foundation) script was written to tally frequencies within each category.

Statistical Plan

To examine differences in the distribution of thematic codes across participant groups, a chi-square test of independence was conducted. A contingency table was constructed using the frequency of statements categorized under each code by the 3 participant groups. The test assessed whether the observed frequencies of codes were independent of participant roles, with a significance level set at α=.05. This analysis was used to determine if there were significant differences in how each group contributed to various themes, helping to identify potential biases or group-specific priorities in the data.

XSL•FO
RenderX

Ethical Considerations

The Emory University IRB approved this study (IRB STUDY00003902). Consent was obtained from participants both in signature form and prior to the interviews using an IRB-approved oral consent script. Interview recordings, transcripts, and participant data from the surveys were stored on a secured server in the Department of Biomedical Informatics. Participants were assigned ID codes, and transcripts were deidentified prior to analysis to keep responses anonymous. Participants will not be individually identified in any publications, presentations, or supplemental materials. Participants received a US $10 electronic Amazon gift card after each interview.

Results

Participants

After successfully concluding the recruitment phase, our study enlisted 15 participants, comprising 7 registered nurses, 6 physicians, and 2 advanced practice providers (APPs). The demographic profile of the study participants is summarized (Table 1). The sex distribution was predominantly female, with 11 (73%) participants, compared to 4 (27%) male participants. The average age of the participants was 35.9 (SD 8.5) years, and the ages ranged from younger physicians with an average age of 31.8 (SD 2.0) years to APPs with an average age of 42.0 (SD 5.7) years.

Experience in the ICU varied, with nurses and APPs having an average of 8.9 (SD 8.2) and 8.5 (SD 2.1) years, respectively, while physicians had a notably shorter average duration of 2.9 (SD 2.0) years. Exposure to health care robots ranged from 6 (40%) of the participants having encountered nonsurgical health care robots and 4 (27%) having experience with surgical robots.

Table 1. Demographic characteristics of 15 intensive care unit (ICU) clinicians from 6 hospitals in the Southeastern United States (January to August 2023), describing participant roles, age, sex, years of ICU experience, and prior exposure to robotic systems.

	Overall (N=15)	Nurse (n=7)	Physician (n=6)	APP[a] (n=2)
Sex, n (%)				
Female	11 (73)	7 (100)	3 (50)	1 (50)
Male	4 (27)	0 (0)	3 (50)	1 (50)
Age (years), mean (SD)	35.9 (8.5)	38.0 (11.7)	31.8 (2.0)	42.0 (5.7)
Working in the ICU (years), mean (SD)	6.4 (6.3)	8.9 (8.2)	2.9 (2.0)	8.5 (2.1)
Previous encounter with a robot in health care (except for surgical robot), n (%)	6 (40)	1 (14)	4 (67)	1 (50)
Previous encounter with a surgical robot, n (%)	4 (27)	2 (29)	2 (33)	0 (0)

[a]APP: advanced practice provider.

Coding Analysis

After the completion of the first and second cycles of coding analysis, primary codes and 7 secondary codes have been discerned. The secondary codes are administrative, comment or question about the interview, concerns, direct patient care, indirect patient care, minimum capacity, and perceptions (Table 2). Some statements were deemed not codable due to their ambiguous nature or because they were off topic.

XSL•FO
RenderX

Table 2. Secondary codes and associated primary codes derived from a directed content analysis of 15 intensive care unit clinicians showing the framework of perspectives on robotic integration.

Secondary codes	Primary codes
Administrative	• Administrative
Comment or questions about the interview	• Enquiry or comment about study
Concerns	• Cost • Human connection • Job insecurity • Lack of familiarity • Legal or HIPAA[a] • Privacy—patient • Privacy—clinician • Quality patient care • Safety—clinical judgment • Safety—malfunctioning • Safety—need evidence
Direct patient care	• Direct—any procedure • Direct—communicating • Direct—food • Direct—monitoring • Direct—performing procedure • Direct—supporting procedure • Direct—transporting • No physiotherapy • No ventilator
Indirect patient care	• Indirect—communicating • Indirect—custodial • Indirect—monitoring • Indirect—delivering supplies • Indirect—picking supplies • Indirect—supporting procedure • Indirect—transporting
Minimum capacity	• Audio • Device compatibility • Dexterity • Movement • Simultaneous localization and mapping • Storage • Touch screen • Video
Perceptions	• “Complex solution for a simple problem” • “Tasky things” • Reduce burden • Task delegation comfort differ by clinician • User perception—fearful (patients and clinicians) • User perception—need education (patients and clinicians) • User perception—negative (clinicians)

[a]HIPAA: Health Insurance Portability and Accountability Act.

1. Administrative: This category pertains to the logistical and management-related facets of incorporating robots into the ICU. It addresses the administrative duties and potential ramifications therein. Statements within this category, such as “They would function akin to ICU techs and secretaries,” exemplify the envisioned roles robots could undertake to support the administrative backbone of ICU operations.
2. Comment or question about the interview: This category captures any feedback or queries participants had regarding the interview process itself, helping to clarify the interview structure or content. Some statements in this category are “What exactly is your study looking at?” or “What kind of robots you are building?”
3. Concerns: Clinicians shared a broad range of apprehensions about introducing robots into the ICU environment. Their concerns span financial aspects, workforce implications, the impact on patient privacy, the quality of health care delivery, and the loss of “human touch.”

XSL•FO
RenderX

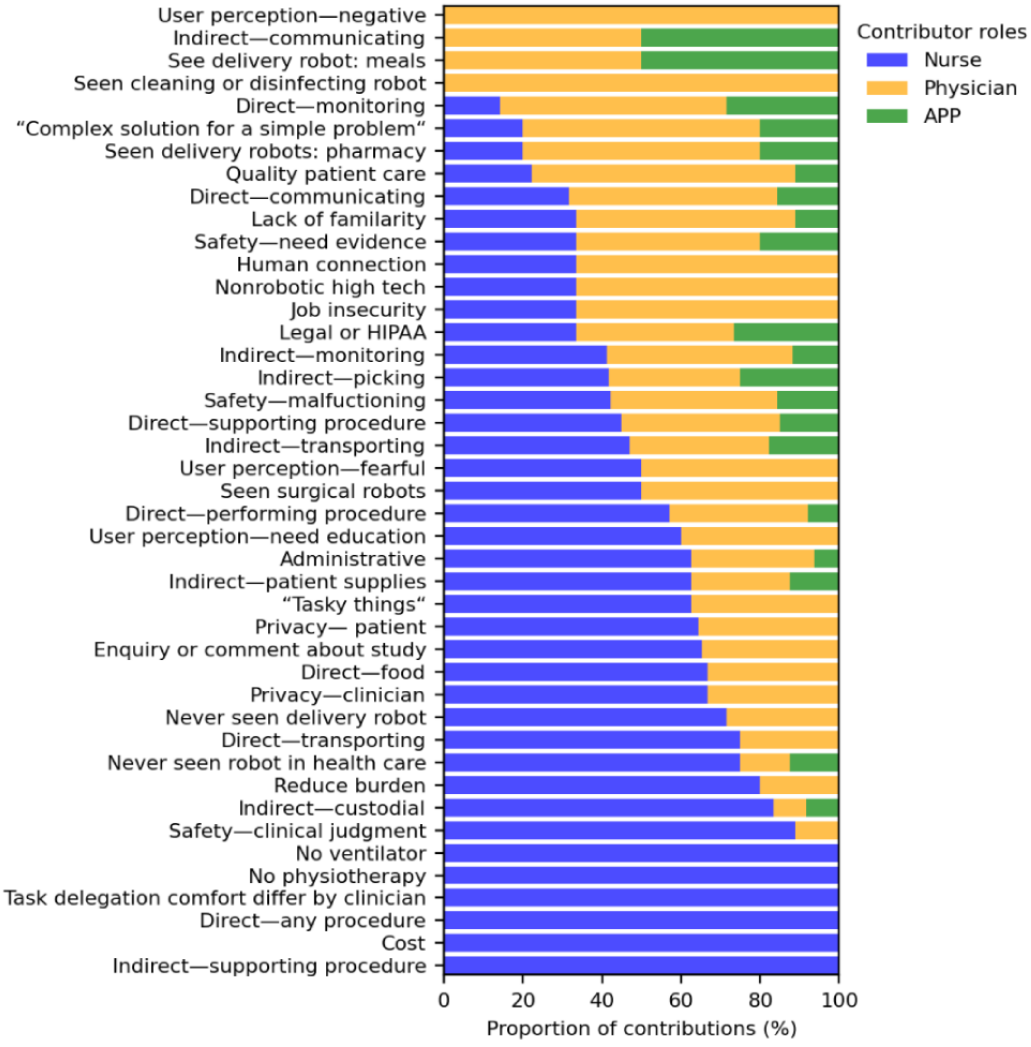
4. Direct patient care: This category refers to tasks and activities where robots would be involved in the immediate clinical management and treatment of patients. Clinicians showed particular interest in the potential of robotics for routine tasks and procedures that require precision and can be standardized, such as turning and repositioning the patient, assisting with physical therapy, assisting bedside procedures, or checking cognition.
5. Indirect patient care: The category includes activities where robots assist with nonclinical tasks that indirectly contribute to patient well-being and the efficient functioning of the ICU. Many participants recognized the utility of robots in roles such as transporting supplies, managing inventory, and performing cleaning tasks, which, while not directly related to patient care, are vital for maintaining a safe and operational environment.
6. Minimum capacity: In addressing the potential role of robots in the ICU, our interview protocol specifically included questions aimed at understanding the essential capabilities such technologies would need. This category collects the discussions focusing on the fundamental requirements that robots must satisfy to function effectively within the intensive care framework. Participants delineated baseline functionalities that robots should possess, such as the ability to navigate complex environments, respond to dynamic situations, and interface with existing hospital systems.
7. Perceptions: Clinicians' perceptions of robotics in the ICU were complex and dualistic. While there was excitement about the innovation and the potential efficiency gains, there was also skepticism about the practicality and readiness of such technologies for the sensitive ICU milieu. The prevailing belief among clinicians is that, while numerous tasks in the ICU could potentially be automated, the present state of robotic technology is best suited for delegating routine tasks to alleviate the heavy workload burden from the clinical staff.

Participant Insights and Perceptions

Guided by insights from clinicians, our coding analysis revealed a total of 78 tasks, where robotic systems might be introduced into ICU practice (Multimedia Appendix 4). Of these tasks, 50 (64%) were primarily related to direct patient care (eg, repositioning patients and assisting with simple procedures), whereas 19 (24%) focused on indirect patient care activities such as delivering supplies or cleaning. An additional 6 (8%) tasks addressed administrative roles (eg, handling patient call lights), and 3 (4%) were classified as mixed, encompassing both direct and indirect elements (eg, sitting with a patient to help keep them calm). These tasks are systematically categorized according to primary codes from our coding analysis. Recognizing the intricate nature of ICU operations, we acknowledge that some tasks may be multifaceted, overlapping across multiple categories. For clarity and coherence, tasks that serve similar purposes have been consolidated and are detailed in Multimedia Appendix 5.

A notable finding from our analysis is the significant number of tasks identified under the category of "direct—performing procedure," where 30 specific tasks were listed as shown in Multimedia Appendix 5. This category encapsulates tasks where robots could directly engage in patient care procedures, highlighting a substantial potential for robotic assistance in hands-on care activities. Additionally, the category "direct—supporting" includes 9 tasks, reflecting the supportive roles that robots could play in enhancing the efficiency and effectiveness of direct patient care.

The distribution of statements across various secondary codes, segmented by participant group (nurses, physicians, and APPs), is illustrated (Table 3). The table provides a quantitative overview of the engagement and contributions of each group in different thematic areas. The "nurse count," "physician count," and "APP count" columns represent the number of participants from each respective group who contributed to the discussions on each secondary code, while the "statements" columns reflect the total number of comments made by each group. In Figure 1, the stacked bar chart shows the proportion of statements contributed by nurses, physicians, and APPs for each primary code, providing a visual overview of how each group engaged with different thematic areas. Primary codes in "minimum capacity" were removed to maintain clarity and ensure emphasis on the most relevant thematic categories.



XSL•FO
RenderX

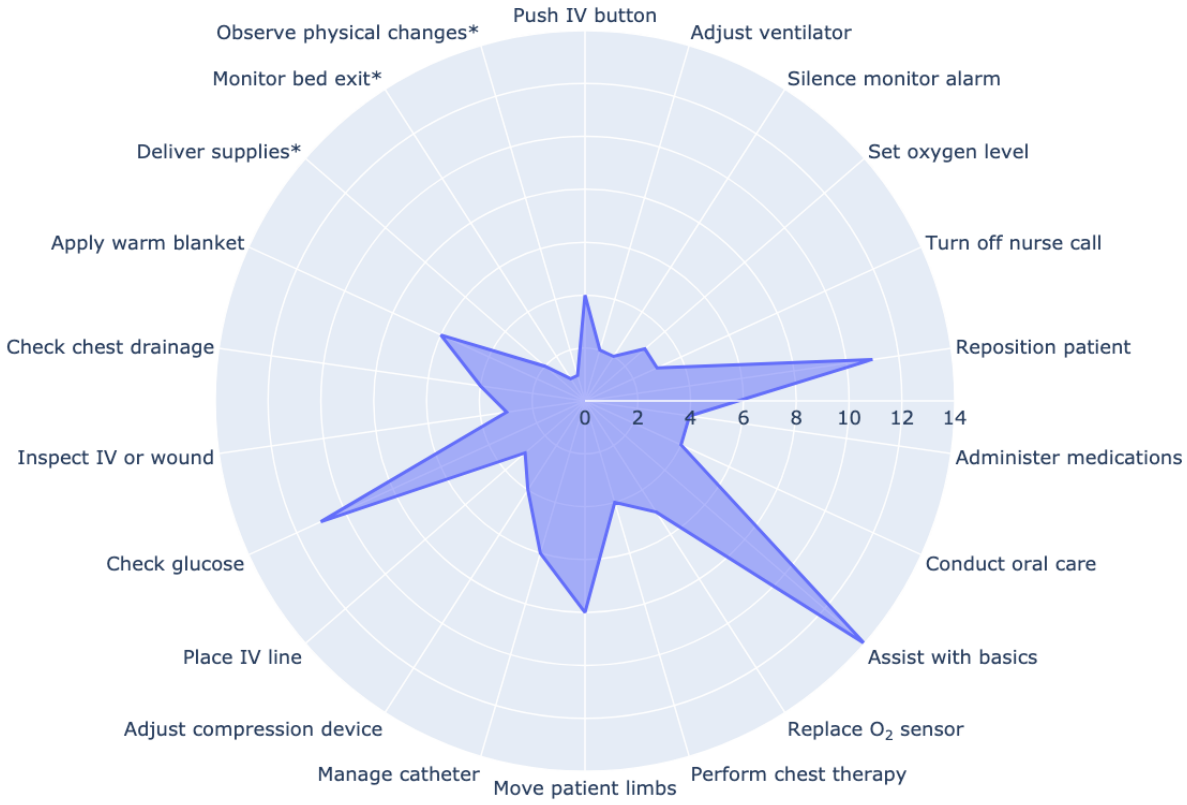
Table 3. Distribution of discussion topics across secondary codes among 15 intensive care unit clinicians.

Secondary codes	Participant count				Statements count			
	Total, n	Nurse, n (%)	Physician, n (%)	APP[a], n (%)	Total, n	Nurse, n (%)	Physician, n (%)	APP, n (%)
Administrative	10	5 (50)	4 (40)	1 (10)	16	10 (63)	5 (31)	1 (6)
Comment or questions about the interview	10	6 (60)	4 (40)	0 (0)	23	15 (65)	8 (35)	0 (0)
Concerns	15	7 (47)	6 (40)	2 (13)	109	49 (45)	48 (44)	12 (11)
Demographic	15	7 (47)	6 (40)	2 (13)	30	15 (50)	12 (40)	3 (10)
Direct patient care	14	6 (43)	6 (43)	2 (14)	125	64 (51.2)	48 (38.4)	13 (10.4)
Indirect patient care	14	7 (50)	5 (36)	2 (14)	71	38 (54)	22 (31)	11 (15)
Minimum capacity	15	7 (47)	6 (40)	2 (13)	61	26 (43)	25 (41)	10 (16)
Not codable	3	2 (67)	0 (0)	1 (33)	5	2 (40)	0 (0)	3 (60)
Perceptions	11	5 (45)	5 (45)	1 (10)	32	19 (59)	12 (38)	1 (3)

[a]APP: advanced practice provider.

Figure 1. Distribution of thematic contributions by clinician role in a qualitative intensive care unit robotics study. This stacked bar chart illustrates the percentage of statements contributed by 7 nurses (blue), 6 physicians (orange), and 2 advanced practice providers (green) across distinct primary codes derived from interviews at 5 Southeastern United States hospitals between January and August 2023. Technical codes are removed. Each code on the horizontal axis represents a thematic category identified through directed content analysis, and the vertical axis shows the proportion of total statements. APP: advanced practice provider; HIPAA: Health Insurance Portability and Accountability Act.

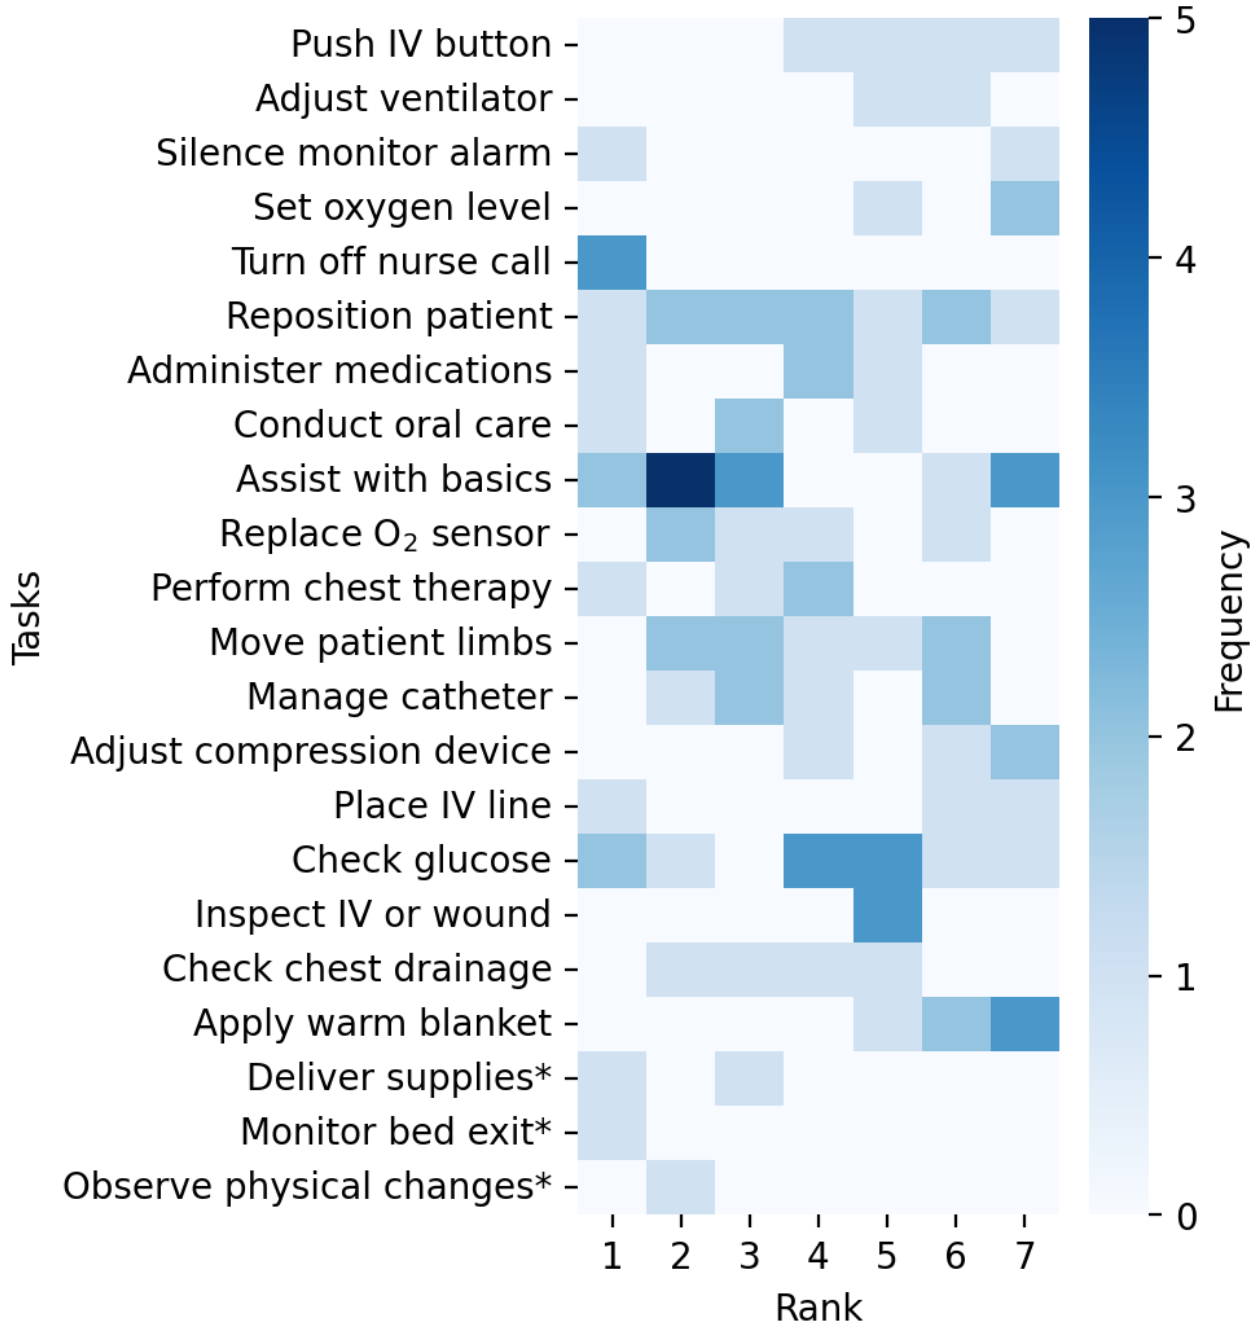
XSL•FO
RenderX



The “concerns” and “direct patient care” categories were the most frequently discussed topics, with nurses and physicians contributing the most statements, indicating shared apprehensions and interests. The “indirect patient care” and “minimum capacity” categories also received considerable attention from all participant groups, with a notably consistent number of statements from physicians and nurses. This suggests a common understanding of the importance of support tasks and the fundamental capabilities that are deemed necessary for robotic systems in the ICU.

Detailed distribution of statements across various primary codes is listed in Multimedia Appendix 6. The chi-square test of independence yielded a chi-square statistic of 112.87 with 102 degrees of freedom and a *P* value of .22. These results indicate no statistically significant differences in the distribution of thematic codes across nurses, physicians, and APPs, suggesting a relatively uniform contribution to the identified themes.

Participant Evaluation of Proposed Tasks



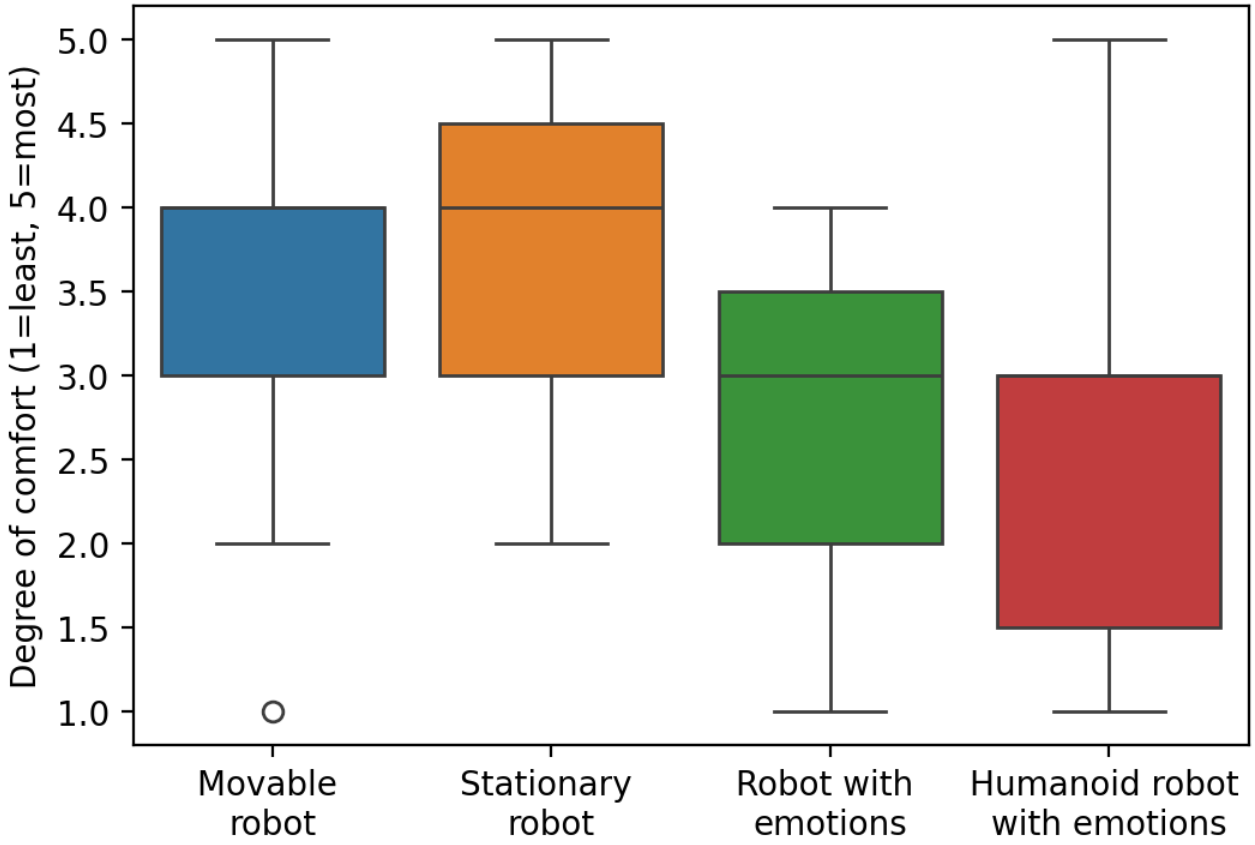
Following the completion of the interviews, clinicians were presented with our preprepared list from the literature of 19 health care tasks performed by robots. There was some overlap with the tasks discussed during the interviews as well as previously unmentioned tasks. Participants were asked to rank the top 7 tasks they believe could be performed by a robot in the ICU. They could also add tasks not on the preprepared list. This yielded a total of 22 tasks for consideration. A radar and heatmap charts visualizing the rankings (Figures 2 and 3) demonstrate the variance in priority assigned to each task by the different clinician groups. The tasks are denoted by short codes for brevity, with detailed descriptions provided in Multimedia Appendix 3. These 2 figures succinctly illustrate the areas where clinicians feel robotic assistance would be most beneficial in the ICU, reflecting their assessment of where robots could best support the clinical team and patient care.

Figure 2. Radar chart of clinician-prioritized robotic tasks in intensive care unit settings. This radar chart illustrates the frequency with which 15 intensive care unit clinicians ranked each task within their top 7. Tasks involve a range of direct, indirect, and administrative care activities, with * highlighting newly suggested tasks. IV: intravenous.

XSL•FO
RenderX

Figure 3. Heatmap of clinician-prioritized robotic tasks in intensive care unit settings. This heatmap shows task rankings by 15 intensive care unit clinicians (7 nurses, 6 physicians, and 2 advanced practice providers) from 5 Southeastern United States hospitals between January and August 2023. Darker cells indicate higher priority for robotic assistance, and tasks marked with * were newly proposed by participants. IV: intravenous.

Interestingly, tasks perceived as less critical to direct clinical judgment were ranked higher. These tasks included controlling the nurse call button to mitigate interruptions, acting as a personal assistant for patient-related nonclinical tasks, and performing routine glucose checks. Conversely, tasks that require more nuanced clinical judgment, such as push button on the intravenous machine, adjusting ventilator, and adjust oxygen level from wall fixtures, while ranked, were not as highly prioritized, suggesting clinicians' preference for retaining direct control over complex decision-making processes.



The radar chart reveals a pattern of prioritization among clinicians, with tasks such as acting as the personal assistant, performing glucose checks, and repositioning or boosting a patient in bed consistently appearing as top-ranked tasks. This indicates clinicians' clear preference for assigning routine, recurring tasks requiring less clinical judgment to robotics. However, while these tasks are generally seen as routine, they may not always be suitable for autonomous robotic execution without human oversight. Tasks such as repositioning a patient can vary significantly in complexity depending on the patient's condition. For patients with chest tubes, drains, pressure wounds, or those on ventilators, such movements require heightened situational awareness and clinical judgment.

XSL•FO
RenderX

Survey Responses

Figure 4 presents box plots of responses collected from the survey. There is a similar level of median comfort for both movable and stationary robots, indicating no significant preference for robot mobility. Additionally, the survey responses indicate a division in opinion regarding the simultaneous operation of multiple robots in the ICU, with a majority of 9 (60%) participants comfortable with the idea. In contrast, the remaining 6 (40%) participants expressed discomfort with multiple robots performing tasks concurrently.

Figure 4. Box plot that compares clinicians' comfort levels with different types of robots in the intensive care unit. This box plot compares self-reported comfort levels (1-5 scale) among 15 intensive care unit clinicians (7 nurses, 6 physicians, and 2 advanced practice providers) across 4 categories of robots—movable, stationary, a robot expressing emotions, and a humanoid robot with emotions. Data were collected between January and August 2023 from 5 Southeastern US hospitals. The vertical axis indicates the degree of comfort, and the horizontal axis lists each robot type, revealing varying levels of acceptance for different robotic designs and capabilities in high-acuity health care environments.

Robots that can express emotions and humanoid robots are met with a lower median comfort level compared to the other types, which may reflect clinicians' uncertainties or concerns about the unpredictability and implications of such features in a clinical setting.

Discussion

Principal Findings

Our study reveals a broad receptiveness among ICU clinicians to the integration of robotic technology, building on mounting evidence that such innovations can reduce staff burden and enhance care delivery in critical settings. While prior investigations have noted that telepresence and task-oriented robots can enhance workflow and reduce clinical workload, our qualitative analysis contributes a more nuanced view by detailing a diverse range of potential tasks—78 in total—where robots might assist without compromising patient safety or clinical judgment. This list offers valuable insights for future research and development, guiding the creation of technologies that align with the real-world needs and preferences of health care professionals.

Clinician Preferences for Robotic Assistance

Clinicians prioritized tasks for robotic assistance that are routine, recurrent, and do not necessarily require clinical judgment. High-frequency, low-complexity tasks such as responding to the nurse call button and performing glucose checks were favored for robotic automation. This suggests that clinicians are interested in leveraging robotic technology to reduce the burden of basic tasks, potentially increasing efficiency and allowing them to focus on more patient-centric care.

On the other hand, tasks requiring higher clinical judgment, such as adjusting ventilator settings, were not as highly prioritized for robotic assistance. An illustrative comment from a nurse highlighted this: "One of the things nurses always learn is that you're not treating the monitor. You're treating a patient so there's plenty of time that the monitor is wrong, and we have to use our nursing judgment." Although such tasks are recognized as potentially automatable, clinicians expressed a

XSL•FO
RenderX

need to maintain human oversight for these critical interventions, underlining an essential preference for direct human involvement in high-stakes decision-making and the delivery of compassionate care. This highlights a key insight that clinicians may prefer to retain control over critical tasks, possibly due to concerns about the consequences of errors and the current limitations of robotic technology in making nuanced decisions.

These insights have significant implications for the design and integration of robotic systems in the ICU. There is an opportunity for technology developers to focus on creating robotic systems that are seen as helpers rather than replacements for clinicians. Systems that can seamlessly integrate into the ICU environment and perform tasks that are perceived as helpful by clinicians are likely to be more readily accepted. Furthermore, the mixed comfort levels with humanoid robots and robots that express emotions suggest that while some clinicians might find these features enhance the patient experience, others might view them as unnecessary or potentially unsettling. This indicates a need for careful consideration of the human-robot interaction design and for the provision of adequate training and familiarization for clinicians.

Ethical and Safety Considerations

Indirect references to the foundational biomedical ethical principles of autonomy, beneficence, nonmaleficence, and justice were reflected in many of the views shared by participants. With respect to autonomy, beneficence, and nonmaleficence, 10 participants explicitly stated that robots in patient rooms must comply with HIPAA (Health Insurance Portability and Accountability Act) protections regarding the privacy and security of patients' individually identifiable personal health information. This is a requirement throughout the health care setting regardless of the introduction of robots. However, 5 participants believed that robots with audiovisual features would pose increased risks for breaches of patient privacy and confidentiality. In contrast, 3 participants noted that while patient personal health information must be protected, patients currently have decreased personal privacy in ICU by design (eg, glass doors and walls) to help clinicians monitor them for safety. Two participants asserted that monitoring for safety (regardless of machine or human) is reasonable if it improves response times and quality of patient care, provided that data are kept secure. One participant was concerned with the possibility of recordings "being used against staff." Three other participants noted that if clinicians are practicing within scope and protocol, they should not worry about being recorded by the hospital. Two other participant comments around privacy and confidentiality were the use of robots in direct patient care should be stated on the consent to receive treatment form, and there should be indicators (eg, a light) when robots or other devices are using audiovisual features.

Specific to beneficence and nonmaleficence, all participants expressed concern about patient safety to varying degrees if robots perform direct patient care. Three participants described how ICU nurses use clinical judgment when treating patients who are critically ill. They described this as "treating the patient" and not responding to clinical device readings in isolation. They did not believe robots would be capable of applying this often experiential clinical decision-making. However, 3 other participants noted that errors and injuries currently occur in hospitals. Akin to safety concerns, 2 nurses explicitly stated that they would want 24×7 support in troubleshooting any robot malfunctions.

Related to justice, one participant noted their belief, "patients who might have limited health literacy or are older ... might be more likely to go to an ICU ... more likely to have complications for all sorts of reasons ... the people who would benefit most from technology tend to already have high health literacy [which leads to the concern of social and identity] inequity." Further patients with a lower understanding about technology or who are in a compromised psychological state such as delirium might be frightened or confused by the presence of robots.

The focus on patient and clinician privacy and safety as well as the concern about missing the "human touch" underscore the need for patient, family, and staff education when deploying robots into the clinical setting to address these concerns. Resources or support would be needed for clinicians to detect and possibly troubleshoot issues with the robots. Three participants noted that their confidence in robots performing direct patient care would increase when they observed this occurring in their clinical setting without any complications. One further commented that robot functions in the ICU should be limited to functions posing less risk to patients and with patients themselves who are less medically fragile. Once the use of robots in ICUs becomes more proven and standardized, then functionality can be increased.

An ethics-related concern emerged about the loss of human connection when robots are included in direct care, regardless of whether process efficiencies are gained. Six clinicians made statements such as patients in ICU are "already prone to feeling isolation ... feeling like there wasn't a person in there with them enough." Would patients miss the human touch or feel "less than" with a robot caregiver? What impact would this have on patients and clinicians? A patient-centered approach to incorporating robots into the ICU setting would be to identify tasks, interactions, and possibly specific patients requiring the expression of human compassion and caring and preserve the human connection in those contexts [27,28].

Strengths and Limitations

This study has several limitations. In addition to the small sample size, which restricts generalizability, there is also a possibility of selection bias, as clinicians who chose to participate may have had greater interest in or familiarity with robotics. Moreover, participants came from a limited geographic region, which may not reflect the diversity of ICU settings across different health care systems and patient populations. Since this study is cross-sectional, it only reflects clinicians' perceptions at a single point in time, without accounting for how attitudes toward robotics may evolve as technology advances. Future investigations should include larger, more diverse samples from multiple institutions and regions, allowing researchers to draw broader conclusions. It would also be beneficial to conduct longitudinal studies to observe how the comfort levels and task preferences of clinicians shift over time with increasing exposure to robotic systems. Finally, collecting input from patients and

XSL•FO
RenderX

their representatives is critical to fully understanding the ethical and practical ramifications of integrating robotics into patient care.

Conclusions

This study aimed to explore the perceptions of ICU clinicians regarding the integration of robotics in critical care, focusing on identifying tasks where robots can effectively reduce clinician workload. Our findings confirm that clinicians view robotics as a supportive tool rather than a replacement for human expertise. By aiding with routine and physically demanding tasks, robots can free providers and nurses to focus on more complex, human-centric aspects of patient care. However, the ethical dimension—encompassing privacy, patient autonomy, and the preservation of the clinician-patient relationship—remains paramount. Ensuring robust oversight of robotics in the ICU, coupled with appropriate safeguards for patient data and clinician well-being, is essential for successful and responsible adoption.

Abstract

Background: An increasingly aging population, accompanied by a shortage of residential aged care homes and workforce and consumer feedback, has driven a growing interest in enabling older people to age in place through home-based care. In this context, smart home technologies for remote health monitoring have gained popularity for supporting older people to live in their own homes.

Objective: This study aims to investigate the impact of smart home monitoring on multiple outcomes, including quality of life, activities of daily living, and depressive symptoms among older people living in their own homes over a 12-month period.

Methods: We conducted an open-label, parallel-group randomized controlled trial. The control group continued to receive their existing care from aged care service providers. Meanwhile, the intervention group, in addition to receiving their usual aged care services, had their activities of daily living monitored using a smart home platform. Surveys including the Adult Social Care Outcomes Toolkit (ASCOT), EuroQol-5 Dimensions-5 Levels (EQ-5D-5L), Katz Index of Independence in Activities of Daily Living (Katz ADL), Lawton Instrumental Activities of Daily Living Scale (IADL), and Geriatric Depression Scale (GDS) were conducted at baseline and 6 and 12 months from baseline. Linear mixed-effects models were used to compare the difference between the intervention and control groups, with the ASCOT as the primary outcome measure.

Results: Data from 130 participants were used in the analysis, with no significant differences in baseline characteristics between the control group (n=61) and the intervention group (n=69). In comparison to the control group, the intervention group had a higher ASCOT score at the 6-month assessment (mean difference 0.045, 95% CI 0.001 to 0.089; Cohen *d*=0.377). However, this difference did not persist at the 12-month assessment (mean difference 0.031, 95% CI –0.014 to 0.076; Cohen *d*=0.259). There were no significant differences in EQ-5D-5L, Katz ADL, IADL, and GDS observed between the intervention and control groups at the 6-month and 12-month assessments.

Conclusions: The study demonstrates that smart home monitoring can improve social care–related quality of life for older people living in their own homes. However, the improvement was not sustained over the long term. The lack of statistically significant findings and diminished long-term improvements may be attributed to the influence of the COVID-19 pandemic during the later stage of the trial. Further research with a larger sample size is needed to evaluate the effect of smart home monitoring on broader quality-of-life measures.

Introduction

Globally, the aging population is steadily increasing, with 703 million individuals aged 65 years or over as of 2019, and this number is projected to reach 1.5 billion by the year 2050, with a global average life expectancy of around 77.1 years [1]. By 2041, the population of Australia aged 65 years and older is expected to see a 54% increase, rising from 4.31 million in 2021 to 6.66 million [2]. This demographic trend presents unique challenges in providing adequate care and support for older individuals, particularly those who choose to age in their own homes. Residential aged care facilities have traditionally been the primary setting for delivering aged care services. However, an aging population, coupled with a global shortage of aged care facilities and workforce, poses significant challenges to residential aged care. This leads to compromised access to essential care services, overburdened existing facilities, and increased strain on caregivers, impacting the quality of care [3-5]. To address these challenges, there has been a growing policy emphasis on aging in place, the concept of older people living longer in their own homes and communities as they age [6,7]. This allows older people to remain connected to their communities, friends, and family networks, promoting overall well-being and social support. Aside from older people's preference, the lack of residential care placements and the rising costs associated with institutional care make aging in place a more feasible and cost-effective option for many individuals.

In this context, smart home technologies have emerged as a promising solution to support the well-being and independence of older individuals living in their own homes. These technologies encompass a wide range of devices and systems, including sensor networks, remote monitoring, and assistive devices, which can enhance safety, health monitoring, and overall quality of life for older adults [8,9]. By integrating these technologies into the home environment, smart home solutions have the potential to address various challenges associated with aging in place, such as falls, medication adherence, and social isolation [10].

While the potential benefits of smart home solutions in supporting aging in place have been widely acknowledged, the evidence base, particularly from randomized controlled trials (RCTs), remains limited [11,12]. The evaluation of smart home technologies through RCTs is important to establish their efficacy, effectiveness, and cost-effectiveness in real-world settings. Moreover, previous studies investigating the influence of smart home technologies on the well-being of older individuals largely focused on health-related quality of life [13-16]. Smart home technologies can detect emergencies, monitor health, and assist in daily tasks, which can lead to increased autonomy and security, not only promoting physical well-being but also addressing critical social and emotional needs [11,17]. However, an increased emphasis on health-related quality of life and less attention to the social care–related quality of life has created a gap in our understanding of how smart home technologies can affect broader aspects of older people's quality of life, beyond health functioning [18-20].

Following our previously published protocol [21], we conducted an RCT, with the primary aim of evaluating how the use of the Smarter Safer Home (SSH) platform impacts the social care–related quality of life in older people living in their own homes. As a secondary aim, we examined whether this technology impacts the health-related quality of life, ability to perform activities of daily living (ADLs), and severity of depression. The findings of this study enhance our understanding of how smart home technologies can impact older people who live in their own homes. Moreover, they have the potential to inform policy and practice in the field of aged care, providing valuable insights into the effectiveness and feasibility of implementing smart home solutions to support aging in place.

Methods

Study Design

This study is a mixed-methods, open-label, parallel-group RCT. Participants were allocated randomly to a control group and an intervention group. The control group received regular aged care services subsidized by the Australian government, which can be categorized into 2 types: the Commonwealth Home Support Programme (CHSP) and the Home Care Package (HCP). CHSP provides basic support to help older Australians live independently, while HCP offers more comprehensive and personalized care for those with higher or more complex needs. The intervention group, in addition to usual aged care services, had the SSH platform installed at their residence. The SSH platform is an in-home monitoring system that uses distributed ambient sensors to track the physical environment and human activities within a household. The sensor data is transmitted to a cloud computing server that assesses residents' ADLs and sleep patterns. During the trial, the assessment was accessible to participants, their families, and aged care service providers through a tablet app or web portals. Survey questionnaires completed by the participants were used to measure primary and secondary outcomes at baseline, 6 months, and 12 months. Additionally, the trial collected various other types of data, including raw sensor data, evaluations from both informal and formal carers, participants' health services utilization, and log spreadsheets kept by aged care service providers detailing their usage of the SSH system [21]. This paper is specifically focused

XSL•FO
RenderX

on the survey questionnaires completed by the participants. Analyses of the additional data types collected during this RCT will be presented in separate publications.

Ethical Considerations

Ethics approval for this study was obtained from the Commonwealth Scientific and Industrial Research Organisation (CSIRO) Human and Medical Research Ethics Committee (CHMREC; HREC 4/2018). The trial was registered at the Australian New Zealand Clinical Trials Registry (ACTRN12618000829213). All participants consented to join the study. They are free to withdraw or suspend their participation at any time with no need to provide a reason.

Inclusion and Exclusion Criteria

The inclusion criteria were as follows: (1) older adults (65 years and older), (2) living at home, in the care of a designated aged care service provider, and (3) English-speaking with proficiency in written English. The exclusion criteria were as follows: (1) residing in long-term residential care, (2) unable to give informed consent due to reasons such as severe cognitive impairment, and (3) unwilling to leave their electricity on overnight.

SSH Platform

This study used the SSH platform presented in the protocol paper [21]. The SSH platform included an in-home network of distributed sensors, a cloud server, and a client module with a tablet app, a family web portal, and a service provider web portal (Figure 1). The sensor network consisted of ambient sensors that measured the physical environment (eg, room temperature, humidity) as well as human activities (eg, motion, door opening or closing) within the home. The sensors wirelessly sent data to a gateway hub, which relayed the data to a secure cloud server through a local WiFi network. A cloud computing service was implemented to process the sensor data, assessing the resident's ADLs across 5 domains, including mobility, transfer, hygiene, dressing, and meal preparation. The ADL scores were then compared with the participant's individual baseline profile established with the data collected over the initial 21 days of the trial period. Deviations from the baseline in each ADL domain were categorized as expected, unexpected, or very unexpected. Apart from ADL performance, the resident's sleep measures were also collected with sleep sensors placed under the bed mattress. The analytic results were made accessible to the participants, their families, and associated aged care service providers through a tablet app, a family web portal, and a service provider web portal, respectively.

The setting was home-based, with participants living in their own residences in the community. Participants were recruited from the customer bases of the aged care service providers in metropolitan and regional areas in Queensland, Australia, as defined by the Rural Remote Area and Metropolitan Area classification criteria [22].

Figure 1. The user interface of (A) the SSH tablet app and (B) the SSH web portal. SSH: Smarter Safer Home.

XSL•FO
RenderX

Trial Setting

The RCT was conducted between April 2019 and November 2020, in partnership with 3 aged care service providers (Textbox 1).

Textbox 1. Overview of aged care service providers involved in the study.

- Anglicare Southern Queensland is a member of the Anglicare Australia Network providing support to aged Australians in partnership with government and other support organizations, in response to identified care needs throughout South East Queensland.
- integratedLiving Australia receives funding from the Australian and state governments to provide care services. They provide in-home support services to older people in regional, rural, and remote Australia (including North and Eastern Queensland) and have been focusing on ensuring equitable access for health support to these communities.
- All About Living partners with federal, state, and local government departments and a number of community organizations to deliver a range of high-quality services. All About Living has developed governance, management, and service delivery expertise and excellence that enable consistent service delivery.

Recruitment

The aged care service providers identified eligible clients from their services and provided details to a team of project officers independent from the aged care service providers, who recruited and consented participants to the trial. The project officers contacted potential participants after an introduction by the aged care service provider. The project officer, via phone call, briefed the individual on the trial and assessed their interest in participating. If the individual agreed to participate, they were asked to nominate their informal carer to act as a witness in a future face-to-face meeting, where the project officer confirmed that the prospective participants met the inclusion criteria. Potential participants were provided with the Participant Information and Consent Form and a verbal description of the trial requirements by the project officer. Individuals who agreed to participate were asked to sign the Participant Information and Consent Form.

Procedures

Once participants had been consented, baseline surveys were administered to them by the project officer. After completing the baseline surveys, participants were allocated randomly to either the intervention or control groups. Stratified randomization was used with metropolitan and regional strata to preserve the ratio of the 2 geographical areas in both intervention and control groups. An independent researcher conducted the randomization using a computer program and anonymized identifiers. All participants (intervention and control) continued to receive their existing care and social services in line with local aged care service provider protocols for the 12 months of the trial. In addition, participants allocated to the intervention group received an SSH kit, including sensors, a tablet, and a gateway hub. The installation of the SSH kit was coordinated by the project officer, typically within 2 weeks of group allocation. All participants were contacted by a project officer to complete the follow-up surveys at 6 months and 12 months from baseline. The surveys were conducted either over the phone or in person and were managed using the REDCap (Vanderbilt University) hosted by CSIRO. During the trial period, the project officer was the point of contact for any problems or questions. If an intervention group participant wished to withdraw from the trial, the project officer arranged for the SSH kit to be uninstalled from their home as quickly as possible. Upon completion of the project, all homes had their SSH kits removed by the project officer.

Intervention

The intervention involved monitoring ADLs of participants through the SSH platform. During the trial, the aged care service providers aimed to review the trends in the participants' ADL performance through the SSH service provider portal 5 days a week, specifically on business days. When the aged care service providers identified a participant's ADL performance to be in an unexpected or very unexpected range for 2 consecutive days, they would contact the participant via phone or send an email to the participant's case manager. The aged care service providers created their own intervention logs to record information about actions taken for the participants. Given the workload on aged care service providers, maintaining the intervention log was not a compulsory task to form a complete record of the interventions. However, it offered some insights into how aged care service providers used the SSH platform to trigger interventions. Although no specific tasks were mandated, participants and their families were encouraged to monitor the participants' ADL performance and take any actions they deemed appropriate.

Outcome Measures

The primary outcome measure was social care–related quality of life, measured with a self-completion version of the Adult Social Care Outcomes Toolkit (ASCOT [23]). Secondary outcomes included EuroQol-5 Dimensions-5 Levels (EQ-5D-5L [24,25]), Katz Index of Independence in Activities of Daily Living (Katz ADL [26]), Lawton Instrumental Activities of Daily Living Scale (IADL [27]), and Geriatric Depression Scale (GDS [28]).

Sample Size Calculation

The power calculation for the randomized trial design was based on a clinically significant difference of 10% in ASCOT, with a distribution of 0.80 (SD 0.16) as indicated in prior research [29]. Given a null hypothesis of $\alpha \geq .05$, an effect size of 0.5 (0.08/0.16), identical allocation ratio for the 2 groups in our trial, and a 30% attrition rate, the sample size of this trial was computed to be 100 participants per group to achieve 80% statistical power [21].

XSL•FO
RenderX

Statistical Analysis

Descriptive statistics summarized the baseline characteristics and outcome measures by groups. For continuous variables and categorical variables, means and SD or numbers and percentages were reported, respectively. The primary and secondary outcome measures were analyzed using a linear mixed-effects model to compare the difference between the intervention and control groups. Fixed effects included group allocation, time (6 months and 12 months from baseline), group-by-time interaction, and baseline scores. Additionally, the analysis considered Participant ID as a random effect to account for within-individual correlations. Cohen *d* was used to describe the standardized mean difference of an effect. We conducted sensitivity analyses to examine whether the impact of the SSH platform varied across subgroups defined by baseline demographics, such as gender, care package, and living status. Marriage status and aged care service provider were not included in the sensitivity analyses due to insufficient sample sizes in certain subcategories.

Data Exclusion

COVID-19 Impact

In 2020, while the trial was ongoing, Australia was struck by the COVID-19 pandemic, presenting the country's older community with unexpected and significant challenges. Older adults faced considerable health risks due to their vulnerability to severe illness from COVID-19. Additionally, public health restrictions such as lockdowns and social distancing imposed by the Australian government could have both direct and indirect effects on the physical and mental health of older adults [30-32]. While quantifying the exact impact of the pandemic is challenging, we performed data exclusion to ensure consistency in the pandemic's impact on outcome measures within the 6-month and 12-month assessments.

There were 2 distinct peaks in COVID-19 cases in Australia during the trial period. The first wave, characterized by infections imported from overseas, peaked in March and April 2020. The second wave, largely resulting from increased community transmission, peaked in August 2020 and subsided by October 2020 [33]. Therefore, we identified 2 key dates, April 26, 2020, and October 26, 2020, marking the progression of COVID-19 transmission and the implementation of Australian government public health measures.

April 26, 2020: The Queensland government applied mandatory social distancing, following a series of measures, including restrictions on home confinement, movement, and gathering [34].

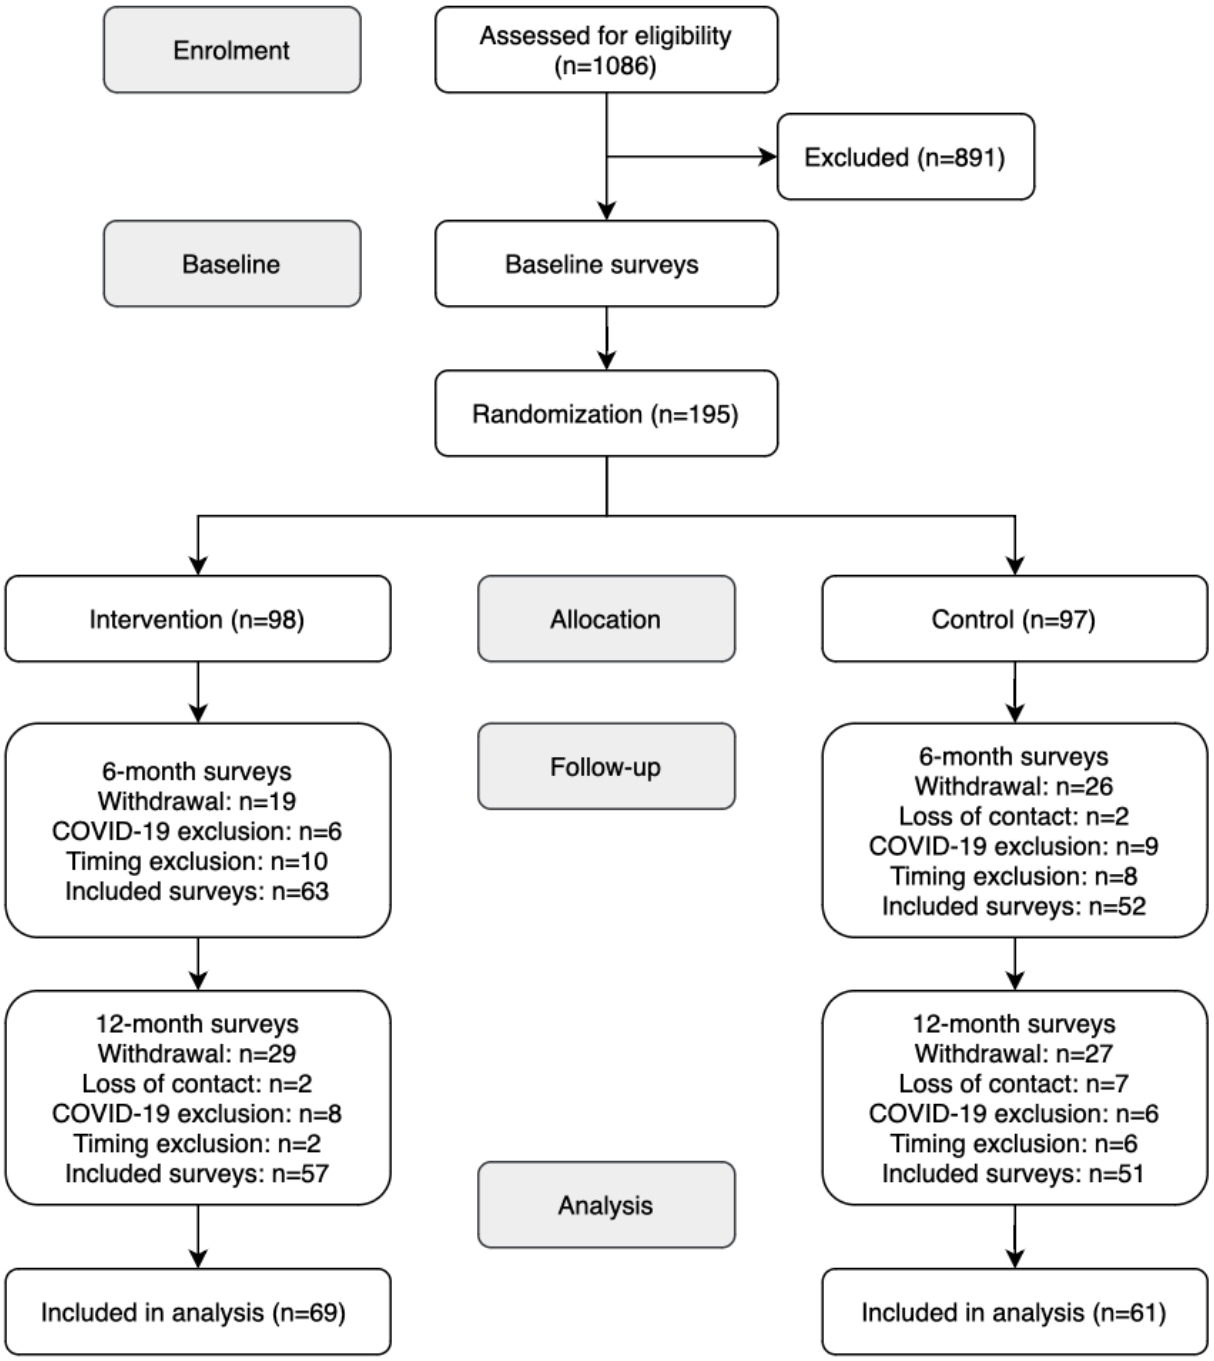
October 26, 2020: The end of Australia's second wave of COVID-19 infections in 2020 [35,36].

During the period from April 26 to October 26, 2020, the participants presumably experienced a heightened impact of COVID-19 due to more strict government measures and increased local transmission compared to periods outside this timeframe. Notably, most of the 6-month surveys were administered prior to April 26, 2020, while most 12-month surveys were conducted between April 26 and October 26, 2020. Taking these factors into account, we excluded 6-month surveys conducted after April 26, 2020, and 12-month surveys conducted either before April 26, 2020, or after October 26, 2020. As a result, the 6-month and 12-month assessments were separated into different scenarios, reflecting periods of lower and higher COVID-19 impact, respectively.

Temporal Precision

The 6-month and 12-month surveys were designed to assess participants' outcome measures at 6 months and 12 months from the baseline, respectively. However, the actual timing of these surveys varied depending on participant availability. To enhance the temporal precision of the survey results, we excluded data collected outside a 1-month window around the intended survey time.

Results



Participants

A total of 1086 clients of our partnering aged care service providers were assessed. From those, 195 provided consent to participate in the trial and completed the baseline surveys (Figure 2). Randomization resulted in 97 participants in the control group and 98 participants in the intervention group. The final analysis included the surveys from 61 participants in the control group and 69 participants in the intervention group. The absence of follow-up surveys can be attributed to participants' withdrawals (n=56) or loss of contact (n=9). Additionally, 29 surveys were excluded to account for the impact of COVID-19, and 26 surveys were excluded to ensure the temporal precision of the data.

In total, across the 73 participants included in the aged care service provider's intervention logs, on 284 occasions a decision was made to contact the participant. The contact was made either directly with the participant (144 instances) or through an email sent to the participant's case manager, requesting they contact the participant (140 instances).

XSL•FO
RenderX

Figure 2. Flow diagram of inclusion process and number of included participants.

Baseline Characteristics

The sample included 130 participants, with 69 in the intervention group and 61 in the control group. The average age of all participants at the baseline was 82.4 (SD 7.3) years.

Most participants were male (70% overall), with a slightly higher percentage of males in the control group (73.8%) compared to the intervention group (66.7%). Both groups received their regular aged care services, either CHSP (45.4%) or HCP (54.6%). In terms of baseline survey results, there were slight variations between the intervention and control groups in ASCOT, EQ-5D-5L, Katz ADL, IADL, and GDS scores. Additional details are available in Table 1.

[a]CHSP: Commonwealth Home Support Programme.

[b]HCP: Home Care Package.

[c]ASCOT: Adult Social Care Outcomes Toolkit ranges from –0.17 to 1, with higher scores indicating better social care–related quality of life.

[d]EQ-5D-5L: EuroQol-5 Dimensions-5 Levels ranges from –0.301 to 1, with higher scores indicating better health-related quality of life.

[e]Katz ADL: Katz Index of Independence in Activities of Daily Living ranges from 0 to 6, with higher scores indicating greater independence in daily activities.

[f]IADL: Lawton Instrumental Activities of Daily Living Scale ranges from 0 to 8, with higher scores indicating greater ability to perform instrumental activities of daily living.

[g]GDS: Geriatric Depression Scale ranges from 0 to 15, with higher scores indicating more severe depression symptoms.

Primary and Secondary Outcomes

Table 2 presents the effects of the SSH platform for the intervention and control groups on primary and secondary outcomes. At 6 months, there was a statistically significant difference (P=.046) in ASCOT scores between the intervention and control groups. The mean difference indicated that the intervention group had a 0.045 (95% CI 0.001 to 0.089) higher ASCOT score than the control group. The Cohen d effect size of 0.377 indicated a moderate effect in favor of the intervention group. At 12 months, the mean difference between the intervention and the control group reduced to 0.031 (95% CI –0.014 to 0.076; P=.18). The Cohen d effect size of 0.259 also suggested a smaller effect size compared to the 6-month assessment. The overall test of the group variable suggests there was a statistically significant difference in ASCOT scores between the intervention and control groups (P=.04). However, the overall test of group × time interaction was not significant (P=.59).

XSL•FO
RenderX

As shown in Table 2, there were no statistically significant differences between the 2 groups in the secondary outcomes (EQ-5D-5L, Katz ADL, IADL, and GDS) at 6 months or 12 months.

Table 2. Effects of the Smarter Safer Home platform for the intervention and control groups on primary and secondary outcomes.

Outcome	Intervention, mean (SD)	Control, mean (SD)	Mean difference (95% CI)	*P* value	Cohen *d* (95% CI)	Group, *P* value	Group × time, *P* value

[e]GDS: Geriatric Depression Scale ranges from 0 to 15, with higher scores indicating more severe depression symptoms.

Sensitivity Analyses

Significant improvements in ASCOT scores were observed, particularly among female participants (mean difference 0.089, 95% CI 0.016 to 0.162; *P*=.02) and HCP recipients (mean difference 0.079, 95% CI 0.015 to 0.142; *P*=.02) at 6 months (Tables S1 and S2 in Multimedia Appendix 1). Participants living with others showed a marginal improvement in ASCOT (mean difference 0.057, 95% CI –0.003 to 0.117; *P*=.06) at 6 months (Table S3 in Multimedia Appendix 1). The impact of the SSH platform on ASCOT for male participants, CHSP recipients, and participants living alone was not statistically significant. The impact on EQ-5D-5L, Katz ADL, IADL, and GDS was generally consistent with the main analysis (Tables S1, S2, and S3 in Multimedia Appendix 1).

Discussion

Principal Findings

In this RCT, 195 older people living in place were randomly assigned to intervention (using the SSH platform) and control groups. The analysis included 130 participants following withdrawals, loss of contact, and data exclusion. The effects of the SSH platform were assessed through the ASCOT, EQ-5D-5L, Katz ADL, IADL, and GDS collected at baseline, 6 months, and 12 months. The results demonstrated significant improvements in the primary outcome, social care–related quality of life, with the intervention group displaying higher ASCOT scores compared to the control group at 6 months. However, the long-term effect of the smart home solution on

XSL•FO
RenderX

social care–related quality of life, as observed in the 12-month assessment, did not align with the initial findings.

The improvement in ASCOT can be interpreted through several factors related to the characteristics of the SSH platform. ASCOT measures different aspects of quality of life that can be affected by social care, such as safety, social participation, and dignity. The SSH platform's features, including daily updates on activities and carer involvement, can improve social care–related quality of life by providing a sense of security and connectivity. On the other hand, EQ-5D-5L, Katz ADL, and IADL are associated with functional capacities and daily activities that may require specific interventions that the SSH platform does not directly address. For GDS scores, while the SSH platform can provide a sense of security and support, it may not be sufficient to significantly impact depressive symptoms without targeted interventions.

The diminished impact of the SSH platform on ASCOT observed at 12 months might be explained by an unprecedented peak of local COVID-19 transmission and strict public health measures. This is consistent with the studies indicating that the COVID-19 pandemic, characterized by concerns about virus transmission, limitations on social interactions, and disruption of daily activities, can lead to increased loneliness and reduced quality of life [37,38]. Therefore, the ability of smart home solutions to enhance the social care–related quality of life among older individuals needs continued adaptation to external factors, such as the COVID-19 pandemic, which can influence these outcomes.

Although the mean difference in secondary outcomes was not statistically significant, the intervention group demonstrated better point estimates (higher scores in EQ-5D-5L, Katz ADL, and IADL, and lower scores in GDS) compared to the control group at 6 months. Additionally, the estimates of mean difference in the GDS scores showed an increase by the 12-month assessment. However, this study's sample size might have limited the power to detect the effect of the SSH on the secondary outcomes.

Limitations

When interpreting the results of this study, some limitations must be taken into account. The primary limitation stemmed from the unforeseen impact of COVID-19 on trial operations and data analysis. First, implementing blinding for group allocation in this trial was not feasible due to the nature of the intervention, which required installation of SSH in participants' houses. The COVID-19 pandemic had adverse effects on the mental and physical health of older individuals, leading to increased rates of depression, anxiety, and cognitive decline, ultimately affecting their overall quality of life [30-32]. We excluded some data to maintain the consistency of COVID-19's impact on outcome measures at the same time points. This effectively separated the 6-month assessment and 12-month assessment into different scenarios with lower and higher COVID-19 impact, respectively. The adverse impact of COVID-19 might have, to some degree, overshadowed the effects of the SSH platform during the 12-month assessment, influenced by the heightened transmission of COVID-19 and the implementation of public health measures in Australia. In addition, the reduction in sample size from the initial sample size calculation may have reduced the statistical power of the study to detect a difference between groups.

While this study aimed to investigate how the SSH impacts older adults living in their own homes, the original protocol [21] excluded those residing with others, placing an additional emphasis on independent living. However, during the initial phase of recruitment, it became apparent that excluding older adults living with others significantly limited the number of participants available for recruitment and compromised the final sample size. Consequently, we removed this exclusion criterion. This adjustment allowed us to enhance our recruitment efforts and more effectively pursue the main objective of this study.

In addition, among the 195 participants recruited in this trial, 47 participants did not complete the 6-month assessment, and 65 participants did not complete the 12-month assessment. We noted that the participants without 6-month or 12-month follow-up data had lower EQ-5D-5L or IADL scores at baseline (Table S4 in Multimedia Appendix 1).

Comparison With Prior Work

Quality of life has been extensively investigated as one of the health outcomes associated with the use of smart home technologies [9,12,39,40]. However, most studies have primarily examined the impact of these technologies on health-related quality of life, with limited focus on social care–related quality of life within the smart home context. An RCT found that telemonitoring of biometric data along with administering symptom questionnaires did not significantly improve the mental health component of health-related quality of life. However, it may have led to a worsened physical component of health-related quality of life in the telemonitored group compared to the usual care group over the study period [16]. In another RCT of an in-home weight monitoring system in patients with advanced heart failure, the intervention group displayed an increasing trend in quality of life, but the difference was not statistically significant [15]. A systematic review reported that there was no evidence supporting that smart home and home health monitoring technologies improved the health-related quality of life for older adults [9]. Similarly, a meta-analysis of 5 RCTs investigating the effects of smart homes on older patients with chronic conditions indicated that the telemonitoring group did not yield a statistically significant impact on quality of life [12]. A scoping review examining the effectiveness of smart home technologies in supporting community-dwelling older adults with dementia found no significant effects on health-related quality of life in the 5 included studies [40]. In sum, the existing body of literature on RCTs related to smart home technologies has not conclusively demonstrated their positive influence on health-related quality of life. Moreover, evidence regarding the impact of smart home solutions on social care–related quality of life remains considerably limited.

In this study, a significant improvement in social care–related quality of life has been observed among the intervention group as compared to the control group after the first 6 months of using the SSH platform. Despite the heightened COVID-19 impact on the 12-month assessment, the intervention group displayed a possible improvement (mean difference 0.031, 95%

XSL•FO
RenderX

CI –0.014 to 0.076) in social care–related quality of life at 12 months. The ASCOT employed in this study has been proven to be a promising measure to evaluate care services for older people by broadening the evaluative space beyond the health domain to well-being [41,42]. Several studies have recommended the use of the ASCOT in combination with the widely adopted EuroQol-5D (EQ-5D) to measure broader aspects of quality of life beyond physical functioning and health dimensions [18-20]. Even though statistical significance was not achieved in secondary outcome measures, including health-related quality of life, this study filled in a gap in existing literature by assessing the effect of smart home technologies on social care–related quality in community-dwelling older people. This study presented, for the first time, evidence from an RCT, highlighting the possibility of smart home technologies in enhancing the social care–related quality of life for older people living in their own homes.

Future Directions

This RCT has yielded an extensive collection of data, including survey responses from older adult participants, data collected from smart home sensors, and evaluations from both informal and formal caregivers. Beyond this paper, there are several ongoing or planned future research projects that will use various data sources derived from this RCT. For instance, in an exploratory study, we analyzed the correlation between GDS and motion sensor data from participants' homes, aiming to determine if signs of depression could be detected through observed changes in in-home movement patterns [43]. This approach is currently being expanded through machine learning techniques to discover digital biomarkers for various health risks. In addition, a cost-utility analysis will be carried out to evaluate the cost-effectiveness of the intervention. Future research will also include a qualitative analysis to integrate the log spreadsheet maintained by aged care service providers, documenting the usage of SSH throughout the trial, with feedback from both participants and caregivers. The analysis of this data has the potential to open new avenues for predictive health analytics and proactive healthcare interventions. Besides, additional trials should be conducted to further evaluate the effect of the SSH platform on the secondary outcomes or in specific subgroups.

Conclusions

This RCT is a pioneering step in the direction of assessing the impact of smart home technology on older adults' well-being while living in their own homes. It uniquely focused on social care–related quality of life using the ASCOT, along with EQ-5D-5L, Katz ADL, IADL, and GDS measures. The study found significant improvements in ASCOT among participants using the SSH platform during the first 6 months. However, after 12 months, the improvement did not maintain statistical significance. The increased impact of the COVID-19 pandemic on the 12-month assessment was a noteworthy factor, as the pandemic introduced unforeseen challenges and restrictions that might have obfuscated the long-term effects of the SSH platform. While no significant changes were observed in the secondary outcome measures, this study contributes to understanding the potential of smart home technologies in enhancing social care–related quality of life, underscoring the need for further research to investigate the long-term effects and broader implications of such technologies in the care of older adults.

Abstract

Background: The global aging population poses critical challenges for long-term care (LTC), including workforce shortages, escalating health care costs, and increasing demand for high-quality care. Integrating artificial intelligence (AI), the Internet of Things (IoT), and edge intelligence (EI) offers transformative potential to enhance care quality, improve safety, and streamline operations. However, existing research lacks a comprehensive analysis that synthesizes academic trends, public interest, and deeper insights regarding these technologies.

Objective: This study aims to provide a holistic overview of AI, IoT, and EI applications in LTC for older adults through a comprehensive bibliometric analysis, public interest insights from Google Trends, and content analysis of the top-cited research papers.

Methods: Bibliometric analysis was conducted using data from Web of Science, PubMed, and Scopus to identify key themes and trends in the field, while Google Trends was used to assess public interest. A content analysis of the top 1% of most-cited papers provided deeper insights into practical applications.

Results: A total of 6378 papers published between 2014 and 2023 were analyzed. The bibliometric analysis revealed that the United States, China, and Canada are leading contributors, with strong thematic overlaps in areas such as dementia care, machine learning, and wearable health monitoring technologies. High correlations were found between academic and public interest, in key topics such as “long-term care” (τ=0.89, P<.001) and “caregiver” (τ=0.72, P=.004). The content analysis demonstrated that social robots, particularly PARO, significantly improved mood and reduced agitation in patients with dementia. However, limitations, including small sample sizes, short study durations, and a narrow focus on dementia care, were noted.

Conclusions: AI, IoT, and EI collectively form a powerful ecosystem in LTC settings, addressing different aspects of care for older adults. Our study suggests that increased international collaboration and the integration of emerging themes such as “rehabilitation,” “stroke,” and “mHealth” are necessary to meet the evolving care needs of this population. Additionally, incorporating high-interest keywords such as “machine learning,” “smart home,” and “caregiver” can enhance discoverability

XSL•FO
RenderX

and relevance for both academic and public audiences. Future research should focus on expanding sample sizes, conducting long-term multicenter trials, and exploring broader health conditions beyond dementia, such as frailty and depression.

Introduction

The global long-term care (LTC) sector faces significant challenges, primarily driven by an aging population and increasing demand for services [1]. This surge strains existing systems, exposing critical issues such as workforce shortages and the physically and emotionally demanding nature of LTC work [2,3]. Additionally, the rising costs associated with delivering high-quality care challenge the sustainability of current LTC models, emphasizing the urgent need for innovative and efficient solutions [4,5]. In this context, integrating technologies such as artificial intelligence (AI), the Internet of Things (IoT), and edge intelligence (EI) into LTC presents substantial advantages [6]. AI facilitates predictive health care by enabling timely interventions and personalized care strategies, while IoT devices such as sensors and wearables provide continuous health monitoring, enhancing resident safety and autonomy [7,8]. EI complements these technologies by enabling real-time decision-making through local data processing, reducing latency, and improving responsiveness in care settings [9,10]. Together, these not only improve care quality but also alleviate the workload of health care staff by automating routine tasks.

Numerous studies have investigated the adoption and understanding of these technologies through methods such as bibliometric analysis, Google Trends, and content analysis. Bibliometric analysis provides a quantitative evaluation of academic literature, highlighting key contributors, research trends, and emerging topics within a field [11]. Google Trends offers valuable insights into public interest and search behaviors, tracking the popularity of specific topics across regions over time [12]. Meanwhile, content analysis allows for a qualitative examination of thematic patterns and sentiment across textual data sources [13]. Representative examples are as follows: Maugeri et al [14] analyzed global public and research interest in telemedicine from 2017 to 2022 using Google Trends and bibliometric data, highlighting the impact of COVID-19 on interest and publication growth; Wang et al [15] mapped the global research landscape on AI applications in geriatrics using bibliometric analysis, identifying major contributors and key topics such as dementia and Alzheimer's care. Additionally, Voleti and Bhat [16] conducted a bibliometric analysis focused on IoT and edge computing in health care, revealing the growing application of these technologies in smart health care, with significant challenges in data management and scalability. Similarly, Ziwei et al [17] performed a deep bibliometric study on IoT in smart health care, highlighting key trends such as the increasing integration of blockchain-based security and network connectivity in health care systems. However, while these studies provide valuable insights into specific aspects of these technologies, they often remain limited in scope by focusing solely on either bibliometric analysis, Google Trends, or content analysis. This fragmented approach may hinder a comprehensive understanding of the broader landscape. Therefore, there is a need for a more integrative overview that explores the combined impact of these advanced digital tools on LTC. By synthesizing bibliometric analysis, Google Trends, and content analysis, this study aims to bridge this gap and offer a more holistic perspective on how these smart systems are applied in LTC.

This paper seeks to address the identified gaps by offering a more comprehensive and integrated analysis of AI, IoT, and EI applications in LTC for older adults. By combining bibliometric analysis, Google Trends, and content analysis, the study provides both broader and deeper insights into the usage of these technologies. The bibliometric analysis approach maps the intellectual structure of the field, identifying key contributors and thematic areas, while Google Trends analysis reveals public interest in the same topics, expanding the scope of understanding. Content analysis of the top 1% of the most-cited, high-impact studies offers in-depth insights into the practical applications and challenges of these technologies in real-world LTC settings. This interdisciplinary approach not only enriches the academic discourse but also provides a clearer road map for future research and development in care technologies for older adults.

This study aims to comprehensively explore the integration of AI, the IoT, and EI in LTC for older adults, addressing diverse perspectives, including academic frameworks, public interest, and in-depth insights from high-impact research. Specifically, bibliometric analysis is used to map the intellectual structure of the field, identifying leading contributors, influential publications, and key research trends. Public interest is examined through Google Trends, offering insights into societal attention to relevant topics and their alignment with academic focus. Additionally, a detailed content analysis of the top 1% most-cited research papers is conducted to uncover practical applications and challenges associated with the deployment of these technologies in real-world LTC environments. By synthesizing these diverse methodological approaches, our study results could construct a comprehensive framework that enhances the understanding of current developments and informs future innovations in AI, IoT, and EI for improving the quality and efficiency of care for older adults.

Methods

Overview of the Research Process and Analytical Methods

Figure 1 illustrates the complete research process undertaken in this study. The process begins with defining the research question, which focuses on investigating the application of AI, IoT, and EI among older adults in LTC. After establishing the research focus, relevant bibliometric records were extracted from the chosen databases. A comprehensive bibliometric analysis followed, encompassing the generation of a 3-field plot, performance analysis (based on publication and citation metrics), co-occurrence network analysis, thematic analysis, and keyword analysis to identify key research themes. To enhance the findings from the bibliometric analysis, a Google Trends analysis was conducted, where the top 16 keywords from the bibliometric analysis were expanded with synonyms. Kendall tau (τ) correlation analysis was performed to explore the relationship between keyword occurrences in bibliometric analysis and Google Trends data. Finally, a content analysis of the top 1% of the most-cited papers was conducted, offering deeper insights into practical applications. The results of these analyses inform the discussion and provide recommendations for future research directions.

Figure 1. The overview of workflow in this study.

For our analysis, we used the R package "Bibliometrix" (version 4.1.4; R Foundation) for bibliometric analysis, and Python 3.8 (Python Foundation) was used to conduct statistical analyses and create figures [18].

Ethics Considerations

The data utilized in this research were sourced from publicly accessible repositories, qualifying as secondary data and negating the necessity for direct human participant engagement. Consequently, this study does not present any ethical concerns warranting approval from an institutional review board.

The Extraction and Cleaning Process of Bibliometrics Data

We collected data through bibliographic searches across 3 major databases: Web of Science, PubMed, and Scopus. These searches, conducted in early September 2024, used a combination of keywords categorized into 3 groups: (1) terms about older adults; (2) terms linked to AI, IoT, or EI; and (3) terms associated with LTC, with the specific keywords detailed in Table S2 in Multimedia Appendix 1. Our inclusion criteria encompassed proceedings and early access papers, while we excluded papers published before 2013 or after 2023, non-English papers, and those classified under journal categories such as reviews, editorials, letters, books, corrections, and notes. The final search strategy used in each database is listed in Table S3 in Multimedia Appendix 1. Following recommendations from existing literature for ensuring robust bibliometric analysis, we set a minimum sample size of 200 papers for our qualitative review [19].

After the initial data extraction, we used Biblioshiny, a web-based application within the R Bibliometrix package designed for bibliometric analysis, to perform an automated data cleaning process aimed at improving data quality and reliability [18]. Duplicates arising from entries across multiple databases were identified and removed. To ensure consistency,

XSL•FO
RenderX

we also standardized author affiliations, retaining only the most relevant affiliation for each author at the time of publication. This process minimized potential errors, such as incorrect or multiple affiliations, which could have affected the accuracy of the analysis. By implementing this cleaning procedure, we ensured that the final data set accurately represented the scholarly landscape.

Bibliometric Analysis

This study used bibliometric analysis, a quantitative approach that leverages bibliographic data—such as authorship, citations, references, and keywords—to explore relationships and impacts within the field [11]. We focused on 5 distinct analysis methods to gain a comprehensive understanding of the intellectual structure of our research domain: 3-field plot, performance analysis (publication and citation metrics), co-occurrence network analysis, thematic analysis, and keyword analysis (author keywords). These methods are described in detail in the following sections.

Overview Using the Three-Field Plot

To gain a comprehensive understanding of the intellectual landscape of our research field, we used a 3-field plot, a robust method for providing an insightful overview of the research cohort [20]. The 3-field plot, also known as a Sankey diagram, visually represents the flow and connections between different bibliometric dimensions. In this study, we integrated 3 critical dimensions: the geographic distribution of research (country), the dissemination mediums (journal), and the thematic concentration (keywords). This multidimensional approach is instrumental in mapping the intellectual territory of the research field, allowing us to visualize the relationships and transitions between where research is conducted, how it is disseminated, and the thematic focus of the studies.

Performance Analysis Using Publication and Citation Numbers

To measure output performance, we used both the number of publications and citation counts [21]. The number of publications serves as a fundamental and credible metric for quantifying research output, systematically categorized by specific journals, institutions, or countries, providing a reliable measure of scholarly productivity and impact. Citation counts are a robust indicator of a paper's influence within the scientific community, with higher citation counts suggesting that the paper's findings have significantly supported subsequent research, reflecting increased scholarly interest and relevance in the field. Citation counts can be further categorized into 2 distinct metrics: total global citations (TGCs) and total local citations (TLCs). TGCs measure a paper's citations across external publications, highlighting its global influence, while TLCs track citations within our curated data set, providing a focused view of its impact within a specific context. Additionally, the H-index was used to evaluate both the quantity and impact of scientific output, combining aspects of productivity and citation impact. This multifaceted approach, encompassing publication counts, global and local citations, and the H-index, offers a comprehensive view of scientific contributions and their influence within our research domain.

Co-Occurrence Network Analysis

We used a co-occurrence network analysis, a methodological tool designed to visually map the interrelationships among various elements in scholarly literature [22]. This technique is particularly effective for illustrating connections formed through the simultaneous occurrence of elements such as keywords, authors, references, or terms in academic papers. In this study, we focused on analyzing the relationships among countries, institutions, and author's keywords. In the co-occurrence network, each element is represented as a node, with connections (edges) drawn between nodes that frequently appear together in the same articles or contexts. The strength of these connections is determined by the frequency of co-occurrence; more frequent appearances result in thicker, more pronounced links. By examining these networks, researchers can identify clusters of interrelated works or concepts, revealing patterns and intellectual currents that shape academic research. Specifically, the clusters identified through the co-occurrence network of the author's keywords provided the foundation for subsequent thematic mapping, where these clusters were further analyzed to explore thematic concentration and development within the research domain.

Thematic Analysis

Thematic analysis is a method used to identify and interpret patterns (themes) within data, particularly the research themes emerging from bibliometric data. It categorizes and maps research themes based on 2 dimensions: Relevance degree (Centrality), which measures a theme's importance within the research field, and Development degree (Density), which reflects how well-developed a theme is. The results are visually represented in Figure S5 in Multimedia Appendix 1, with themes plotted across 4 quadrants:

- Quadrant I (Motor Themes): Highly relevant and well-developed themes, central to the field and influential in driving research.
- Quadrant II (Niche Themes): Well-developed but less central themes, often specialized within narrower areas of study.
- Quadrant III (Emerging or Declining Themes): Less relevant and underdeveloped themes, either emerging trends or topics in decline.
- Quadrant IV (Basic Themes): Highly relevant but less developed themes that provide a foundation for broader research.

We divided our analysis into 3 phases, 2014-2016, 2017-2020, and 2021-2023, to observe how research themes have evolved. This approach allowed us to track shifts in focus, identify emerging trends, and highlight themes that have remained consistently relevant throughout the periods.

Keyword Analysis Using Author Keywords

In this study, we performed a keyword analysis using author keywords, which are terms selected by authors to encapsulate the core themes of their research papers. These keywords are essential for identifying major research trends and understanding focus areas within a field, as they reflect the concepts scholars consider most important in their studies. We selected the 16

XSL•FO
RenderX

most frequently occurring author keywords from our data set and analyzed their yearly trends to track their prominence in academic research over time. This analysis provided insights into which topics gained or lost attention, highlighting shifts in research priorities. To further explore the relevance of these keywords beyond academia, we used Google Trends to examine public interest in the same 16 keywords, allowing us to compare academic trends with public search behavior and gain a broader understanding of the societal impact of these research themes.

Enhancing Bibliometric Analysis With Public Interest Insights From Google Trends

We incorporated Google Trends as an analytical tool to capture public interest in the research topics identified through our keyword analysis [12]. Google Trends provides search volume scores ranging from 0 to 100 for each keyword, with 100 representing peak popularity, 50 indicating half of the peak popularity, and 0 reflecting insufficient data. The keywords selected for the Google Trends analysis were based on the most frequently occurring keywords from the bibliometric analysis, with the top 16 most frequent ones being chosen. To capture broader variations in public interest, we consulted with experts and selected 4 synonyms for each of these keywords, thereby expanding the search scope. The searches were conducted globally, covering the period from January 1, 2014, to December 31, 2023, with data provided on a monthly basis. We then calculated the annual search interest by averaging the monthly data for each year. Additionally, a weighted average of the search volumes for each keyword and its synonyms was computed to represent the overall Google Trends search interest for each term.

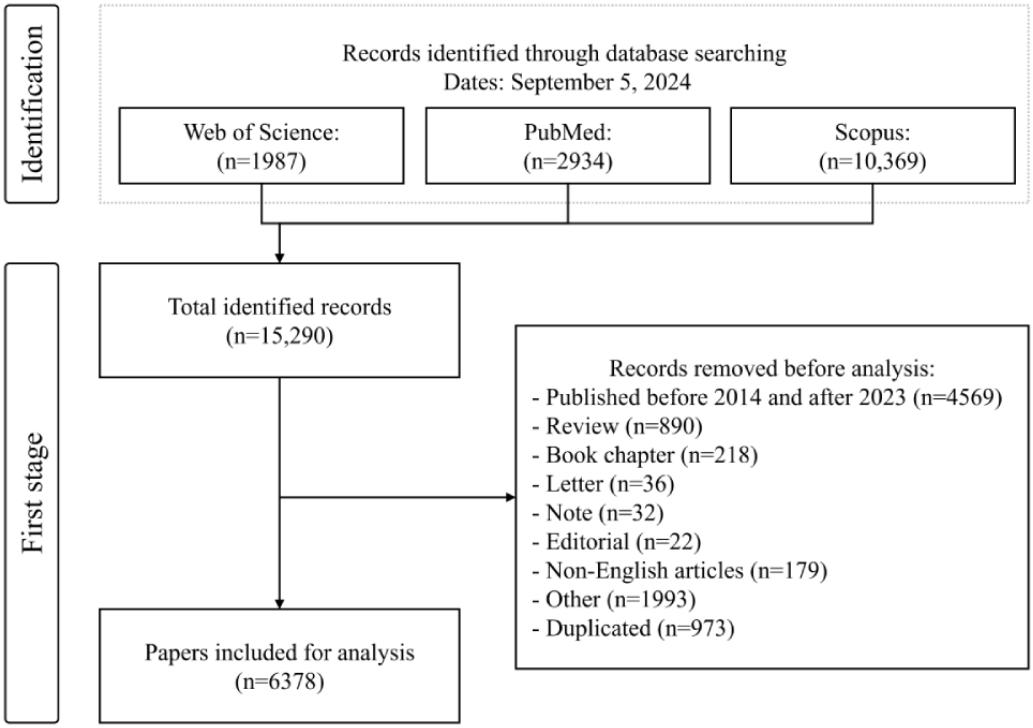
To align the units of comparison between academic keyword trends (from bibliometric analysis) and public interest (from Google Trends), we applied min-max scaling. This scaling was done globally across the 16 keywords and the period from 2014 to 2023, with the maximum and minimum values for both data sets used to normalize the data. After scaling, we multiplied each result by 100, ensuring that every value falls within the range of 0-100, enabling direct comparison between academic research frequency and public search volume. Finally, we applied the Kendall tau correlation coefficient, a nonparametric statistic, to measure the ordinal association between academic focus and public interest by comparing concordant and discordant pairs [23]. The correlation coefficient ranges from –1 (perfect inverse correlation) to +1 (perfect direct correlation), with $P<.05$ considered statistically significant. This method allowed us to quantitatively assess how well academic keyword trends aligned with public search interest over time.

Content Analysis and Quality Assessment

To gain a deeper understanding of the research focus in this study, we conducted a content analysis on the most impactful studies, specifically those with higher TLCs. Content analysis is a qualitative research method used to systematically classify and interpret text data by identifying themes and patterns [13]. This approach allowed us to explore key terms, concepts, and themes related to AI and IoT applications in LTC, helping to uncover trends, patterns, and gaps in the existing research.

Before undertaking the content analysis, a quality assessment was performed to evaluate the methodological rigor of the papers included in our review. We used the Mixed Methods Appraisal Tool to assess the quality of the selected studies (Table S4 in Multimedia Appendix 1). This tool is designed to evaluate a wide range of study types, including qualitative studies, randomized controlled trials, nonrandomized quantitative studies, quantitative descriptive studies, and mixed methods research. Each study was assessed using a nominal scale (yes/no/cannot tell), ensuring that only high-quality papers were included in the content analysis. Two independent reviewers (SCC and CCL) carried out the quality assessment, with discrepancies ultimately resolved by the corresponding author (RHC).

For the content analysis, we selected the top 1% of papers from the overall cohort, ranked primarily by TLC and secondarily by TGC. This selection process ensured that the studies analyzed not only had substantial local impact within the field but also possessed significant global relevance. From these papers, we extracted key information, including the country or region of the corresponding author, whether the study was conducted at a single center or multiple centers, the total number of participants, the percentage of female participants, the illness type of participants, whether assistive robots were used, the study's primary objective, main findings, and stated limitations. Based on this analysis, we gained deeper insights and provided recommendations for future research directions to address the identified gaps and challenges.



Results

Data Collection and Screening Process for Bibliometric Analysis

The keyword search across Web of Science, PubMed, and Scopus yielded 1987, 2934, and 10,369 records, respectively (Figure 2). Our screening process excluded papers published before 2014 or after 2023, resulting in 4569 eliminations. Additionally, we removed 890 review papers, 218 book chapters, 36 letters, 32 notes, 22 editorial materials, and 1993 other types of documents. Furthermore, 179 non-English papers were excluded. An additional 973 papers were discarded due to duplication. Ultimately, 6378 papers were selected for bibliometric analysis in the subsequent step. We also present the distribution of yearly publications and the average TGC per paper in Figure S6 in Multimedia Appendix 1.

XSL•FO
RenderX

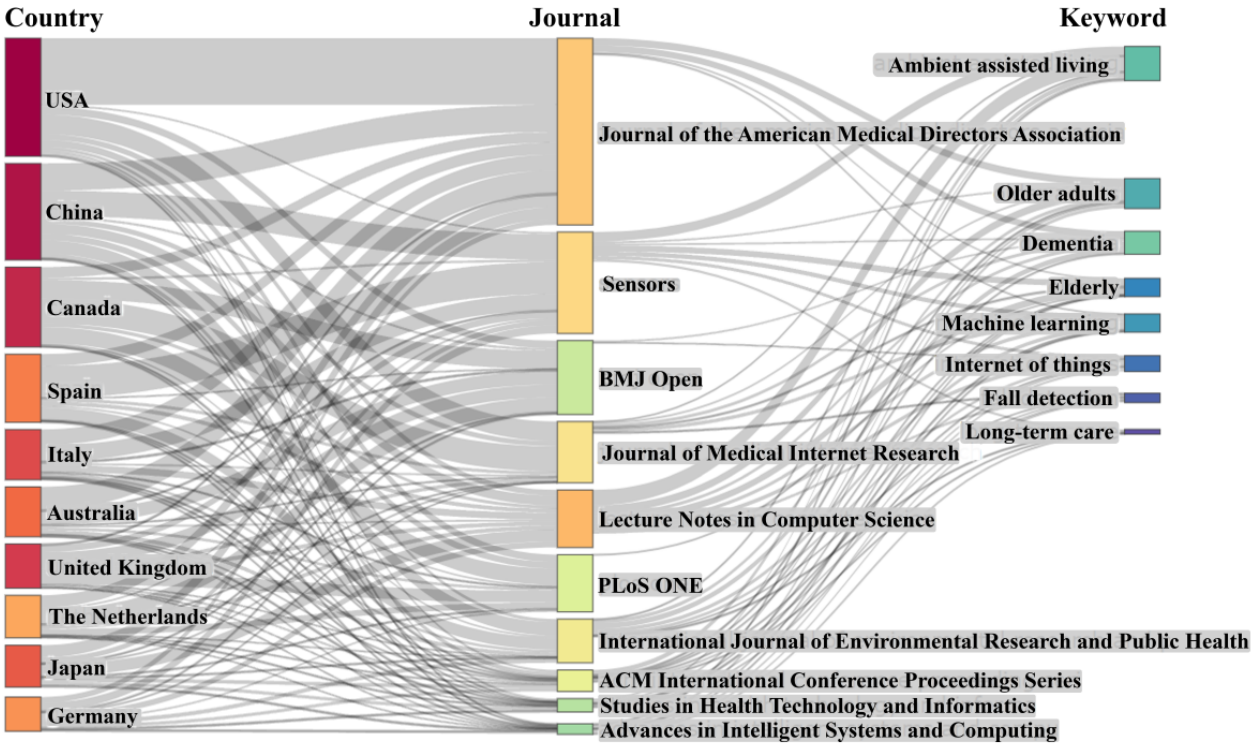


Figure 2. The procedure involved in choosing appropriate papers.

An Overview of This Study Field

We used a Sankey diagram to analyze and illustrate the distribution and interplay among countries, journals, and keywords in the articles. This method effectively highlights the usage of AI, IoT, and EI among older adults in LTC across various countries (Figure 3).

Figure 3. Three-field plot (country, journal, and keyword).

In terms of country contributions, the United States leads with 291 articles, followed by China (n=238), Canada (n=197), Spain (n=168), and Italy (n=124). Other notable contributors include Australia (n=123), the United Kingdom (n=109), the Netherlands (n=105), Japan (n=103), and Germany (n=84). As for journals, the Journal of the American Medical Directors Association

XSL•FO
RenderX

stands out with 460 articles, followed by Sensors (n=250), BMJ Open (n=182), and the Journal of Medical Internet Research (n=151). Other key journals include Lecture Notes in Computer Science (n=142), PLoS ONE (n=141), and the International Journal of Environmental Research and Public Health (n=108). These journals play a critical role in disseminating research on AI, IoT, and EI applications in LTC for older adults. Regarding keywords, prominent terms include “ambient assisted living” (n=84), “older adults” (n=74), “dementia” (n=57), and “elderly” (n=45). Other frequently used keywords are “machine learning” (n=45), “internet of things” (n=39), “fall detection” (n=23), and “long-term care” (n=12), reflecting the research focus on technological solutions aimed at improving the care and well-being of older adults.

The relationships between countries and journals reveal that major contributors such as the United States, China, and Canada publish across a wide range of journals, demonstrating a broad scope of research dissemination. Regarding journal-keyword relationships, distinct focus areas become apparent. For instance, the Journal of the American Medical Directors Association predominantly emphasizes studies on older adults and dementia, while Sensors focuses on topics such as ambient assisted living, machine learning, and care for older adults. By contrast, BMJ Open addresses general studies related to dementia and the IoT without a distinct keyword focus on other specific areas.

Most Productive Journals and Institutions

Table 1 presents a detailed overview of the most productive journals publishing research related to AI, IoT, and EI in LTC for older adults, focusing on key metrics such as publication counts, TGC, and H-Index. Leading the list, Lecture Notes in Computer Science plays an important role in this domain, with 223 publications (N=6378, 3.50%) and a TGC of 1217. The Journal of the American Medical Directors Association, which specializes in geriatrics, aging, and LTC, follows closely with 113 publications (N=6378, 1.77%) and an impressive TGC of 5812. Meanwhile, Sensors, a journal primarily dedicated to technology and sensor applications in health care and IoT, has contributed 108 publications and a TGC of 2560. The Journal of Medical Internet Research, focused on digital health and eHealth technologies, adds 89 publications with a TGC of 1822. Notably, the International Journal of Social Robotics, which focuses on robotics and its applications in social settings, has a smaller output of 36 publications, but its TGC of 1471 highlights its substantial impact per article.

Table 1. Most influential journals (sorted by the number of publications; N=6378).

Ranking	Journals	Item, n (%)	Total global citations	Total global citations per item	H-Index
1	Lecture Notes in Computer Science	223 (3.50)	1217	5.46	15
2	Journal of the American Medical Directors Association	113 (1.77)	5812	51.43	32

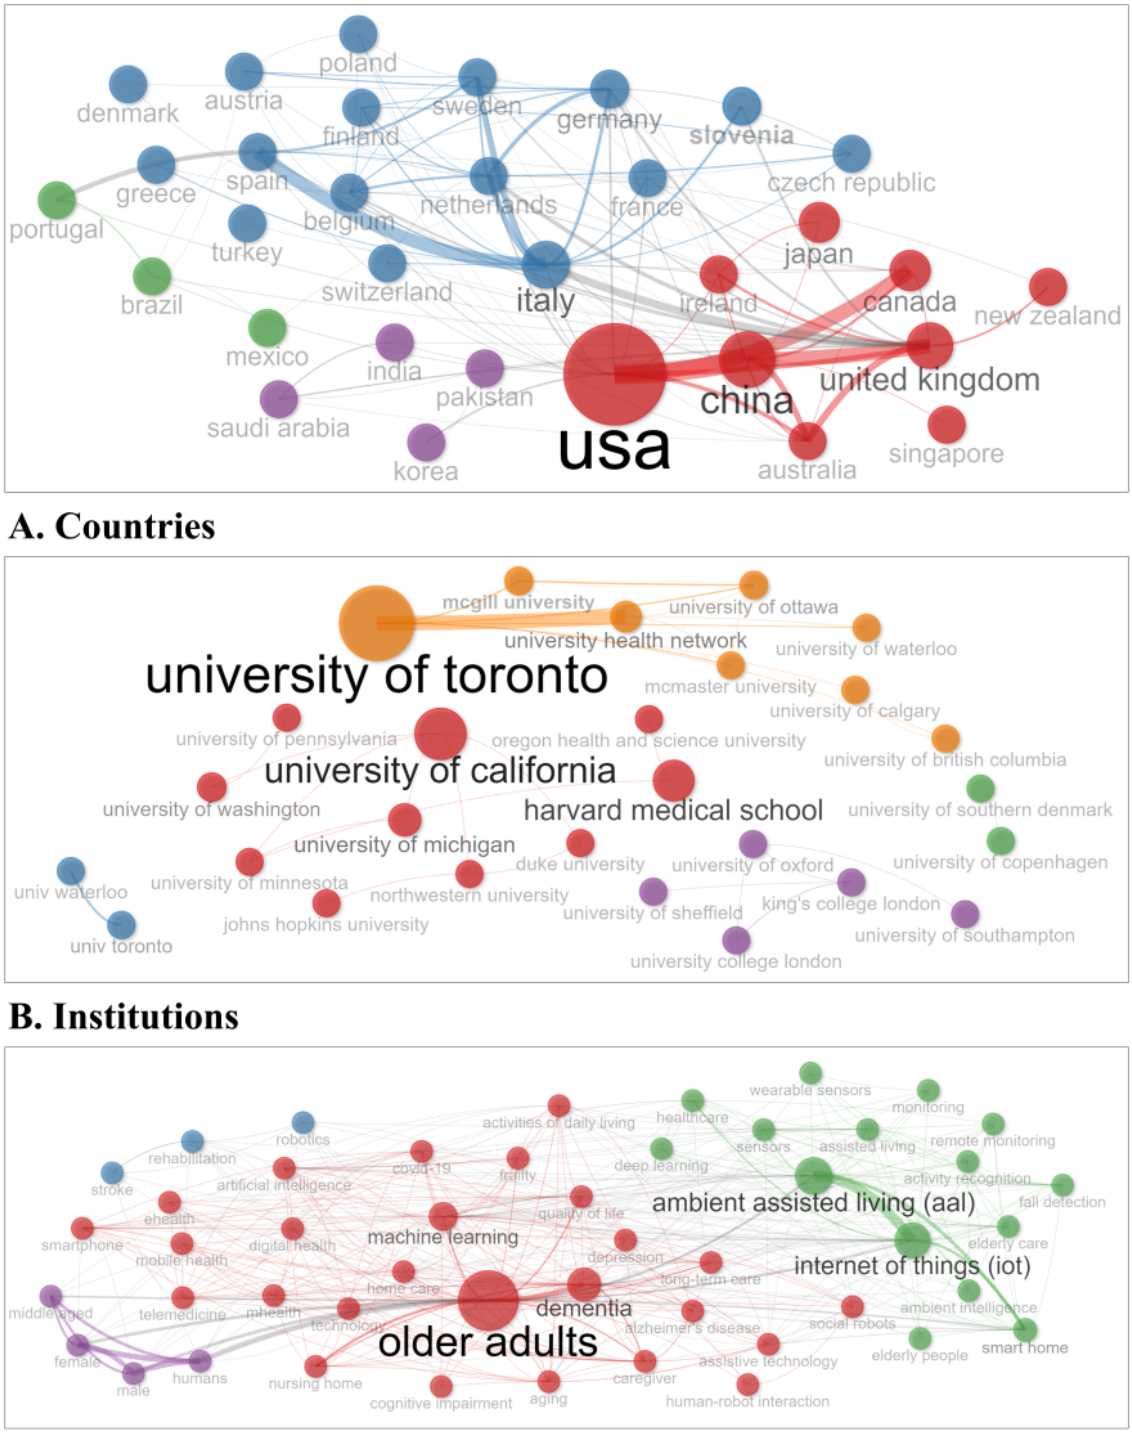
The H-Index further underscores the influence of these journals in the field. The Journal of the American Medical Directors Association stands out with a robust H-Index of 32, reflecting its high citation impact. Sensors and Lecture Notes in Computer Science follow with H-Indices of 25 and 15, respectively, illustrating their diverse influence within the field. The Journal of Medical Internet Research also demonstrates substantial scholarly impact, with an H-Index of 24. Finally, despite its

XSL•FO
RenderX

smaller publication count, the International Journal of Social Robotics achieves an impressive H-Index of 20, underscoring the considerable influence of its limited number of publications.



We also identified the 20 most productive institutions worldwide based on their publication output, as detailed in Table S5 in Multimedia Appendix 1. Leading the list are the University of Toronto with 246 publications, the University of California with 169 publications, and the University of Michigan with 136 publications. Following closely are the University of Washington (n=120), Griffith University (n=106), and the University of Pittsburgh (n=102). Our analysis of the top 20 institutions reveals a diverse range of geographic locations, including institutions from Canada, the United States, Australia, the United Kingdom, Sweden, and Denmark. This global distribution underscores the widespread interest and active involvement in this field. The broad geographic representation not only highlights the substantial contributions of these institutions but also offers insights into potential collaboration opportunities across different regions.

Co-Occurrence Network and Thematic Analysis

In the bibliometric analysis, we constructed a co-occurrence network to explore the relationships and thematic intersections across 3 distinct fields: countries, institutions, and author's keywords, covering the period from 2014 to 2023. As shown in Figure 4, the network highlights the complex interactions within the research landscape, delineating patterns of collaboration and thematic focus. The figure visually represents the prominence and centrality of specific countries, institutions, and keywords, revealing key players and dominant themes in the field. This network provides valuable insights into how different entities contribute to and shape research on AI, IoT, and EI in LTC for older adults.

XSL•FO
RenderX

Figure 4. Co-occurrence network with three different fields.

Regarding the countries, the bibliometric network analysis reveals a robust international collaboration framework within the research landscape, as depicted in Figure 4A. The United States is prominently positioned at the core of this network, underscoring its pivotal role in spearheading research initiatives on a global scale. Notable are the substantial bilateral links connecting the United States with other research-heavy nations such as China, the United Kingdom, and Canada, which suggest a high degree of cooperative research activity. European countries, represented by the cohesive cluster of Germany, Italy, and France, demonstrate strong intracontinental connections, indicative of their collective research endeavors. Meanwhile, countries such as Portugal and Brazil, though less central in the visualization, reveal their targeted and specialized contributions to the research community.

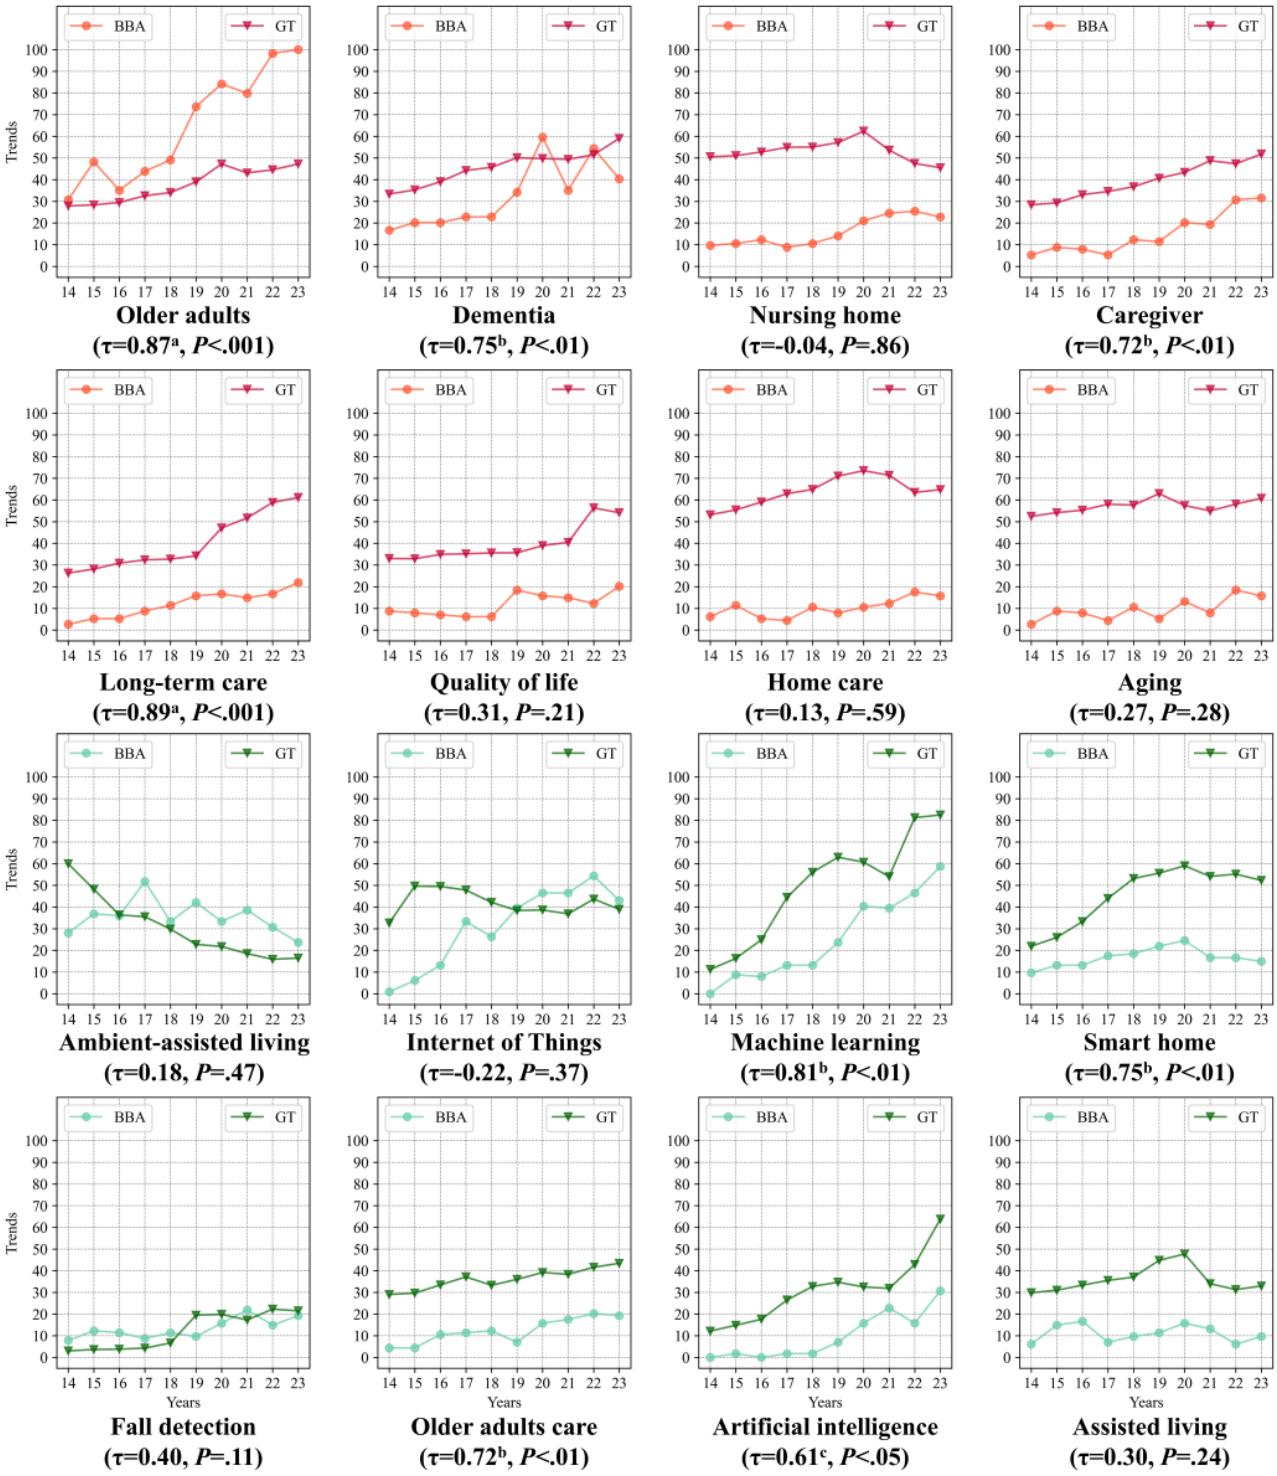
The visualization of institutional collaborations (Figure 4B) positions the University of Toronto as a central node within the network, highlighting its significant research output and

XSL•FO
RenderX

influence across disciplines. Other institutions, such as the University of California and Harvard Medical School, also command prominent places within the network, signifying their crucial roles in fostering extensive academic partnerships and knowledge dissemination. The depiction of a wide array of institutions from various corners of the globe points to a richly diverse and interdisciplinary academic milieu, signifying the breadth and depth of research collaborations and intellectual exchange.

The network of the author's keywords (Figure 4C) is dominated by the term "older adults," which acts as a thematic epicenter linking diverse research topics. Surrounding this pivotal term, we find noticeable nodes such as "dementia," "health care," and "assistive technology," reflecting concentrated areas of research focus and societal impact. The prevalence of cutting-edge technological terms such as "artificial intelligence," "internet of things," and "machine learning" adjacent to care topics for older adults underscores the integration of technology in addressing the complexities of aging. Additionally, emergent terms such as "COVID-19," "digital health," and "telemedicine" are a testament to the field's responsiveness to evolving global health issues and the increasing relevance of digital innovation in health care solutions.

To further understand the evolving research landscape, we conducted a thematic analysis of author keywords across 3 distinct periods: 2014-2016, 2017-2020, and 2021-2023. This analysis allowed us to track the shifts in research focus over the years and identify emerging or declining trends. The results, detailed and thoroughly documented in Multimedia Appendix 1 (see the section titled "Using Thematic Analysis for a Meticulous Examination Across Three Periods") show noticeable changes in central research themes such as "older adults," "dementia," and "nursing home," alongside the rise of newer themes such as "mHealth," "digital health," and "artificial intelligence" in recent years (see Figure S1 in Multimedia Appendix 1). These findings provide insights into how the integration of advanced technologies has increasingly shaped the research landscape in care for older adults, reflecting broader societal and health care trends.



Keyword Analysis: Enhancing Bibliometric Analysis With Google Trends for the Top 16 Keywords

We also adopted the keywords analysis to explore the evolving trends and key focus areas in AI, IoT, and EI applications for older adults in LTC. In our study, we first identified the top 16 most frequently occurring keywords from the bibliometric analysis between 2014 and 2023. To further enhance the insights gained, we assessed public interest in these keywords using Google Trends. The detailed results of the keyword analysis, both from bibliometric analysis and Google Trends, are presented in Multimedia Appendix 1 under the section titled "Top 16 Frequent Keywords From Bibliometric Analysis and Their Google Trends Search Interest" (also see Table S1 and Figures S2-S4 in Multimedia Appendix 1). Among the most notable findings, "older adults" ranked as the most frequent keyword in the bibliometric analysis with 733 occurrences, and it consistently showed high search interest in Google Trends, peaking at 65 in 2020. Similarly, "machine learning" appeared 287 times in the bibliometric analysis and saw a notable rise in public interest, with its search score increasing from 15 in 2015 to 95 in 2023. The term "internet of things," which occurred 353 times in the bibliometric analysis, also showed a modest growth in public interest, with its score rising from 39 in 2014 to 46 in 2023. By contrast, "ambient assisted living" peaked at 59 occurrences in the bibliometric analysis in 2017, but its search interest declined from 40 in 2017 to 18 in 2023. Additionally, "fall detection" exhibited lower public interest in the first 5 years, beginning to grow slowly in 2019 but remaining relatively steady over the last 5 years, despite being mentioned 152 times in the bibliometric analysis.

Next, we analyzed the relationship between the keyword results from bibliometric analysis and Google Trends by calculating the correlation using the Kendall rank correlation coefficient. To address differences in scale between the 2 data sets, we applied min-max scaling to normalize the values into a range of 0-100 before conducting the analysis. The results are shown in Figure 5, and the statistical outcomes of this comparison are detailed in Table S6 in Multimedia Appendix 1. In the figure, the red trend lines represent keywords related to the older adults category. Among these, "long-term care" showed the strongest positive correlation (τ=0.89, P<.001), followed by "older adults" (τ=0.87, P<.001), both of which had significant positive correlations (P<.05), indicating a strong alignment between academic and public interest. The terms "dementia" (τ=0.75, P=.003) and "caregiver" (τ=0.72, P=.004) also exhibited significant positive correlations, reflecting growing public attention in these areas.

XSL•FO
RenderX

Figure 5. Correlation between bibliometric analysis and Google Trends volume.

For the green trend lines, which represent keywords related to the ambient assisted living category, the strongest significant correlation was observed for "machine learning" (τ=0.81, *P*=.001), indicating increasing public and research interest. This was followed by "smart home" with a significant positive correlation (τ=0.75, *P*=.003). Similarly, "older adults care" showed a significant positive correlation (τ=0.72, *P*=.004), while "artificial intelligence" exhibited a moderate correlation (τ=0.61, *P*=.02). However, terms such as "fall detection" (τ=0.40, *P*=.11) and "ambient assisted living" (τ=0.18, *P*=.47) did not demonstrate statistically significant correlations, indicating weaker public interest compared with academic research in these areas.

Content Analysis

To gain a deep understanding of the papers, we conducted a content analysis of the top 1% of most impactful papers, ranked primarily by TLC and secondarily by TGC, totaling 64 papers [24-87]. The quality assessment outcomes using the Mixed Methods Appraisal Tool are listed in Table S7 in Multimedia Appendix 1, along with the reasons. For the content analysis, we extracted key information such as the country or region of

XSL•FO
RenderX

the corresponding author, whether the study was conducted at a single center or multiple centers, the total number of participants, the percentage of female participants, the illness type of participants, whether assistive robots were used, the study's primary objective, main findings, and stated limitations in Table S8 in Multimedia Appendix 1.

The content analysis of the top 1% of impactful papers reveals key trends in the use of assistive technologies, particularly social robots, in care for older adults, especially for individuals with dementia. Many studies, such as those involving the robot PARO, consistently highlight its positive impact on reducing agitation and depression, and improving mood among patients with dementia. Long-term benefits were observed in several cases, with the psychosocial environment playing a critical role in the success of these interventions. Despite the overall positive outcomes, limitations such as small sample sizes, short study durations, and difficulties in maintaining participant engagement across various care settings were frequently noted.

A recurring theme is the exploration of the human-robot interaction and how it shapes care outcomes. For instance, multiple studies compared the effectiveness of robotic pets such as PARO against plush toys or live animals. These studies found that robots generally outperformed nonrobotic alternatives in enhancing engagement and managing symptoms. However, some studies, such as the one by Thodberg et al [53], noted a diminishing novelty effect over time, with live animals often prompting more sustained interaction. This highlights the need for future work to focus on maintaining long-term engagement with robotic interventions.

There is a significant focus on addressing the emotional and cognitive needs of older adults, especially those with mild cognitive impairment or more advanced dementia. Robots such as RobuLAB and CuDDler demonstrated potential in supporting cognitive and social functions, though customization and usability were critical factors influencing their acceptance. For example, Pino et al [39] highlighted how older adults and informal caregivers appreciated socially assistive robots for their adaptability, emphasizing the importance of designing robots that can be personalized to meet individual needs. Nevertheless, limitations such as small sample sizes and lack of direct interaction in some studies restricted generalizability.

Table 2 outlines key research gaps and future directions. A major limitation across studies is the absence of long-term follow-up, which constrains understanding of the sustained impacts of these technologies. Furthermore, the small sample sizes limit the generalizability of results. The narrow focus on dementia care, with limited exploration of other conditions such as frailty or depression, represents another critical gap. Lastly, there is insufficient research on the real-world implementation and scalability of these technologies. Future studies should prioritize long-term investigations, expand sample sizes through multicenter collaborations, broaden the scope to include other health conditions, and focus on real-world applicability, particularly scalability and cost-effectiveness.

Table 2. The summary of current research gaps and suggestions.

Current research gap	Suggestion
Studies focus on short-term outcomes.	Conduct longitudinal studies to assess long-term impact.
Small sample sizes limit generalizability.	Increase sample sizes through multicenter studies.
Research mostly targets dementia care.	Expand research to include conditions such as frailty and depression.
Limited real-world implementation and scalability data.	Prioritize studies in real-world settings and assess scalability and cost-effectiveness.

Discussion

Principal Findings

In this study, we utilized bibliometric analysis, Google Trends, and content analysis to gain a comprehensive understanding of the research interest in AI, IoT, and EI applications for older adults in LTC over the last decade. Our bibliometric analysis results included 6378 papers that revealed geographic diversity, with leading contributions from countries like the United States, China, and Canada and institutions such as the University of Toronto and the University of California. The increasing focus on keywords such as "older adults," "machine learning," and "internet of things" highlights their growing importance in enhancing care delivery. Additionally, the convergence of societal and research interests is reflected in the strong correlations between "long-term care," "dementia," and "caregiver" in both bibliometric analysis and Google Trends. Content analysis of the most impactful papers demonstrated that assistive technologies, particularly social robots such as PARO, consistently benefit patients with dementia by improving mood and reducing agitation. Overall, AI, IoT, and EI show significant potential in transforming personalized care, safety, and decision-making in care settings for older adults.

Implications

Artificial Intelligence: The Usage in LTC

AI's potential in the care of older adults is profoundly impactful, particularly in enhancing personalized care and engagement for older adults. Social robots, such as PARO, exemplify how AI can address the emotional and psychological needs of older adults, especially those with dementia. In Norway, a study involving 60 participants found that the use of PARO significantly reduced agitation and depression among patients with dementia, with positive effects lasting up to 3 months after intervention [34]. Similarly, in Australia, a larger study with 415 participants demonstrated that PARO fostered higher engagement and improved mood when compared with a plush toy used in control settings [61]. These results suggest that AI-powered robots can simulate companionship and therapeutic interactions, providing psychological comfort and enhancing the quality of life in LTC facilities. Furthermore, AI's adaptability enables tailored interventions, where robots such

XSL•FO
RenderX

as PARO adjust their responses based on real-time emotional cues, offering a more personalized and human-like experience for older residents. As such, AI is not merely a tool for automation but a transformative technology in care for older adults, contributing to improved mental health, reduced reliance on pharmacological interventions, and enhanced social interaction.

Internet of Things: The Impact on Health Monitoring and Safety in LTC

IoT technologies are revolutionizing safety and continuous health monitoring in older adult care settings by providing real-time data and immediate interventions. Wearable devices and sensors are increasingly used to monitor vital signs such as heart rate, movement, and sleep patterns, significantly contributing to the well-being of older adults. For example, a Hong Kong study developed an Internet of Medical Things system that monitored real-time biometric data, enabling health care providers to proactively modify care plans based on continuous monitoring [83]. This system demonstrated improved operational efficiency in care facilities, reducing the likelihood of health crises such as falls or cardiovascular events. Additionally, IoT solutions such as fall detection systems have been widely adopted in care facilities to enhance resident safety. Studies have shown that IoT-enabled wearable sensors effectively track motor activity and detect falls in real time, thus preventing serious injuries by alerting staff immediately [27,28,57]. These technologies not only improve patient outcomes but also alleviate the burden on caregivers by providing constant, automated oversight. By promoting greater independence among older residents, IoT devices allow them to age in place, contributing to both their safety and quality of life.

Edge Intelligence: Enhancing Real-Time Decision-Making in LTC

EI plays a pivotal role in enhancing care for older adults by enabling the processing of data directly at the source, thus reducing latency and ensuring real-time decision-making. EI allows care facilities to make immediate adjustments to care plans based on real-time data, optimizing both AI and IoT applications in care for older adults. For example, in an Italian study, a radar smart sensor utilizing edge computing successfully detected falls and monitored vital signs in older adults, providing immediate feedback to caregivers [57]. This approach minimizes the delay associated with cloud-based systems, ensuring that critical health decisions are made without the need for external data processing. Another study integrated EI into an IoT-based monitoring system, which facilitated the detection of behavioral changes in older adult residents, enabling care providers to make real-time interventions to prevent health deterioration [77]. By processing data locally, EI enhances the reliability and responsiveness of care systems, reducing the risk of system failures or connectivity issues. Moreover, EI ensures the security of sensitive health data by limiting the amount of personal information transmitted over networks, thus addressing privacy concerns that are prevalent in older adult care technologies.

Summary and Suggestions for Future Research

AI, IoT, and EI collectively form a powerful ecosystem in LTC settings, addressing different aspects of care for older adults. Based on our results, we propose the following suggestions for future research directions. **First**, the co-occurrence network shows that this research topic is globally recognized, with various countries leading relevant studies. We recommend continuing to enhance international collaboration. The thematic map reveals emerging trends in “rehabilitation,” “stroke,” “robotics,” “caregiver,” “mHealth,” and “digital health.” Future research should focus on integrating these themes into broader studies to address the evolving needs in care for older adults. In addition, keyword analysis shows increasing interest in areas such as “older adults,” “machine learning,” and “internet of things.” The correlation of keywords between bibliometric analysis and Google Trends, including “long-term care,” “machine learning,” “dementia,” and “smart home,” reflects alignment between academic and public interest. Thus, we suggest that future research papers could enhance their discoverability by incorporating these keywords, ensuring they resonate with both scholarly communities and the general public. Finally, content analysis shows the potential of assistive technologies, particularly social robots such as PARO, in improving mood and reducing agitation among patients with dementia. Future studies should address limitations such as small sample sizes and short study durations by conducting larger, multicenter trials that examine long-term impacts. Expanding research to cover a wider range of health conditions, such as frailty or depression, would provide a more holistic understanding of how AI, IoT, and EI technologies can transform older adult care.

Comparison With Previous Studies

Previous studies have consistently demonstrated the role of AI and IoT in care for older adults, especially in addressing cognitive impairments such as dementia. Wang et al’s [15] bibliometric analysis identified the United States as a leading contributor to AI applications in care for older adults, particularly in areas such as Alzheimer disease and dementia. Our study corroborates Wang et al’s findings by also highlighting a strong focus on AI and IoT for these conditions; however, we provide a more comprehensive analysis, evaluating over 6000 publications compared with Wang et al’s 230. Similarly, the study by Loveys et al [88] explored the acceptance of AI-augmented social robots and sensors, noting their varied effectiveness across care settings. Our findings align with Loveys et al’s observations, especially in high-income facilities where technologies such as PARO show greater efficacy. Additionally, Lukkien et al’s [89] study emphasized the need for user-centered AI and the importance of contextual sensitivity in older adult care applications—themes that resonate with our focus on personalized interventions. Similar to Maugeri et al [14], we use both bibliometric and Google Trends data to analyze trends in health technologies. However, our study differs by incorporating content analysis, which offers deeper insights by examining the most-cited papers to explore study designs, popular topics, and potential limitations for future research.

XSL•FO
RenderX

Regarding EI, Zhou et al [10] explored EI's potential to enhance real-time decision-making through edge computing, particularly in environments that generate vast amounts of data, such as those supported by IoT devices. Reis [90] emphasized EI's role in optimizing operational efficiency in health care, particularly by processing data closer to the source to ensure timely care interventions. However, our study reveals that EI is not a standalone concept in LTC for older people. Instead, it functions as part of an integrated system, combining AI and IoT to support health care providers in making real-time decisions and offering personalized, technology-assisted interventions for care recipients. This fusion of technologies enables a more efficient and responsive older adult care environment, allowing health care providers to deliver tailored interventions based on immediate data, while providing older adults with customized assistive devices and services. By demonstrating how EI complements AI and IoT in this context, our study contributes to a deeper understanding of how these technologies work together to enhance care quality and personalization in LTC settings.

Limitations

This study has several limitations. First, our analysis was confined to research from the past 10 years, even though the topic has been explored for over 3 decades. This choice was intentional to ensure the inclusion of the most recent and relevant data reflecting current trends. However, it may have excluded some foundational studies that provide historical context. Second, we only included English-language publications, which could introduce language bias and affect the global representativeness of our findings. Additionally, while content analysis was used to address some limitations of quantitative methods, it was restricted to the top 1% (n=64) of highly cited papers, potentially overlooking other important research. Future studies could benefit from adopting methods such as the Delphi study, as suggested by one of the reviewers, to gain deeper insights from expert opinions. This would further strengthen the qualitative depth of the research and make the study even more robust.

Conclusions

The integration of AI, IoT, and EI is driving the evolution of an interconnected ecosystem in LTC for older adults. Our study underscores the significance of this field across multiple regions, emphasizing the need to promote diversity and international collaboration to enhance regional and institutional cooperation. Key themes such as "dementia care," "machine learning," and "wearable health monitoring" are emerging as focal areas of growing research interest. Keywords such as "long-term care," "older adults," "machine learning," "dementia," "smart home," and "caregiver" demonstrate a strong correlation with the public interest, suggesting that incorporating these terms can increase research visibility. Despite the valuable insights into technology acceptance, care quality improvements, and outcomes from interventions, frequently cited studies often face limitations such as small sample sizes, short study durations, and a narrow focus on dementia care, restricting the generalizability of their findings. Future research should broaden the scope to include a wider range of health conditions, conduct long-term trials, and strengthen international cooperation. This approach will significantly enhance the scalability and real-world impact of these technologies globally.

Abstract

Background: Health care is experiencing new opportunities in the emerging digital landscape. The metaverse, a shared virtual space, integrates technologies such as augmented reality, virtual reality, blockchain, and artificial intelligence. It allows users to interact with immersive digital worlds, connect with others, and explore unknowns. While the metaverse is gaining traction across various medical disciplines, its application in thyroid diseases remains unexplored. Subclinical hypothyroidism (SCH) is the most common thyroid disorder during pregnancy and is frequently associated with adverse pregnancy outcomes.

Objective: This study aims to evaluate the safety and effectiveness of a metaverse platform in managing SCH during pregnancy.

Methods: A randomized controlled trial was conducted at Fujian Provincial Hospital, China, from July 2022 to December 2023. A total of 60 pregnant women diagnosed with SCH were randomly assigned into two groups: the standard group (n=30) and the metaverse group (n=30). Both groups received levothyroxine sodium tablets. Additionally, participants in the metaverse group had access to the metaverse virtual medical consultations and metaverse-based medical games. The primary outcomes were adverse maternal and offspring outcomes, and the secondary outcomes included the neurobehavioral development of offspring and maternal psychological assessments.

Results: Of the 30 participants in each group, adverse maternal outcomes were observed in 43% (n=13) of the standard group and 37% (n=11) of the metaverse group (P=.60). The incidence of adverse offspring outcomes was 33% (n=10) in the standard group, compared to 7% (n=2) in the metaverse group (P=.01). The Gesell Development Scale did not show significant differences between the two groups. Notably, the metaverse group demonstrated significantly improved scores on the Self-Rating Depression Scale and the Self-Rating Anxiety Scale scores compared to the standard group (P<.001 and P=.001, respectively).

Conclusions: The use of metaverse technology significantly reduced the incidence of adverse offspring outcomes and positively impacted maternal mental health. Maternal adverse outcomes and offspring neurobehavioral development were comparable between the two groups.

KEYWORDS

metaverse; subclinical hypothyroidism; adverse pregnancy outcomes; psychological health; neurobehavioral development

Introduction

The metaverse is a shared virtual space that seamlessly blends the physical and digital realities. It offers an immersive environment where users can interact in a computer-generated universe while gaining real-world benefits [1]. Built upon the foundations of mixed reality, artificial intelligence, and blockchain technology, the metaverse leverages these cutting-edge innovations to deliver dynamic, interactive, and secure user experiences [1-3]. Mixed reality, which includes both augmented reality and virtual reality (VR), bridges the continuum between physical and virtual experiences. Artificial intelligence enables adaptive and intelligent environments, while blockchain technology ensures secure transactions and ownership of digital assets, thereby supporting a resilient digital economy within the metaverse. In health care, the metaverse holds transformative possibilities [4,5]. Compared to traditional health care models, it enables secure and customizable therapeutic environments tailored to the unique needs and treatment goals of individual patients. By integrating the virtual and physical realms, it also allows for real-time monitoring and feedback [1,6]. By 2030, the global metaverse health care market is projected to reach US $98.3 billion, with the United States expected to lead this growth, followed by Europe and the Asia-Pacific region [2]. Early applications of metaverse technologies in health care have primarily focused on surgery, particularly in urology, neurosurgery, and surgical training [7-9]. Recently, its applications have expanded to areas such as cognitive rehabilitation, mental health, and chronic disease management [1,2,10]. Despite these promising developments, its potential role in the management of thyroid disorders remains unexplored.

Subclinical hypothyroidism (SCH), characterized by elevated thyrotropin levels with normal free thyroxine (FT4), is increasingly prevalent during pregnancy [11,12]. SCH is associated with adverse pregnancy outcomes, including spontaneous abortion, preeclampsia, and placental abruption [11,13]. Timely treatment with levothyroxine (LT4) sodium tablets is critical but is often hindered by limited awareness and delayed diagnosis [14].

Aligned with the Institute of Medicine's framework for high-quality health care—which prioritizes patient-centeredness, equity, safety, effectiveness, timeliness, and efficiency—our team has developed an innovative metaverse-based platform tailored for pregnant women with SCH [15]. This digital solution provides personalized care through comprehensive follow-up, starting from the antenatal period and extending to 3 months post partum. The platform aims to enhance SCH management by enabling timely and effective interventions, optimizing resource use, and promoting long-term maternal health. Our primary goal is to assess the safety and effectiveness of this metaverse-based platform in managing SCH during pregnancy. By addressing unmet clinical needs, the initiative seeks to reduce complications and improve the overall quality of prenatal and postnatal care.

Methods

Ethics Approval

This single-center, randomized, open-label trial was approved by the Fujian Provincial Hospital Institutional Review Board (K2022-06-016) and the research ethics board. The trial was registered under ChiCTR2300076803. Recruitment, treatment, and follow-up were conducted from July 2022 to December 2023.

Participants in this clinical trial received compensation for their time and involvement. Compensation was provided to recognize the participants' contributions and to help offset any expenses associated with their participation. Participants who attend the screening visit will receive compensation for their time and travel expenses. Participants will be compensated for each study visit attended. This includes time spent on medical assessments, laboratory tests, and any other required procedures (¥500-600, US $70-$80). Any out-of-pocket expenses incurred during participation, such as transportation or childcare, may be reimbursed upon submission of receipts. Upon successful completion of all study visits, participants will receive a completion bonus (¥1000, US $150).

Participants

Study participants were conveniently recruited from the Fujian Provincial Hospital outpatient practice and prescreened during appointments scheduled for SCH evaluations. Eligibility was confirmed through in-person assessments to ensure compliance with inclusion criteria. Written informed consent was obtained from all participants, and all data were anonymized or deidentified to protect confidentiality.

The inclusion criteria were as follows: pregnant women diagnosed with SCH, as defined by the 2017 American Thyroid Association Guidelines for the Diagnosis and Management of Thyroid Disease During Pregnancy and Postpartum (serum thyrotropin levels above the pregnancy-specific upper reference limit, or ≥4.0 mIU/L, with normal FT4 levels [16]), diagnosis and initiation of LT4 treatment before 8 weeks of gestation, singleton pregnancy, and age ≥18 years. The exclusion criteria were a history of thyroid disease; history of residence in areas with endemic goiter; use of LT4 before pregnancy or medications that affect thyroid function; history of nonthyroidal autoimmune diseases; preexisting cardiovascular, liver, or kidney diseases; or any prepregnancy condition that could interfere with the study. A total of 60 participants were enrolled in the trial.

Randomization and Masking

Participants were randomly assigned in a 1:1 ratio to either the standard or metaverse group using computer-generated randomization. Both groups were managed by the same medical team. Investigators and participants were not masked to treatment allocation. The research team, data manager, and statistician were aware of group assignments during the process of data collection. Data were securely stored in the Fujian

XSL•FO
RenderX

Provincial Hospital database, with the first author overseeing data accuracy and integrity. No placebo was used in the study. As predefined guidelines exist for LT4 use, the potential bias introduced by the nonblinded design on the primary outcome was considered minimal.

Procedures

The research team comprised a chief endocrinologist, an attending endocrinologist, an obstetrician-gynecologist, and a physician specializing in health management, all with extensive experience in thyroid disorder management. Eligible patients were prescribed oral LT4 (Euthyrox, Berlin-Chemie AG, Germany; H20110178, 50 μg × 100 tablets) based on thyroid function test results [16]. Initial dosages ranged from 25 to 50 μg and were adjusted according to pregnancy status [16]. Patients took one tablet daily on an empty stomach in the morning, with thyrotropin and FT4 levels monitored every 14 days for dose adjustments. Once thyrotropin levels were within 0.1-2.5 mIU/L, monitoring was conducted every 4 weeks, with doses adjusted to maintain trimester-specific target ranges [16]. Treatment continued consistently until delivery.

Participants in the standard group attended regular in-person follow-ups to monitor blood pressure, heart rate, weight, thyroid function, medication dosage, and other pregnancy-related indicators. Participants in the metaverse group only visited the hospital for enrollment, blood tests, and required pregnancy assessments. Follow-ups for the metaverse group were conducted through the platform, with medications delivered to their homes. The metaverse platform enabled secure communication between participants and investigators at any time, enhancing adherence to treatment protocols. Technical support was provided, with hardware promptly replaced if issues could not be resolved remotely. Participants used home monitoring devices under investigator guidance, with training provided for platform use. Weekly assessments ensured proficiency. Participants identified as “unfamiliar” received additional training until they could fully engage in medical activities on the platform. The platform supported uploading and recording thyroid function test results and other relevant health data. It also offered lifestyle guidance, psychological counseling, and educational games focused on endocrinology. Immersive experiences using Pico VR glasses (Fujian Huayu Education Technology Co Ltd, China) provided gamified learning and live discussions with physicians. The standard group participated in similar educational activities during weekly in-person sessions.

Adverse pregnancy outcomes were tracked through follow-ups and patient self-reports. Offspring neurobehavioral development was assessed using Gesell Development Scale (GDS) scores at 1 and 3 months of age, evaluating gross motor, fine motor, adaptability, language, and personal-social skills. Maternal mental health was assessed using the Self-Rating Anxiety Scale (SAS) and Self-Rating Depression Scale (SDS) at baseline, during the last trimester, and 6 weeks post partum. Psychological support was offered based on the SAS/SDS results, with interventions delivered via the metaverse platform for the metaverse group and through outpatient sessions for the standard group.

The intervention spanned from pregnancy through 3 months post partum, with participation continuing unless interrupted by withdrawal or loss to follow-up.

Outcomes

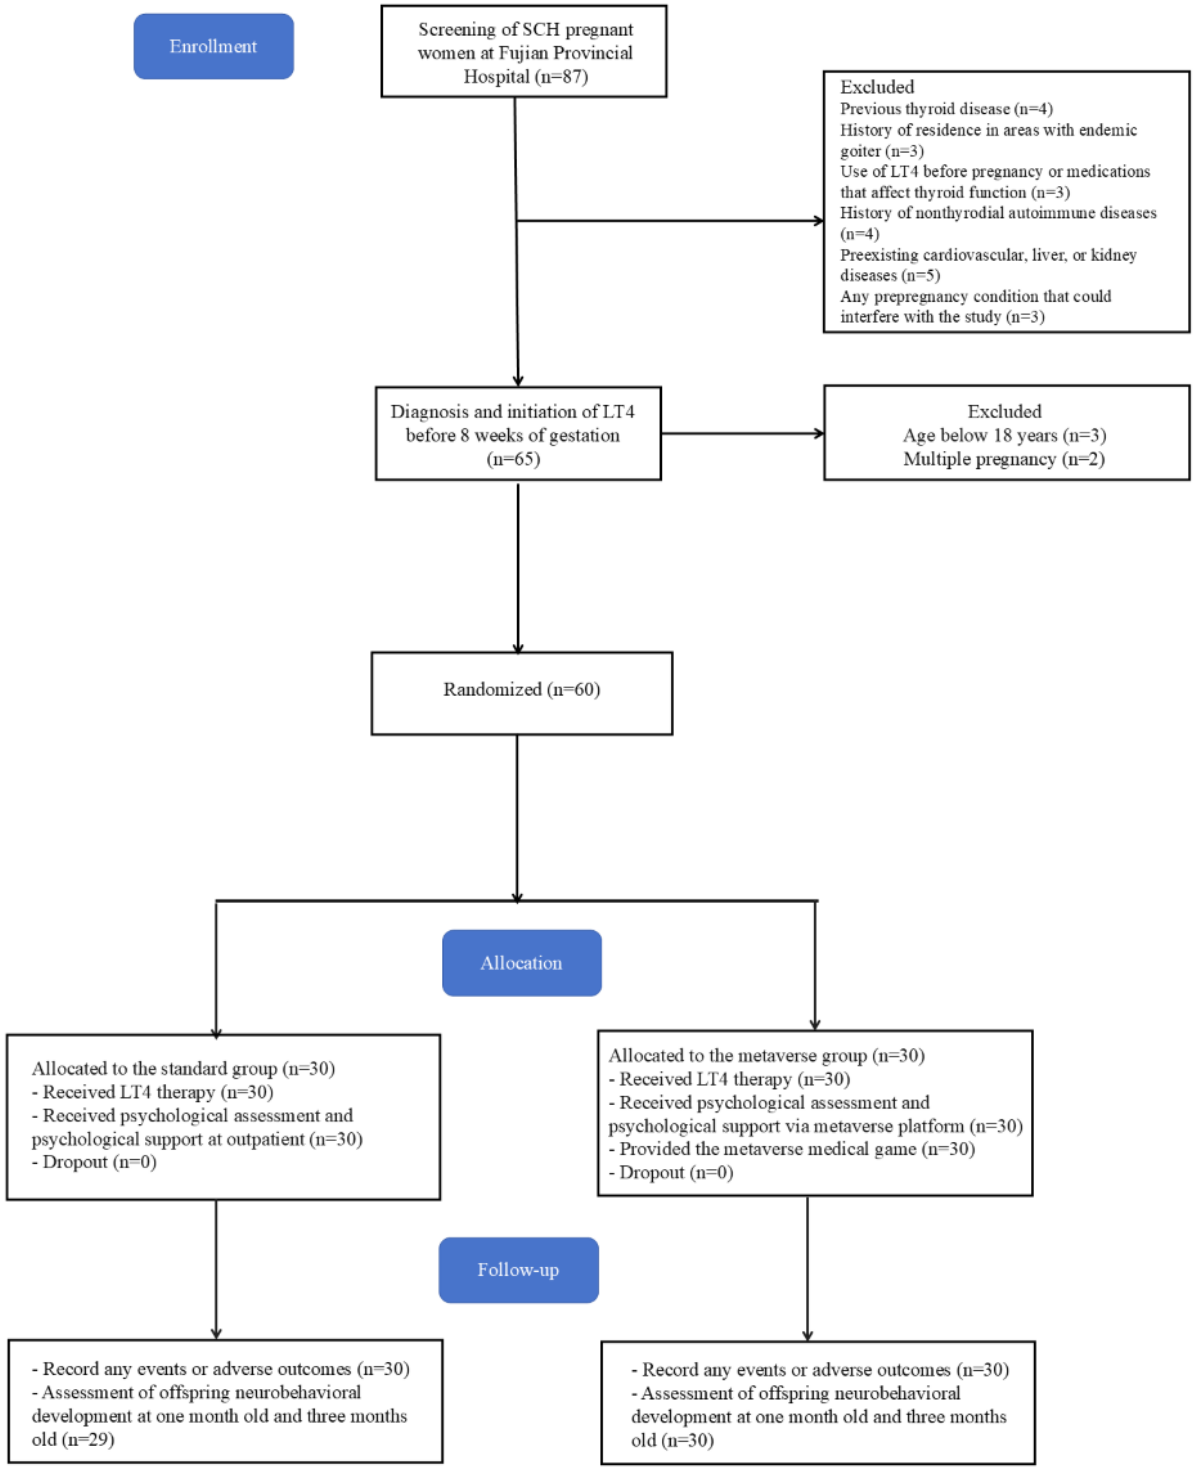
The primary outcomes of the study focused on assessing adverse maternal and offspring outcomes. Maternal adverse outcomes included gestational diabetes, gestational hypertension, premature rupture of membranes, amniotic fluid abnormalities, postpartum hemorrhage, and related complications [17]. Offspring adverse outcomes included fetal distress, abortion, stillbirth, preterm birth, neonatal asphyxia, and related complications [13,17]. Secondary outcomes focused on offspring neurobehavioral development and maternal mental health. Neurobehavioral development was considered normal if the developmental quotient on the GDS exceeded 85 [18]. Anxiety was defined as SAS scores greater than 50, and depression was defined as SDS scores greater than 53 [19]. Investigators conducted GDS assessments, while participants completed SAS and SDS questionnaires independently, which were collected immediately after completion.

Statistical Analysis

Based on a significance level of 5%, statistical power of 90%, and an anticipated 5% loss to follow-up, a total of 60 participants (30 per group) was calculated as sufficient for this randomized controlled trial.

Quantitative data were expressed as means and SDs, while categorical data were presented as percentages. Between-group comparisons of normally distributed variables used the independent samples 2-tailed *t* test or Mann-Whitney *U* test, while categorical variables were analyzed using Pearson χ^2 test or Fisher exact test. Analysis of covariance, with baseline thyroid function and initial psychological scores as covariates, was performed to assess postintervention differences in thyroid function and psychological outcomes between groups. Statistical analyses were conducted using SPSS 25.0 (IBM Corp), with a *P* value <.05 considered statistically significant.

Results



Overview

Between July 2022 and July 2023, 87 individuals were screened for eligibility, with 60 participants randomized equally into the standard group (n=30) and the metaverse group (n=30; Figure 1). By December 2023, all participants had completed the trial, including follow-up through 3 months post partum (Figure 2).

The median age of participants was 30 years in both groups, with age ranges of 20-40 years in the standard group and 23-38 years in the metaverse group. The median gestational age at delivery was 39 weeks, ranging from 23 to 40 weeks in the standard group and 36 to 40 weeks in the metaverse group. The median prepregnancy BMI was 22.8 (IQR 15.8-32.7) kg/m^2 in the standard group and 21.5 (IQR 17.6-30) in the metaverse group. There were 19 (63%) nulliparous participants in the standard group and 18 (60%) in the metaverse group. Three participants in each group had a history of obstetric abnormalities (Table 1).

Primary Outcome

At baseline, the mean thyrotropin levels were 4.6 (SD 1.4) mIU/L in the standard group and 4.4 (SD 0.9) mIU/L in the metaverse group. After LT4 treatment, the mean thyrotropin level at delivery was 2.0 (SD 0.1) mIU/L in the standard group and 1.9 (SD 0.1) mIU/L in the metaverse group (*P*=.83). At 6 weeks post partum, the mean thyrotropin levels were 2.7 (SD 0.1) mIU/L in both groups (*P*=.78).

Maternal adverse outcomes occurred in 43% (13/30) of the standard group and 37% (11/30) of the metaverse group (*P*=.60). These included gestational diabetes, preeclampsia, premature rupture of membranes, and amniotic fluid abnormalities (Table 2). Offspring baseline characteristics showed no significant differences between the two groups (Table S1 in Multimedia Appendix 1). The median birthweight was 3290 (IQR 1830-3940) g in the standard group and 3315 (IQR 2870-3660) g in the metaverse group (*P*=.91). Two newborns in the standard group were diagnosed as small for gestational age. Adverse offspring outcomes were significantly lower in the metaverse group (2/30, 7%) compared to the standard group (10/30, 33%; *P*=.01). These outcomes included preterm birth, fetal distress, neonatal intensive care unit admissions, and neonatal hypoxemia (Table 3).

[c]Fetal asphyxia refers to an Apgar score <4 at 1 minute or an Apgar score <7 at 5 minutes.

[d]Pearson χ^2 test.

Neonatal thyroid function showed no significant differences between the groups at birth, 14 days post partum, and 28 days post partum (Tables S2-S4 in Multimedia Appendix 1). The median thyrotropin levels at birth were 7.0 (IQR 3.2-16.2) mIU/L in the standard group and 6.2 (IQR 3.0-16.4) mIU/L in the metaverse group (*P*=.31). By 14 days post partum, the median thyrotropin level had decreased to 5.3 (IQR 3.5-7.8) mIU/L in the standard group and 5.0 (IQR 3.2-5.7) mIU/L in the metaverse group (*P*=.26). At 28 days post partum, median thyrotropin levels were 4.8 (IQR 3.2-6.1) mIU/L in the standard group and 4.7 (IQR 3.2-5.4) mIU/L in the metaverse group (*P*=.68). FT4 levels also showed no significant differences between the groups at any time point (all *P*>.05).

Secondary Outcomes

At 1 month of age, neurobehavioral scores showed no significant differences between the groups across all domains (Table 4). The median scores for the standard group in gross motor, fine motor, adaptability, language, and social-emotional domains were 99 (IQR 85.5-109.8), 100 (IQR 83.3-109), 99 (IQR 86-107.3), 101.25 (IQR 85-106.8), and 101 (IQR 87.8-107), respectively. The corresponding scores for the metaverse group were 100 (IQR 90.8-109), 100.9 (IQR 93-108), 100 (IQR 95-109.0), 102 (IQR 94-107.8), and 100.5 (IQR 92-109), respectively. At 3 months of age, similar results were observed, with neurobehavioral scores remaining comparable between groups (Table 4). The median scores for the standard group were 100 (IQR 88-111) for gross motor, 101 (IQR 89-113.3) for fine motor, 102.8 (IQR 88-112.8) for adaptability, 103.7 (IQR 88.8-111.3) for language, and 104.0 (IQR 90.8-111) for social-emotional domains. Scores for the metaverse group were 102 (IQR 92.8-109.8), 103.0 (IQR 95-112.8), 104 (IQR 96-114), 104.4 (IQR 96-111.0), and 104.9 (IQR 92.8-110), respectively.

Maternal mental health outcomes were assessed via the SAS and SDS. The baseline of the mean SAS scores was 44.1 (SD 8.3) in the standard group and 43.8 (SD 7.9) in the metaverse group. It showed significantly lower scores in the metaverse group compared to the standard group at delivery (SAS: mean 44.9, SD 1.0 vs mean 50.0, SD 1.0; *P*=.001; SDS: mean 44.7, SD 0.9 vs mean 49.7, SD 0.9; *P*<.001). This trend persisted at 6 weeks post partum, with the metaverse group continuing to exhibit lower scores (SAS: mean 46.9, SD 1.0 vs mean 51.3, SD 1.0; *P*=.002; SDS: mean 47.9, SD 1.0 vs mean 51.6, SD 1.0; *P*=.009).

Discussion

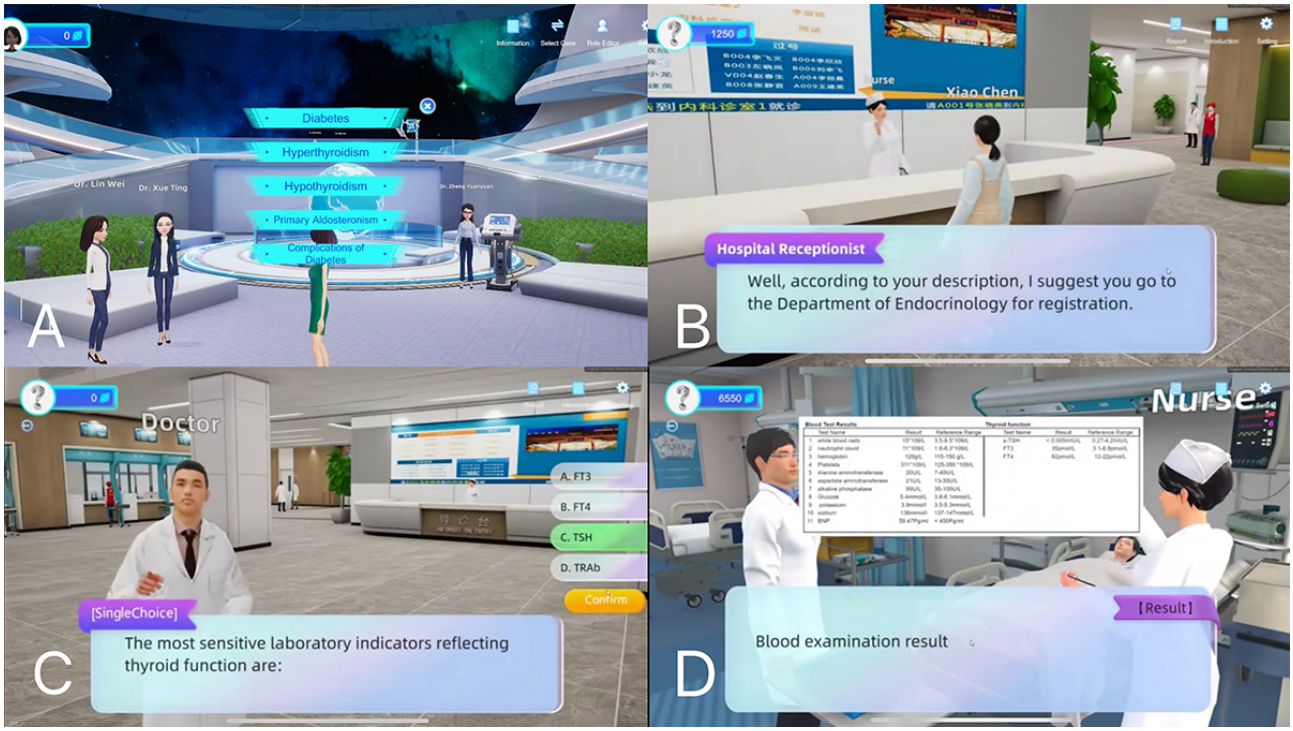
The post–COVID-19 era has underscored the transformative potential of Health 4.0, which integrates advanced technologies such as the metaverse, blockchain, and intelligent algorithms into health care systems [20]. The metaverse presents expansive opportunities, including avatar-based consultations for remote diagnoses, immersive simulations for medical training, and social interactions to enhance patient engagement [21]. Despite its growing application in various medical fields, its use in managing thyroid disorders, particularly during pregnancy, remains underexplored [22]. Thyroid dysfunction during pregnancy, especially SCH, has gained increasing attention due to its often overlooked association with adverse pregnancy outcomes [23]. The adoption of innovative technologies like the metaverse to provide personalized care for pregnant women with SCH is crucial for improving maternal and neonatal health.

Recent studies have focused on the etiology, diagnosis, and management of adverse pregnancy outcomes [23,24]. Mounting evidence links SCH during pregnancy to elevated risks of complications. For instance, a meta-analysis reported a higher incidence of preterm birth in women with SCH (odds ratio 2.9, 95% CI 1.0-1.6) [25]. Similarly, a retrospective study found that SCH was associated with increased risks of preterm birth (relative risk 2.2, 95% CI 1.1-4.0) and neonatal respiratory distress syndrome (relative risk 2.8, 95% CI 1.0-7.8), particularly in early pregnancy [26]. These findings emphasize the importance of timely and effective interventions to improve outcomes [17]. Inspired by the establishment of virtual home hospitals in the United States in 2019, our study used virtual simulation technologies for remote monitoring, enabling timely evaluations and interventions [27]. Notably, the incidence of adverse offspring outcomes was significantly lower in the metaverse group compared to the standard group. Although maternal adverse outcomes did not differ significantly between groups (13/30, 43% vs 11/30, 37%), a favorable trend was observed. Neurodevelopmental outcomes, assessed using GDS scores, showed no significant differences between groups. To our knowledge, this is the first study to explore the application of a metaverse-based platform for the management of pregnant women with SCH. Regular treatment and continuous monitoring are essential for this population, and the dynamic follow-up capabilities of the metaverse platform are particularly well suited to their needs. The platform facilitates remote consultations, real-time monitoring, and comprehensive patient education through individualized treatment plans [24-26,28]. Compared to conventional health care services, the metaverse platform offers a more immersive and accessible experience, which may improve engagement and adherence to care protocols.

As illustrated in Figure 3, a virtual clinic was developed to simulate a traditional outpatient environment. Both investigators and participants created digital avatars, enabling seamless access to the virtual clinic from any location. This setup allowed participants to communicate directly with investigators, sharing critical information on medication dosages, test results, diet, lifestyle, and emotional well-being. By eliminating the need for frequent hospital visits, this model fostered greater engagement in the treatment process. Moreover, the platform addressed health care disparities by delivering specialized care to patients in remote or underserved areas.

Maternal mental health is a vital component of perinatal care. Studies indicate that approximately one-quarter of pregnant women with SCH are diagnosed with depression [29]. Impaired mental health during the perinatal period has been linked to adverse outcomes for both mothers and their offspring, including preterm birth, miscarriage, impaired fetal development, and an increased risk of autism spectrum disorders [30-33]. Improving the emotional well-being of perinatal mothers has therefore become a focus of recent research aimed at enhancing pregnancy outcomes [34,35]. Our study explored the use of a metaverse

XSL•FO
RenderX



platform to address emotional disorders in pregnant women with SCH. Evidence supports the efficacy of VR in managing anxiety, depression, and fear [36]. Additionally, metaverse platforms have demonstrated success in providing nonpharmacological interventions for conditions such as posttraumatic stress disorder, depression, and cognitive decline [37]. These platforms enable the creation of highly customized therapeutic environments tailored to individual needs and treatment goals. The incorporation of gamification and interactive scenarios further enhances patient engagement, improving adherence to treatment plans [38,39] (Figure 4). Compared to the standard group, patients in the metaverse group showed significant improvements in emotional well-being and a lower incidence of adverse offspring outcomes, consistent with previous studies. These findings underscore the positive impact of addressing maternal emotional health on offspring outcomes. However, pregnancy is a complex process, and further mechanistic studies are necessary to elucidate the pathways underlying these effects. Our study suggests that the metaverse platform has the potential to benefit all pregnant women, not just those with SCH. By alleviating anxiety and providing foundational medical knowledge, such platforms could enhance maternal well-being and perinatal outcomes on a broader scale.

This study has several notable strengths. To our knowledge, it is the first to use a metaverse platform for managing pregnant women with SCH. Compared to traditional telemedicine services, the metaverse offers advancements, particularly in safeguarding patient privacy. The secure virtual environment minimizes data leakage risks, alleviating psychological burdens and reducing the embarrassment often associated with medical consultations. The anonymity afforded by virtual interactions encourages patients to communicate more openly and confidently with physicians, enhancing both diagnostic and therapeutic efficacy. Furthermore, the study extends beyond pregnancy-related adverse outcomes to include assessments of psychological well-being. The metaverse platform also demonstrates the potential to address global disparities in medical resources by enabling equitable access to high-quality health care services, regardless of geographic or economic constraints. This approach represents a step forward in fostering a more balanced distribution of medical resources and advancing global health systems.

Despite these strengths, the study has limitations. Its single-center design and relatively small sample size may restrict the generalizability of the findings. Efforts are underway to expand the application of the metaverse platform to more diverse populations and other endocrine disorders to evaluate its broader effectiveness. Furthermore, the current platform remains in its developmental stage. Dependence on high-quality interactive devices and associated costs limited participant recruitment, potentially introducing statistical bias.

The study highlights the efficacy of an innovative metaverse-based follow-up management system for pregnant women with SCH. Compared to conventional care, this platform significantly reduced adverse offspring outcomes, achieved comparable maternal adverse outcomes, and markedly alleviated psychological distress during pregnancy. By enabling remote access to specialized and personalized care, the metaverse platform addresses disparities in medical resource distribution. In the digital era, this technology offers a transformative approach to managing endocrine disorders, particularly thyroid diseases, with the potential to enhance patient outcomes and advance equitable health care delivery.

Acknowledgments

This research received the following grants: Fujian Provincial Department of Science and Technology, Joint Fund for Science and Technology Innovation (2023Y9290); Department of Endocrinology (National Clinical Priority Specialties; 2023001); and Fujian Clinical Medical Research Center for Type 2 Diabetes (2022Y2013).

We also thank the Fujian Huayu Education Technology Co Ltd for developing and constructing the metaverse platform.

Abstract

Background: The widespread availability of internet-based pornography has led to growing concerns about its impact on mental health, particularly among young adults. Despite increasing recognition of problematic pornography use, standardized diagnostic criteria for pornography addiction are lacking.

Objective: This study aimed to address this gap by applying adapted *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) criteria to evaluate "pornography-watching disorder" (PWD) in a large sample of young adults in Hungary. The primary objective was to assess the prevalence of PWD among young adults and identify key risk factors associated with its development using *DSM-5* criteria adapted for pornography use. It also aimed to advance the understanding of PWD as a potential behavioral addiction.

Methods: A cross-sectional web-based survey was conducted between September and December 2018, targeting young adults aged 18-35 years in Hungary. Participants were recruited through social media and the University of Szeged Albert Szent-Györgyi Medical School's web page. Of the 9397 respondents, 7187 (76.5%) had previously consumed pornography and were included in the analysis. PWD was measured using 10 statements adapted from the *DSM-5* substance use disorder criteria. Multivariable binary logistic regression was used to identify significant predictors of PWD.

Results: The prevalence of PWD in the sample was 4.4% (n=315). Frequent pornography consumption was a significant risk factor, with weekly users (odds ratio [OR] 0.45, 95% CI 0.33-0.62, *P*<.001), monthly users (OR 0.18, 95% CI 0.11-0.28, *P*<.001), and less than monthly users (OR 0.05, 95% CI 0.03-0.10, *P*<.001) showing significantly lower odds compared with daily users as a reference category. Male sex was associated with a higher risk (OR 0.53, 95% CI 0.39-0.72, *P*<.001), as were early exposure to pornography (OR 0.94, 95% CI 0.90-0.98, *P*=.006), paraphilia (OR 3.95, 95% CI 2.37-6.56, *P*<.001), dissatisfaction with sexual life (OR 0.94, 95% CI 0.90-0.98, *P*=.006), difficulty forming personal relationships (OR 0.93, 95% CI 0.88-0.98, *P*=.005), and strong adherence to religious norms (OR 1.12, 95% CI 1.06-1.19, *P*<.001). Protective factors included adequate sexual education (OR 0.67, 95% CI 0.53-0.87, *P*=.02) and residing in the capital (OR 0.52, 95% CI 0.30-0.91, *P*=.02). The use of an anonymous web-based questionnaire likely reduced the influence of stigma, resulting in more accurate self-reporting of sensitive behaviors.

XSL•FO
RenderX

Conclusions: This study is among the first to apply *DSM-5* criteria to evaluate PWD, providing important insights into its prevalence and associated risk factors in young adults. The findings highlight the need for standardized diagnostic tools for PWD and suggest targeted interventions, particularly for high-risk groups. These results contribute to the ongoing discussion about whether pornography addiction should be recognized as a distinct behavioral disorder.

Introduction

Background

The use of pornography has increased significantly in the last few decades, in parallel with the development of the technological means of its transmission, so that access is much easier nowadays than before. Internet pornography shows an increasing trend worldwide, according to Pornhub statistics [1]. To obtain exact data is almost impossible since the number of websites providing erotic content intended for adults is untraceable, and there are no exact data available regarding their use. The massive and ongoing increase in internet use, and internet porn use in particular, has had a profound effect on human sexual behavior over the last decades and related social dynamics [2]. It is estimated that 46%-74% of men and 16%-41% of women in developed countries are active pornography users [3]. Consumption on a weekly basis was found in approximately 50% of young adults under the age of 25, with a general decrease in pornography use with increasing age. According to a study performed in Australia, 84% (8442/10,049) of men from a representative sample population watched porn in their lifetime, while weekly porn consumption was reported in 76% (6131/10,049) in the sample [4]. With the global spread of COVID-19, the use of pornography increased by 4%-24% in several countries in 2020 [5]. Additional features that contribute to the high popularity of internet pornography are the novelty and diversity of the provided contents, which might become a driving force for problematic consumption, as the abundance of sexual imagery can entice further use and lead to tolerance and habituation, well-known in addiction disorders such as alcoholism [6].

Several studies highlight that pornography consumption is often presented as a symptom of sex addiction [7-9]. Individuals with compulsive sexual behavior may misuse the internet in the forms of problematic internet porn use and sex chats as a novel source of sexual gratification, imposing several hazards for themselves and, indirectly, a risk to society [10]. Reid et al [11] found in a field trial on hypersexual disorders that excessive use of pornography was one of the significant behavioral traits of individuals seeking a cure for their disorder, in addition to forced masturbation and frequent casual sex.

Excessive use of internet pornography has emerged as a new type of behavioral addiction, which is in contrast to compulsive sexual behavior disorder being classified as an impulse control disorder rather than an addictive condition in the *ICD-11* (*International Classification of Diseases for Mortality and Morbidity Statistics Eleventh Revision*) [12]. However, the entity pornography addiction is not officially recognized as a disease due to continuous debate among researchers regarding its definition and nature [13]. There is ongoing debate among researchers and clinicians about whether pornography addiction meets the criteria to be considered a distinct mental health disorder. Some researchers contend that compulsive consumption of internet pornography could represent a distinct manifestation of sex addiction or hypersexuality [14], while alternative perspectives advocate for its categorization as a unique subtype of internet addiction [15].

Neither *ICD-11* nor the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders*, [Fifth Edition]) provided accepted criteria to identify and define pornography addiction as a type of behavioral addiction so far [16-18].

Reflecting the urgent need for measuring excessive and problematic consumption of pornography characterized by impulsive and compulsive behavior, an alternative definition of self-perceived pornography addiction (SPPA) was suggested [13]. Based on evidence from neurobiological studies demonstrating an overlap between the mechanisms observed in excessive pornography use and those seen in substance addictions, the existing diagnostic criteria for addiction disorders may also be applicable to pornography addiction [19]. Diagnosing addiction to pornography presents challenges due to the subjective nature of defining problematic use, the diversity of individual experiences with pornography, and the lack of clear diagnostic criteria. Without consensus on standardized diagnostic criteria, it is difficult to establish a clear definition of pornography addiction for inclusion in diagnostic manuals.

Numerous procedures are available to measure problematic (compulsive or addictive) use of pornography. Bőthe et al [20] published the Problematic Pornography Consumption Scale (PPCS), which is based on previous addiction models. Nevertheless, research on problematic internet pornography consumption might be limited or lacking due to the absence of formally accepted scales that are compatible with widely accepted diagnostic criteria. Furthermore, 2 scales that aim to assess the addiction characteristics of internet pornography are the Internet Sex Screening Test (ISST) [21] and the Cyber-Pornography Use Inventory (CPUI) [22], both of which work accurately but with limited clinical relevance. The use of compulsive sexual behavior is not suitable for measuring addiction to pornography, as it is an umbrella term that includes many compulsive behaviors and cannot be reduced to specific aspects of pornography [23].

XSL•FO
RenderX

On the other hand, a functional MRI (magnetic resonance imaging)-based study focused on internet pornography addiction revealed similar brain activity patterns in porn addicts as in drug or alcohol addicts. The observation of more robust activation in compulsive sexual behavior than in healthy volunteers was similar to that seen in drug addiction, suggesting neurobiological similarities between the disorders [24].

Defining sexuality-related addictions is challenging because, although sexual addiction and substance dependence share similarities in brain function and behavior, effectively addressing sexuality-related addictions requires a nuanced understanding of the complex interplay among biological, psychological, and social factors that influence human sexuality.

Objectives of the Study

In the present study, the first aim was to transform the substance use disorder criteria of DSM-5 for measuring porn use based on the above finding. This set of criteria was then used to measure and characterize what we call here "pornography-watching disorder" (PWD) in a young adult population. Such a new measurement method seems to be necessary because the previous methods examined excessive porn use as a behavioral problem, while in the present study, the clinically more relevant criteria of disorder could be assessed. Our second aim was to find relationships between personal features and PWD, which can help future prevention.

Methods

Study Design and Recruitment

The cross-sectional exploratory study was conducted using a web-based questionnaire between September and December 2018 in Hungary. A convenience sampling technique was applied. The questionnaire link was made available on the Hungarian-language website of the Albert Szent-Györgyi Medical School. The survey was conducted in Hungarian. Participants were recruited through internet channels, including advertisements on social media platforms such as Facebook (Meta) and Instagram (Meta), as well as through announcements at university lectures. Given the widespread use of social media among internet users, it was chosen as a key platform for participant recruitment. Opt-in sampling in this research was essential to detect and define the problem. Because of the stigmatized nature of the problem, the opt-in sample was best suited to enable the research participants to disclose their problems more easily. While specific measures to confirm residency in Hungary were not used, recruitment was primarily targeted at Hungarian residents through the University of Szeged Albert Szent-Györgyi Medical School's platforms and Hungarian-language content. Our exploratory research could form the basis for a subsequent representative sample study. The target population was young adults (18-35 years old). We focused on this age group because participants are at a similar stage of life, reducing confounding variables. This age range is relevant because it is when individuals are discovering their sexuality and forming lasting habits. It targets a demographic group that is vulnerable to the effects of pornography because of its accessibility and developmental stage. Narrowing the focus will facilitate subsequent comparative analysis with other age groups, providing insights into developmental trajectories and generational trends.

Survey Development

The study, titled "The Great Sex Test" (in Hungarian: "A nagy szexteszt"), used a comprehensive questionnaire that addressed various topics, including general sexual health, sexual disorders, sexual satisfaction, contraception, sexually transmitted diseases, pornography addiction, and sexual abuse. This paper specifically focuses on the analysis related to pornography. The questionnaire was developed by a multidisciplinary team, including psychiatrists, sociologists, epidemiologists, medical students, as well as a sexologist and an information technology specialist, whose combined expertise ensured the robustness of the tool.

Pilot testing, which included in-depth interviews, was conducted to ensure the clarity and consistency of the questions. Clear instructions were provided to respondents to facilitate accurate responses. The Cantril scale was frequently used to measure attitudes, and validated variables from previous research were incorporated into the question design, ensuring the questionnaire remained concise without compromising quality.

The final questionnaire was created using Google Forms, a widely accessible platform that adheres to Google's public data protection policies. The responses were collected in an aggregated, anonymized form and downloaded as a Microsoft Excel spreadsheet.

The questionnaire, which was administered on a voluntary basis, included 218 questions covering all topics, including both male and female sexual disorders. The use of adaptive questioning significantly reduced the number of questions presented to each respondent based on their relevance. Before beginning the survey, participants were required to read and agree to a consent form that detailed the study's objectives, assured data security, and guaranteed anonymity. The consent form also emphasized the importance of providing accurate information.

An email address was required for questionnaire completion to minimize the risk of multiple submissions. The system handled email addresses separately from the questionnaires. After providing their email, participants were directed to the questionnaire interface through a link. The provided email addresses could not be linked to the completed questionnaires. Although IP address tracking or cookies were not used due to platform limitations, respondents were allowed to review and correct their responses before submission using the back button. Participants could also choose to skip questions by selecting "I don't know" or "I prefer not to answer." Irrelevant questions were filtered out through adaptive questioning, ensuring that participants only encountered questions pertinent to them (eg, those who had never viewed pornographic content were not asked related questions).

The number of questions per page was thematically determined, with most pages containing 5-6 questions. The total number of pages varied based on the relevance of the questions to the respondent, with the average questionnaire completion time being 24 minutes. Only fully completed and submitted questionnaires were included in the final analysis. A multistep

XSL•FO
RenderX

filtering process was used to exclude questionnaires with unrealistic, frivolous, or inappropriate answers, as well as those completed significantly faster than the average time to maintain the integrity of the results.

Measurements

Dependent Variable: Use of Pornography

An adapted version of DSM-5 criteria for substance use disorder was used in this study, omitting the question on withdrawal. The criteria applied to pornography can be classified as non–substance-related addictions. In these disorders, somatic withdrawal symptoms are not observed, and psychological withdrawal symptoms are difficult to differentiate. Withdrawal is typically a consequence of the sudden stop of some substance. A possible alternative, the criteria for gambling disorder, was considered but abandoned as financial gains and losses are irrelevant here. The criteria of *DSM-5* provide standardized, comprehensive, and clinically valuable guidelines. They are integrated into health care systems and have strong research validity. Furthermore, these criteria have been developed through a rigorous process that involves expert consensus and empirical evidence. It is important to note that using these criteria is not intended to create a new health condition but only to better define an existing problem.

The questionnaire used to identify people with PWD consisted of 10 statements. The first 5 statements reflect the loss of control, and the following 5 questions reflect the negative effects associated with pornography use. The respondents had to decide whether the 10 statements were typical of them (0=false and 1=true) in the past year. The answers were summarized by simple addition, resulting in a 0-10 scale (Cronbach α=0.70), where the cutoff point was set at 3. Accordingly, the group of people with PWD included those who stated that 4 or more statements were typical of them in the past year. The cutoff value was the same as for alcohol use disorder in the *DSM-5* criteria [17]. We did not differentiate between mild, moderate, and vigorous disorders. It is important to emphasize that *DSM-5* does not use the term addiction because of its vague definition and negative connotations. Furthermore, addiction is a broader term used to describe physical dependence and psychological compulsion without specific criteria. By using more precise terminology like “substance use disorder,” the *DSM-5* aims to provide more explicit diagnostic criteria and improve clinical communication. Since the PWD criteria were developed using the *DSM-5* criteria, we have avoided the term addiction.

Independent Personal Variables

The questionnaire assessed the demographic characteristics of the participants, including biological sex (0=male and 1=female), age (0=18-24 years and 1=25-35 years), place of residence (0=not in the capital and 1=in the capital), the highest educational attainment of the mother or father (corresponding to International Standard Classification of Education [ISCED] 2011: 0-2, 3 without a general certificate of education, 4 with general certificate of education, 5-8 tertiary education), employment status (working, studying, studying and working, and not studying and not working), parental status (1=have children or 0=not), and relationship status (0=single and 1=in a relationship). We also studied family structure in childhood (1=grew up in a 2-parent family or 0=not) and whether the parents in childhood family are divorced (0=no and 1=yes). A 10-point scale was used to examine the respondent's ideological orientation (between 1=conservative and 10=liberal) and degree of religiosity (by responses to the question, “How much do you adhere to religious norms?”; between 1=not respecting religious norms at all and 10=fully respecting religious norms).

Social relationships and attitudes toward others were captured by a 10-point scale variable that measures the difficulty of establishing personal relationships (“How easily do you make a personal relationship with others?”; from 1=with great difficulty to 10=very easily).

Further questions were aimed at the sexual orientation of the respondents (0=nonheterosexual and 1=heterosexual), the age when they had their first sexual intercourse, the experience in their first sexual intercourse (between 1=very bad and 10=very good), the number of sexual intercourses they had in the last year, the use of sexual performance enhancers (0=not used yet and 1=already used), their satisfaction with their sexual life, body, and genitals (between 1=not satisfied at all and 10=completely satisfied), and how sexually attractive they consider themselves (between 1=not at all and 10=completely). Subjective evaluation areas were measured similarly to the Cantril ladder scale [25].

The questionnaire also covered various sexual disorders. For men, delayed ejaculation, premature (early) ejaculation, hypoactive sexual desire disorder, and erectile disorder, while for women, female sexual interest or arousal disorder, genito-pelvic pain or penetration disorder, and female orgasmic disorder were explored. The answers were summarized into a sexual disorder variable describing the participants being affected by some sexual disorder according to the criteria of *DSM-5* (0=no and 1=yes) [26]. Involvement in paraphilias was measured using the 2 criteria found in *DSM-5*. Criterion “A” explores the qualitative nature of paraphilia, while criterion “B” focuses on the negative consequences. According to *DSM-5*, paraphilic disorders can be diagnosed if both diagnostic criteria are met, and this is also how this disorder was defined in the present study (0=no paraphilia and 1=have paraphilia).

We further measured the frequency of masturbation (1=no masturbation, 2=less than monthly, 3=monthly, 4=weekly, and 5=daily), if the respondents used to talk about their sexual life with others (0=no and 1=yes), and their sexual education, that is, if they received adequate and sufficient sexual information before their first sexual intercourse (0=no and 1=yes), and whether they were ever sexually abused (0=no and 1=yes).

The survey examined the age when the respondents first encountered pornographic content, what kind of experience this first time was (between 1=very bad and 10=very good), and how often they watched porn in the last year (1=never in the last 1 year, 2=less than monthly, 3=monthly, 4=weekly, and 5=daily).

Statistical Analysis

In addition to descriptive statistics and correlation tests (chi-square test and independent samples *t* test), multivariable

XSL•FO
RenderX

binary logistic regression was performed using the Enter method (whereby all variables are added to the model simultaneously) to identify characteristics predicting the risk of PWD. Our model-building strategy was guided by finding the most straightforward, yet most robust model. Since the distribution of those with PWD and those not affected in the sample is very unequal, in order to avoid overfitting and find the simplest model, we built our model based on suggestions by Hosmer et al [27]. The final model includes only those variables that were found to be significant at the $P<.05$ significance level. The final model did not include any variables with interaction effects that were professionally relevant (ie, well-founded, informative, interpretable, significant, and improving model fit). The relative importance of the variables included in the final model was determined using Dominance Analysis [28]. All statistical analyses were conducted with IBM SPSS Statistics (version 28.0) for Windows.

Ethical Considerations

The study protocol was reviewed and approved by the Regional and Institutional Human Medical Biological Research Ethics Committee of the University of Szeged (ethical approval 161/2017-SZTE). Participation in the study was entirely voluntary, and informed written consent was obtained from all participants before their involvement. The study was conducted in accordance with the principles of the Declaration of Helsinki. All data collected were anonymized to ensure the privacy and confidentiality of the participants.

Informed consent was obtained from all participants before their participation in the study. Participants were provided with detailed information about the purpose of the research, the procedures involved, and the nature of the data being collected. They were informed that their participation was voluntary, and that they could withdraw from the study at any time without any consequences. The consent form also assured participants of the confidentiality of their data, which was anonymized during analysis to protect their privacy. The original informed consent explicitly included provisions for the use of the collected data in subsequent analyses, including secondary research. Therefore, no additional consent was required for the secondary analysis performed in this study, as it was covered by the initial consent obtained from the participants.

The privacy and confidentiality of all participants were rigorously protected throughout the study. All data collected through the web-based survey were anonymized, ensuring that no personally identifiable information was linked to the responses. The survey platform used, Google Forms, provided data in a deidentified format, further ensuring that individual participants could not be identified. The anonymized data were securely stored on the internal servers of the University of Szeged Albert Szent-Györgyi Medical School's Department of Public Health and Department of Behavioral Sciences with access restricted to authorized research personnel only. In compliance with ethical guidelines, no personal information, such as names or IP addresses, was collected or stored, thereby maintaining the highest level of confidentiality for the study participants.

To encourage participation, tangible incentives such as theater tickets, movie tickets, and spa passes were offered. These prizes were raffled among participants after the data collection was completed. To ensure transparency and fairness in the compensation process, participants were informed about the raffle at the beginning of the survey. Winners were selected randomly and notified through the email addresses they provided.

Results

A total of 9397 individuals completed the questionnaire. Of these, 7187 had previously consumed pornographic content, and only these participants were included in the present analysis.

A detailed description of the study sample is presented in Tables 1 and 2. The sample consisted of 2398 men and 4789 women. Most of the respondents lived in rural areas and had a relationship. More than one-tenth of the participants (782/7187, 10.9%) have used sexual performance enhancers, while some form of paraphilia was detected in 1.5% (108/7187). Most of them felt that they received adequate sexual information before their first sexual intercourse (5030/7187, 70%). Almost a quarter of them (1631/7187, 22.7%) had not watched porn in the past year, while a quarter of them (1748/7187, 24.3%) did that less often than monthly, less than one-fifth of them (1234/7187, 17.2%), monthly, three-tenths of them (2223/7187, 30.9%), weekly. Every 20th respondent (351/7187, 4.9%) watched porn every day (Table 1).

Table 2. Means of scales in the affected and non-affected subgroup of the study sample, and independent-samples t tests by variables in the study sample.

Variables	Pornography-watching disorder absent (n=6872), mean (SD)	Pornography-watching disorder present (n=315), mean (SD)	*t* test (*df*)	*P* value	Cohen *d*
Sociodemographic background					
Ideological orientation[a]	6.04 (2.08)	5.79 (2.23)	2.09 (7185)	.04	0.12
Religiosity[b]	1.94 (1.91)	2.21 (2.20)	–2.11 (7185)	.04	0.14
Social relationships					
Building personal relationships[c]	7.19 (2.11)	6.71 (2.37)	3.55 (7185)	<.001	0.23
Sexuality					
Age at first sexual intercourse	16.43 (1.91)	16.74 (2.18)	–2.54 (7185)	.01	0.17
Experience of first sexual intercourse[d]	6.22 (2.67)	6.61 (2.72)	–2.55 (7185)	.01	0.15
Number of sexual partnerships in the last year	1.87 (3.03)	2.07 (2.89)	–1.15 (7185)	.26	__[e]
Satisfaction with sex life[f]	6.75 (2.76)	5.58 (2.95)	6.89 (7185)	<.001	0.42
Satisfaction with genitals[f]	7.48 (2.36)	6.93 (2.49)	4.07 (7185)	<.001	0.23
Being sexually attractive[f]	6.54 (2.02)	6.25 (2.16)	2.32 (7185)	.02	0.14
Pornography					
Age at first encounter with pornographic content	13.98 (3.02)	12.56 (2.90)	8.22 (7185)	<.001	0.47
Experience of the first encounter with pornographic content[d]	6.20 (2.27)	7.09 (2.29)	–6.77 (7185)	<.001	0.39

[a]1=conservative; 10=liberal.

[b]1=not respecting religious norms at all; 10=fully respecting religious norms.

[c]1=with great difficulty; 10=very easily.

[d]1=very bad; 10=very good.

[e]Not applicable.

[f]1=not satisfied at all; 10=completely satisfied.

Responses to questions on a 10-point scale presented in Table 2 were not normally distributed. Nevertheless, after careful consideration, the means with SD and results of the 2-sample *t* tests are presented. The following were our rationale for this decision. First, a large literature argues that parametric tests can be robust to deviations from the normal distribution, that is, the distribution of the variable is not necessarily and not exclusively the relevant criterion [29-31]. One such criterion may be sample size, that is, for large samples (in our case N=7187), parametric tests are reliable even if the distribution is not perfectly normal. Second, for 5 scales (religiosity, building personal relationships, age at first sexual intercourse, satisfaction with sex life, and being sexually attractive), the variances can be said to differ according to the Levene test. This also means that the results of the Mann-Whitney test may not be robust and should be interpreted cautiously because the test looks at the difference in distributions and not just the medians. Third, the results of parametric tests are easier to interpret and, especially for large samples, parametric tests tend to have greater statistical power than nonparametric tests. The latter means that a nonparametric test is less likely to detect true deviations if they really exist. Fourth, we repeated our analysis using nonparametric tests (Mann-Whitney test) and reached the same conclusions as with the parametric tests presented in the manuscript (independent-sample *t* test). Furthermore, the same conclusions can be drawn from the effect sizes (Cohen *d* and r=rank-biserial correlation coefficient). Most of the respondents considered themselves rather liberal (mean 6.03, SD 2.08, 95% CI 5.98-6.08) and nonreligious, that is, they did not follow religious norms (mean 1.96, SD 1.92, 95% CI 1.91-2.00). They found it relatively easy to establish personal relationships with others (mean 7.17, SD 2.12, 95% CI 7.12-7.22). Their first sexual intercourse usually took place between the age of 16 and 17 years (mean 16.44, SD 1.92, 95% CI 16.40-16.48), which they look back on as a moderately good experience (6.23, SD 2.67, 95% CI 6.17-6.30). Their satisfaction with sexual life was also moderately good (mean 6.70, SD 2.78, 95% CI 6.64-6.76). Satisfaction with the own genital organs showed the highest average value (mean 7.46, SD 2.37, 95% CI 7.40-7.51). The respondents tended to consider themselves sexually attractive but not extraordinarily (mean 6.53, SD 2.03, 95% CI 6.48-6.58). On average, the respondents saw pornographic content first at the age of 14 (mean 13.92, SD 3.03, 95% CI 13.85-13.99),

XSL•FO
RenderX

which they had a moderately good experience with (mean 6.24, SD 2.28, 95% CI 6.19-6.29; Table 2).

Among the characteristics listed above, a significant difference was observed between those with PWD and those unaffected by this problem. Concerning all other examined characteristics, no significant differences were detected.

Table 3 displays the number and percentages of individuals who identified the statements related to PWD as true. The regression model's outcome variable is the presence (1) or absence (0) of PWD. The prevalence of PWD was 4.4% (315/7187). Due to the presence of multicollinearity tested using linear regression (tolerance index<0.20), we excluded 3 variables from the initial set of 32 variables (building partnerships, satisfaction with the own body, and frequency of masturbation) from the model. Thus, a total of 29 independent variables were included in the model. Of the 29 independent variables, 12 examine the sociodemographic background of the respondents, 1 examine their attitudes related to the formation of social relationships, 13 examine their sexual characteristics, and 3 are related to pornography.

Table 3. The number and percentage of "true" answers for the pornography-watching disorder-related statements among the respondents (N=7187).

Statement	Answers, n (%)
Pornography is often watched more times or over a longer period than was intended.	698 (9.7)
There is an unsuccessful effort to cut down or control pornography watching.	490 (6.8)
A great deal of time is spent watching pornography.	378 (5.3)
Craving, or a strong desire or urge to watch pornography.	1210 (16.8)
Recurrent pornography watching resulting in a failure to fulfill major role obligations at work, school, or home.	167 (2.3)
Continued pornography watching despite having persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of pornography.	162 (2.3)
Important social, occupational, or recreational activities are given up or reduced because of pornography watching.	62 (0.9)
Recurrent pornography watching in situations in which it is hazardous (eg, in public places, workplaces, and classrooms).	409 (5.7)
Pornography watching is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by pornography.	912 (12.7)
Needs to watch an increasing amount or more extreme types of pornography in order to achieve the desired excitement.	185 (2.6)

Based on the likelihood ratio chi-square test, the final binary logistic regression model run to further analyze the relationship between PWD and the background variables examined is significant (for n=7187, χ^2_{13}=510.6, P<.001); the Hosmer and Lemeshow tests also indicate a suitable model fit (for n=7187, χ^2_8=7.8, P=.46). Based on the Nagelkerke R^2 indicator (0.23), the variable set in the final model explains 22.7% of the variance. Based on the receiver operating characteristics curve analysis, which indicates the probability of true positive classification (sensitivity) as a function of true negative classification (specificity), the area under the curve is 0.84 (cutoff value=0.50; P<.001; 95% CI 0.82-0.86), indicating excellent discrimination [27].

In the final model after variable selection, 10 variables were found to be significant (Table 4).

The most powerful factor in the model was the frequency of watching porn. Compared with those who watched porn daily, the odds of having PWD were significantly lower among those who did not watch porn daily (never in the last 1 year, odds ratio [OR] 0.02, 95% CI 0.01-0.06; less than monthly, OR 0.05, 95% CI 0.03-0.10; monthly, OR 0.18, 95% CI 0.11-0.28; and weekly, OR 0.45, 95% 0.33-0.62). A less powerful but still strongly influential factor was biological sex: females were half as likely as males to have the PWD (OR 0.53, 95% CI 0.39-0.72). The other significant variables are of relatively minor importance. The chance of occurrence of PWD is reduced if the participants encountered pornographic content later (OR 0.94, 95% CI 0.90-0.98), were more satisfied with their sexual life (OR 0.94, 95% CI 0.90-0.98), established personal relationships with others more easily (OR 0.93, 95% CI 0.88-0.98), received adequate sexual information before their first sexual intercourse (OR 0.67, 95% CI 0.53-0.87), or lived in the capital (OR 0.52, 95% CI 0.30-0.91). On the other hand, the chance of developing PWD increased if the respondents were affected by some paraphilia (OR 3.95, 95% CI 2.37-6.56) or sexual disorder (OR 2.01, 95% CI 1.45-2.80) and if they followed the norms of their religion as much as possible (OR 1.12, 95% CI 1.06-1.19).

In summary, the predisposing factors for PWD were higher frequency of pornography watching, male sex, occurrence of paraphilia, an early encounter with pornographic content, lower level of satisfaction with sexual life, difficulties in establishing personal relationships, occurrence of a sexual disorder, stronger adherence to religious norms, inappropriate sexual education, and living in the capital.

Table 4. Results of binary logistic regression for predicting the likelihood of pornography-watching disorder.

Variables	Odds ratio[a] (95% CI)	*P* value	Relative importance (%)
Frequency of pornography watching (Reference: daily)			53.94
Never in the last 1 year	0.02 (0.01-0.06)	<.001	
Less than monthly	0.05 (0.03-0.10)	<.001	
Monthly	0.18 (0.11-0.28)	<.001	
Weekly	0.45 (0.33-0.62)	<.001	
Biological sex (Reference: male)	0.53 (0.39-0.72)	<.001	17.41
Paraphilia (Reference: absent)	3.95 (2.37-6.56)	<.001	7.48
Age at first encounter with pornographic content	0.94 (0.90-0.98)	.006	6.84
Satisfaction with sex life[b]	0.94 (0.90-0.98)	.006	5.59
Building personal relationships[c]	0.93 (0.88-0.98)	.005	2.13
Sexual disorder (Reference: absent)	2.01 (1.45-2.80)	<.001	1.90
Religiosity[d]	1.12 (1.06-1.19)	<.001	1.70
Adequate and sufficient sexual education (Reference: absent)	0.67 (0.53-0.87)	.002	1.51
Place of residence (Reference: Capital)	0.52 (0.30-0.91)	.02	1.50

[a]Values of odds ratio above 1 mean a higher likelihood of inclusion, and values below 1 mean a lower likelihood of inclusion compared with the given reference group. In the table, the variables are listed in descending order of relative importance. Relative importance was determined using dominance analysis.

[b]1=not satisfied at all, 10=completely satisfied.

[c]1=with great difficulty, 10=very easily.

[d]1=not respecting religious norms at all, 10=fully respecting religious norms.

Discussion

Principal Findings

This study found that 4.4% of young adults in Hungary exhibit signs of PWD. Key factors contributing to PWD include frequent pornography use, being male, having paraphilic interests, early exposure to pornography, and dissatisfaction with sexual life. Furthermore, individuals who struggle to form personal relationships, experience sexual disorders, strongly adhere to religious norms, received inadequate sexual education, or live in the capital were also more prone to developing PWD.

Our study identified several important risk factors for PWD. The most significant factor was the frequency of pornography consumption, with daily viewers being much more likely to develop PWD than those who watched less often. Sex was also a critical factor, as males were at higher risk. Furthermore, early exposure to pornography and the presence of paraphilia were strongly linked to PWD. In contrast, higher satisfaction with sexual life and greater ease in forming personal relationships were associated with a lower likelihood of developing PWD, indicating these factors might offer some protection against the disorder.

Comparison With Previous Work

A large-scale survey study of 18,034 participants on gender, sexual orientation, and hypersexuality found a significant association between problematic pornography use and sexual identity because the prevalence was higher among nonheterosexuals than in heterosexuals. The results suggested that GBTQ+ (gay, bisexual, trans, queer, questioning, non-binary or otherwise gender or sexuality-diverse) males have a higher risk of engaging in hypersexual behavior (including high-frequency porn watching) compared with their heterosexual counterparts [32]. The results of our study highlight the role of biological sex, which, in our case, is more relevant than sexual orientation, although the dual association of gender with sexual identity and PWD was not examined.

In connection to religion and ideology, our results suggested a higher prevalence of PWD associated with being religious and having more conservative than liberal views. Both connections were statistically significant. An American study from 2016, on a sample of 713 adult participants, found a higher prevalence of SPPA in religious participants versus nonreligious ones [33], which is in accordance with the current study's findings.

Regarding relationship status (single or in a relationship), a higher prevalence of PWD was found among singles than among those living in a relationship. Kraus et al [34] examined different characteristics of men interested in finding a treatment for their pornography use within a sample of 1298 male participants and found that more single or unmarried individuals were seeking treatment.

Also related to relationship factors was that people affected with PWD found it, on average, more difficult to form any personal relationship than the control group. Those dissatisfied with sexual education, that is, information obtained before the first sexual intercourse, were also more likely to develop the PWD.

XSL•FO
RenderX

These 2 phenomena have apparently not been described in the literature.

Regarding satisfaction with sexual life, the results indicated a significant connection, namely, problematic pornography use was associated with lower levels of satisfaction with sexual life. Results from a study performed on a sample of 832 adults on SPPA, sexual function, and sexual satisfaction indicated that SPPA was associated with sexual dysfunctions and lower sexual satisfaction [35].

Strengths and Limitations

This study is among the first to apply *DSM-5* criteria to assess PWD in a large sample of young adults, providing a clinically relevant approach to understanding this condition. The large sample size and the inclusion of diverse sociodemographic and psychological variables contribute to the robustness of our findings.

A key strength of the study is the use of a self-report web-based questionnaire with ensured anonymity, which likely reduces the influence of stigma and taboo associated with discussing sensitive topics such as sexuality and pornography. This method also allows for the inclusion of a larger and more diverse sample, enhancing the generalizability of the findings and enabling the application of the modified *DSM-5* criteria to a broader population.

However, the study has several limitations. First, its cross-sectional design limits the ability to draw causal inferences; while associations between certain factors and PWD were identified, cause-and-effect relationships cannot be established.

Second, the study was limited to young adults in Hungary, which may affect the generalizability of the findings to other populations. Cultural differences in attitudes toward pornography and sexual behavior could influence both the prevalence and the risk factors for PWD, suggesting a need for future studies that include participants from diverse geographic locations.

Third, the reliance on self-reported data introduces potential bias, as participants may underreport or overreport their behavior due to social desirability or stigma. Although the anonymity of the survey helps mitigate these issues, future research should consider incorporating more objective measures of pornography consumption and related behaviors.

Fourth, the study did not distinguish between mild, moderate, and vigorous forms of PWD, limiting the granularity of the findings. Future research could benefit from examining the full spectrum of PWD severity to provide a more nuanced understanding of the disorder.

Finally, the use of the Cantril ladder scale for measuring subjective attitudes instead of validated question blocks was chosen to prevent respondent fatigue and maintain the quality of responses. However, this choice, along with differences in data-collection methods compared with other studies, may contribute to variability in the results. Despite these challenges, the study's methodological approach, particularly the anonymity provided to respondents, remains a valuable tool in exploring sensitive topics like PWD.

Future Directions

Future research should investigate the longitudinal relationships between early exposure to pornography and the development of PWD to gain a clearer understanding of causality. Furthermore, studies involving more geographically and culturally diverse samples are essential to determine if the risk factors identified in this study are applicable to broader populations. Finally, the development and validation of standardized diagnostic tools for PWD are crucial for advancing our understanding and treatment of this disorder.

Conclusions

This study characterizes PWD and its prevalence in a large sample population using adapted *DSM-5* criteria based on a web-based survey. The information obtained from this study can be used as a base for further research on pornography consumption and can be used as part of public health prevention programs to advance sexual well-being. In addition, the methods and results of the study can be used to standardize other pornography scales and possibly to supply some evidence required to officially recognize pornography addiction as a disorder. The questionnaire used in this study might enable to development of a web-based interface (website or app) that measures and evaluates the user's porn consumption and offers them a quiet assistance program in case of need.

Acknowledgments

This study would not have been possible without the support of the University Szeged Albert Szent-Györgyi Medical School.

The manuscript publication was funded by University of Szeged Open Access Fund (grant 6322).

This research did not involve any costs or funding. All authors met the conditions described in the recommendations by the International Committee of Medical Journal Editors Recommendations and gave final approval to the submitted paper.

Data Availability

The datasets generated and/or analyzed during this study are not publicly available due to the fact that this study was conducted using a portion of the database, and ongoing analyses and publications are based on the database, which is in continuous use, but data are available from the corresponding author on reasonable request.

Abstract

Background: China has recently implemented a strategy to promote and facilitate community organization involvement in HIV prevention among men who have sex with men (MSM). Although community-based strategies have been shown to increase HIV testing uptake, the relative effectiveness of mobile social media promotion compared with volunteer-driven recruitment remains underexplored. Limited research has investigated how these strategies differentially affect MSM who have not undergone previous HIV testing.

Objective: This study aimed to compare the differences between a mobile social media promotion strategy and a volunteer-driven strategy for community organizations to recruit MSM for HIV testing.

Methods: A cross-sectional study was conducted from July to December 2023 among MSM in Zhejiang Province, China. Participants aged 16 years with an HIV-negative or unknown status were recruited either through a mobile social media promotion strategy or through a volunteer-driven strategy by a community organization. They completed a questionnaire that collected information on demographics, sexual behavior, and HIV testing history. All participants were tested for HIV after completing the questionnaire. A multivariate logistic regression model was used to identify factors associated with recruitment through mobile social media promotion.

Results: The study included 4600 MSM, of whom 3035 (66%) were recruited through the mobile social media strategy. Overall, 1.4% (66/4600) of participants tested positive for HIV, and 18.8% (865/4600) underwent HIV testing for the first time. Recruitment via the mobile social media promotion strategy was significantly associated with several factors: having only gay sexual partners (adjusted OR [aOR] 1.23, 95% CI 1.05-1.45), having more than 2 sexual partners in the past 3 months (aOR 1.74, 95% CI 1.42-2.11), frequently using rush poppers during sex (aOR 1.39, 95% CI 1.14-1.99), having a history of sexually transmitted infections (aOR 1.56, 95% CI 1.02-2.39), having awareness of pre-exposure prophylaxis (aOR 1.42, 95% CI 1.19-1.71), having awareness of postexposure prophylaxis (PEP; aOR 1.49, 95% CI 1.24-1.79), using mail-in HIV self-testing kits (aOR 2.02, 95% CI 1.77-2.31), testing HIV-positive (aOR 2.02, 95% CI 1.10-3.72), and first-time HIV testing (aOR 1.28, 95% CI 1.09-1.52).

Conclusions: Community organizations play a critical role in expanding HIV testing and identifying undiagnosed individuals infected with HIV. Compared to the volunteer-driven outreach, mobile social media promotion strategies had a higher proportion of first-time testers and a higher rate of HIV positivity. We recommend prioritizing mobile social media strategies in regions with limited LGBTQ+ organizations or HIV health services to increase HIV testing coverage and interventions among MSM.

KEYWORDS

men who have sex with men; MSM; internet; recruit; HIV testing; community organization; strategy; China; mobile phone

Introduction

Men who have sex with men (MSM) represent a significant proportion of individuals living with HIV in China. According to recent estimates, the national prevalence of HIV among MSM was 5.7% in 2018 [1] and rose to 7% in 2022 [2]. Moreover, the percentage of newly diagnosed HIV infections attributed to homosexual transmission increased from 2.5% in 2006 to 25.6% in 2022 [2]. To achieve the United Nations Program on HIV/AIDS 95-95-95 targets (95% diagnosis, 95% treatment, and 95% viral suppression) by 2030, a renewed focus on MSM is essential [3]. While China is on track to meet the second and third 95% targets (treatment and viral suppression) [4], achieving the goal of diagnosing 95% of individuals infected with HIV by 2030 remains a significant challenge. Our previous study demonstrated that 12.9% of MSM will have never undergone HIV testing by 2023 [5]. It is, therefore, crucial to identify MSM who have not been tested, implement targeted HIV education and testing, and expand testing efforts to facilitate early diagnosis. This approach is pivotal for China to meet its 2030 diagnostic target.

Historically, MSM in China has faced significant barriers to HIV awareness, intervention, and counseling services. Traditional social norms and cultural values make it difficult for MSM to disclose their sexual orientation [6], leading many to conceal their identity. This hidden population poses a challenge for the current HIV service network, which is managed by the Centers for Disease Control and Prevention (CDC) and various medical institutions [7,8]. In recent years, China has implemented a series of comprehensive measures aimed at preventing and controlling HIV infections among MSM. One of the primary strategies is to promote and facilitate community organizational involvement in HIV prevention and control initiatives [2]. These encompass the implementation of public education initiatives, disease prevention and intervention strategies, and the provision of testing and counseling services. The community organization is composed of MSM volunteers, which allows for forming trusting relationships and facilitates contact with the MSM population, thus bringing attention to this previously hidden demographic [9,10]. A previous study revealed that 567 MSM community-based organizations in China participated in initiatives funded by the AIDS fund for nongovernmental organizations, facilitating HIV testing for over 250,000 people by 2022 [11]. Of these, 7963 were newly diagnosed, representing 28.9% of all MSM HIV cases nationwide. The involvement of community organizations has increased the reach of MSM communities, facilitating greater access to HIV prevention services and the identification of new infections [12].

HIV testing is a highly effective intervention strategy [13]. The implementation of HIV testing can facilitate early diagnosis, prompt treatment, and subsequent transmission reduction [14]. Studies have shown that MSM who have been tested for HIV are less likely to engage in high-risk sexual behaviors compared to those who have never been tested [15]. Consequently, a significant proportion of funding allocated to community organizations in China is directed toward HIV testing services [9]. Community organizations primarily use 3 methods to recruit MSM for HIV testing. The initial approach was a volunteer-driven strategy that involved active recruitment. Community-organized volunteers and peer educators were recruited from venues frequented by MSM, including parks, bars, and bathhouses, for in-person HIV testing and interventions. In addition, MSM who have not been tested for HIV for over 6 months are also mobilized for testing by these volunteers. Second, a mobile social media promotion or recruitment strategy is also used. Information on HIV promotion, prevention, and testing is disseminated through MSM websites, dating apps, and communication groups, which are then used to recruit MSM to offline service outlets. Alternatively, HIV self-testing kits may be ordered mobile and mailed home. Third, a regular testing strategy is implemented. Some MSM who were initially recruited through the aforementioned strategies continue to test regularly after receiving HIV education without the need for further mobilization by community organizations.

With the rapid growth of China's internet economy and the widespread use of smartphones, mobile dating apps for MSM have surged in popularity [10]. Many MSM now use the internet and dating apps to find sexual partners. This shift has changed HIV testing recruitment from in-person volunteer outreach to internet-based strategies. Studies have shown that the internet is an effective tool for recruiting MSM, especially those who have never been tested, thus expanding the reach of HIV testing and reducing the number of undiagnosed infections [16,17]. Zhejiang Province, an economically developed and thriving internet economy in China, relies heavily on community organizations to implement HIV prevention and provide testing for MSM. In 2023, approximately 66,000 HIV tests have been conducted among MSM in the province, accounting for about 10% of the national total [4]. Notably, over 90% of these tests are performed by community organizations. To improve testing coverage among MSM, these organizations must use a dual recruitment strategy that uses both mobile social promotion and volunteer-driven initiatives. This approach is essential for identifying and engaging MSM who have not yet been tested for HIV. This study, based on the findings of a large-scale survey, aimed to analyze the effectiveness of 2 recruitment strategies, which are mobile social media promotion and volunteer-driven outreach. The results of this analysis will provide a foundation for promoting HIV testing within communities and contribute to recruiting MSM who have never been tested for HIV in China.

Methods

Study Design

A cross-sectional study based on a large-scale survey was conducted among MSM between July and December 2023.

Study Participants

MSM were eligible to participate if they met certain criteria, which include being (1) 16 years or older, (2) reported having sex with men in the past year, (3) were HIV-negative or had an unknown HIV status, (4) received HIV testing as a direct result of mobile social media promotion or volunteer-driven recruitment, and (5) resided in Zhejiang Province, China.

Participant Recruitment and Data Collection

Sunshine Coast Public Welfare is a social service agency that employs 13 full-time and 22 part-time social workers, with over 400 registered volunteers. The organization established a digital HIV prevention service using location-based services. MSM in Zhejiang Province are invited to visit the official "Sunshine Test" account on WeChat, a popular Chinese communication platform, to request free HIV testing and prevention counseling. MSM can choose between mailed self-testing kits or visiting offline services for HIV testing. Full-time and part-time social workers are responsible for regularly recruiting a specified number of MSM for HIV testing. Meanwhile, registered volunteers assist in promoting HIV testing within the MSM community periodically.

Questionnaires

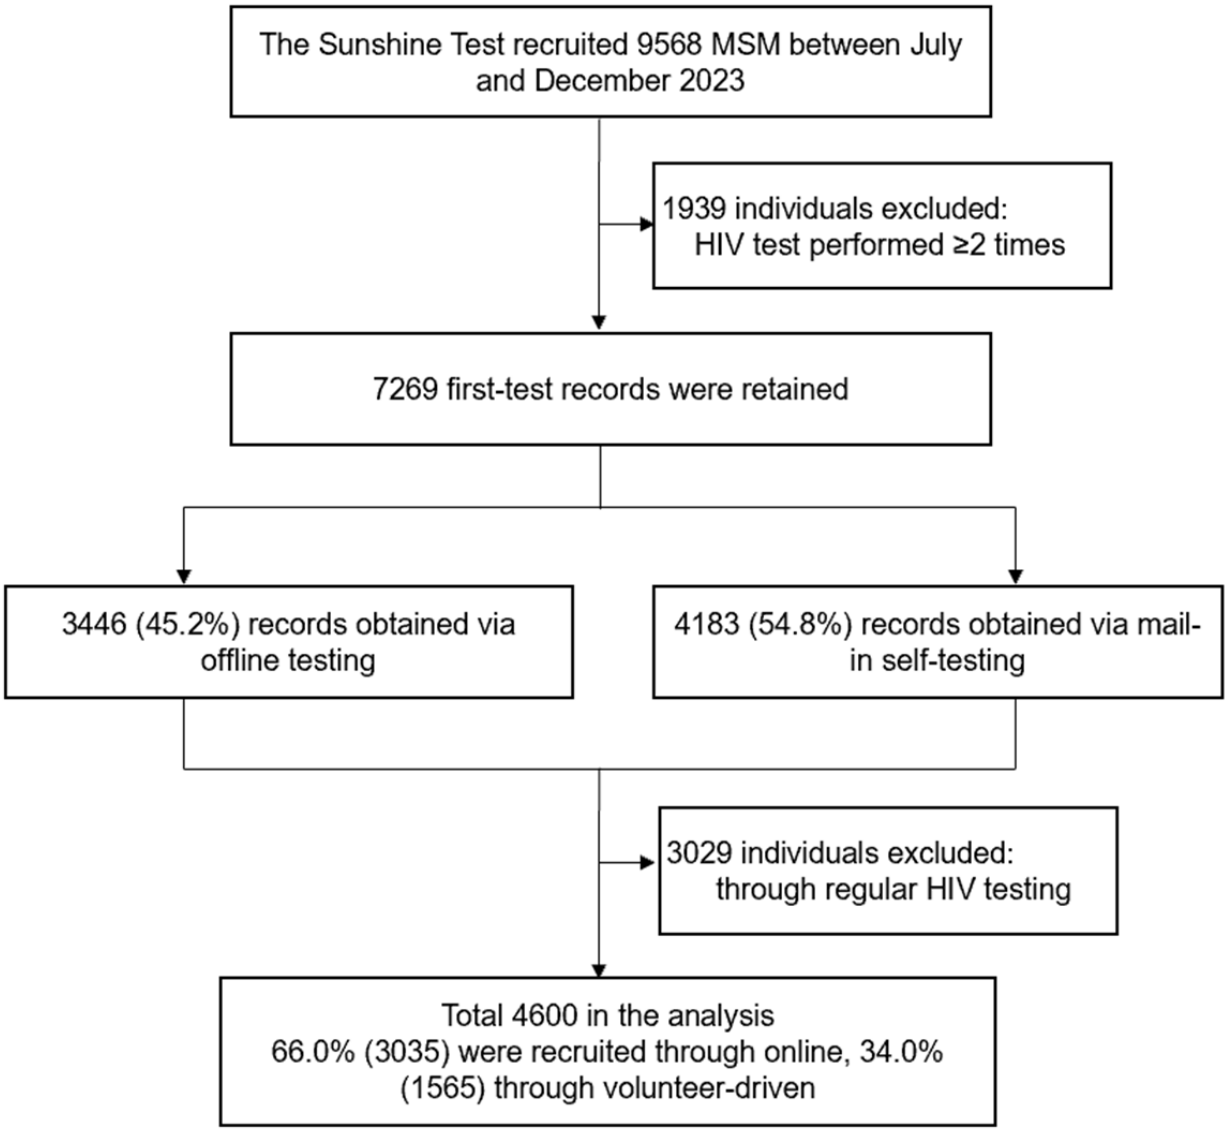
All individuals who engaged with Sunshine Test were required to complete a routine surveillance questionnaire consisting of 20 questions. These questions covered demographic information such as age, marital status, and education level, as well as sexual behavior including sexual roles (receptive, insertive, or both), number of sexual partners, use of rush poppers, sexual history, awareness of pre-exposure prophylaxis (PrEP) and PEP (postexposure prophylaxis), and HIV testing history.

Recruitment through direct engagement by social workers or registered volunteers was classified as "volunteer-driven recruitment." Conversely, if MSM were recruited after encountering HIV prevention information posted by the community organization on internet platforms (such as dating apps, communication groups, or websites) and subsequently applied for testing, this was categorized as "mobile social media promotion recruitment." If MSM had undergone an HIV test at the organization of their own volition, without being prompted by volunteers or mobile social media promotion, their case was classified as a "regular test." During the study, the participating MSM underwent repeated HIV testing on more than 2 occasions, but only the first record was included in the analysis. Details of the Sunshine Coast Public Welfare Program have been described in previous literature [10].

Statistical Analysis

Descriptive analyses were performed, with categorical variables presented as frequencies and proportions and continuous variables presented as median with IQR or mean with SD. The chi-square test (X^2) was used to assess significant differences in demographic characteristics between MSM recruited through mobile social media promotion and those recruited through volunteer-driven recruitment. Factors associated with differences in the sociodemographic characteristics of mobile social media promotion recruitment were included in multivariate logistic regression models, and adjusted odds ratios (aORs) with 95% CIs were calculated. Statistical significance was set at $P<.05$, with $\beta=.1$. All statistical analyses were conducted using SPSS (version 19.0; IBM Corp).

Ethical Considerations



This study was approved by the Zhejiang Provincial Centre for Disease Control and Prevention (approval number 2022-011-01). Written informed consent was obtained from all participants before survey completion, and participants had the ability to drop out anytime during the survey. All data were anonymous; participants received free HIV testing, health counseling, and no compensation; and all study procedures were conducted in accordance with approved guidelines and regulations.

Results

A total of 4600 MSM were enrolled in the study (Figure 1), of whom 3035 (66%) were recruited via mobile social media promotion and 1565 (34%) through volunteer-driven recruitment. The mean age of the participants was 30.0 (SD 9) years. Overall, 78.4% (3606/4600) were single, and 74.5% (3425/4600) had a college degree or higher education. Most participants (3455/4600, 75.1%) reported having male sexual partners. Over the past 3 months, 30.8% (1419/4600) reported having more than 2 sexual partners, and 30.7% (1410/4600) reported using rush poppers during sexual activity. In addition, 43.6% (2007/4600) were aware of their sexual partner's HIV status, 2.7% (126/4600) had a history of sexually transmitted infections (STIs), 47.2% (2169/4600) had used a mailed self-testing kit for HIV testing, 1.4% (66/4600) tested positive for HIV, and 18.8% (865/4600) were undergoing HIV testing for the first time (Table 1).

Figure 1. Study design. MSM: men who have sex with men.

Overall, 66% (3035/4600) of MSM recruited through mobile social media promotion were aged 20-29 years (1842/2719, 67.7%), single (2404/3606, 66.7%), had a master's degree or higher education (283/424, 66.7%), reported insertive anal sex (1037/1512, 68.6%), had exclusively gay sexual partners (2394/3455, 69.3%), had more than 2 sexual partners in the past 3 months (1001/1419, 70.5%), frequently used rush poppers during sex (529/698, 75.8%), were consistently aware of their sexual partner's HIV status (1371/2007, 68.3%), had a history of STIs (96/126, 76.2%), had HIV testing through mail reagent self-testing (1592/2169, 73.4%), tested HIV-positive (52/66, 78.8%), and had been previously tested for HIV (592/865, 68.4%) (Table 1).

[a]aOR: adjusted odds ratio.

[b]STI: sexually transmitted infections.

[c]PrEP: pre-exposure prophylaxis.

[d]PEP: postexposure prophylaxis.

In multivariate logistic regression analysis, the following factors were significantly associated with mobile social media recruitment: having only gay sexual partners (aOR 1.23, 95% CI 1.05-1.45), having more than 2 sexual partners in the past 3 months (aOR 1.74, 95% CI 1.42-2.11), frequently using rush poppers during sex (aOR 1.39, 95% CI 1.14-1.99), having a history of STIs (aOR 1.56, 95% CI 1.02-2.39), having awareness of PrEP (aOR 1.42, 95% CI 1.19-1.71), having awareness of PEP (aOR 1.49, 95% CI 1.24-1.79), testing positive for HIV (aOR 2.02, 95% CI 1.10-3.72), and undergoing HIV testing for the first time (aOR 1.28, 95% CI 1.09-1.52) (Table 2). MSM who were recruited by the mobile platform were more likely (aOR 2.02, 95% CI 1.77-2.31) to take the mailed HIV self-test (Table 3).

Discussion

Principal Results

This study compared the sociodemographic and behavioral characteristics of MSM who were recruited through 2 different recruitment strategies by community organizations to engage in HIV testing in Zhejiang Province, China. The strategies examined were a mobile social media promotion strategy and a volunteer-driven recruitment strategy. The findings indicated that 66% (3035/4600) of MSM were recruited through mobile social media promotion, while both strategies together reached 18.8% (865/4600) of MSM who had never been tested for HIV. Consistent with previous studies [18], community organizations proved effective in increasing HIV testing rates among MSM, particularly those who had not been tested before. The implementation of both strategies successfully expanded intervention coverage and recruited MSM who had not been previously tested for HIV. Furthermore, ongoing support for community organizations is recommended to facilitate the implementation of MSM prevention and control initiatives.

Comparison With Previous Work

Our findings revealed a higher proportion of individuals undergoing their first HIV test (592/3035, 19.5% vs 273/1565, 17.4%) and a higher prevalence of HIV-positive results (52/3035, 1.7% vs 14/1565, 0.9%) among those engaged via mobile social media promotions compared to those recruited through volunteer-driven initiatives. These observations are consistent with previous studies and empirical data. A meta-analysis demonstrated a 50% increase in HIV testing uptake following social media interventions [19], and another study showed a 22% increase in testing through mobile platforms [20], particularly among MSM engaging in high-risk behaviors. In these populations, the HIV-positive rate was 3.5% [21]. These findings suggest that mobile social media promotion may be an effective approach for recruiting MSM, improving HIV-testing coverage, and identifying individuals infected with HIV, particularly those who have not previously undergone HIV testing. As the proportion of MSM who use the internet and dating software continues to grow, it may be beneficial to expand the use of mobile social media promotion strategies to enhance HIV testing among MSM and facilitate the identification of more individuals infected with HIV. This could

XSL•FO
RenderX

be a crucial step toward achieving the goal of diagnosing 95% of individuals infected with HIV by 2030.

Similar to previous studies [22,23], our findings indicate that MSM recruited through mobile social media were more likely to use mail-based HIV self-testing kits. Mobile promotion strategies can facilitate the recruitment of MSM who have not accessed HIV testing services by providing convenient mail-in self-testing kits, thus increasing overall testing and identifying more individuals infected with HIV. Another study demonstrated that HIV self-testing services have the potential to enhance test uptake and reduce undiagnosed infections [24]. It would be beneficial to provide targeted outreach to MSM, such as offering HIV self-testing [25]. The utilization of social media platforms may prove effective in enhancing HIV self-testing rates among MSM aged ≤35 years [26]. Nevertheless, research has indicated that mobile social media may not necessarily increase the rate of HIV testing [27]. This may be attributed to the fact that the testing rate may not be enhanced by repeated HIV publicity and intervention in large cities but rather in areas where HIV testing is not easily accessible and where supportive gay social networks and health professionals are scarce. Therefore, priority should be given to implementing mobile social media promotion in areas lacking LGBTQ+ organizations or HIV health services. This approach can facilitate MSM recruitment, thereby increasing intervention coverage and improving HIV testing. Concurrently, it is also recommended to continue increasing publicity about HIV self-testing and to provide convenient self-testing services.

Consistent with other studies [28,29], we found that MSM recruited via mobile social media promotion were more aware of PrEP and PEP. Dating apps and social media have been identified as underutilized tools for increasing PrEP awareness, uptake, and knowledge among MSM [28,29]. PrEP and PEP represent effective prevention tools for individuals at high risk of HIV exposure, effectively reducing HIV infection and transmission [30]. Since 2021, PrEP and PEP have been widely used in China [31], with much of the advertising and promotion happening mobile. This has substantially increased awareness among MSM using the Internet. This study demonstrated that most MSM initially learned about PrEP through mobile sources [32]. Efforts should be made to further promote PrEP and PEP through mobile platforms while also disseminating preventive information through offline volunteer-driven strategies.

Our findings also revealed that MSM recruited mobile were more likely to report using rush poppers, a recreational drug that has gained considerable popularity among MSM [33], and their rate of use has continued to increase in China [34]. The use of rush poppers has been linked to abnormal arousal and pleasure, and prolonged sexual activity; these factors may increase the likelihood of engaging in unprotected sexual activity with consequent adverse outcomes such as HIV infection [30] and transmission [35]. Furthermore, a greater proportion of MSM seeking sexual activity through social media have reported recreational drug use compared to those using traditional venues [21]. Therefore, it is recommended that internet-based HIV interventions include information on the risks associated with rush poppers and their link to HIV transmission to raise awareness and reduce high-risk behaviors.

The study also revealed that MSM recruited mobile had more sexual partners and a higher prevalence of STIs compared to those recruited through volunteer-driven strategies. A meta-analysis conducted in China revealed that MSM who engage in substance abuse are more likely to seek sexual partners through the internet or social media and engage in unprotected anal intercourse [36]. One potential explanation for this is that the volunteer-driven strategy for MSM tends to focus on offline recruitment in venues such as bars, parks, and bathhouses, where social circles are relatively limited. The advent of the Internet has provided MSM with more opportunities to search for sexual partners. Mobile social media have demonstrated efficacy as a tool for increasing PrEP use [29] and HIV-testing uptake [32]. While PrEP reduces the risk of HIV infection, it does not prevent STIs [37] and may even increase the risk due to reduced condom use and increased high-risk sexual behaviors [38]. Therefore, alongside PrEP promotion, other targeted interventions promoting condom use and awareness of STI risks should be integrated into internet-based HIV prevention efforts.

Limitations

First, the participants recruited by the community organization were primarily younger MSM who use the internet, meaning older MSM (particularly those over 50) were underrepresented. Future research should explore recruitment strategies targeting older MSM who do not engage mobile. Second, the costs associated with the human and financial resources invested in these recruitment strategies were not assessed. Further research on the cost-effectiveness of these strategies is necessary. Finally, the study relied on routine surveillance questionnaires, which may not have captured all relevant factors influencing the effectiveness of the 2 investigated recruitment strategies.

Conclusions

Community organizations effectively use mobile social media promotion and volunteer-driven strategies to recruit MSM, playing an important role in improving HIV testing and identifying undiagnosed individuals infected with HIV. There are notable differences in recruitment outcomes between the 2 strategies, with mobile social media promotion leading to a higher proportion of first-time HIV testing and HIV-positive individual identification. In areas where LGBTQ+ organizations or HIV health services are scarce, mobile social media promotion should be prioritized to increase MSM recruitment and expand the coverage of HIV interventions.

Abstract

Background: Nowadays, optimal patient care should be based on data-driven decisions. In the course of digitization, hospitals, in particular, are becoming complex organizations with an enormously high density of digital information. Ensuring information security is, therefore, essential and has become a major challenge. Researchers have shown that—in addition to technological and regulatory measures—it is also necessary for all employees to follow security policies and consciously use information technology (compliance), because noncompliance can lead to security breaches with far-reaching consequences for the organization. There is little empirical research on information security–related behavior in hospitals and its organizational antecedents.

Objective: This study aimed to explore the impact of specific job demands and resources on resident physicians' information security–related compliance in hospitals through the mediating role of work engagement and information security–related awareness.

Methods: We used a cross-sectional, survey-based study design to collect relevant data from our target population, namely resident physicians in hospitals. For data analysis, we applied structural equation modeling. Our research model consisted of a total of 7 job demands and resources as exogenous variables, 2 mediators, and information security–related compliance as the endogenous variable.

Results: Overall, data from 281 participating physicians were included in the analyses. Both mediators—work engagement and awareness—had a significant positive effect on information security–related compliance (β=.208, *P*=.001 vs β=.552, *P*<.001). Quality of leadership was found to be the only resource with a significant indirect effect on physicians' compliance, mediated by work engagement (β=.086, *P*=.03). Furthermore, awareness mediated the relationships between information security–related communication and information security–related compliance (β=.192, *P*<.001), as well as between further education and training and the endogenous variable (β=.096, *P*=.02). Contrary to our hypothesis, IT resources had a negative effect on compliance, mediated by awareness (β=–.114, *P*=.02).

Conclusions: This study provides new insights into how a high standard of information security compliance among resident physicians could be achieved through strengthening physicians' security work engagement and awareness. Hospital management is required to establish an information security culture that is informative and motivating and that raises awareness. Particular attention should be paid to the quality of leadership, further education and training, as well as clear communication.

Introduction

Information Security–Related Issues in Hospitals

Nowadays, direct, easy, and quick access to and transmission of information are essential factors for health professionals to provide optimal patient care based on data-driven diagnosis and treatment. In the course of digitization, hospitals, in particular, are becoming complex organizations with an enormously high density of such information, which comes from a wide variety of sources and is available in different information systems. In order to make the decision-making process in hospitals more efficient, increasingly more (medical) devices are being digitally connected to hospital networks, providing health care professionals with data from multiple sources at a central access point. In a recently published study, the average number of active medical devices in large university hospitals in Germany was 25,150, with 4500 (17.9%) of them being digitally connected, a rate that is expected to increase rapidly in the near future [1]. Despite their major benefits in terms of the enhanced quality and efficiency of patient care, the use and high variety of connected devices poses potential information security risks to hospitals. Many of the devices used in hospitals are not only connected to local networks but also directly or indirectly connected to the internet or other external systems. For example, patient data can be transitioned to other stakeholders outside the local network or a cloud where they will be further processed [2,3]. Adding to this, with the increasing usage of personal mobile devices for work purposes by health care professionals, the issue becomes even more complex and difficult to handle for hospital management [4-6].

Information security in hospitals refers to the state of full functionality of all information systems, processes, and components and, therefore, the protection of all information required for optimal patient care. It must be guaranteed at all times. Continuous monitoring, as well as rapid responses to breaches and attacks, are essential. Due to the immense impact of poor information security on patient care, as well as the critical standard of security due to years of underinvestment and neglect of this issue, hospitals around the world have recently become targets of cyberattacks, with massive increases each year [7-10]. A study from 2020 shows how vulnerable the German hospital landscape is to ransomware attacks: the authors analyzed the publicly visible system attack surface of hospitals located in Germany and found that more than 1 in 3 hospitals analyzed had vulnerabilities, including those that were part of the critical infrastructure at the time [11]. In times of scarce financial and human resources, ensuring information security is an enormous challenge [4]. In addition to technological and regulatory measures, research literature also highlights and discusses organizational measures to enhance information security in hospitals [2,8,9]. The reason for this is that a large proportion of information security breaches still occur internally as a result of employee misconduct [2,9,12]. German politicians have already recognized that a high level of information security in hospitals can only be achieved with holistic measures at a human, technological, and organizational level. In addition to providing the technological basis, employees must be made aware of security-relevant issues and obliged and motivated to comply with policies. The hospital management must revise information and communication processes and create appropriate support structures (eg, responsibilities, IT, and training) [13].

Empirical research on information security–related behavior of employees at work and its supporting organizational and individual factors is a relatively new field. Several researchers have found that in addition to the technological equipment of the organization to ensure information security, it is also necessary for the employees to follow security policies and consciously use information technology (compliance), because noncompliance can lead to security breaches with far-reaching consequences for the organization.

To explain information security–related behavior within the organization, various behavioral theories and frameworks have been used, including the Theory of Planned Behavior (TPB), Organizational Behavior (OB), and the Job Demands-Resources Model (JDRM) [14]. Hu et al [15] used the TPB to investigate the role of top management, organizational culture, and individual cognitive beliefs on information security–related behavior among alumni of Management Information Systems and Master of Business Administration programs, finding significant effects. D'Arcy and Greene [16] combined different theories for their research model and examined the influence of security culture, job satisfaction, and perceived organizational support on security compliance intentions among computer-using professionals, finding positive effects on security culture and job satisfaction. Solomon and Brown [17] used the TPB and showed relationships between organizational culture, information security culture—as an organizational subculture—and compliance. They further argued that goal orientation among employees has a stronger influence on compliance than rule orientation.

There is little empirical research on information security behavior in hospitals. Yeng et al [18] recently conducted a study in a paperless hospital in Ghana and assessed the security behavior of health care staff. In their study, the authors covered different individual, psychosocial, cultural, and work factors and found several significant correlations with participants' security behavior [18]. In their case studies, Hedström et al [19] showed that employees in health care organizations are exposed to different value conflicts, for example, health care values versus information security values, which they have to resolve quickly for each situation during their practice. This poses security risks that need to be considered by hospital management [19]. In our first article on information security published in 2022, we examined specific security-related practices of physicians when using smartphones and medical apps in everyday clinical practice. Among the apps examined, some were found to pose a certain risk to data protection, information security, and patient safety. A large majority of the participating physicians who communicated by their smartphone did not use General Data Protection Regulation (GDPR)–compliant messenger services and paid little attention to some security-relevant criteria (such as manufacturer information, information on data protection, and information security) when selecting medical apps for professional use [20]. Both the papers from 2022 described above and the following paper are based on the same dataset. While our first paper focused on specific

XSL•FO
RenderX

security-related practices, this paper builds on this and examines the underlying constructs of this behavior.

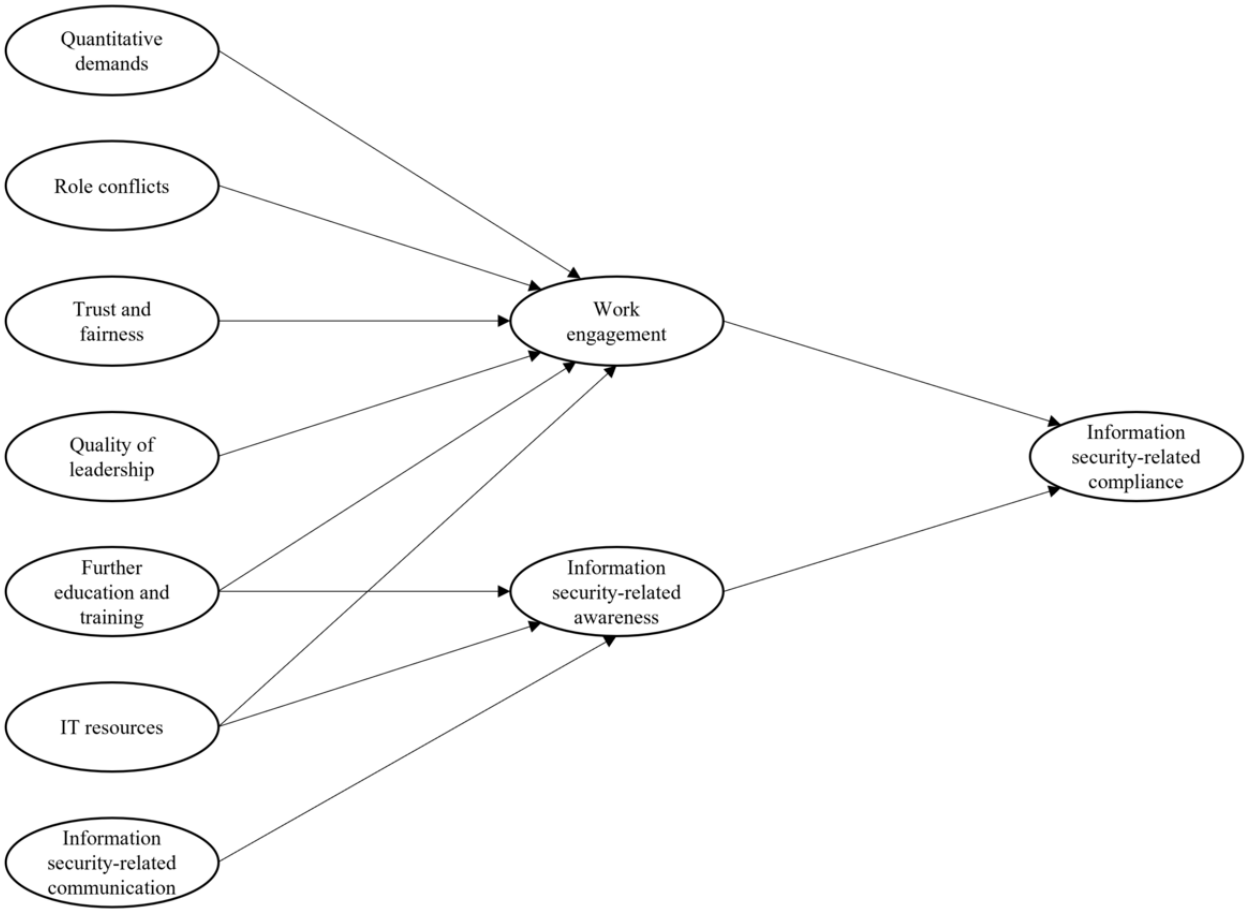
Due to the particular threat of cyberattacks, the ongoing digitization, increasing regulatory requirements and the existing research gap on information security–related behavior in hospitals, the aim of this study was to explore the impact of job demands and job resources on resident physicians' information security–related compliance.

Theoretical Framework

To develop our research model, we used elements from the Extended JDRM as well as the OB research field.

JDRM Framework

The JDRM by Demerouti et al [21] postulates that working conditions can be divided into 2 categories—demands and resources—and are associated with different job-related outcomes. Demerouti et al [21] originally intended to use the JDRM to explain the development of burnout: in one of their studies, they confirmed the links between high demands and exhaustion and between a lack of resources and disengagement [21]. Three years later, a revised version was presented by Schaufeli and Bakker [22]. Their model included burnout and engagement as mediators between different predictors and different possible consequences. Since then, the JDRM has served as a theoretical basis in many studies in industrial and organizational psychology [23]. The JDRM has proven to be flexible, with researchers adapting it to their specific study context regarding the outcomes, demands, and resources to be considered, as well as the presumed mediators and moderators [24]. Pham et al [25] used the JDRM for their qualitative research on the information security–related behavior of employees in Vietnam, finding 3 security resources, 3 security demands, and 2 personal resources that affected security engagement and security compliance burnout as the mediators of security compliance [25].



OB Framework

OB research has been around for about 100 years now [26]. There are 3 levels at which OB can be studied: the individual, the group, and the organizational level [27]. By analyzing information security–related compliance, our study focuses on how resident physicians behave as individuals in the organization and which job-related antecedents promote or inhibit compliance. Amankwa et al [28] chose—among others—concepts from OB research to explain information security–related compliance, showing that supportive organizational culture and end-user involvement had a significant effect on employees' attitudes toward compliance, which in turn had a positive effect on their behavioral intentions.

Research Model and Hypotheses

Our initial research model is presented in Figure 1. The relevant constructs, definitions, and corresponding items of the questionnaire can be found in Multimedia Appendix 1.

Figure 1. Research model.

XSL•FO
RenderX

As the first mediator, we have chosen work engagement ("WENG"). In a revised version of the JDRM presented by Schaufeli and Bakker [22], work engagement is considered to be a mediator of the relationship between job resources and job-related outcomes. The authors explained their findings through an underlying motivational process. Next to quality of leadership ("LEAD"), education and training ("EDUC"), and IT resources ("ITRE"), we chose trust and fairness ("TRFA") as the fourth potential resource. Unlike Schaufeli and Bakker [22], we also assumed a negative effect of certain job demands—quantitative demands ("QUAD") and role conflicts ("ROLC")—on work engagement. Here, we wanted to refer to the specific working conditions of physicians in hospitals, which are in general associated with high quantitative demands, but also—as Hedström et al [19] showed—different value conflicts.

Awareness ("AWAR"), as the second mediator, is one of the most commonly investigated variables related to information security–related behavior [29-32]. It is mostly considered to play a mediating role between the exogenous variables and the endogenous compliance variable ("COMP"). In our research model, it also acts as a mediator and reports on physicians' awareness of the risks, threats, policies and responsibilities related to information security in their hospital. In addition to information security–related communication ("COMM"), for which a relationship with information security–related behavior has already been shown in several studies [16,17,28,32], we added EDUC as well as ITRE as potential exogenous variables in our model. Here, the assumption was that both job resources the provision of adequate IT resources and good education and training could lead to greater information security–related awareness. A summary of our research hypotheses is provided in Table 1.

Table 1. Research hypotheses.

#	Hypotheses
H1a	Work engagement is positively related to information security–related compliance.
H1b	Information security–related awareness is positively related to information security–related compliance.
H2a	There is a negative relationship between quantitative demands and information security–related compliance mediated by work engagement.
H2b	There is a negative relationship between role conflicts and information security–related compliance mediated by work engagement.
H2c	There is a positive relationship between trust and fairness and information security–related compliance mediated by work engagement.
H2d	There is a positive relationship between quality of leadership and information security–related compliance mediated by work engagement.
H2e	There is a positive relationship between further education and training and information security–related compliance mediated by work engagement.
H2f	There is a positive relationship between IT resources and information security–related compliance mediated by work engagement.
H3a	There is a positive relationship between further education and training and information security–related compliance mediated by awareness.
H3b	There is a positive relationship between IT resources and information security–related compliance mediated by awareness.
H3c	There is a positive relationship between information security–related communication and information security–related compliance mediated by awareness.

Methods

Study Design

We used a cross-sectional, survey-based study design. A structured questionnaire in German was developed and designed with the free online survey tool LimeSurvey, whereby the first page contained information on the target group, the research project, the content of the questionnaire, and the estimated processing time. After accepting the privacy policy, participants were taken to the second page with demographic questions. These were followed by the main part including seven sections: (1) working conditions; (2) resilience; (3) job satisfaction and work engagement; (4) IT resources, information security, and data protection; (5) information security–related awareness and compliance; (6) technical affinity and innovative work behavior; and (7) mobile device usage. At the end of the survey, participants had the opportunity to share their comments with us. The sections relevant to this report are explained below.

- Working conditions: To assess working conditions, we used the following scales from the Copenhagen Psychosocial Questionnaire (COPSOQ): Quantitative Demands, Predictability, Role Conflicts, Quality of Leadership, Social Support, Feedback, Sense of Community, Trust and Fairness, and Appreciation. The COPSOQ is an internationally established instrument to measure psychosocial work factors, with good to very good validity and reliability for most of its scales [33]. In Germany, the third version of the questionnaire, which we used in our study, was published in 2019 [34]. In contrast to the original questionnaire, we divided the Social Support and Feedback scales into 2 subscales each (supervisors versus colleagues) to separate social support and feedback from supervisors from social support and feedback from colleagues, which could be rated differently, especially in hierarchical organizations. In addition, we used 2 scales (Uncertainty, and Further Education and Training) and 2 individual questions on working hours and shifts from the German instrument for stress-related job analysis for hospital

XSL•FO
RenderX

physicians (ISAK) [35,36]. We also included 4 self-developed items regarding IT resources in the hospital because we could not find a suitable scale in the research literature.

- Information security–related awareness and compliance: In addition to state-of-the-art technical information security solutions, employees of an organization should be aware of the importance of information security and trained accordingly to behave in a compliant manner [31,37]. The items that we used to assess information security–related communication, awareness, self-efficacy, top management commitment, and compliance are based on the works of Hu et al [15], D'Arcy and Greene [16], Karlsson et al [30], and Solomon and Brown [17]. We adapted the items to the clinical situation. Overall, this resulted in 4 items on communication and awareness, 2 on self-efficacy, 1 on top management commitment, and 4 on compliance.

The Work Engagement scale is also part of the COPSOQ and comprises 3 items. All English scales and single items were translated into German, checked independently by 2 bilinguals, and then adapted based on their comments. We used 5-point Likert scales, spanning from "To a very high degree" to "To a very low degree," from "Not true" to "Completely true," from "Always" to "Never/almost never," and from "Strongly disagree" to "Strongly agree," respectively.

We followed the Checklist for Reporting Results of Internet E-Surveys (CHERRIES; Multimedia Appendix 2) [38]. To ensure content validity, the survey was reviewed by faculty members and statisticians and modified accordingly. It was then piloted with a group of residents, who highlighted and took notes on any remaining ambiguities, which we corrected in the final questionnaire. We also tested the usability and technical functionality of the questionnaire before fielding it.

Determining the sample size for structural equation modeling (SEM) is difficult due to its flexibility. There are no generalized guidelines regarding sample size requirements [39]. Therefore, we used the rule of thumb of N≥200 [40].

Data Collection

Data were collected between March and June 2022. Our target group comprised physicians who are currently undergoing medical specialist training/residency training in hospitals in Germany (henceforth referred to as "residents" or "resident physicians"). We focused on residents because they predominantly belong to Generation Y and, compared with older generations, have been used to using digital technologies and especially mobile devices since childhood or youth; therefore, they represent a homogeneous target group in terms of this characteristic. An invitation with a link to the questionnaire was sent directly to the residents by email or social media channels, or indirectly by our contacts in the medical field. Important contacts were chief physicians, senior physicians, university professors, hospital managers, alumni networks, as well as presidents of the German medical societies. In addition, we asked medical experts with significant influence on social media platforms to share the link. The Hartmannbund, an important association of physicians in Germany, forwarded the link to its resident members.

Data Analysis

In total, we examined 2 job demands (QUAD and ROLC) and 5 job resources (TRFA, LEAD, EDUC, ITRE, and COMM) as exposure variables, 2 mediators (WENG and AWAR), and 1 outcome variable (COMP). All variables were measured using Likert scales and are interval scaled. A summary of our research hypotheses is provided in Table 1. To be statistically precise, we would like to highlight that the hypotheses are always intended to analyze the unique effects of the variables in the model and not the bivariate correlations.

For the analysis of our collected data, we applied SEM using the free software environment for statistical computing and graphics R (R Foundation for Statistical Computing) and the *lavaan* package. SEM refers to a family of data analysis techniques for complex relationships between multiple variables in a single research model and has become popular in the social and behavioral sciences [41,42]. Based on our research model and hypotheses, we followed the widely adopted 2-step approach to SEM by Anderson and Gerbing [43], in which the assessment of the measurement model is followed by the analysis of the structural model including tests of the research hypotheses. While the measurement model describes how the latent variables are measured by the indicator variables, the structural model shows how the latent variables are related. In the first step, a confirmatory factor analysis was performed to determine whether the initially proposed measurement model fits the data or needs to be respecified accordingly. Various fit indices exist for evaluating the global model fit. In accordance with Hu and Bentler [44], we used the standardized root mean squared residual (SRMR), the comparative fit index (CFI), and the root mean squared error of approximation (RMSEA). The authors recommended the following thresholds for fit indices that characterize a good global fit: SRMR<.08, CFI≥.95, and RMSEA<.06 [44]. Modification indices were also analyzed to determine the local fit. Here, we only made changes that were theoretically sensible in terms of our model. In addition, the results obtained were assessed regarding reliability, validity, and plausibility. If respecification was indicated, the entire evaluation process was repeated until a good model fit was achieved. In the second step, the relationships between the latent variables are analyzed by again evaluating the model fit and afterward interpreting the path coefficients β and the coefficient of determination R^2. To calculate the results, we used the robust WLSMV (weighted least squares means and variance adjusted) estimator. To ensure model identification, we only used factors with 3 or more items in the initial measurement model.

Ethical Considerations

Ethical review and approval were waived for this study. We are thus following the guidelines of the German Research Foundation (DFG) and the German Data Forum (RatSWD). The RatSWD is an independent body of empirically working scientists and representatives of the most important public institutions for data collection in Germany. It recommends a careful self-examination of research ethics in order to decide whether an ethical review by a committee is necessary for the planned research project. After careful self-examination, we were able to classify our research project as unobjectionable in

XSL•FO
RenderX

terms of research ethics: neither patients nor other vulnerable groups took part in the study. Also, our study was not likely to trigger powerful emotions or cause severe psychological stress or traumatic experiences. It did not involve physical risks to the participants or result in physical pain. Furthermore, the participants were informed of the study. Potential risks of participation (such as social risks, risks of criminal or civil liability, financial loss, professional disadvantages, or damage to reputation; risk due to a difficult security situation in the study room) did not exist. Participation in the study did not involve any type of deception [45,46]. No compensation was provided.

Results

Sample Characteristics

A total of 611 people entered the survey, of whom 349 completed it. An exact statement on the response rate cannot be made because we do not have information on the number of residents who received the questionnaire indirectly through our contacts. Data from 6 participants had to be excluded due to conspicuous response patterns (n=4), work in a hospital abroad (n=1), and specific information in the comment section (n=1). Furthermore, only data from participating physicians who had a clear understanding of information security as distinct from data protection were included. This was checked with the help of a single comprehension item. Overall, data from 281 participants could be used for our analyses.

Table 2 shows the sociodemographic characteristics of the study participants. A large majority of the participants were female (173/281, 61.6%). The two age groups with the highest frequency were 31-35 years (114/281, 40.6%) and 26-30 years (108/281, 38.4%). There was a total of 16 specialties represented by at least two participants. Most participants were part of a residency program for internal medicine (62/281, 22.1%), followed by anesthesiology (47/281, 16.7%), surgery (43/281, 15.3%), and pediatrics and adolescent medicine (30/281, 10.7%). Participants were distributed across all residency levels, with the fewest residents in their fourth year (43/281, 15.3%) and most residents in their fifth year or above (82/281, 29.2%). The majority of the participants worked in a public hospital (174/281, 61.9%), while approximately one-fifth (62/281, 22.1%) worked in a nonprofit hospital and 14.2% (40/281) in a private hospital. Most of the participants were employed in a university/teaching hospital (230/281, 81.9%). The size of the hospitals (measured by the number of beds) in which the residents underwent their training varied, whereby most of them worked in a hospital with more than 800 beds (109/281, 38.8%), followed by hospitals with 300-800 beds (104/281, 37%). Fewer than one-fifth (52/281, 18.5%) of the residents had a job in a hospital with less than 300 beds.

Evaluation of the Measurement Model

We analyzed the model fit, the reliability, and the validity of the measurement model and respecified it accordingly until we received sufficient results. We began with an assessment of the global fit of our original measurement model. Table 3 shows the measurement model fit indices for the initial and the final models. It revealed that the CFI was below the recommended threshold, whereas the RMSEA and SRMR already showed acceptable values.

XSL•FO
RenderX

Table 3. Fit indices of the measurement model (N=281).

Model	Chi-square (*df*)	*P* value	CFI[a]	RMSEA[b]	SRMR[c]
Initial measurement model	1217.7 (657)	<.001	.933	.055	.070
Respecified final measurement model	794.3 (514)	<.001	.965	.044	.055
Recommended thresholds	__[d]	≥.05	≥.95	<.06	<.08

[a]CFI: comparative fit index.

[b]RMSEA: root mean squared error of approximation.

[c]SRMR: standardized root mean squared residual.

[d]Not applicable.

Looking at Cronbach α of the latent variables of the initial measurement model, we received a poor value (<0.70) for the latent variable AWAR. Here, we decided to drop the first two items (AWAR1 and AWAR2) because, compared to the third and fourth items, they seem to be too special and an own latent variable, asking about concrete information security–related knowledge. One reason could be that at the time of the survey, information security policies and officers were not yet implemented in most hospitals and could, therefore, not be known to the physicians. After removing those 2 items, the Spearman-Brown coefficient was acceptable.

We further respecified the model according to the modification indices and added an error covariance between QUAD1 and QUAD2. We then dropped items with loadings <.50 (TRFA1 and ITRE1). Although the χ^2 goodness-of-fit statistic was still significant (*P*<.001), these respecifications resulted in global fit indices above the thresholds, as shown in Table 3, meaning that the measurement model can be considered to be an acceptable approximation of the empirical data. According to the Fornell-Larcker [47] criterion, we also compared the square root of the average variance extracted (AVE) for each variable with the corresponding correlations of all other constructs [47]. Since the square root of the AVE was higher than the correlations on the respective horizontal and vertical lines, as shown in Table 4, the discriminant validity of the variables can be confirmed. In addition, the AVE of each variable should be higher than .50 to achieve acceptable convergent validity. All AVEs were above this threshold. Afterward, we looked again at Cronbach α and the composite reliability of each latent variable. All values were higher than the recommended threshold of .70, indicating acceptable reliability of the latent variables. In summary, we obtained acceptable model fit, reliability, and validity for the measurement model. A summary of the quality indicators of the measurement model is presented in Table 5.

Analysis of the Structural Model and Hypotheses Testing

The initial structural model already showed a good global fit (Table 6). Nevertheless, we followed a proposed modification index and added a direct effect of COMM on COMP, resulting in the final structural model. The R^2 value for the endogenous variable COMP was .512, indicating that 51.2% of the variance of this variable can be explained by our structural model (Figure 2). The R^2 values for the mediators were .229 (WENG) and .154 (AWAR).

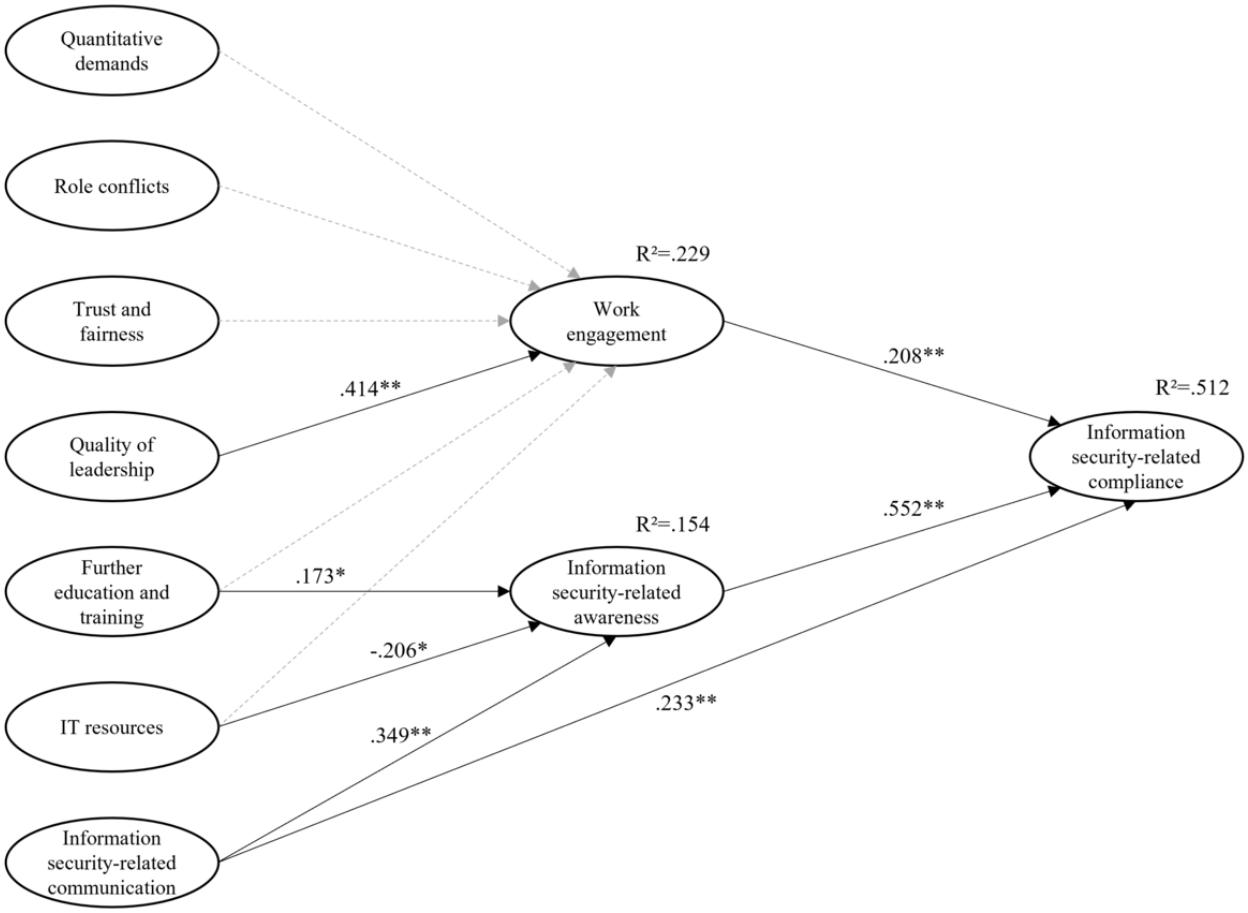
Figure 2 also presents the significant direct effects and standardized path coefficients (β). A summary of the hypotheses tested is provided in Multimedia Appendix 3. The results show a significant relationship between LEAD and WENG (β=.414, *P*=.001). There were no significant unique effects of the other exogenous variables tested (QUAD, ROLC, TRFA, EDUC, and ITRE) on WENG (all *P*>.05). Furthermore, we found a significant positive relationship between EDUC and AWAR (β=.173, *P*=.01), as well as between COMM and AWAR (β=.349, *P*<.001). In addition, there was a significant negative relationship between ITRE and AWAR (β=–.206, *P*=.01). Both mediators WENG (β=.208, *P*=.001) and AWAR (β=.552, *P*<.001) were significantly associated with the endogenous variable COMP, which supports H1a and H1b.

In order to test the mediation hypotheses, we calculated the partial indirect effects. A summary of the results is also presented in Multimedia Appendix 3. The results showed that WENG significantly mediated the relationship between LEAD and COMP (*P*=.03), supporting hypothesis H2d. The positive indirect effect resulted from the positive direct effects between LEAD and WENG and between WENG and COMP. AWAR mediated the relationships between the exogenous variables EDUC (*P*=.02), ITRE (*P*= .02), and COMM (*P*<.001) and the endogenous variable COMP, which supports H3a and H3c. Since we expected a positive indirect effect of ITRE on COMP, H3b could not be confirmed. The positive indirect effects of EDUC and COMM resulted from the positive direct effects involved.

Table 6. Fit indices of the structural model (n=281).

Model	Chi-square (*df*)	*P* value	CFI[a]	RMSEA[b]	SRMR[c]
Initial structural model	799.1 (527)	<.001	.966	.043	.059
Respecified final structural model	769.5 (526)	<.001	.970	.041	.056
Recommended thresholds	—[d]	≥.05	≥.95	<.06	<.08

[a]CFI: comparative fit index.



[b]RMSEA: root mean squared error of approximation.

[c]SRMR: standardized root mean squared residual.

[d]Not applicable.

Discussion

Principal Findings and Comparison With Previous Work

With this study, we could statistically prove the influence of resident physicians' job resources and job demands on their information security–related compliance through the mediating roles of work engagement and awareness. This is one of the first studies to empirically analyze organizational antecedents of physicians' information security–related behavior in hospitals. Intensified research activities in this field are of great importance given that increasing digitization in hospitals and the associated risks from cybersecurity attacks require—in addition to technical solutions—well-considered organizational measures to enhance information security.

It was shown from the results that the information security–related compliance of resident physicians is significantly related to their work engagement. The assumed positive effect from our hypothesis was, therefore, confirmed. Pham et al [25] already described this relationship in their explorative study using interview analyses, which could be now supported by our results. In line with the findings of the study by Schaufeli and Bakker [22] and their revised version of the JDRM, in which they stated that "engagement is exclusively predicted by available job resources," we did not find unique relationships between the job demands involved (quantitative demands and role conflicts) and work engagement. Both demands also had no significant indirect effect on compliance. It can be, therefore, assumed that decreasing job demands would not be the most effective strategy in enhancing physicians' information security–related compliance, which would need to be further investigated by subsequent studies. Instead, our study highlights the importance of the job resource "quality of leadership," which had a significant indirect effect on information security–related compliance mediated by work engagement. Based on that, we can conclude that supervisors have the power to increase resident physicians' compliance through the motivational path: a good relationship with their direct supervisors, who are mostly senior physicians, increases resident physicians' work engagement, which leads to better compliance with the hospital's information security measures. According to our study, this relationship can be supported by the supervisor's efforts in the areas of staff development, job satisfaction, work planning, and conflict-solving. In light of the increasing digitization, this should be accompanied by digital and change management competencies [48].

Besides work engagement, awareness was the second mediator in our model, and based on our results, it is also significantly related to information security compliance. Here, our findings are in line with the results of several other studies, analyzing the role of awareness as a mediator in various industries [22,31,32]. We found 2 job resources with a unique positive effect on awareness and also a significant indirect effect on compliance: information security–related communication and

XSL•FO
RenderX

further education and training. Communication is a highly effective factor in improving information security–related compliance, as has been shown in other studies [16,17]. Regular, comprehensible information security–related communication increases physicians' awareness of potential information security risks and threats. Here, we see a particular responsibility on the part of the hospital management. A communication strategy should be developed that makes all employees aware of the risks and threats and their particular information security responsibilities. In addition, information security–related communication had a direct effect on compliance. It could be assumed here that good communication also triggers automatic mechanisms for resolving critical situations. Furthermore, our results show that awareness can be created not only by communication but also by good education and training. Modern training concepts take a holistic approach and use various methods to raise awareness, for example, through personalized phishing simulations for training purposes and classic learning sessions with subsequent skills tests and personalized follow-up training based on individual results. Contrary to our hypothesis, IT resources are negatively related to awareness. One possible explanation could be that digitization and technologization increase confidence in the security of the tools used. On the other hand, if only outdated IT resources are available, physicians might be more sensitive to possible security risks.

Overall, our study provides initial insights into how the hospital as an organization could influence the individual information security–related behavior of resident physicians during clinical practice. In our opinion, the core element is the creation of an information security culture as a subculture of the organizational culture, which increases both the work engagement and the awareness of resident physicians through good leadership, information, and training.

Limitations

A few limitations should be taken into account when considering and evaluating our results, one of which pertains to the study design. First, since our study was conducted in Germany, it is not possible to directly apply the results to other countries. However, our study is intended to create incentives to conduct studies in hospitals in other countries to explore organizational factors for improving information security–related behavior. Second, when using a survey, comprehension problems on the part of the participants cannot be identified and addressed. However, we believe that the approach was the most suitable for the aim of the study and the selected target group as—for example—interviews would have resulted in a much smaller sample, which might have reduced the validity of the results. Third, the cross-sectional design does not allow us to form causal relationships between organizational antecedents, work engagement, awareness, and compliance, but only correlations. Any alterations in physicians' behavior due to changes in organizational factors can only be assessed with a longitudinal design. Nevertheless, we assume causal relationships based on logical considerations.

Even though it was an anonymous questionnaire, the risk of social desirability bias remains, with participants trying to be much more positive about their job-related attitudes and behavior. Furthermore, the fact that we cannot precisely determine the response rate represents another limitation. Since we do not have information on the number of residents who received the questionnaire indirectly through our contacts, for example, through chief physicians or the hospital management, we are not able to make an exact statement on the number of residents being invited, which is the basis for calculating the response rate. However, based on the information available to us, we estimate that fewer than 10% of those who received the questionnaire actually responded. If there are systematic differences between the responders and nonresponders, the results of our survey may not be representative of the target population. This so-called nonresponse bias may threaten the external validity of our study by reducing the representativeness of the results. However, previous research suggests that physician surveys are less susceptible to nonresponse bias than general population studies because they are a more homogeneous study population [49]. Furthermore, it is not always the case that a low response rate automatically reduces the representativeness, which is why the response rate should not be considered in isolation [50]. We believe the main reason for the low response rate was the heavy workload, which did not allow physicians the time to participate. Another indicator of the representativeness of a study is the sampling method [51]. The approach chosen for the data collection, in which residents were invited through different channels, may have led to a selection bias. For example, it is possible that digitally active and networked physicians were primarily addressed. The high proportion of physicians who received the questionnaire through the Hartmannbund may also contribute to the selection bias. Our study may have appealed to physicians with a higher average digital affinity than in the target population. To sum up, statistical conclusions on the entire target population should, therefore, always be drawn, taking into account the supposedly limited representativeness.

Future studies could use a longitudinal design to investigate the specific introduction of information security–related measures and the associated change in behavior. Furthermore, objective criteria, such as the number of breaches, could also be used as a measure of compliance instead of subjective self-reports. In addition, qualitative studies in the form of interviews are suitable for recording specific activities, opinions, perceptions, and concerns of physicians. It would also be interesting to conduct a study among senior physicians who have been working in hospitals for significantly longer and may need other measures to ensure that they behave in accordance with information security. For example, existing habits may be more difficult to change by adjusting resources and demands, and the resource "quality of leadership" may play a weaker role than for resident physicians.

Conclusions

A high standard of information security can only be achieved holistically through coordinated technical and organizational measures. In hospitals, this includes achieving a great level of work engagement among physicians through good leadership, but also creating awareness of the risks and threats relating to information security through communication and training. Hospital management is required to establish an information

XSL•FO
RenderX

security culture that is informative and motivating and that raises awareness.

Acknowledgments

This study was actively supported by the Hartmannbund. The APF is paid for under the ATLAS project “Innovation and digital transformation in healthcare” funded by the State of North Rhine-Westphalia, Germany (grant ITG-1-1). The authors declare that they did not use generative artificial intelligence (AI) in any portion of the manuscript writing.

Data Availability

The datasets used and/or analyzed in the context of this study are available from the corresponding author upon reasonable request.

Authors' Contributions

JK designed the study, and SB-J made important contributions during this phase. With the kind support of the Hartmannbund, JK recruited most of the participants. SB-J helped distribute the questionnaire through her professional network. JK analyzed and interpreted the data. JK wrote the manuscript. SB-J was a major contributor to the revision of the manuscript. Both authors have approved the manuscript before submission. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Health care systems in low- and middle-income countries (LMICs) can greatly benefit from artificial intelligence (AI) interventions in various use cases such as diagnostics, treatment, and public health monitoring but face significant challenges in sharing data for developing and deploying AI in health care.

Objective: This study aimed to identify barriers and enablers to data sharing for AI in health care in LMICs and to test the relevance of these in a local context.

Methods: First, we conducted a systematic literature search using PubMed, SCOPUS, Embase, Web of Science, and ACM using controlled vocabulary. Primary research studies, perspectives, policy landscape analyses, and commentaries performed in or involving an LMIC context were included. Studies that lacked a clear connection to health information exchange systems or were not reported in English were excluded from the review. Two reviewers independently screened titles and abstracts of the included articles and critically appraised each study. All identified barriers and enablers were classified according to 7 categories as per the predefined framework—*technical*, *motivational*, *economic*, *political*, *legal and policy*, *ethical*, *social*, *organisational*, and *managerial*. Second, we tested the local relevance of barriers and enablers in Thailand through stakeholder interviews with 15 academic experts, technology developers, regulators, policy makers, and health care providers. The interviewers took notes and analyzed data using framework analysis. Coding procedures were standardized to enhance the reliability of our approach. Coded data were reverified and themes were readjusted where necessary to avoid researcher bias.

Results: We identified 22 studies, the majority of which were conducted across Africa (n=12, 55%) and Asia (n=6, 27%). The most important data-sharing challenges were unreliable internet connectivity, lack of equipment, poor staff and management motivation, uneven resource distribution, and ethical concerns. Possible solutions included improving IT infrastructure, enhancing funding, introducing user-friendly software, and incentivizing health care organizations and personnel to share data for AI-related tools. In Thailand, inconsistent data systems, limited staff time, low health data literacy, complex and unclear policies, and cybersecurity issues were important data-sharing challenges. Key solutions included building a conducive digital ecosystem—having shared data input platforms for health facilities to ensure data uniformity and to develop easy-to-understand consent forms, having standardized guidelines for data sharing, and having compensation policies for data breach victims.

Conclusions: Although AI in LMICs has the potential to overcome health inequalities, these countries face technical, political, legal, policy, and organizational barriers to sharing data, which impede effective AI development and deployment. When tested in a local context, most of these barriers were relevant. Although our findings might not be generalizable to other contexts, this

XSL•FO
RenderX

study can be used by LMICs as a framework to identify barriers and strengths within their health care systems and devise localized solutions for enhanced data sharing.

artificial intelligence; data sharing; health care; low- and middle-income countries; AI tools; systematic review; case study; Thailand; computing machinery; academic experts; technology developers; health care providers; internet connectivity; data systems; low health data literacy; cybersecurity; standardized data formats; AI development; PRISMA

Introduction

Overview

Artificial intelligence (AI) has the potential to revolutionize health care by empowering health care practitioners in supporting clinical decision-making, enhancing diagnostic accuracy, and refining administrative processes for health care providers, payers, and pharmaceutical organizations [1-5]. Applications such as AI-driven predictive analysis and personalized treatments can improve health care delivery, even in low- and middle-income countries (LMICs). However, despite the promising aspects of AI in health care, there are significant challenges related to limited data sharing and accessibility that impede the development and localization of AI applications in health care, particularly in LMICs [1-3,6-9].

Rationale

Previous studies have identified challenges to health information exchange (HIE) and data sharing, more generally [10-14]. Akhlaq et al [10] reviewed barriers and facilitators to implementing and adopting HIE. This systematic review identified 7 themes influencing HIE—sociopolitical, financial, infrastructure, organizational, technical, individual, and data management [10]. Similarly, Figueiredo [11] and van Panhuis et al [13] identified 20 potential barriers to data sharing across 6 domains—technical, motivational, economic, political, legal, and ethical. However, gaps exist in current research. First, these studies did not focus specifically on the granular and often sensitive data required for AI models in health care, such as high-quality clinical datasets and high-resolution medical images. The complexity of these data types introduces additional challenges, such as ensuring data interoperability across different systems and institutions, addressing heightened privacy concerns, and maintaining data quality for AI algorithms. Furthermore, current studies do not fully test these AI-specific barriers. Second, the absence of empirical testing of frameworks using in-depth formative research is also a pressing gap across current literature. Engaging stakeholders (eg, policy makers, health care providers, and data scientists) in LMICs is critical for identifying practical solutions and for refining theoretical frameworks to fit real-world contexts. Defining clear metrics for the success of data sharing, for example, improved interoperability, increased data accessibility, and reduced privacy risks within national and organizational frameworks, not only informs scalable, adaptable solutions for AI in LMICs but also allows for their evaluation [15].

Thailand

Thailand is developing its AI capabilities and promoting AI adoption, but significant obstacles remain, particularly regarding data sharing. The fragmented nature of its health care service landscape and unclear data-sharing guidelines restrict the effective use of AI in health care. The Thailand National AI Strategy and Action Plan (2022-2027) attempts to close this gap by establishing a data-sharing guideline to enable AI deployment [16]. According to the Government AI Readiness Index 2021, Thailand ranked 59th globally and 9th in East Asia, demonstrating moderate progress in AI readiness but highlighting areas that require improvement, especially in health data governance [17,18].

Aims

This study aimed to address the research gaps by conducting a systematic review to identify the barriers and enablers to data sharing for AI in LMICs. The study further builds on existing literature by testing these findings through stakeholder interviews in Thailand—collecting empirical evidence on local challenges and enablers for AI-related data sharing and future recommendations for sharing data related to AI tools in Thailand. This mixed methods approach allows us to capture both the broader trends from LMICs and context-specific insights from Thailand, contributing to a more nuanced understanding of the intersection between AI and health care data sharing. Our findings will inform policy makers, health care organizations, and technology developers on building effective AI data-sharing frameworks, closing the gap between policy and implementation.

Methods

Overview

We conducted the study in 2 phases. First, we performed a systematic search to identify the literature assessing barriers and facilitators to sharing data for AI in health care. We synthesized and categorized findings using a predefined framework. Second, we conducted semistructured qualitative stakeholder interviews, which we analyzed thematically using the framework's domains. The qualitative interviews' findings validate, complement, and reiterate findings from the systematic review to a localized context (ie, Thailand) and supplement possible gaps in the framework.

Framework

We devised a predefined framework to categorize barriers and enablers on the basis of 2 previously published frameworks for

XSL•FO
RenderX

data sharing [13,19]. The framework included 7 domains categorizing barriers and enablers to data sharing: technical; motivational; economic; political, legal, and policy; ethical; social; organizational, and managerial. These categories are defined in detail in Textbox 1.

Textbox 1. Classification of factors of data sharing and their definitions.

- Technical: barriers and enablers relating to health information system capacity and other technological tools
- Motivational: barriers and enablers relating to personal or institutional motivations to share data
- Economic: barriers and enablers relating to the financial sustainability and costs of data sharing
- Political, legal, and policy: barriers and enablers relating to political principles, regulations, and public policy
- Ethical: barriers and enablers relating to moral principles, values, and ethical guidelines
- Social: barriers and enablers relating to societal norms and attitudes toward data sharing and health technology
- Organizational and managerial: barriers and enablers relating to organizations' strategy, leadership, and management practices

Systematic Review

Search Strategy and Inclusion and Exclusion Criteria

We used the SPICE (settings, perspective, intervention, comparison, and evaluation) framework (Textbox 2) to inform our search strategy and inclusion and exclusion criteria. The selection process focused on studies that explored AI tools, machine learning (ML), electronic decision support systems, or digital interventions, specifically in the context of HIE. We included primary research studies (empirical studies investigating the development, implementation, or evaluation of digital health tools related to HIE); perspectives (opinion or viewpoint articles offering expert insights into AI, ML, electronic decision support systems, or HIE systems); policy landscape analyses (reviews examining the policy or regulatory environment around digital health and HIE); and commentaries (discussions of challenges, advancements, or ethical considerations related to the use of digital interventions in HIE). Only studies published until October 2022 were considered. The inclusion criteria required studies to have a specific focus on the technical and practical aspects of HIE, such as how AI or ML tools facilitate data exchange, the role of interoperability, or the establishment of secure access protocols. Articles that did not address these core components or lacked a clear connection to HIE systems were excluded from the review. All included studies had to be performed in or involve an LMIC context, according to the World Bank country classification (fiscal year 2019) [20]. We excluded studies not reported in English. We defined AI in health care as any software or algorithm made to automate intelligent behavior in a health care setting for diagnosis or treatment directed toward patients, caregivers, health care providers, or a combination [21]. We registered the review protocol with PROSPERO before commencing data extraction (CRD42022343604).

We systematically searched PubMed, SCOPUS, Embase, Web of Science, and ACM. In the search strategy, we incorporated keywords and controlled vocabulary terms for the key concepts of data sharing, AI tools, health care, and barriers and enablers (Multimedia Appendix 1). A librarian at the National University of Singapore vetted the strategy.

Textbox 2. The SPICE (settings, perspective, intervention, comparison, and evaluation) framework for conducting the systematic review.

S (settings)

- Health care domain

P (perspective)

- Experiences, perspectives related to barriers and enablers to data sharing

I (intervention)

- Artificial intelligence tools, machine learning, digital health, electronic decision support systems

C (comparison)

- Traditional health setting or not applicable

E (evaluation)

- Challenges and barriers to data sharing
- Facilitators and enablers to data sharing
- Identification of groups or stakeholders and their perspectives

Data Synthesis

The retrieved search results were imported to Clarivate Endnote (version 20.3) and deduplicated. The remaining articles were imported to Rayyan. Two reviewers independently screened the titles and abstracts of the included articles. All articles that potentially met the inclusion criteria and were agreed upon by both reviewers were included in the review for full-text screening. A third reviewer resolved conflicts.

Data extraction tools were developed, and the data were synthesized. These included article title, first author, year of publication, study characteristics—including country of origin, study design (qualitative and semistructured), description of AI tool, and a summary of barriers and enablers to data sharing. Data synthesis was on the basis of The Joanna Briggs Institute's (JBI) meta-aggregative approach for qualitative systematic reviews [22]. The qualitative data were pooled and represented as a narrative summary for each study per domain.

Critical Appraisal

Two reviewers (AK and CB) critically appraised each study independently using the Critical Appraisal Skills Programme checklist for qualitative studies (Multimedia Appendix 2) [1-3,6-9,23-36] [37]. The Critical Appraisal Skills Programme checklist was used because it is appropriate for all types of qualitative research (including landscape analysis and perspectives).

Stakeholder Interviews

We tested the relevance of barriers and enablers using Thailand as a case study. Thailand was chosen because of the publication of its recent National AI Strategy and Action Plan (2022-2027) and because coauthors of this study had access to local stakeholders [16]. We conducted an exploratory qualitative study to better understand the various challenges faced by the stakeholders in data sharing for AI and the facilitators that help overcome this at a local level.

Study Design

We identified and mapped potentially relevant stakeholders through social media (LinkedIn), search engines, personal, company (university and ministry), and official websites. We included stakeholders aged ≥21 years who could communicate verbally in English, academic experts, technology developers, regulators, or policy makers in governance, regulation, and implementation of digital health technology and novel technology in Thai health care. We used purposive and snowball sampling techniques for stakeholders until saturation was reached.

All mapped stakeholders were contacted via an email titled "Invitation to discuss data sharing for artificial intelligence in Thailand" that included the semistructured interview guide (Multimedia Appendix 3) and the standard letter of invite entailing a short summary of the project, information for the participants regarding the type of data collected, and how data will be used. This aimed to ensure participants could make informed decisions about which interview questions they preferred to answer.

All 5 authors conducted stakeholder interviews on Zoom from December 20, 2022, to February 10, 2023. Interviews followed a semistructured interview guide. The interview guide was vetted by all authors and included relevant comments as per each author's expertise and was further revetted by our partners at the Office of National Higher Education Science Research and Innovation Policy Council, Thailand, to test the local relevance of the topics included and to avoid any potential bias.

Data Collection

Interviewers took detailed written notes, which were subsequently reviewed for accuracy and completeness. The notes were then coded based on predefined domains of barriers and facilitators aligned with the framework. Two researchers independently coded the data using MS Excel, systematically comparing coded segments and themes across interviewees. Illustrative, nonattributable quotations supported the findings, providing a rich, contextual understanding of the data. The coded data were reverified during the analysis, and themes were readjusted where necessary with consensus to avoid researcher bias.

Data Analysis

We conducted a thematic analysis using framework analysis to qualitatively analyze the interview data. This approach is well-suited for applied policy research, as it systematically explores stakeholders' views, knowledge, and perspectives while retaining the contextual integrity of individual narratives. The framework analysis method involves 5 distinct stages: familiarization, identifying a thematic framework, indexing, charting, and mapping and interpretation, which provides a structured approach to organizing and interpreting the data [38].

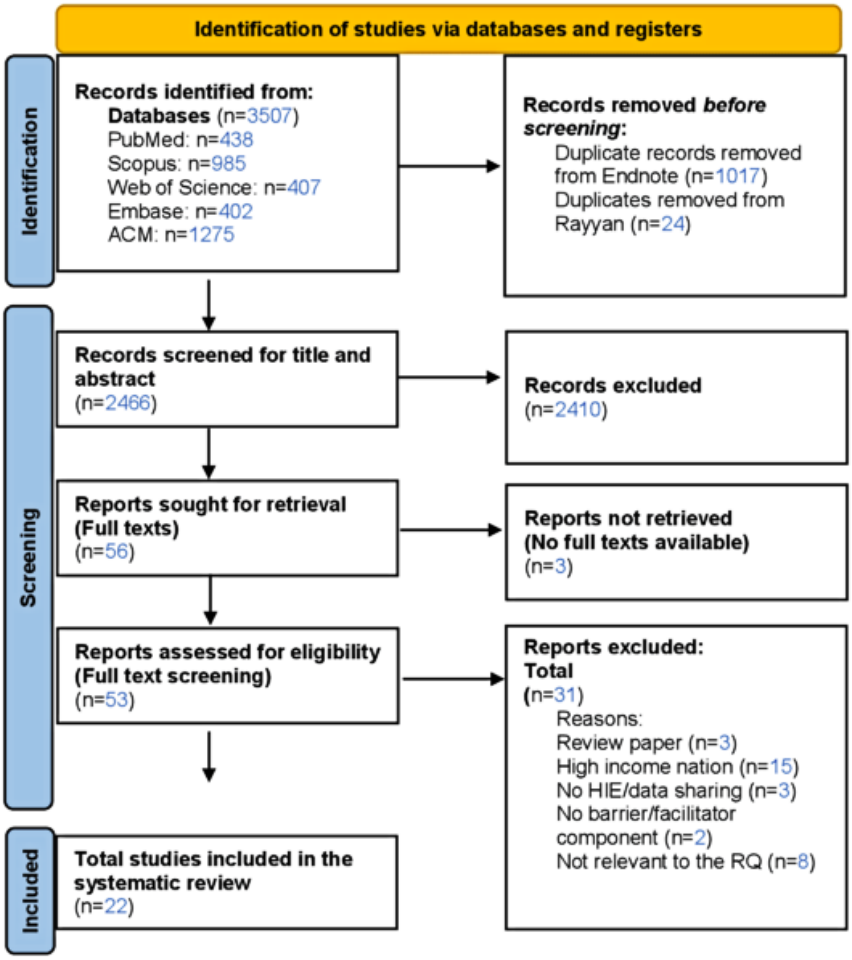
Throughout the analysis, reflexivity was emphasized, as the researchers continuously examined their own perspectives and potential biases by engaging in discussions to ensure that personal assumptions did not influence the interpretation of the data. We addressed the 3 key criteria for ensuring trustworthiness in qualitative research. (1) Confirmability: we documented the coding and thematic development processes and conducted consensus meetings between coders to ensure that the findings were grounded in the data rather than influenced by researcher bias. (2) Dependability: to enhance the reliability of our approach, we standardized the coding procedures. Consistent data management practices were followed, and any discrepancies between coders were resolved through discussion. (3) Credibility: illustrative, nonattributable quotations supported the themes and ensured that the findings accurately reflected the participants' views.

Ethical Considerations

The National University of Singapore Institutional Review Board approved the qualitative component of this study (NUS-IRB-2022-550). No interviews were recorded, and consent was obtained via email and at the start of the interview. The interview data were not anonymized and were retained solely for potential future contact regarding the study. Participants were informed and consented that their personal information (limited to name, email address, and designation) would be securely stored according to the National University

XSL•FO
RenderX

of Singapore's data storage principles and policies, accessible only to the project team. Consent was obtained to use select quotes from the interviews, ensuring that no identification of individual participants is possible. No compensation in any form was provided to participants.



Results

Systematic Review

Study Characteristics

We retrieved 3512 records, with 2471 articles left after removing duplicates (Figure 1). After excluding titles and abstracts, 58 articles were eligible for full-text screening. Finally, the data extraction and qualitative synthesis included 22 articles published between January 2010 and October 2022 that fulfilled the inclusion criteria.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for included studies. HIE: health information exchange; RQ: research question.

Quality Appraisal

Table S1 in Multimedia Appendix 2 presents the quality appraisal results. All studies reported a clear statement of the aims and findings of the research. The qualitative methodology was appropriate to all studies, while the research design was appropriate to all except one [3]. The appropriateness of recruitment strategy and data collection was unclear or inappropriate for 7 [2,3,23-26,39] and 6 studies [2,3,23,25-27], respectively. Whether the relationship between researchers and participants or ethical issues was adequately considered was unclear or not appropriate for 11 [1,2,6,23,24,26-31] and 12 studies [1,6,23,24,26-28,30,32-34], respectively. All studies were valuable to the local context.

Table 1 shows the characteristics of the included studies. Of all the studies, 8 (36%) were landscape analyses, 7 (32%) had a qualitative design, 2 (9%) were mixed methods, 3 (14%) were case studies, and 2 (9%) were perspective articles. Of all the studies, 12 (55%) studies were from Africa, 6 (27%) from Asia, and 2 (9%) from Latin America and the Caribbean.

Factors Associated With Data Sharing

Figure 2 summarizes the factors associated with data sharing according to the framework.

Figure 2. Factors associated with sharing of health care data using artificial intelligence tools.

Technical Factors

We identified 7 technical factors associated with data sharing for AI in LMICs; 5 were related to infrastructure, and 2 were related to data management practices. Limited access to information and communications technology and poor infrastructure lead to poor internet connectivity, power shortages, and software crashes, causing difficulty in backing up and exchanging data [7,23,28,35,36]. Inappropriate and inconsistent data management software and software versions can lead to data fragmentation and format issues [2,29]. Health systems in LMICs often neither use consolidated data management systems (ie, a system that seamlessly brings together various subsystems into one for easier management and coordination [40]) nor use central repositories (ie, a singular storage location for data within an organization, providing visibility, collaboration, and consistency within data management [41,42]). HIEs are often standalone [8,9,35] with limited communication across different databases and various health systems and electronic medical record (EMR) systems implemented in different districts or provinces, leading to duplication [25,32]. This can lead to inconsistent use of data definitions and labels, reducing interoperability [2,8,33]. Investing in a multisourced data triangulation system, storing data in a single database and central repository, and using standardized electronic health records (EHRs) can promote data collection and reduce fragmentation [1,6,9,28-30,35].

Regarding data management, many health care systems in LMICs use handwritten records, often in native (ie, regional) languages [26,34], limiting shareability. Ensuring that the platforms and software used for data handling are ergonomic, user friendly, and tailored to local and regional contexts will increase their uptake and use among health care staff [6].

Motivational Factors

We identified 3 motivational factors. First, health care staff often lack the motivation to systematically collect data and adopt new standards for uniform data collection [8,33]. Education and awareness about the value of health data exchange can address staff resistance to digital data collection [24,27]. Second, managers and organizations might not perceive the value of collecting health care data or emphasize the importance of data quality to their staff [8,43]. Third, incentives for adopting and using AI can improve the digitization of medical data [24,27].

Economic Factors

We identified 3 economic factors associated with data sharing. First, the uneven distribution of financial, human, and technical

XSL•FO
RenderX

resources in LMICs [24,35] is a significant barrier for small clinics or hospitals to collect high-quality data [7,9]. Limited resources constrain the use of data audits for confidentiality, privacy, and standardized data field terminologies [25,31,33]. High equipment costs are a significant barrier for small clinics or hospitals to collect. Financial support enables the adoption of EMR systems and promotes the implementation of regional HIEs by addressing infrastructural barriers, lack of human resources, adequate training, data quality, and security challenges [7,24,35].

Political, Legal, and Policy Factors

We identified 4 political, legal, and policy factors. First, transparent regulations, defined standards for intersystem communication, anonymization of personal data, and security frameworks promote data sharing [3,9,23,27,30,39]. Second, national policy and legal facilitators for data sharing include a national strategy [24,33,35] and data-sharing guidelines to clarify national personal data protection acts [2,3,32]. However, even when national data policies are in place, ensuring regulatory compliance can be challenging [7,24,25]. Data auditing mechanisms can promote compliance [30,39]. Finally, clear institutional-level data-sharing guidelines promote information transfer and increase data-sharing motivation. Similarly, having confidentiality agreements helps uphold data accuracy and privacy protection requirements [25,30,31]. Aligning the description of data elements with current clinical practices and workflows will facilitate work for health care staff and enhance collaboration among entities involved in health data sharing [39].

Ethical Factors

We identified 3 ethical factors. The absence of explicit informed consent and patient confidentiality concerns are significant data-sharing barriers, while unauthorized access caused by bypassing security mechanisms can cause ethical concerns, further putting the patient's data in jeopardy and thus creating a reluctance to share data among patients and practitioners [3,9,26]. Frameworks focusing on ethics and privacy at the national and institutional level facilitate trust among data users and patients [27]. Creating secure channels for data sharing and state-of-the-art security standards will also be important to securing patient privacy [23,31]. Novel technologies such as decentralized consent management blockchain systems might be a potential solution, enabling patients to share consented data through data requests [32].

Social Factors

We identified 3 social factors associated with data sharing. First, the complexity of the types of stakeholders involved in data sharing limits collaboration and interoperability [2,3]. Second, a lack of public awareness regarding patient rights and data laws can also be a barrier that may hinder consent processes [26]. Third, national protocols, certification systems, and increased awareness and information about the benefits and risks associated with data sharing will help build trust between health care practitioners and patients [3,27,30].

Organizational and Managerial Factors

There were 4 organizational and management factors. Workforce limitations [12,13], limited provider digital literacy [24,25,32,35,36,43], and the absence of expert IT teams [6] reduce data capture and quality. Overburdened health care workers' conflicting priorities limit the time to enter high-quality data into digital systems [36,43]. A shortage of staff and leaders can lead to ill-defined responsibilities and ambiguity of data-related roles, further enhancing the ineffectiveness of organizational procedures [7,29,33]. Poor organizational clarity on data rights and permissions, central coordination, and terminology are barriers to data sharing [9]. This can be addressed using standard operating procedures to facilitate health data exchange across facilities [1,29]. Health personnel training can enable the staff to use EMR systems, manage data dictionaries, address data quality challenges, and address reluctance to use digital technology [7,24,31,33,35,43]. The complexity of stakeholders and multiple system contractors and organizations involved in digital health in developing nations is a significant barrier to interoperability [11].

Stakeholder Interviews

We mapped 50 relevant stakeholders for interviews, of which 15 confirmed participation (response rate: 15/50, 30%). Most interviewees were academic experts (6/15, 40%) and technology developers (5/15, 33%). The remaining were policy makers, regulators, and health care experts. Table 2 summarizes the major themes from the interviews. We identified multiple barriers and enablers relevant to the context of Thailand, which were classified under the 7 main domains. Most stakeholders reiterated the technical, economic, political, and social factors of data sharing identified during the systematic review.

Thematic synthesis of the interviews yielded multiple barriers and enablers relevant to Thailand's context, which were classified under 7 main categories of our framework.

XSL•FO
RenderX

Table 2. Summary of major themes identified through in-depth stakeholder interviews.

Framework	Subthemes identified by stakeholders
Technical factors	• Inconsistent data architecture, formats, and standards, eg, different data formats between different EHR_a platforms of the same organization • Misalignment in terminology and structure and data inaccuracy • Different data collection practices between private and public health care sectors • Manual data management and paper-based EHRs
Motivational factors	• Lack of staff time • General unawareness of the value of sharing data, creating awareness and empowerment • Limited incentives to sharing data beyond the organization; therefore, providing incentives such as tax rebates and funding to private sectors
Economic factors	• Lack of financial support and resources (mainly manpower and trained staff) • High equipment costs • Financial disparity between private and public sectors increases the gap in digital skills proficiency
Political, legal, and policy factors	• Complex or unclear data-sharing regulations and guidelines (eg, what data can be shared and what needs to be protected) between organizations or hospitals cause fear of sharing data wrongly • Too many laws and types of laws cause confusion, making data integration cumbersome • Low applicability of international standards • Having clear guidelines mandating standardized practicing on data entry, data protection, and data storage • Identifying a single government organization responsible for collaborating and strengthening all branches of data sharing
Ethical factors	• Confidentiality and consent issues • Frequent breaches of hospital information systems • Improving adherence to practices that mitigate data breaches, such as separating personal and professional use of computers, using 2-factor authentication or a password-protected log-in
Social factors	• Lack of public awareness of data laws and low digital health literacy • Limited stakeholder collaboration
Organizational and managerial factors	• Lack of clarity on what data can be shared • Issue of data ownership, ie, considering data as private and profitable assets • Lack of an organizational protocol, ie, standard operating procedures with necessary steps to approve data-sharing, data protection, and staff training guidelines

[a]EHR: electronic health record.

Factors Associated With Data Sharing: Thematic Analysis

Technical Factors

Stakeholders reported that current data architecture and inconsistent data standards (multiple or uneven systems) did not allow hospitals to share data throughout the health care system. There can be a lack of software standardization even within the same company. In addition, manual data management and paper-based EHRs are common. In lower-income regions or smaller clinics, there is a lack of equipment and infrastructure to collect data (and share data safely), leading to uneven and fragmented data. One participant mentioned that different data collection and health information systems in the clinical workflow are barriers to efficiently sharing data. Most participants also noted the lack of uniformity in gathering data across private and public health sectors:

> *In some clinics, their systems are not fully electronic yet (e.g., patient hand writes, then the document is scanned into a PDF form and is uploaded).* [Policy expert]

> *Previously, governments had no standards for sharing data, which led to each hospital having their own system, format, and structure.* [Health care expert]

> *There is neither a centralised system nor initiative to streamline all the healthcare data into a single platform like a National EMR system.* [Academic expert]

To overcome these technical barriers, stakeholders emphasized the need for a decentralized data infrastructure system to enable data sharing. This can be achieved by making routine data collection electronic, keeping in mind its user friendliness, which would not exacerbate staff workload:

> *All healthcare facilities need to use one single platform for data input in the future. This is important to ensure comparability of the data.* [Academic expert]

Economic Factors

Stakeholders reported a lack of funding and resources (mainly manpower and staff time) as a barrier to standardization, scaling, and data sharing. They cited high equipment and software costs as a reason for still using paper-based data collection. Funding

XSL•FO
RenderX

inequity caused the disparity in digital skills between low versus high-income facilities. Stakeholders mentioned that regular top official turnover limited consistent IT staff training. All these barriers led to a lack of technical capacity to digitize patients' records, especially in most rural hospitals:

> *There is a lack of equity (in funding)... In low-income health facilities, the manpower may not have the technical capabilities to update data and link the data to a central database.* [Policy expert]

> *...The public sector in Thailand should work on security, but it is beyond their budget to buy large tools such as firewalls.* [Academic expert]

> *... unclear who would bear the cost of operating a unifying health data platform in the future.* [Academic expert]

None of the stakeholders mentioned any solutions to the aforementioned economic barriers that would help facilitate data sharing.

Political Factors

Most reported political- and policy-level barriers revolved around the lack of data-sharing regulations and guidelines (eg, who can share what data and under what circumstances), complex and unclear policies, and the low applicability of international data standards. Participants mentioned that there were no clear regulations and national policies on data sharing between hospitals, which may cause the doctors to reject patient requests to share their information with another hospital. Declining requests to share data was also attributed to a fear caused by the lack of clear laws: no laws would protect and support hospitals if they wrongly released a patient's health data. Therefore, too many laws or types of laws were reported to cause confusion and make data integration even more difficult. Other reported barriers were the lack of cross-ministry collaboration and the absence of a central regulatory authority that modulates data-sharing practices among health care providers:

> *The Ministry of Health should work with other ministries to develop these (data sharing guidelines).* [Technology developer]

> *Current law (law that governs digital platforms) is not enough to cover digital health services; an extension of the law is required.* [Regulator]

Possible solutions to these political-level barriers ranged from government decisions to standardize data inputs and sharing to using digital health sandboxes. It was suggested that data sharing between data collectors should be mandated by law, that regulations should be implemented, that there should be an intermediary between all ministries to facilitate collaboration, and that there should be a national committee on AI in health care with a high priority for data sharing:

> *It is suggested that both the public and private sector agree on a set of standards so that they are willing to share the data collected nationally.* [Technology developer and policy expert]

> *Steer the development of regulatory sandboxes as testbeds for regulatory innovation ... it is also important to provide clear costs and benefits for start-ups to join the sandboxes right at the beginning.* [Technology developer]

Social Factors

Important social barriers included a lack of awareness of data laws, data sharing, and collaboration. Hospitals often feel reluctant to share data with private companies because of limited awareness of laws on data sharing (eg, Personal Data Protection Act [PDPA]). Perceived gray areas and limited regulatory clarity exacerbate unclarity on who can share what data under which circumstances. Another significant barrier included the absence of a central body that overlooks communication between different ministries to facilitate interministerial collaboration and data transfer:

> *The implementation of PDPA was launched in Thailand and people stopped sharing data altogether. This is clear evidence that the people have misunderstood the meaning of data sharing.* [Policy maker]

> *There is poor collaboration between the public and private sector; limited evidence and experience related to data sharing.* [Academic expert]

In response to these barriers, interviewees suggested collecting input from various stakeholders involved in data sharing. These should include individuals in the medical field, companies, ministries, and patient organizations. Identifying a single government organization responsible for collaborating and strengthening all branches of data sharing is an unmet need. Another critical consideration was enhancing the Thai population's awareness and knowledge of data sharing:

> *Various stakeholders will need to come together to work together in building a conducive digital ecosystem that facilitates responsible data sharing.* [Academic expert]

Motivational Factors

One participant reported a lack of staff time as a barrier. Other motivational barriers included people's (eg, patients, health care providers, and health staff) unawareness of the value of sharing data and limited incentives for organizations to share data:

> *Doctors often lack the motivation to share data as they dislike sharing data amongst themselves, as they do not like to share their logic and treatment process for a patient.* [Health care expert]

> *Public and private healthcare facilities are unlikely to pull resources and share their data across the public and private spheres.* [Academic expert]

Creating incentive structures for hospitals to share data was among the most widely suggested enablers. One participant suggested that the government can consider providing funding and tax incentives to the private sector if they share data for the public good. Regarding creating awareness about data sharing and data laws, interviewees suggested that executive-level players in organizations, entrepreneurs, and policy makers must

XSL•FO
RenderX

be empowered and educated. Patients should receive information on the benefits of sharing their data. Furthermore, data owners should have an understandable and unambiguous process to share their data securely:

> *Doctors currently do not have the mindset to share the data that they collect. Therefore, it is suggested that there should be incentives from sharing data, such that the one that collects the data (medical doctors) as well as the individual that analyses the data both benefits.* [Policy expert]

> *For instance, an application to use safe drugs would encourage hospitals and drug stores to provide information directly to patients. The inventive for these pharmacies would be patient engagement; there is a greater demand and therefore greater profit which acts as an incentive to the pharmacy. This would allow the information of the individual and the history of purchases to be recorded—whether in the form of websites or memberships—which would encourage customers to come back and buy from the same drug store.* [Technology developer and policy expert]

> *Increase the awareness of data owners; create simpler consent form that is clear, concise and explicit.* [Technology developer]

Ethical Factors

Ethical barriers included a lack of awareness of data laws (eg, PDPA) and data privacy and security issues:

> *Patients are afraid of sharing their data because of the increased rate of cyberattacks on hospitals.* [Policy expert]

Data security discipline among users can mitigate data breaches and help overcome ethical barriers. Possible solutions include separating personal and professional computer use, using 2-factor authentication, and using password-protected log-in and log out:

> *To enable responsible data sharing in digital health, cybersecurity of the health information systems will have to be strengthened. The country will also need to come up with a clear structure to compensate victims whose data are compromised.* [Academic expert]

Organizational and Managerial Factors

Interviewees reported that there are regulations whereby management teams are unable to ensure whether data are secure and safe enough to share, which acts as a barrier at the organizational level (ie, there are certain workflows and policies that fall within a gray area, as mentioned previously). Bureaucracy was also mentioned as a barrier if considering the top-down approach, as changes in high-level leadership in the ministries and organizations caused delayed processing and changed regulations related to data sharing. Data ownership was reported to be a disputed area where health care providers and private hospitals were unwilling to share the collected data, considering it an asset for business profitability. The managerial mindset of organizations regarding data ownership, that is, the notion that if they have generated the data, the data belongs to them, causes unwillingness to share data with other organizations:

> *Mindset of care providers that just because the patients are willing to share their data, the data is now owned by the hospital. However, this is untrue as the hospitals are simply data collectors, and fundamentally, the Personal Data Protection Act (PDPA) states that the personal health information belongs to the patient.* [Technology developer and policy expert]

> *Different organisations (and even departments in the same organisation) do not want to share data as they believe that it is valuable and profitable.* [Academic expert]

Only a few interviewees provided solutions to some organizational barriers. One suggested that having an organizational protocol with the necessary steps to approve data sharing would enhance structure and increase trust:

> *Hospital administrators need to be trained on cybersecurity safeguards, data security, and be given access to resources to improve their digital infrastructures to enable digital transformation (i.e., transforming paper-based data to machine readable data).* [Academic expert]

Discussion

Principal Findings

Our systematic review identified 29 unique factors across the 7 domains associated with data sharing for AI in LMICs. These factors can significantly influence the ability of health care organizations to share data with AI developers and limit the implementation of AI solutions in health systems. Our case study in Thailand demonstrated the relevance of the domains, serving as an example of how the factors identified in the systematic review can be contextualized locally. Strategies to address barriers to data sharing in countries with nascent AI industries can consider the factors identified in this systematic review for policy development.

Two previous studies identified barriers to HIE adoption in LMICs [10] and sharing research and scientific data [11]. Our review is distinct from this previous work by focusing on factors associated with data sharing for AI in health care. Data used to develop AI require more granularity (eg, in the form of text or images). This influences the factors associated with data sharing. For example, data used to deploy AI often involve more sensitive information, such as biometric data, which can be used to identify individuals [44]. This means that data used in AI are often associated with more significant privacy concerns than administrative data, such as birth and death registries. Our study is the first to address specific factors related to data sharing for AI in LMICs, which is of critical importance given AI's potential to enable developing health systems to leapfrog global health inequalities [45].

XSL•FO
RenderX

The most relevant factors we identified were technical and infrastructural, policy based, or motivational. Many of the factors we identified in our review were also seen in 2 previous studies focusing on HIE adoption and barriers to sharing research and scientific data [10,11]. For example, van Panhuis et al [13] found that similar technical factors, such as lack of data standards, guidelines, and policies, were important barriers to sharing data in public health. In our study, infrastructural factors, such as limited access to information and communications technology, unreliable internet connectivity, frequent power shortages, equipment deficiencies, and software instability, were important factors hindering data storage and management. The unavailability of appropriate software and the persistence of handwritten records (often in regional languages) were particular challenges to data integration and sharing efforts. These findings were consistent with previous literature [46-49] and are also seen when data are shared for reasons other than AI, such as global health emergencies and disease outbreaks [50,51]. We found that limited data digitization is an important upstream barrier to downstream data sharing in LMICs. Furthermore, barriers at the political and policy level were significant limiting factors to data sharing for AI in health care. Previous studies have emphasized the need for data-sharing governance mechanisms to protect vulnerable populations in the global south [52-54]. Our results confirm earlier studies and suggest that developing clear policies and closing regulatory gaps can promote data sharing [10,46,48,55]. The motivational barriers we identified, including poor staff and management motivation, confirm previous results [56]. Public and staff education, a clear data-sharing incentive structure, and user-friendly software could improve staff motivation [48,57].

Many barriers identified in the systematic review were relevant to the Thai context. For example, limited staff time to collect data, a limited understanding of data's value, and low health literacy were important barriers in Thailand and the systematic review. Aljunid et al [47] previously reported that Thailand's fragmented financing schemes and service provision limit stakeholder cooperation in data sharing. Our findings concur that this health system fragmentation may hinder clinical and management staff from sharing data. Furthermore, stakeholders pointed to a lack of software standardization within the same organization and continued reliance on manual data management and paper-based EHRs. These findings differ from a previous qualitative study [58], where Thai stakeholders did not see technical challenges as a primary barrier to health care data sharing and instead placed greater weight on ethical concerns, such as informed consent and data control. However, Thai-specific literature [47,54] supports our findings that fragmented databases and software unavailability limit local health data sharing. Finally, we found that unclear data-sharing regulations and guidelines in Thailand, that is, complex and unclear policies and low applicability of international data standards—prevent health care stakeholders from sharing data. These findings are supported by earlier studies, emphasizing health data sharing in Thailand echoes the importance of establishing clear data management and sharing policies [54,55].

During interviews, stakeholders suggested several improvements to overcome barriers to sharing data. First, building a conducive digital ecosystem and having shared data input platforms for health facilities can ensure data uniformity and compatibility. Currently, similar initiatives are being undertaken by the Thai National Health Information Standards Development Centre under the Health System Research Institute of the Ministry of Public Health, Thailand. This organization develops and promotes national standards for health information systems, including data elements, codes, and terminologies, to ensure interoperability across health care organizations [59]. Singapore's National Electronic Health Record initiative is also an example of creating a unified health information system by standardizing data formats and terminologies for seamless data exchange across health care providers [60]. Second, developing predefined templates, easy-to-understand consent forms, and standardized guidelines for data sharing, intellectual property rights, and compensation for data breach victims can help Thailand overcome social-, ethical-, political-, and policy-level barriers at various levels. These measures will increase data owners' and health care professionals' awareness of data sharing and prevent misunderstandings of data sharing guidelines such as the PDPA. In addition, these steps will help developers create and validate transparent and mutually trustworthy data-sharing models across health facilities. Singapore's Advisory Guidelines for Key Concepts on PDPA can serve as a framework for Thailand, offering detailed guidance and examples to understand and interpret key terms and obligations in the PDPA [61]. The document provides illustrative examples of important PDPA terms, including what qualifies as "personal data," the concept of "controlling and owning one's personal data," and the "roles and obligations of data intermediaries." Third, training health care professionals such as hospital administrators, doctors, and care providers can improve the effectiveness of the aforementioned measures. Access to improved digital infrastructures and adequate training on cybersecurity safeguards will enable efficient and standardized data sharing.

Limitations

Although the study focused on a specific context, we have provided detailed descriptions of the settings and participants to allow readers to judge the applicability of the findings to other contexts. Studies included in our systematic review output were mostly from Africa and Asia. Therefore, results might not be generalizable to other regions. LMICs can use this study as a framework and leverage their individual health systems' barriers and strengths to devise local solutions for enhanced data sharing. While the classification of barriers and enablers across domains was done objectively and cross-checked by multiple authors, some factors identified were relevant to various framework categories. This is inevitable due to the complexity of health information systems, the various stakeholders involved, and their interrelationships. Furthermore, the response rate for our stakeholder interviews was low, reducing the sample's representativeness.

Conclusions

AI has the potential for LMICs to leapfrog health inequalities and deficiencies in health systems. Our review identified

XSL•FO
RenderX

significant barriers to sharing data for AI according to a comprehensive framework. In a localized case study, most barriers from the systematic review were relevant to the Thai context. In Thailand, data architecture, inconsistent data standards, complex and unclear policies, uneven distribution of financial resources across institutions, and confidentiality breaches were reported as important barriers to data sharing for AI. Together, our results provide insight into the challenges that LMICs' health systems face regarding data sharing for AI.

Acknowledgments

The authors want to thank the key stakeholder interviewees for their time and wisdom. They also want to thank their partners at the Office of National Higher Education Science Research and Innovation Policy Council for their careful review of the findings and helpful discussions. Finally, the authors thank the Association of Pacific Rim Universities and the United Nations Economic and Social Commission for Asia and the Pacific for their support of the project and Google for the generous funding.

Data Availability

The datasets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

AK, CB, and JT conceived the design of the study. AK and CB conducted the data extraction, data collection, data analysis, interpretation, and initial drafting of the manuscript. JT contributed to the verification of results. All authors contributed to the critical review and final approval of this manuscript.

Conflicts of Interest

JT is supported by the National University of Singapore Start-up grant, the tier 1 grant from the ministry of education, and the CS-IRG New Investigator Grant from the National Medical Research Council; has received consulting or speaker fees from Daiichi-Sankyo, Boehringer Ingelheim, Roche diagnostics, and Us2.ai; and owns patent US-10702247-B2 unrelated to this work. All other authors declare no other conflicts of interest.

Abstract

Background: Heart failure (HF) is a significant global health problem, affecting approximately 64.34 million people worldwide. The worsening of HF, also known as HF decompensation, is a major factor behind hospitalizations, contributing to substantial health care costs related to this condition.

Objective: This study aimed to explore the perspectives of health care professionals and data scientists regarding the relevance, challenges, and potential benefits of using machine learning (ML) models to predict decompensation from patients with HF.

Methods: A total of 13 individual, semistructured, qualitative interviews were conducted in Portugal between October 31, 2022, and June 23, 2023. Participants represented different health care specialties and were selected from different contexts and regions of the country to ensure a comprehensive understanding of the topic. Data saturation was determined as the point at which no new themes emerged from participants' perspectives, ensuring a sufficient sample size for analysis. The interviews were audio recorded, transcribed, and analyzed using MAXQDA (VERBI Software GmbH) through a reflexive thematic analysis. Two researchers (JS and AH) coded the interviews to ensure the consistency of the codes. Ethical approval was granted by the NOVA National School of Public Health ethics committee (CEENSP 14/2022), and informed consent was obtained from all participants.

Results: The participants recognized the potential benefits of ML models for early detection, risk stratification, and personalized care of patients with HF. The importance of selecting appropriate variables for model development, such as rapid weight gain and symptoms, was emphasized. The use of wearables for recording vital signs was considered necessary, although challenges related to adoption among older patients were identified. Risk stratification emerged as a crucial aspect, with the model needing to identify patients at high-, medium-, and low-risk levels. Participants emphasized the need for a response model involving health care professionals to validate ML-generated alerts and determine appropriate interventions.

Conclusions: The study's findings highlight ML models' potential benefits and challenges for predicting HF decompensation. The relevance of ML models for improving patient outcomes, reducing health care costs, and promoting patient engagement in disease management is highlighted. Adequate variable selection, risk stratification, and response models were identified as essential components for the effective implementation of ML models in health care. In addition, the study identified technical, regulatory and ethical, and adoption and acceptance challenges that need to be overcome for the successful integration of ML models into clinical workflows. Interpretation of the findings suggests that future research should focus on more extensive and diverse samples, incorporate the patient perspective, and explore the impact of ML models on patient outcomes and personalized care in HF management. Incorporation of this study's findings into practice is expected to contribute to developing and implementing ML-based predictive models that positively impact HF management.

KEYWORDS

heart failure; machine learning system; decompensation; qualitative research; cardiovascular diseases; heart failure management; interview

Introduction

Heart failure (HF) is a complex clinical syndrome characterized by frequent and rapid decompensation; even long-term, stable patients with HF might rapidly deteriorate in days or hours [1]. HF decompensation is a major cause of hospitalization in patients with HF, negatively influencing prognosis [1], representing the highest share of health care costs for this disease [2].

Several factors can precipitate HF decompensation, including respiratory infections, noncompliance with dietary recommendations or pharmacological treatment, and atrial fibrillation [2]. Early detection of HF decompensation is crucial to allow timely intervention and to prevent hospitalizations and increased morbidity [3].

Studies suggest that telemonitoring systems and predictive models for clinical support and patient empowerment may improve HF management [4]. Based on telemonitored data, artificial intelligence (AI) techniques have been increasingly used to predict and analyze HF decompensation events. AI and machine learning (ML) algorithms have the power to assimilate and integrate multidimensional, multimodal data and create accurate prediction models. The application of AI/ML algorithms could potentially improve workflow and outcomes for patients with HF due to the ever-growing data, particularly time series data gathered via remote monitoring [5]. Furthermore, there have been other health conditions in which AI models have been successfully developed for early detection and screening. A study published in the scientific journal *Nature* showcased a model that surpassed radiologists' performance in interpreting mammograms [6], while another study introduced an ML model that reliably predicts the onset of diabetes [7].

However, there is a limited understanding of health care professionals' perspectives on using such systems and the specific considerations necessary for designing an ML model to be integrated into clinical practice. To bridge this knowledge gap, we conducted a semistructured interview study involving health care professionals and data scientists with profound expertise in health care. The primary objective of this study was to explore their viewpoints concerning an ML system tailored for the early detection and management of HF decompensation. Additionally, this study sought to provide the experts' perceptions on developing crucial features in the ML system, identify potential implementation challenges, and establish design principles to enhance overall system efficiency and effectiveness.

Methods

Study Design

A qualitative research design was used, using individual semistructured interviews to explore the perspectives of health care professionals and data scientists regarding the relevance, challenges, and potential benefits of using ML models to predict decompensation in patients with HF.

Eligibility Criteria

Health care professionals working with patients with HF and data scientists with expertise in the health care field were considered eligible to participate in this study.

Recruitment Strategies

Participants were selected through intentional sampling to ensure the representation of diverse perspectives and expertise in HF and health care data management.

Potential participants were identified based on their expertise in the field. With prior authorization from the experts, key contacts from the researchers' network shared their email addresses with the primary researcher, facilitating direct communication.

The primary researcher emailed potential participants and invited them to a semistructured interview. This email included attachments to the interview guide and a consent form. The participants were required to provide written consent to participate in this study by signing the consent form.

Participants

A total of 13 participants, representing a diverse range of health care professionals and data science experts, were interviewed for this study. The participants recruited were primary care physicians (n=1), cardiologists (n=3), internal medicine physicians (n=3), nurses (n=3), and data scientists (n=3). The composition of this poll of experts aimed to capture the perspective of the health care professionals who usually provide care to patients with HF and the technical perspective of the data scientists. Geographically, participants were in different areas, with 2 participants based in the north of Portugal, 8 participants in the Lisbon area and its surroundings, 2 participants in the south, and 1 participant working outside of Portugal. The diversity of locations is especially relevant to guarantee the results are not biased by the local context.

The sample size of 13 participants was determined based on data saturation, where no new themes emerged from participants' perspectives, aligning with a recent systematic review's findings indicating that saturation can be achieved within a narrow range of interviews (9-17) in qualitative research [8].

XSL•FO
RenderX

Data Collection

The primary researcher conducted face-to-face and online semistructured interviews in Portuguese, using an interview guide (Multimedia Appendix 1) developed by the authors after the participants provided written informed consent to participate. All interviews were conducted in private rooms by a single researcher and were audio recorded to ensure accurate data capture.

The interview guide explored the participants' perspectives on an ML model for predicting HF decompensation. Open-ended questions were included in the interview guide, allowing participants to express their thoughts and opinions freely.

Before the formal data collection, an initial interview was conducted with an internal physician to test and adjust the interview guide, ensuring its relevance and appropriateness; this first interview was not included in the subsequent analysis.

Data Analysis

Each interview lasted, on average, 31 (range 15-48) minutes. The interviews were audio recorded, transcribed verbatim, and assessed for accuracy.

The participant's data were analyzed using interactive and inductive processes following a thematic analysis approach as proposed by Braun and Clarke [9], since the purpose of the research was explanatory and intended to generate new knowledge. The data analysis was conducted in the following phases: (1) familiarizing with the dataset, (2) generating initial codes, (3) searching for themes, (4) reviewing the themes, (5) defining and naming the themes, and (6) producing the report [9].

In the first phase, two authors engaged with the dataset by reviewing the interviews multiple times to understand the content's depth, identifying key expressions, and formulating and validating meanings through discussions. In the second phase, the MAXQDA (VERBI Software GmbH) was used to generate initial codes, allowing for simplified data analysis and management. Subsequently, codes were categorized into overarching themes.

During the third phase, the two authors (JS and AH) systematically identified and organized themes into clusters and categories. In the fourth phase, a third author (ARP) with expertise in qualitative research reviewed the findings to enhance the credibility of the analysis. The author provided feedback on the analytical process and the developing themes, facilitating their refinement.

In the fifth phase, the authors refined and defined the themes by re-examining the dataset and developing a comprehensive description of the themes. In the sixth phase, excerpts of the interview, derived from coding, were translated from Portuguese to English and further edited for clarity, resulting in the report of the analyzed dataset.

Researchers' Reflexivity

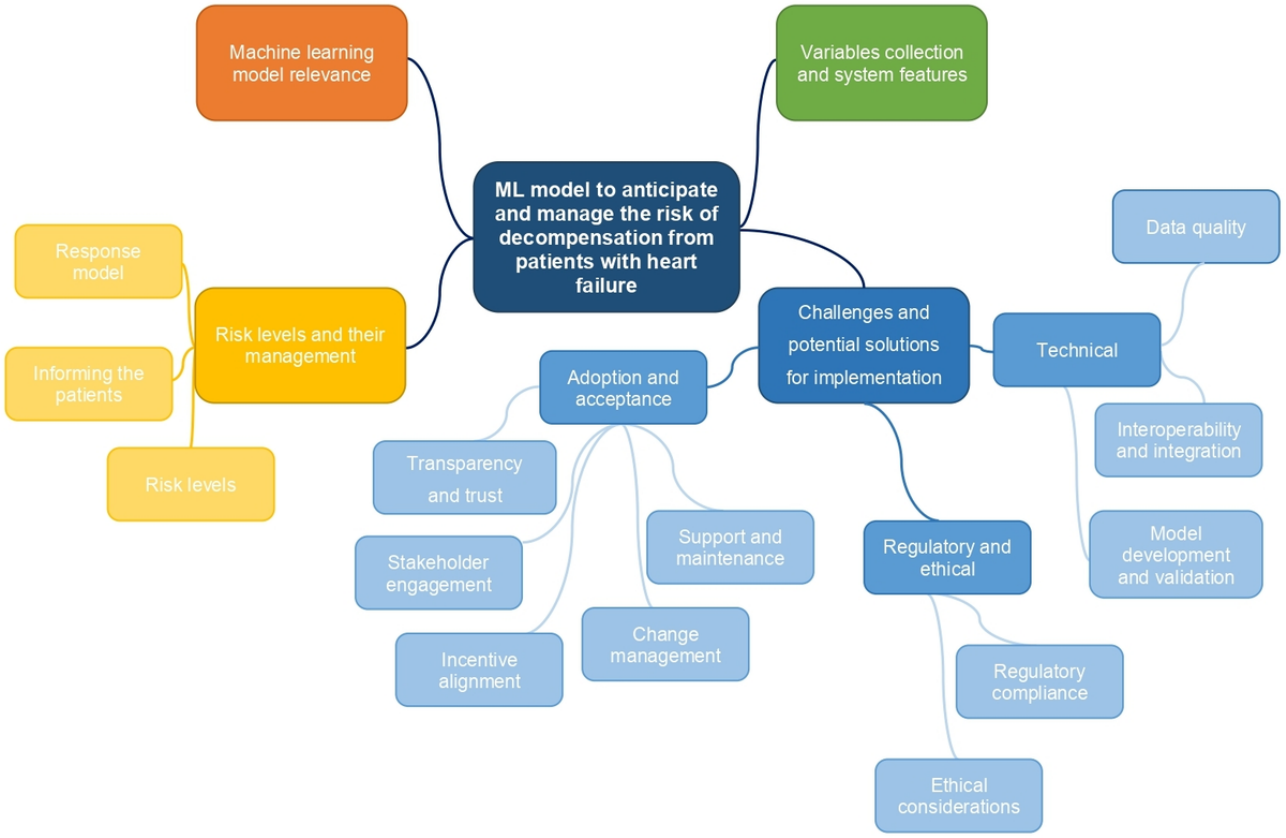
In reflexive thematic analysis, the researchers incorporate their knowledge and experiences into their analytical practice [10]. It is important to highlight that all the authors, as health care researchers, have engaged with patients diagnosed with chronic diseases, including HF, and are particularly focused on understanding how digital health can contribute to better management of these conditions. Therefore, our values and assumptions might have influenced the analysis produced. However, efforts were made to minimize this influence through rigorous data analysis and researchers' discussions.

Ethical Considerations

The research was conducted per the Helsinki Declaration (World Medical Association, 2018), and written informed consent was obtained from every participant. All data collected during the interviews were anonymized to ensure participant confidentiality. Only the primary researcher has access to the original recordings, which are securely stored and protected. To ensure anonymity, all participants were assigned unique codes, and personal identifiers were removed during data transcription to safeguard the privacy of participants. No participant received any type of compensation for taking part in this study. The study was approved by the NOVA National School of Public Health research ethics committee (CEENSP no 14/2022).

Results

Overview



Saturation was achieved with the seventh interview, and 6 participants were then interviewed to confirm thematic saturation. Four themes or categories emerged from the analysis: "Machine learning model relevance," "Variables collection and system features," "Risk levels and their management," and "Challenges and potential solutions for implementation."

Thematic Content

Subgroups and themes or categories identified in the analysis of health care professionals and data scientists' perspectives of an ML model to predict the risk of decompensation from patients diagnosed with HF are illustrated in Figure 1. Excerpts of the interview presented in the results were extracted from the coding analysis, and the themes and subgroups resulting from the qualitative coding are reported below.

XSL•FO
RenderX

Figure 1. Subgroups and themes or categories identified in the analysis. ML: machine learning.

ML Model Relevance

Most participants highlighted the potential benefits of using an ML model to predict decompensation from patients with HF. These benefits included identifying patients at risk of decompensation earlier, allowing for more personalized care, improving patient outcomes, and reducing health care costs.

> *Is a very relevant thing, and early detection of decompensation is something that allows for reducing the number of hospitalizations, which is fundamental. Not only for the patient's quality of life but also for the burden on the National Health Service.* [Cardiologist 2]

> *Regarding models in general, predictive models, I think they are well received by health professionals...There is a clear notion that we are evolving toward an increasingly personalized medicine. We also know that today, waiting for these changes that start as subclinical to become clinical so that professionals or patients then feel that they exist; we are losing, in quotes, time, where intervention could be done earlier and more deleterious outcomes could be avoided, which in the case of heart failure in particular, the one always intended to be achieved is to avoid hospitalizations. Since any additional hospitalization in these patients has a worse prognosis in the natural history of the disease, the earlier we can adjust therapy so that no decompensation of heart failure leads to hospitalization, not only from the individual's perspective but also from the institution's perspective, avoiding pressure on emergency services and hospitals in general.* [Internal medicine physician 2]

Participants also considered the model could contribute to better management of the disease by the patient.

> *For me, the great advantage of digital technology in heart failure, for health professionals, is that it allows us to start preventing hospitalizations earlier. I think that for the patient, even those who are more reluctant to adhere to therapy because in heart failure, therapeutic adherence is also a problem; it gives them a certain empowerment over the disease.....So, I think it's a win-win for both sides.* [Nurse 2]

Variables Collection and System Features

Participants discussed the importance of identifying the correct variables for the ML model. Some variables mentioned include rapid weight gain and symptoms such as tiredness, shortness of breath, and swelling of the ankles (see Textbox 1 for a complete list of variables). Participants noted that selecting variables should be evidence-based and consider the complexity of HF management.

> *Weight gain of more than 2kg in 3 days; increase the number of pillows, the patient who sleeps with one pillow to two or three, or to sleep sitting up; increased edema of the lower limbs; increased coughing at night; finally, a feeling of worsening tiredness for minor efforts.* [Internal medicine physician 1]

XSL•FO
RenderX

Textbox 1. List of variables mentioned by the participants.

- Patient characterization: sex, age, comorbidities, and previous hospitalizations
- Heart failure characterization: New York Heart Association Classification and left ventricular ejection fraction
- Vital signs: weight, height, systolic blood pressure, diastolic blood pressure, heart rate, and blood oxygen saturation
- Laboratory results: creatinine, glomerular filtration rate based on the chronic kidney disease epidemiology collaboration equation, hemoglobin, hematocrit, urea, N-terminal pro b-type natriuretic peptide (NT-Pro BNP), ferritin, sodium, potassium, iron (fix capacity, iron), saturation (from transferrin), natriuretic peptide (BNP), and iron
- Prescribed medication: furosemide, bisoprolol, dapagliflozin, spironolactone, sacubitril, valsartan, carvedilol, lisinopril, nebivolol, ramipril, perindopril, torsemide, enalapril, empagliflozin, captopril, eplerenone, propranolol, atenolol, timolol, trandolapril, fosinopril, metoprolol, and sotalol

The collection of vital signs through wearables was deemed relevant by the participants.

> *I think asking someone every day, and even if it's every week, to record their weight, blood pressure, and frequency is tough. I don't think that's feasible in the long run. So the simpler, the better, and there, the devices are clearly in the way.* [Internal medicine physician 3]

However, as HF is prevalent among older people, using such devices was considered a challenge by some interviewees.

> *Most people with HF are elderly, and the likelihood of using wearables will be low.* [Primary care physician 1]

Interviewers also highlighted the need to select the population to use these tools properly.

> *Telemonitoring has two secrets. One of them is, to be cost-effective, the population you choose; I don't think it's a technology applied to all patients.* [Cardiologist 1]

Risk Levels and Their Management

Risk Levels

Participants emphasized the importance of developing an ML model capable of stratifying patients into distinct risk levels (high, medium, and low risk of decompensation), considering the patient's HF journey stage. This approach would facilitate health care professionals to provide more targeted interventions.

> *The literature in cardiovascular patients structures patients into three levels, possibly four. Roughly speaking, therefore, that is low risk, moderate risk, high risk, and, in some situations, there is a very high or very high-risk level. In the case of heart failure, risk stratification will also depend on the type of patient, namely the stage of their heart failure journey.....three levels, roughly speaking, sounds good, I think it's interesting in your work that you can adjust this risk stratification also to the stage of the heart failure patient journey.* [Internal medicine physician 2]

Response Model

Several participants discussed the importance of having a response model to validate the alerts generated by the ML model. They noted that the validation process should involve a health care professional, such as a nurse or a physician, who could assess the patient's condition and determine the appropriate response.

> *On the first level, the ideal situation would be to activate a call from a specialist heart failure nurse who would help the patient identify what they are doing right and what they are doing wrong. At an intermediate level...the structure would be the equivalent of an open consultation, a day hospital...a medical team. They may go through a nursing assessment first while consulting with the heart failure medical team. In the red level, I think the medical team must be activated to help decide what is going on and how the patient will be assessed.* [Internal medicine physician 3]

Informing the Patients

Participants discussed the potential benefits and challenges of providing alerts to patients identified as high-risk by the ML model. They noted that alerts could help patients take proactive steps to manage their condition, but there were concerns about patient anxiety.

> *When the information is to be given to the patient, either because it is considered that it has to be given, or because the patient has asked for this information, it cannot just be "you have an alert," there has to be an explanation. There has to be an explanation and especially a recommendation of what to do next, because otherwise, it creates a level of anxiety, "you have a change in your oxygen (levels)" (alert) and that's it. It would be a bit distressing for anyone.* [Internal medicine physician 2]

Challenges and Potential Solutions for Implementation

The participants identified several challenges regarding implementing the ML model, along with suggestions to address the identified challenges. They can be grouped into the following categories.

Technical Challenges

Data Quality

Participants emphasized the importance of obtaining high-quality and reliable health care data for training accurate ML models. They noted that health care data can often be messy,

XSL•FO
RenderX

incomplete, or contain errors, posing challenges in data preprocessing and cleaning.

> *There are other issues, not only of having rich data set but also types of quality of data sets, trying to understand how that type of data was collected, how that data was treated, how they were coded. For example, whether ICD 10 or 11 (is used), how are the coding practices like, the standard practice in terms of coding...all of this is necessary to understand the rules inherent to the type of data we have.* [Data scientist 1]

Model Development and Validation

Participants highlighted that designing and developing ML models suitable for health care applications requires domain expertise. It involves selecting appropriate algorithms, fine-tuning models for accuracy, interpretability, and generalizability, and conducting robust testing for model validation.

Interoperability and Integration

The participants mentioned that integrating ML models into existing health care systems and workflows can be challenging. They pointed out issues related to interoperability, compatibility with different data formats and systems, and the need for seamless integration with electronic health records and other health care software.

> *All of this (defining which data to feed into an ML model, EHRs, prescription drugs) also influences the cardiac care...and of course...take into account that many of these systems do not talk to each other, so there is no interoperability of systems, and this makes it difficult from the outset. There is, therefore, work to do beyond quality (assurance) to make all the data talk to each other, trying to see how possible it is to go to the individual level, that is, what data do you have and how can you have as much information as possible at the individual level...But in any case, interoperability here will be very crucial for how fast you can have the data ready for the model, even before deciding which model will be the best for this type of function.* [Data scientist 2]

Regulatory and Ethical Challenges

Regulatory Compliance

Compliance with regulatory frameworks, such as the General Data Protection Regulation in the European Union, was identified as a significant challenge in implementing ML models in health care. Participants stressed the importance of adhering to legal and ethical guidelines regarding data use, consent, and transparency, mainly due to the sensitive nature of health care data, such as patient records. Ensuring patient privacy and data security while using ML models posed notable challenges.

> *Without a doubt, there is a need to ensure that there is some guarantee here in terms of privacy and data security; this becomes immediate when you are joining many sources of data.* [Data scientist 2]

Ethical Considerations

The participants emphasized the need to develop and deploy ML models with ethical considerations. They underscored the importance of avoiding bias, ensuring fairness and equity in health care outcomes, and maintaining transparency in decision-making processes.

> *The real bias is systemic and must be controlled. Other studies (demonstrate the impact of) minorities who were underrepresented; then obviously when calculating the scores, they were underestimated, and the system continued as it always has, leaving those people on the sidelines.* [Data scientist 1]

> *There is another important issue, which is the representativeness and inclusivity within the data set. Many problems have happened because of the type of data and the conclusions reached that sometimes are not fair, (known as) algorithm justice.* [Data scientist 1]

These aspects were identified as crucial for building trust among health care professionals and patients.

Adoption and Acceptance Challenges

Transparency and Trust

As referred before, participants highlighted the importance of transparency in the ML model to gain the trust of health care professionals and patients, favoring the choice of models that have higher explainability, which refers to a characteristic of an AI-driven system that allows understanding and interpretation of the decisions and predictions made by an AI system [11].

Ensuring transparency in the decision-making process was perceived as crucial to fostering trust among stakeholders, as it allows them to understand the underlying factors and reasoning behind the ML model's recommendations or predictions.

> *As you build a model, there is a need to keep those metrics (sensitivity, specificity, therefore, recall, precision, F-score, accuracy) in mind and to perform a primary assessment of those metrics. Another important part that has been talked about more in the last few years and will involve both patients and clinicians is the technical issue of explainability—the idea that AI models can't just be a black box. If we want some form of engagement, some participation from both doctors and patients, and especially trust at the health care system level, as patients and clinical decisions are involved, the system should be something that we have to be able to explain to both stakeholders and patients and doctors.* [Data scientist 1]

Stakeholder Engagement

Engaging health care professionals, including physicians, nurses, and administrators, in designing and implementing ML models was highlighted as essential for successful adoption. Participants stressed the significance of addressing their concerns, providing training, and demonstrating the benefits of ML models to gain their support and involvement.

XSL•FO
RenderX

> *I think our role has to be to encourage through the constant involvement of the professional in the development of the model and implementation, as well as the validation process and everything, but also to demonstrate how those models are not the panacea.* [Data scientist 2]

Change Management

Participants acknowledged that implementing ML models might change health care organizations' workflows, processes, and roles. Additionally, participants expressed concerns that ML models might create an increased workload for health care professionals. They emphasized the need for careful planning and allocation of resources to ensure that the integration of ML models into clinical workflows does not burden the health care workforce.

> *And the machine learning model was a part that, according to the set of information, whether it is from the electronic medical record, such as comorbidities, etc., whether it is collected daily, we have a model here that basically gives us alert levels, which can be, for example, three alert levels, low, medium, high, etc. and act only on those that are medium or high, so that we do not have too many false positives.* [Cardiologist 3]

Incentive Alignment

Participants raised the issue of financial incentives in health care, particularly the existing payment structure that often rewards hospitals based on the activity (number of admissions) rather than patient outcomes. They acknowledged that highly effective ML models capable of accurately predicting admissions might be challenging to implement due to misaligned incentives.

> *Today, the incentive system in virtually all health care systems is based on procedures, it is based on records made, compliance with a process defined as correct, or the number of surgeries or consultations carried out. So, that's how productivity is measured, and compensation is defined, and that is problematic because the system is conditioned to have a short-term perspective. For example, there is a development of a model that manages to reduce hospitalizations by 50%. But the hospital, like everywhere else in Portugal, only gets reimbursed for the number of hospitalized patients. And the more seriously ill the patients are, the more they may be paid. You run the risk that the hospital thinks your model is very good, but in terms of incentives gained, it doesn't make sense to be applied.* [Data scientist 3]

Support and Maintenance

Participants stressed the importance of having dedicated resources and personnel to provide ongoing support and address the doubts and concerns of health care professionals regarding the ML model.

In addition, the need for a designated team responsible for the maintenance and upkeep of the ML model was identified as crucial for ensuring its continuous performance, addressing any technical issues, and incorporating updates or improvements as needed.

> *We don't have medical information officers...for software. I published an article with colleagues about mental health professionals' perceptions of digital health tools, whether apps, websites, etc. One of the biggest problems was that the professionals did not know when to use these apps; they did not have guidelines or recognition from the societies and professional groups they belonged to. It was also noted that there was no contact and no use of those applications—when questioned about the support given by the tool developers, many participants either responded that they did not know or did not answer.* [Data scientist 3]

Discussion

Principal Findings

The findings of this study have several implications for the practical application of ML models in the early detection and management of HF decompensation. The identified themes and subgroups provide insights into critical considerations that health care professionals and data scientists consider relevant when developing and implementing ML models for predicting the risk of decompensation in patients with HF.

The participants recognized the potential benefits of using ML models for the early identification of patients at risk of decompensation, leading to improved patient outcomes and reduced health care costs, a notion that aligns with the findings from previous research [4,12-14].

The emphasis on the importance of early detection is particularly noteworthy, as it aligns with the evolving trend toward personalized care. The ability to intervene before subclinical changes become clinical can significantly impact patient outcomes, emphasizing the critical role of ML models in leading to timely intervention and avoiding hospitalizations [13,15]. This perception was echoed by health care professionals from various domains, that is, cardiologists, internal medicine physicians, and nurses.

The selection of appropriate variables is crucial for accurately predicting HF decompensation using ML models. The participants emphasized the importance of evidence-based variable selection and the consideration of the complexity of HF management. Variables such as rapid weight gain and reported symptoms such as orthopnea and swelling of lower limbs were mentioned as potentially relevant factors for inclusion in the ML models, which aligns with previous studies that identified these as significant predictors of cardiac decompensation events in patients with HF [13].

Furthermore, the use of wearables for collecting vital signs was seen as relevant, but the challenges related to adoption among older patients must be addressed. Additionally, the importance of adequate population selection to ensure cost-effectiveness was highlighted. These findings align with the current literature that acknowledges the potential benefits of the use of wearables but identifies a set of barriers that need to be addressed for

XSL•FO
RenderX

further implementation of these devices into clinical practice [16].

Participants highlighted the importance of ML models identifying different risk levels for patients with HF, considering the patient's HF journey stage [17,18]. By accurate risk stratification, health care professionals can prioritize their interventions and provide more targeted care to those at higher risk [19,20].

It was also identified the relevance of ML models being designed to provide risk stratification outputs that are easily interpretable and actionable by health care professionals. This may involve the development of user-friendly interfaces or decision support systems that show risk levels clearly and intuitively. This perspective aligns with the recognized need for interpretable ML models, as interpretable models enable users to examine, comprehend, troubleshoot, and potentially enhance ML systems. By clarifying the logic behind predictions, interpretable ML systems provide users with justifications for accepting or rejecting predictions and recommendations [21].

Additionally, the participants emphasized the need for a response model to validate the alerts generated by the ML models. The involvement of health care professionals, such as nurses or physicians, in assessing patients' conditions and determining appropriate responses is crucial for effectively managing decompensation.

The study identified several challenges in implementing ML models for predicting HF decompensation and potential solutions. These can be grouped into three categories: technical, regulatory and ethical, and adoption and acceptance challenges, which are aligned with this literature [22,23].

The importance of high-quality and reliable health care data was recognized, with an acknowledgment of the complexities involved in data preprocessing and cleaning, as already addressed in the literature [24]. The need for domain expertise in designing and developing ML models was emphasized, along with challenges related to interoperability and integration with existing health care systems. The existence of proposed frameworks to guide the development and integration of ML models in health care, such as the one developed by Assadi et al [25], frames the findings of this study within this literature.

Compliance with regulatory frameworks, particularly regarding data protection, was identified as a significant challenge. Ethical considerations, including avoiding bias and ensuring fairness and transparency, were highlighted as crucial for building trust among health care professionals and patients, which is in line with what is stated by the European Parliament [26] and recent literature [27].

Transparency and trust were emphasized as critical factors for the successful adoption of ML models [28]. Stakeholder engagement, particularly involving health care professionals, was recognized as essential, along with considerations for change management to avoid disrupting existing workflows, which had already been identified in a similar study [29].

The presence of misaligned financial incentives within the health care system was recognized as a potential obstacle to the integration of ML models. This underscores the importance of establishing a successful reimbursement strategy to align interests among stakeholders, thereby guiding the application of value-based AI in health care, as payment strategies impact utilization, cost, and quality of care across the clinical use cases for AI [30]. A recent paper in *NPJ Digital Medicine* expands into the discussion on the appropriate method of reimbursement for AI systems in health care [31].

The importance of ongoing support, addressing the concerns of health care professionals, and having a dedicated team for the maintenance of the ML model was also recognized as relevant for successfully implementing these models into practice [32].

In general, this study's findings emphasize the potential of ML models in improving the early detection and management of HF decompensation. Considering the implications for practice outlined above, this study is expected to contribute to developing and implementing ML models that positively impact patient outcomes, health care costs [33], and the delivery of personalized care in HF management.

In addition, this study highlighted the synergy between the perspectives of health care professionals and data scientists not only enhances the accuracy and effectiveness of ML models but also fosters a holistic approach that considers both the clinical and technical facets, promoting the successful integration of these models into health care practices. From the health care professionals' perspective, there is a strong emphasis on evidence-based variable selection, drawing on clinical expertise to identify relevant indicators for predicting decompensation in patients with HF. Their insights into the nuanced aspects of patient care, risk stratification, and the practical implications of ML models contribute crucially to the model's alignment with real-world clinical workflows.

On the other side, data scientists bring technical expertise to the table, highlighting challenges related to data quality, model development, and interoperability. They underscore the importance of domain knowledge in ML model development, recognizing the complexities involved in designing accurate, interpretable, and generalizable models for health care applications. Data scientists also stress ethical considerations, algorithmic fairness, and the need for transparent decision-making processes, emphasizing the broader societal impact of ML models in health care. In short, close collaboration between these two professional domains is paramount [25].

Future research should address these concerns and evaluate the effectiveness of ML models in improving patient outcomes.

Strengths and Limitations

The findings of this study provide relevant insights into health care professionals' and data scientists' perspectives on using ML models for predicting HF decompensation. However, it is essential to consider the strengths and limitations of the study methodology and findings.

Regarding the strengths, using a qualitative research design allowed for an in-depth exploration of health care professionals' and data scientists' perspectives on ML models for HF decompensation prediction. The semistructured interviews

XSL•FO
RenderX

provided rich and detailed data, enabling a comprehensive analysis of themes and subgroups. In addition, the thematic analysis approach used in this study, following the guidelines proposed by Braun and Clarke [9], provided a systematic and rigorous process for analyzing the data. Two researchers were involved in the analysis process, enhancing the credibility and reliability of the findings.

The diverse range of health care professionals, including a primary care physician, cardiologists, internal medicine physicians, nurses, and data scientists, and the high level of experience from the participants are also strengths of the study, enhancing the validity and generalizability of the findings. In addition, the fact that participants were from different contexts and regions across the country is also a positive point, reducing the influence of the local context on the overall results.

The determination of data saturation, where no new themes emerged from participants' perspectives, ensured sufficient sample size was achieved to capture the breadth and depth of the participants' experiences and opinions.

Considering the study's limitations, we emphasize that, although data saturation was reached, the sample size of 13 participants may be considered relatively small. The findings may not fully represent the perspectives of all health care professionals involved in HF management and data scientists' considerations on this specific issue.

In addition, data were collected solely through semistructured interviews. While interviews provide rich qualitative data, multiple data collection methods, such as surveys or observation, could have provided a more comprehensive understanding of the topic.

As with any qualitative study, there is a potential for researcher bias during data collection, analysis, and interpretation. The researchers' perspective may have influenced the findings. However, efforts were made to minimize this influence through rigorous data analysis and researchers' discussions.

In addition, another significant limitation of this study is the potential loss of information during the translation process of the interviews from Portuguese to English. Language translation can be complex, and nuances, cultural references, and contextual information may not always be accurately expressed in the translated version. This could lead to the loss of relevant insights and subtle meanings expressed by the participants in their original language. To mitigate this limitation, cross-validation of translations and back-translation were used to ensure the accuracy of the translated data.

Furthermore, the patients' perspectives were not included in this study. Incorporating patient viewpoints would have provided a more holistic understanding of the potential benefits and challenges associated with ML models for HF decompensation prediction.

Future research should address these limitations by including more extensive and diverse samples, incorporating multiple data collection methods, and considering patients' perspectives.

Conclusions

This study explored health care professionals and data scientists' perspectives on using ML models to predict HF decompensation. The findings provide important insights into the potential benefits, challenges, and considerations associated with implementing ML models in HF management.

The study highlighted several key themes, including the relevance of ML models in identifying patients at risk of decompensation earlier, the importance of selecting appropriate variables for model development, the need for risk stratification and response models, and the challenges and potential solutions for implementing ML models in health care settings. These findings have implications for practice in HF management and the development of effective ML-based predictive models.

Future research should address the limitations of this study, such as expanding the sample size and including patients' viewpoints. Additional research areas include evaluating ML models' impact on patient outcomes, health care costs, and the delivery of personalized care.

The incorporation of this study's findings into practice is expected to contribute to the development and implementation of ML models that can potentially improve the early detection and management of HF decompensation, enhancing patient outcomes and reducing health care costs.

Acknowledgments

The authors are grateful to Vanessa Nicolau and Isabel Andrade for their support and suggestions. Special thanks to all the health care professionals and data scientists who participated in this study. This publication was funded by Fundação Ciência e Tecnologia, IP national support through the Comprehensive Health Research Center (UIDP/04923/2020).

Data Availability

The datasets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

JS collected the data. JS and AH analyzed and interpreted the data. JS wrote the original draft of the manuscript. ARP provided comprehensive feedback during an extensive review of the manuscript and actively participated in discussions about the findings. RS and TM revised the manuscript. All authors contributed to reviewing and editing the manuscript.

Abstract

Background: Patient organizations (POs) are an integral part of the health care landscape, serving as advocates and support systems for patients and their families. As the digitalization of health care accelerates, POs are challenged to adapt their diverse roles to digital formats. However, the extent and form of POs' digital adaptation and the challenges POs encounter in their digital transformation remain unexplored.

Objective: This study aims to investigate the digital transformation processes within POs. We examined the types of digital activities and processes implemented, people involved in respective tasks, challenges encountered, and attitudes toward the digitalization of POs.

Methods: The study was carried out by the multicenter interdisciplinary research network Pandora. We adopted a qualitative exploratory approach by conducting 37 semistructured interviews and 2 focus groups with representatives and members of POs in Germany. Results were obtained using a deductive-inductive approach based on a qualitative content analysis. Methods and results were reported in accordance with the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist.

Results: POs primarily apply basic digital tools to engage in communication, health education, and information dissemination. Some also develop specific mobile apps and collect health data through patient registries. Volunteers cover a considerable part of the workload. Sometimes, POs collaborate with external partners, such as health professionals or other nonprofit organizations. Furthermore, many (13/46, 28%) interviewees referred to the importance of involving members in digitalization efforts to better meet their needs. However, they described the actual practices used to involve members in, for example, developing digital services as limited, passive, or implicit. When evaluating digital transformation processes, representatives and members of POs expressed generally positive attitudes and acknowledged their potential to improve the accessibility of support services, management efficiency, and outreach. Still, resource constraints; the complexity of digital initiatives; and accessibility issues for certain demographic groups, especially older persons, were frequently mentioned as challenges. Several (15/46, 33%) interviewees highlighted POs' increasing responsibility to support their members' digital competencies and digital health literacy.

Conclusions: POs are actively involved in the digital transformation of health services. To navigate challenges and further shape and sustain digital activities and processes, POs may benefit from governance frameworks, that is, a clear plan outlining with whom, how, and with what objectives digital projects are being realized. Support from public, scientific, and policy institutions to enhance the process through training, mentorship, and fostering collaborative networks seems warranted.

Introduction

Background

The digital transformation of health care is an ongoing process in which health care–related services, such as types of care, diagnostic methods, and health information, are being digitalized [1-3]. The degree of digitalization varies considerably between different health care organizations and health sectors, and this gap has widened during the COVID-19 pandemic. This is due to, inter alia, the available resources and organizational structures, the degree of digital literacy of those responsible for implementing digitalization, and attitudes toward digital services [4,5]. Some institutional actors within the health care system, such as health insurance companies, ask individuals to contribute to the digital transformation and develop their own digital literacy.

It has been argued that the development of individual skills and attitudes toward digital transformation requires health care institutions to foster comprehensive governance frameworks that specify necessary goals, needs, and methods [3]. Furthermore, an individual's health is typically not managed by a single health care professional but rather involves multiple entities. To make this possible, these institutions need to provide the necessary resources and define the appropriate levels of contribution and literacy [3]. Overall, digital transformation requires more collective efforts across the health care sector to counter the uneven degrees of digital transformation [5].

Alongside primary care services, patient organizations (POs) are now recognized as key health advocates, providing vital support to patients, people with chronic conditions, and their families. While varying in size and scope, all POs aim to empower individuals to better manage their condition, for example, by providing health information and self-management resources [6,7]. Previous research shows that POs represent patient voices in health care and health care policy making by developing new forms of collaboration [8-10] and research facilitators and partners [11,12]. In fact, for countries such as the United Kingdom, the Netherlands, Sweden, and Germany, POs are now one of the central contributors to health care research, for example, when their members contribute to the planning and implementation of study projects. The main domain in which this takes place is rare disease research [13,14].

Today, POs face the need to join in the digital transformation of society and the medical field specifically [15]. Furthermore, POs face the challenges associated with shifting to digitalized work processes, for example, the search for appropriate resources. PO-specific challenges, such as the proportion of susceptible and older people who seek help from POs [16-18], add to these demands.

Objectives

To assist POs in shaping their own digital transformation, a better understanding of current practices, opportunities, and potential barriers is needed, which is, to the best of our understanding, currently largely lacking [12]. Hence, this study aimed to explore the current state of digital transformation in German POs. We aimed to do so by answering four specific research questions (RQs):

1. Which digital projects and services do POs currently implement? (RQ 1)
2. Who are the individuals and institutional actors involved in the process of planning and implementing digital projects and activities? (RQ 2)
3. To what extent and how are PO members involved in digitalization efforts? (RQ 3)
4. Which experiences with and attitudes vis-à-vis digitalization in POs do representatives and members express? (RQ 4)

Methods

Study Design and Context

This study was conducted as part of the multicenter research network Pandora [19]. Pandora investigates how POs contribute to the digital health transformation, shape their own digital practices, and address the challenges they face therein [20]. For this study, the 3 study sites pursued distinct, although related, objectives within the same overarching RQs defined by the aim of Pandora. Digitalization practices in POs were explored via semistructured interviews and focus groups. An exploratory design was chosen, as these practices have rarely been investigated so far. We used the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist to report our methodology (Multimedia Appendix 1) [21].

Theoretical Foundation

Overview

To determine the scope and contents of this study, we narratively summarized current insights related to the roles and tasks of POs nationally and internationally. We used this understanding for our own investigation of the digital transformation within these organizations, that is, to derive broad content-wise foci. We chose this strategy as there has been no qualitative study on the digitalization practices in PO. The available evidence on the *ways of working* of PO centers on 3 main pillars.

Tasks and Governance Processes

POs' routine daily tasks and responsibilities have been described as centering on 4 main aspects: policy development and advocacy (eg, POs represent patient interests vis-à-vis political decision makers), empowerment and education (eg, POs develop and deliver health information on all kinds of chronic and acute health conditions), peer support (eg, POs conduct self-management courses to foster individuals' coping with chronic diseases), and research (eg, POs collect and provide individual health data from their members for use by clinical researchers) [15]. More generally, previous studies have concluded that, with the evolving existence, role, and scope of work domains of POs, they increasingly prioritize professionalization, such as creating professional management and organizational structures [8].

Actor and Member Involvement

Given the breadth of tasks and responsibilities of POs, their efforts to professionalize services and structures and the

XSL•FO
RenderX

continuous need for sufficient personnel, technical, administrative, and financial resources, they need to engage in collaboration with other stakeholders [10,22]. Herein, POs not only engage with institutions and organizations but also seek to promote exchange with and involvement of their direct members. To date, this has been most evident in relation to research: POs not only act as intermediaries between research and patients or target groups but also, for example, train their members without a scientific educational background, to become active research partners [12,23].

Principles and Values Underlying the Digital Work of POs

So far, the roles and activities attributed to POs, such as competing with other health care stakeholders for resources, using support from industry to develop and maintain their own services, and advocating for patients' interests, have been described in terms of being directly or indirectly related to ethical aspects [18,24]. For example, POs need to be transparent regarding their partners; they need to balance individual protection and autonomy with collective responsibilities, such as in research advances; and they need to handle rapidly increasing amounts of patient data. However, the distinct challenges and ways in which POs go about their digital transformation have not been studied.

Target Group

To explore the digital transformation in POs, we invited representatives and members of POs in Germany to participate in this study. Except for the recruitment, no previous relationships with the target group existed. We defined representatives as those persons who work full time, part time, or voluntarily for a PO and are involved in leadership roles. Being affected by a chronic illness or disability was not a requirement to be recognized as a PO representative. PO members are individuals affected by the disease or disability that the PO they are registered with advocates for. It was inconsequential whether they were involved in the PO's work as long as they were not in a leadership role. We did not include professionals, such as medical staff or clinical researchers. Regarding the sampling procedure, we aimed to include PO representatives and PO members in equal shares. Furthermore, we aimed to approach numerous POs (refer to the Recruitment Strategy section) to increase diversity in terms of geographic location, size, and the specific health conditions or issues they represent. Each study site recruited participants until these criteria were sufficiently met, and no new topics were mentioned by the interviewees.

Recruitment Strategy

We first conducted a manual web-based search and a comprehensive review of German POs' umbrella organizations and their member organizations. These findings were then merged into a single list of German POs. As part of this process, we screened the POs' websites for clear indications of involvement in digital activities beyond merely having a website. POs that did not meet our criteria were excluded, as we focused on organizations where digital transformation processes were already underway, allowing us to explore ongoing practices and experiences in more detail. The final list contained 96 organizations, which were included in a purposive recruitment process at each study center. This included sending invitations by email, making follow-up calls if there was no response to the initial approach, forwarding the invitation to PO members via the POs' channels of communication, and approaching PO members directly via the Pandora advisory board.

Data Collection

Qualitative data collection was conducted from October 2022 to April 2023 mainly through individual telephone interviews and complemented by 2 web-based focus groups with PO representatives, the latter to increase practicability for the interviewees (S Wallraf, SK, and HJVGS). All junior and senior research fellows had a background in public health or medical ethics. To develop the semistructured interview guideline, we drafted headlines, ie, main topics according to the literature-based conceptualization of POs outlined earlier in the first step. Then, we added concrete questions for each topic and added new aspects where necessary, that is, to establish the focus on digitalization. While the interview guidelines varied slightly per study site, each included three common sections: (1) general aspects related to the level and relevance of digitalization in the respective PO (eg, digital governance, digital activities, and involved actors); (2) perceived opportunities and challenges of digital technologies (ie, appraisal of principles and values); and (3) the digital transformation of the German health care system (eg, digital governance and involved actors; Multimedia Appendix 2).

During the interviews, we focused on understanding how and in which areas such processes take place. This approach allowed us to capture a range of digitalization practices and to identify patterns of digital activity, ensuring a comprehensive understanding of digitalization. Specific technologies were discussed when mentioned by the interviewees. As the third step in the development of the interview guideline, we gathered feedback on the contents and wording of the draft from the Pandora patient advisory board (n=4). Fourth, we pretested the preliminary interview guidelines with representatives of the target group (study center 1: n=2, 50%; study center 2: n=1, 25%; and study center 3: n=1, 25%). Adjustments were made to the number of questions asked, the interview length, the wording of questions to further adapt them to the target group, and the sequencing of topics. At the beginning of the interviews, for which only the researcher and the participants were present, we provided general information on the researchers' role in the study without mentioning individual characteristics. We did not conduct repeat interviews and used field notes to structure them.

Data Analysis

Each audio file was transcribed verbatim to ensure the accuracy of the statements, pseudonymized, and then exported for analysis in MAXQDA 22 (VERBI Software GmbH). To generate our findings, we conducted a qualitative content analysis based on the steps described by Kuckartz [25].

First, we deductively derived the initial main categories for analysis based on our interview guidelines and agreed on these categories among the coauthors. Second, we coded

XSL•FO
RenderX

approximately 10% (4/39) of the manuscripts to test the suitability of the main categories. Third, we compared the results of this test phase and further developed and refined the coding system until the main authors agreed (S Wallraf, SK, HJVGS, and JL); refer to the Results section for an overview of the main categories and subcategories. Fourth, we analyzed all remaining manuscripts with the final version of the codebook (S Wallraf, SK, and HJVGS). For this analysis, we used consensual coding; that is, the main person coding discussed any uncertainties with one of the coauthors based on the definitions established for each category in the codebook.

Fifth, once the process of applying the main codes to all manuscripts was complete, we inductively derived subcategories within each main category by screening each code within the main categories to further concretize the content.

Sixth, we added frequencies to each subcategory based on the individual mentions of each aspect to gain an overview of the weight of each aspect mentioned by our participants.

After completing the first full version of the analysis, we presented summaries of the preliminary findings for each main category to the senior Pandora project staff not involved in the data analysis for feedback and interpretation of the findings. Furthermore, the coded segments in the transcripts were peer checked for correct interpretation by those authors who performed the analysis (HJVGS, JL, SK, and S Wallraf) when refining the coding system and during the actual analysis.

Ethical Considerations

Our study adheres to the Declaration of Helsinki, and ethics approval was obtained from the ethics committees of each study center (project 1: 11_6_22_University Medical Center Göttingen and 2022_20_University of Applied Sciences Hamburg; project 2: 10395_BO_K_2022; and project 3: 11_6_22_University Medical Center Göttingen). All participants consented to their participation before data collection and were given the option to opt out. Participants received no financial compensation. All data were pseudonymized. We did not collect patient data or information.

Results

Participant Characteristics

We interviewed 46 participants (n=26, 57% female individuals and n=20, 43% male individuals) who were either a member (n=26, 57%) or a representative, that is, staff (n=20, 43%) of a PO (Table 1).

The mean duration of interviews was 71 (SD 13.7) minutes, and focus groups lasted for 124 minutes. Most (17/46, 37%) interviewees were aged 45 to 59 years, followed by 15 (33%) participants aged ≥60 years. Interviewees often reported having completed secondary (7/46, 15%) or tertiary (32/46, 70%) education, equivalent to a high school or university degree, respectively. The POs, most (18/19, 95%) of them acting at a national level, involved were diverse in size, with 21% (4/19) acting as umbrella organizations (Table 2).

The main themes that were addressed included digital activities (RQ 1), actors involved in POs' digital transformation (RQ 2), participatory approaches to digital transformation (RQ 3), and current attitudes toward POs' digital efforts (RQ 4). Overall, POs engaged in a range of digital activities with distinct aims; relied on and engaged in collaboration with volunteers and other institutions to cover the workload; and faced considerable technical, conceptual, and motivational hurdles along the way.

[a]N/A: not available.

RQ 1: Digital Activities of POs

The analysis of our interviews and focus groups resulted in 4 primary areas where POs engaged in digital activities: communication, administration, health education, and health research.

Subtheme 1.1: Digital Communication

POs mostly used basic communication tools (38/46, 83%), including email, websites, videoconferencing, instant messaging services, and social media, to internally communicate with their members, facilitate communication among members, and externally engage with the wider public (refer to subtheme 1.1 in Table 3).

XSL•FO
RenderX

Table 3. Main themes and subthemes mentioned by research participants.

Main theme and subtheme	Example quotes
Digital activities of POs[a]	
1.1. Digital communication	"Internally,... we started with Zoom and now use Teams for communication. We also use WhatsApp for quick coordination and brief information flows, for example with our self-help group leaders or within the board.... Last year, we started using Office 365 with the goal of working centrally through Teams in the future and using Teams groups, so that, for instance, our treasurer has everything she needs available via Teams. The board can also do its work, and when we collaborate with our partners, we can organize joint projects there."
1.2. Digital administration	"We now have a membership management system, which is also a program where you can fill in all the member data, including account data and so on. We can now also see online who is affected."
1.3. Digital health education	"I know from the PO that they had many offers, especially during the pandemic, where doctors or therapists gave a short lecture on some topic, and where you had the opportunity to submit questions in advance, which were then discussed via the computer."
1.4. Digital health research	"I think we are opening up many things with the register that can go more in the direction of digitalization of care.... So we actually developed this as a hybrid of outpatient clinic, software and register software. This means that the doctor can see everything you enter directly. And also graphically... it looks a bit as if it had at least once swum past Apple."
PO's digital (collaboration) actors	
2.1. POs as independent actors	"This means that I drive forward all digitalization projects within the organization, for example the connection of a new CM system, which was a very large project, or the relaunch of a new website.... I work full-time in our organization and collaborate with many volunteers in the digitalization department."
2.2. Support from volunteers and external partners	"Our homepage is now maintained voluntarily by a member. Whether that's good or bad, I'll leave that for now. Our Instagram is also managed by a member. Neither of them are on the board. The fact that [it] exists at all was also [their own initiative]."
2.3. Public and private financial assistance	"The pharmaceutical company even approached us and offered us this sponsoring membership, and for us it is simply a blessing that we can cover our fixed costs... with it."
Involvement of PO members	
3.1. Motivations to establish and sustain involvement	"It is actually the case that digitalization processes should actually be driven from the bottom up."
3.2. Types and intensity of involvement	"... It's not always easy, there's a lot of tokenism at both national and international level that you involve patients because there may be funding criteria that require it or because it looks good. And that they are not actually taken seriously.... Of course, we are also involved from time to time when it comes to consultation or consultative processes...."
3.3. Requirements	"So what can ultimately diminish the motivation to get involved is if you keep making suggestions that are ultimately not taken into account. I mean, there can certainly be good reasons for this, but if, yes, if you have the feeling that nothing is being taken on board, then I think that would probably have a negative effect."
Attitudes toward digitalization	
4.1. Accelerating management, outreach, and communication	"Young families have also joined us in the meantime.... Of course, that is also a great advantage of digitalization. You can simply put information that is very important online immediately."
4.2. Simplifying access to PO support services	"I thought that was great because it's also a good opportunity for people who don't have the opportunity to travel that far to go somewhere to take part. People who were previously left out somewhere."
4.3. Supporting health research	"Yes, the main reason is because I find it useful for myself and for my treatment, but of course I would like to contribute to making this kind of research possible."
4.4. Ineffective and resource-intensive activities	"[If you introduce digital applications] in healthcare, then... they have to generate added value or have a higher benefit than what has been realized in the previous analog processes.... And this has been almost nonexistent up to now, apart from perhaps the possibility of booking an appointment with a doctor from your computer at home...."
4.5. Challenging personal interaction and access	"And of course there's always the point that we exclude some people who don't have access to the app. Because they simply can't cope with it or are somehow very skeptical about digital. Or because they don't have the means. Yes, those are all things like that."
4.6. Requiring additional efforts	"Financing is a big issue. So where do I get the financing, who takes care of it and so on, I'm busy with all my hands keeping my organization running, I can't write to any foundations, so I say there is money but you have to... know where to get it and... we don't have the manpower at the moment."

XSL•FO
RenderX

Main theme and subtheme	Example quotes
4.7. Encouraging ambivalence	"Well, I think it's a development that probably can't be stopped, because it's happening in many areas now. So as I said, it depends. Sometimes it's helpful. Sometimes, I think, you can do without it. And my big concern is data security."

[a]PO: patient organization.

The aforementioned tools are used by almost all POs, regardless of their size and other digital activities, although not every PO uses all of them combined. In addition, some POs have developed or are developing their own apps or platforms to further support these communication activities. Social media platforms, such as Facebook and Instagram (Meta Platforms, Inc), as well as YouTube (Google LLC) allow POs, for example, to reach a younger and wider audience and disseminate information about the various health care or disease topics they address. While Facebook and Instagram appeared to be relatively established ways of external communication, our interviewees mentioned TikTok (ByteDance) almost never (1/46, 2%), despite the platform's growing reach. PO members used social media platforms to communicate among themselves. However, 1 (2%) interviewee indicated that their organization does not allow WhatsApp (Meta Platforms, Inc) as a formal channel of communication due to considerations regarding data security. Rather, it is used by members on their own initiative and responsibility. Furthermore, POs have established digital or hybrid meetings to supplement or even replace in-person meetings, overcoming contact restrictions as a consequence of the COVID-19 pandemic, accommodating the disabilities of PO members, and appealing to a wider audience from distinct, that is, more distant places (13/46, 28%).

Subtheme 1.2: Digital Administration

Some (9/46, 20%) POs used digital technologies to adapt their administrative and management work (subtheme 1.2 in Table 3). This included managing membership databases digitally, handling bookkeeping via digital systems, generating digital annual financial reports, providing members with digital versions of annual reports, and using collaborative project management software to organize and coordinate their work. Our interview data did not indicate a specific relationship between the use of digital technologies for administrative purposes and the size of the PO. In that sense, digital administration efforts, such as digital membership management, were also found in smaller POs, even if only in a few cases.

Subtheme 1.3: Digital Health Education

The increasingly digitalized world entails a new responsibility of POs as digital health educators (22/46, 48%; subtheme 1.3 in Table 3). As repeatedly stated by our interviewees, many PO members had difficulties in effectively searching for and applying health information or using available digital tools to their advantage. Thus, POs followed at least 4 distinct ways to educate their members in the use of digital technologies as part of their goal to support disease management, improve their digital health literacy, and empower them to take part in the digitalized world. First, POs provided digital health information, primarily via their website (11/46, 24%) but also via an app (4/46, 9%), podcast (2/46, 4%), or in an audiovisual format (2/46, 4%), for instance, via YouTube. Second, they organized digital meetings, events, and conferences to inform members about and engage them in the discussions of recent health care topics, particularly those specific to the disease that a respective PO dealt with (7/46, 15%). Third, POs sometimes offered digital training programs and support groups for their members to help them cope with a disease, for instance, through physical exercises and self-management (5/46, 11%). Fourth, they provided education and training on the use of various digital tools as such to enable them to benefit from such services (8/46, 17%). The overall variety of educational services offered to members tended to vary with the size of the PO, with larger POs generally offering a greater range of services.

Subtheme 1.4: Digital Health Research

Besides providing digital communication and health education as well as digitalizing their administrative work, some POs have started to develop digital technologies, such as mobile health apps (11/46, 24%) and data registries (12/46, 26%; subtheme 1.4 in Table 3). POs did so either on their own or in cooperation with other stakeholders, such as public research institutes and private companies. Through data registries, POs collected health data from their members to facilitate medical and health care services research. Here, they either forwarded such individual health data to research institutions for further investigation or established mutual research cooperations to work together on the data. Remarkably, some of them also applied these registries to conduct their own research projects, that is, without including an external research partner. The management of a data registry appeared to be related to whether the POs had a specific interest in engaging in research rather than their size and resources.

RQ 2: Actors Involved in Planning and Implementing POs' Digital Activities

Subtheme 2.1: POs as Independent Actors

When sufficient personnel and financial resources were available, POs advanced their digital transformation independently by permanently employed staff, that is, individuals with either professional, technical, or media expertise (9/46, 20%). These individuals employed by POs were primarily responsible for planning and implementing activities such as digital projects, services, and strategies (subtheme 2.1 in Table 3). Furthermore, it happened that individual organizations relied on regional or national associations of POs (ie, umbrella organizations) that developed technologies for them (9/46, 20%). For example, the German Rheumatism Association developed an app that each partner of that umbrella organization on the regional level could make use of.

Subtheme 2.2: Support From Volunteers and External Partners

Owing to a lack of expertise within the POs to develop digital services themselves, interviewees frequently mentioned that

XSL•FO
RenderX

they established collaborations with volunteers among their members (13/46, 28%) and external partners (10/46, 22%). Within their own ranks, POs relied on members who, based on their professional background or private interest, had expertise in digital service development and delivery (subtheme 2.2). This support ranged from assisting with short-term tasks to taking full responsibility for certain activities, such as managing the PO's social media channels. Involving members in this direct way rather seemed to be done by smaller POs, with larger POs relying on their regional or national associations or external partners. External partners are needed to develop digital services that are specific to the PO (refer to the Subtheme 2.3: Public and Private Financial Assistance section and Table 3). Examples include the development of an app by which the members can communicate with each other, the design of a new PO website, and the provision of technical infrastructure, for instance, to establish patient registries. Furthermore, external partners are involved in developing health information for the POs' digital formats. Health care professionals, mainly physicians, are asked to provide feedback as an advisory panel.

Subtheme 2.3: Public and Private Financial Assistance

According to some (6/46, 13%) of our interviewees, POs struggled to seek and maintain appropriate financial resources for planning and implementing various activities, such as digital services and projects. In their search for financial support, they applied for external funding from health care insurance and political actors (4/46, 9%). Furthermore, some (4/46, 9%) POs sought funding from pharmaceutical companies (subtheme 2.3 in Table 3).

RQ 3: Involvement of PO Members in Digital Projects

Subtheme 3.1: Motivations to Establish and Sustain Involvement

In general, PO members repeatedly indicated a willingness to be involved in their POs' digital initiatives (10/46, 22%; subtheme 3.1 in Table 3). They cited the benefits of the digital technologies being developed and the feeling that their involvement is making a difference as the main reasons for their involvement. PO representatives and members (13/46, 28%) stated that member involvement is necessary to consider users' (ie, members') needs and preferences regarding digital products. Despite the many positive perceptions and willingness vis-à-vis involvement, interviewees rarely referred to concrete examples of established participatory approaches, indicating a gap between aims or willingness and practice. For instance, only 3 (7%) out of 46 PO members mentioned participatory activities within their POs' digital initiatives, such as members surveys or involving members in the design of a PO website. Regarding a PO's size, interviewees from larger POs more often referred to the importance of and interest in involvement.

Subtheme 3.2: Types and Intensity of Involvement

PO members and representatives indicated rather unanimously that active involvement should take place early in the planning and implementation of the products. However, in contrast, they highlighted several times that currently, member involvement stays rather passive (13/46, 28%), for example, by participating in a member survey (4/46, 9%) or user testing (2/46, 4%). Some (2/46, 4%) representatives mentioned that they do offer members the opportunity to contribute more actively, for example, by serving on an advisory board for the development of a patient registry or on a research committee (subtheme 3.2 in Table 3). Unfortunately, members (7/46, 15%) indicated that they were not aware of such opportunities to become involved. This meshes with representatives, who said that members involved in such digitalization efforts tend to be those who already volunteer within their PO. Moreover, we found more examples of actual involvement practices from interviewees belonging to larger POs.

Subtheme 3.3: Requirements for Involvement

Because of this struggle to achieve "true," that is, active and ongoing involvement, some (5/46, 11%) interviewees pointed out the need to improve the prerequisites and conditions for this. To achieve this, PO members repeatedly emphasized that digital projects should be set up in such ways that involvement is neither too time consuming nor too demanding, for example, in terms of specific professional or technical knowledge (13/46, 28%). This was considered crucial for the motivation of members to get involved (subtheme 3.3 in Table 3). The observation that members can bring specific expertise to digitalization projects, given their professional backgrounds, adds to the importance of involving them.

RQ 4: Attitudes Toward Digitalization in POs

Overview

The impact of the digital activities undertaken by POs can be multiple. These impacts can occur at the individual level by enabling a broader group of members to participate in POs' activities and services (eg, hybrid activities), at the organizational level by streamlining their operations (eg, digital membership system), at the research level by providing better integration into research (eg, digital patient registry), or at the political level by offering better representation in the health care system. In this section, we describe how our participants generally viewed the shift toward more digital communication and the increasing use of digital tools positively. Positive impacts due to digitalization seemed to be expressed more often by interviewees from larger POs, while negative aspects, that is, challenges and disadvantages, were equally expressed by interviewees from smaller and larger POs. However, certain aspects elicited mixed responses, including criticisms regarding how POs are digitally transforming their work.

Subtheme 4.1: Accelerating Management, Outreach, and Communication

Participants (14/46, 30%) mentioned several examples of successful digital initiatives. For instance, POs' websites and, sometimes, social media channels have become key outreach tools to reach a wider audience and attract new members, especially younger people. Moreover, patient registries have been established to support research efforts, and during the COVID-19 pandemic, digital formats for face-to-face interaction and exchange were introduced, further enhancing communication. Furthermore, several (7/46, 15%) representatives highlighted how digital tools help to handle daily or regular tasks related to administration and management.

XSL•FO
RenderX

Participants also mentioned the ability to network at a national or even European level through digital tools, for example by connecting with foreign sister organizations and research institutes that the PO had not previously worked with. Moreover, some (2/46, 4%) mentioned that costs can be reduced by moving from analog to digital formats.

Subtheme 4.2: Simplifying Access to PO Support Services

Many (30/46, 65%) participants described digital tools as helpful and convenient. PO representatives saw videoconferencing software as particularly valuable for simplifying communication or facilitating events. Representatives and members alike appreciated the opportunity to improve access for those who cannot attend PO meetings or events in person, for example, due to a physical impairment.

Subtheme 4.3: Supporting Health Research for People With Chronic and Rare Diseases

Patient registries operated by POs were seen as particularly beneficial and promising by several (11/46, 24%) participants. Registries were seen to advance health research and the development of new treatments. Valuing the potential benefits for themselves and others affected, several (10/46, 22%) PO members indicated that they would generally be willing to provide their data for use in such a patient registry.

Subtheme 4.4: Ineffective, Costly, and Time-Consuming Activities

Despite these various positive aspects, especially PO representatives (8/46, 17%) reported it as costly, requiring significant personnel and financial resources and expertise to implement the projects. This included, but was not limited to, large-scale projects, such as patient registries and mobile apps, for which these resources were not readily available. These challenges were seen as particularly significant for smaller, resource-limited POs. Some PO representatives referred to unsuccessful or failed digital projects (3/46, 7%), although failures were less frequently reported compared to successes (14/46, 30%). For example, a participant noted that the PO's social media channels were not effective enough in reaching a wider audience. Another mentioned a chat forum that was discontinued after a while due to lack of use. The last example is the discontinuance of a patient registry at a smaller PO due to a lack of resources and expertise.

Subtheme 4.5: Challenging Personal Interaction and Access

Representatives and members alike stated that the value of in-person meetings cannot be fully captured by digital alternatives (14/46, 30%). Despite perceived advantages, digital technologies were mainly seen as supplements rather than replacements. In addition, several participants (18/46, 39%) stated that digital formats are less accessible to older PO members or those with medical conditions impairing cognition. Participants stated that these persons may lack access to important information. They lack the literacy to work with digital tools, have physical difficulties using digital equipment, or have concerns regarding the use of digital technologies in general.

Subtheme 4.6: Requiring Additional Efforts for Planning, Training, and Risk Management

Both representatives and members emphasized that POs need to make additional efforts to succeed in their digital transformation (7/46, 15%), which is particularly difficult to achieve for smaller POs (5/46, 11%). Several (15/46, 33%) participants stressed the importance of training members to use digital technologies effectively. Furthermore, they emphasized the importance of digital services meeting members' preferences, providing clear benefits, and being user-friendly. Another key issue our participants brought up is data privacy, for example, of the data stored within patient registries or gathered by the use of digital tools, such as mobile apps. In this study, the participants considered comprehensive privacy policies important and necessary.

Subtheme 4.7: Encouraging Ambivalence or Fostering Undecidedness

Several (11/46, 24%) participants expressed difficulties evaluating the consequences of digital technologies. They were generally uncertain, weighing benefits against potential risks. This was exacerbated, as the digital tools had often only recently been implemented. Others acknowledged that while digital workflows and communication might be feasible and useful in POs, they involved a significant amount of work and financial resources, which were scarce for POs. Furthermore, some (7/46, 15%) representatives pointed out that while digital transformation within the organization was generally positive, this might not be the case for everyone involved in the process. Specifically, they perceived older PO members as being more reluctant to embrace digitalization in the PO, resulting in low motivation levels, skepticism, or even resistance. Moreover, some (5/46, 11%) indicated that the benefits would eventually outweigh the potential drawbacks.

Discussion

Principal Findings

This interdisciplinary interview study explored how German POs enact their digital transformation (RQ 1), who is involved in this process (RQ 2 and RQ 3), and how PO representatives and members evaluate past and current efforts (RQ 4). This study aimed to provide empirical evidence on the *ways of working* of one of the most important institutional actors in health care and research. While digital transformation is seen as promising and potentially transformative for the delivery of care and research, practical insights into this process, its requirements, and the challenges for POs are largely lacking.

First, POs are driving digitalization primarily in 4 key areas: communication, health education, health research, and administration. Communication efforts are the most widespread, with many POs having established *basic* digital formats, such as websites, social media channels, and videoconferencing. Digital health education also plays a central role as POs work to improve members' digital health literacy and provide accessible information. Furthermore, some POs are engaged in health research through digital data collection and have begun to digitalize administrative tasks, although this is comparatively

XSL•FO
RenderX

less common. Second, POs rely heavily on internal support and external collaboration to develop and sustain these digital activities. The participants in our study often referred to volunteer members and collaborations with external public and private partners to manage the necessary workload and resources. Third, while our interviewees considered the active involvement of members, for example, in the design of digital tools, desirable, it is not a *routine* in POs and depends much on the sufficient motivation of those involved. Fourth, the digital transformation in health care comes with a new task for POs: improving the digital health literacy of their members. Finally, PO representatives and members highlighted that digital transformation brings hope to reach a wider audience and attract younger people. However, its advantages may only be realized if several barriers can be overcome. These include, most obviously, a lack of financial resources, the need for digital training for staff and volunteers, and appropriately handling the reduction of face-to-face communication.

Roles and Tasks of POs

Until now, there has been limited research on the roles and tasks of POs in general and especially in relation to digital transformation. Our findings contribute to the evidence base in several ways. For example, according to van de Bovenkamp et al [10], POs seek and depend on collaboration with external stakeholders for a variety of reasons, not least to secure material and immaterial resources, which are often limited, especially in smaller organizations [15]. However, our PO representatives and members were somewhat ambivalent about this fact. On the one hand, POs collaborate in the planning and implementation of digital activities relatively intensively, involving many volunteers (ie, PO members) and, less frequently, sister organizations, such as the national and regional associations. On the other hand, collaboration with external partners, such as pharmaceutical companies or health insurance companies, was often described as hampered. It was perceived that it does not serve *true* collaboration purposes, such as jointly developing a new digital service. Rather, collaboration is meant to secure needed resources or outsource work to external partners given their limited capabilities and skills. However, according to van de Bovenkamp et al [10], POs need to foster actual collaboration to promote their role in the health care system.

While Claus et al [11] state that POs could help to recruit patients for research studies, we found little evidence that POs are indeed using their digital resources for this purpose [12]. Our findings show that POs are using a wide variety of more basic digital tools, mainly for communication purposes. Those tools include websites, social media, and digital events resulting from the POs' internal digitalization efforts. In comparison, the development and use of more elaborate digital tools, such as mobile apps or patient data registries, is less common. A lack of resources, both in terms of finances and skill set, is an important reason for this. Considering the relative novelty of the digital tools and the lack of experience and expertise within the POs to use these tools, a robust digital governance framework is necessary to further advance the digital transformation in POs [3]. Such a governance framework would serve the POs as a guideline in the development and maintenance of their digital activities and services to ensure compliance with their core aims and values.

Although we did not directly assess the impact of these digital activities, participants' experiences and attitudes suggest that digital transformation has a range of effects. For instance, digital tools were perceived as essential for outreach and communication; helpful in facilitating daily administrative tasks; and, in some cases, even reducing costs. Some (11/46, 24%) participants also mentioned that tools, such as videoconferencing, provide better access to support services for members with physical disabilities. In contrast, digital activities were seen as requiring significant financial and human resources, and certain individuals, especially older individuals or those with lower digital literacy, were reported to face barriers in accessing digital tools, potentially leading to exclusion. Hence, the digital transformation in POs, as reported by participants, has a broad impact, including both positive and negative aspects.

Involvement of PO Members

Our findings highlight a consensus among many PO members and representatives regarding the value of participatory approaches to enhance the usability of digital services. This is consistent with the reported general benefits of stakeholder engagement in the development of digital health tools, highlighting the critical role of this approach [26-28].

The interviews revealed a strong willingness among members to engage in digital initiatives, while relatively few (3/46, 7%) reported actual participatory approaches. Some studies, although not specific to the PO context, point to organizational capacity constraints, including time and financial resources, which hinder a more thorough use of participatory approaches [28,29]. Further examining such challenges in the context of POs can provide valuable insights into bridging the gap between intentions to get involved and actual involvement.

To tap into the full range of perspectives and skills of PO's members, organizations need to design involvement methods, as our interview data point to the design of such approaches as a potential pivot point for increasing involvement. For example, participants emphasized the importance of clear benefits, manageable requirements, and early engagement as key factors in their decisions to engage. POs may consider these aspects when planning participatory approaches, as they have also been identified as key participatory design principles for stakeholder engagement in other digital health projects [30,31].

Furthermore, participatory approaches used in POs' digital initiatives seem to focus predominantly on the initial stages of engagement, such as surveys and user testing. The prevalence of these methods in the PO landscape may be due to their relative organizational simplicity and lower demands on participants. More active, collaborative forms, such as advisory boards, were less frequently mentioned. This echoes a trend found in 2 reviews, which identified such collaborations in the participatory development of digital health tools but comparatively more frequently reported forms of involvement that tended toward more passive engagement [29,31]. Regarding the PO context, this may prompt further consideration of the

XSL•FO
RenderX

applicability of active involvement or the potential reluctance of members to take on more control and responsibility.

Building on our findings, future research should explore the willingness of PO members to engage in their PO projects, their specific needs and expectations, and the organizational capacity to support and sustain active involvement. Such studies could guide the design and implementation of participatory approaches in POs' digital initiatives or even establish frameworks to align member expectations with organizational realities.

Ethical Aspects Related to Digital Transformation Within POs

Our findings highlight the ethical complexities that come with the digital transformation. POs are confronted with a wide range of ethical considerations regarding their digital projects and services as well as the processes of developing and maintaining them. Topics such as digital literacy, accessibility of digital tools, and data security [32-34] are highly relevant to the POs' digital transformation processes.

Our findings show the importance of accessibility to the digital services POs provide for their members. Interestingly, digitalizing services can lead both to enhanced and diminished accessibility of the services in question. For an inclusionary approach, POs need to identify the respective groups that will and will not most likely benefit from the digital transformation. One group that was seen as potentially disadvantaged was older members because they might lose the connection to the activities of the PO. This may be due to a lack of resources, insufficient digital literacy, or preferences for analog formats. However, the use of digital tools may also increase the accessibility of PO services. For example, one group for which digital tools increase accessibility is persons unable to attend in-person meetings due to their ailment or disability. Therefore, there is ambivalence concerning accessibility, meaning that POs have to carefully weigh their options and try to forge a path that includes all their members.

Furthermore, a just allocation of scarce resources and collaboration with external partners were considered important. Previous research has found that POs rely heavily on third-party funding; however, there is a lack of transparent information about potential conflicts of interest [18]. POs are challenged with the task of securing enough resources to allow them to develop and maintain their digital activities while remaining independent of undue influences. Their political and economic independence is especially important to maintain integrity and trustworthiness. In this regard, careful consideration is needed when choosing an external partner to safeguard the PO's independence. However, such considerations might be hampered by a lack of choices.

Persons in POs contributing to digitalization projects may easily find themselves in attitudinal and judgmental conflicts when weighing the positive and negative sides of those projects. This stresses the need for an ethical governance framework for POs' digital transformation.

Strengths and Limitations

We were able to include participants from 19 individual POs, which represent a range of target groups, address various aspects in the field of health care and medical issues, and are based in different regions of Germany. By including POs from distinct places, we aimed to reduce potential bias from a concentration of organizations in certain regions and provide a more balanced view regarding digitalization. We believe that the diversity of the included POs may have contributed to a broader range of perspectives on POs' digital transformation while allowing us to clearly identify the most prominent practices, actors, and attitudes. However, as digitalization activities vary considerably between POs, especially regarding their digital educational services, the development of their own technologies, and research activities, there could be a greater differentiation of these digitalization activities and the actors involved depending on the size of a PO, the topics dealt with, and the level of digitalization within each organization. In addition, the observed variations in digital activities are based on subjective reports and may not capture all initiatives. Furthermore, because we included only POs that demonstrated some level of digital activity, the perspectives of those still at the very beginning of their digital transformation or those that have chosen not to engage in this process are not represented in our study; therefore, it may be assumed that for such POs, the extent of digitalization is lower. Given our limited personnel resources, we did not return interview transcripts and the eventual findings to the participants for comments. However, additional steps to increase the validity of the findings were performed, such as peer checks of the coded text segments and peer interpretation of the findings (refer to the Methods section for more validating steps). Our study can be a starting point for further such analyses.

Conclusion

Our study provides insights into the state of digital transformation in German POs. We found that digitalization efforts are particularly evident in 4 core areas: communication, administration, health education, and health research. These processes involve multiple professional and nonprofessional actors, including permanent staff, volunteers, and external partners. Member involvement varies in scope and form, with a high level of willingness to engage. While representatives and members generally view digitalization positively, they also identify barriers, such as resource limitations and accessibility challenges, for certain groups.

In conclusion, German POs are currently investing considerable resources to engage in digital transformation processes, ranging from smaller projects to more sophisticated initiatives, and involving a wide range of stakeholders and individuals. These efforts and collaborations highlight the need for POs to establish more comprehensive ethical governance frameworks to clarify the goals of digitalization, determine what is needed to achieve them, and define how to engage with different stakeholders, including setting clear roles and motivations for their members to become involved. Public institutions could assist POs with these multiple tasks and requirements, for example, by providing training, mentorship, and facilitating networking and sharing among POs.

Acknowledgments

The authors would like to thank all of the interviewees for their time and dedication to participating in this study. The authors are grateful for the feedback during the planning and revision of this study provided by their patient advisory board: Miriam Schlangen, Thomas Duda, Wiebke Papenthin, Thorsten Freikamp, and Heidemarie Haase. They would also like to thank the German Federal Ministry of Education and Research for funding the Pandora research project (grant 01GP2115A-C).

Authors' Contributions

S Wallraf, SK, HJVGS, and JL planned the study and collected and analyzed the data. S Wallraf and JL wrote the first draft. SK and HJVGS provided extensive feedback and revised the draft. CW, S Wohlke, MLD, and MAS provided critical input for the draft. All authors read the final version of the manuscript.

Abstract

Background: eHealth has enormous potential to support the self-management of depressive symptoms in people living with HIV. However, a lack of personalization is an important barrier to user engagement with eHealth. According to goal-directed design, personalized eHealth requires the identification of user personas before concrete design to understand the goals and needs of different users.

Objective: This study aimed to identify user personas for eHealth regarding the self-management of depressive symptoms in people living with HIV and explore the goals and needs of different user personas for future eHealth.

Methods: We used an explanatory sequential mixed methods design at the First Hospital of Changsha City, Hunan Province, China, from April to October 2022. In the quantitative phase, 572 people living with HIV completed validated questionnaires with questions related to demographics, self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. Latent profile analysis was performed to identify different user personas. In the qualitative phase, 43 one-to-one semistructured interviews across different user personas were conducted, transcribed verbatim, and analyzed using conventional content analysis. The findings from both phases were integrated during the interpretation phase.

Results: Three types of user personas could be identified, including “high-level self-managers” (254/572, 44.4%), “medium-level self-managers” (283/572, 49.5%), and “low-level self-managers” (35/572, 6.1%). High-level self-managers had relatively high levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. High-level self-managers had a positive attitude toward using eHealth for the self-management of depressive symptoms and desired access to self-management support for depressive symptoms from eHealth with high usability. Medium-level self-managers had relatively medium levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. Medium-level self-managers felt burdened by using eHealth for the self-management of depressive symptoms and preferred to access self-management support for HIV from eHealth with privacy. Low-level self-managers had relatively low levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. Low-level self-managers had an acceptable attitude toward using eHealth for the self-management of depressive symptoms and desired access to professional guidance from eHealth with privacy and no cost (“free of charge”).

Conclusions: The 3 user personas shed light on the possibility of personalized eHealth to support the self-management of depressive symptoms in different people living with HIV. Further research is needed to examine the generalizability of the user personas across study sites.

KEYWORDS

HIV; depressive symptoms; depression; self-management; eHealth; personas

Introduction

Background

People living with HIV disproportionately experience depressive symptoms. A previous evidence-based study estimated that the global prevalence rate of depression in people living with HIV was approximately 22% to 44% [1], which usually predicts increased sexual risk behavior, poor adherence to antiretroviral therapy, accelerated disease progression, and increased suicidal ideation [2-5].

Self-management plays a crucial role in preventing and reducing depressive symptoms in people living with HIV, and the processes include learning skills, assessing resources, and coping with the illness [6]. However, although a large number of effective resources are available for the self-management of depressive symptoms in people living with HIV, not many seek or receive these [7,8], mainly due to limited access to care, extra financial or commute burdens, and perceived stigma [9-12].

Fortunately, eHealth offers an easily accessible, flexible, potentially cost-effective, and highly anonymous option for the self-management of depressive symptoms in people living with HIV [12-14]. Since the COVID-19 pandemic, eHealth has been greatly recognized for providing better access to mental health services and is being increasingly used as a critical component of normal mental health practices [15-17]. Several existing systematic reviews have demonstrated the effectiveness of eHealth for depressive symptoms in people living with HIV [6,18,19]. Taken together, eHealth has enormous potential to support the self-management of depressive symptoms in people living with HIV [13,20].

It is worth noting, however, that users generally have various goals and needs regarding the use of eHealth [21]. Users may prefer to have an opportunity to select personalized eHealth that can be tailored to their goals and needs, and yet in practice, they always feel “depersonalized” by eHealth and perceive that developers often fail to understand their needs, which can demotivate them when engaging with such resources or even cause them to give up [22-25]. An emerging systematic review found that a lack of personalization is an important barrier to user engagement with eHealth in the mental health domain [26]. Future eHealth needs to encourage user involvement in the development phase to better understand and meet the goals and needs of various people living with HIV for the self-management of depressive symptoms, thereby promoting the adoption and sustained use of future eHealth [27].

Goal-directed design is a user research–based eHealth design method, which requires identifying user personas before concrete design to understand potential or actual user goals and needs (ie, expectations of an end condition) [28]. In this regard, user personas are detailed composite user archetypes that represent different behavior patterns and the goals and needs associated with them, providing a powerful communication tool for developers to better understand different types of users [28]. Previous evidence has indicated that user persona–tailored eHealth could increase user engagement and satisfaction with online user experience [29,30], which holds promise for the adoption and sustained use of eHealth.

According to goal-directed design, user personas can be hypothesized based on demographic variables, domain expertise, and technical expertise. Demographic variables are the most basic factors to help differentiate different types of users. We included age, gender, education, employment status, monthly household income, and health condition as the specific elements of demographic variables based on a literature review [26,31,32]. Domain expertise refers to user proficiency in a specialized subject area relevant to a product. In the area of the self-management of depressive symptoms, patients are empowered to take responsibility for the day-to-day management of their depressive symptoms [33]. However, effective self-management of depressive symptoms requires an individual to have the ability to monitor depressive symptoms and take actions necessary to maintain a satisfactory quality of life [34]. Meanwhile, self-efficacy, which refers to the belief in one’s ability to take specific actions to achieve desired outcomes [35], is closely related to effective self-management of depressive symptoms because self-efficacy, as an important motivational construct, can affect one’s choice of activities, effort, persistence, and achievement in the self-management of depressive symptoms [36]. In other words, both the self-management abilities of depressive symptoms and self-efficacy are indispensable for the desired performance in domain expertise [36,37]. We thus proposed these 2 elements as the specific elements of domain expertise. Lastly, in the eHealth area, technical expertise refers to user proficiency in eHealth technology. We thus defined technical expertise as the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to address or solve a health problem, namely eHealth literacy [38].

Objectives

To inform the design of future eHealth, this study aimed to identify user personas for eHealth regarding the self-management of depressive symptoms in people living with HIV and explore the goals and needs of different user personas for future eHealth. We propose the following hypotheses:

- Hypothesis 1: There will be different user personas for eHealth regarding the self-management of depressive symptoms in people living with HIV.
- Hypothesis 2: Different user personas will reflect different people living with HIV, their characteristics, and their goals and needs for future eHealth.

Methods

Study Design

We undertook an explanatory sequential mixed methods study [39]. First, we conducted a quantitative survey to provide a preliminary understanding of user personas for eHealth

XSL•FO
RenderX

regarding the self-management of depressive symptoms in people living with HIV. Then, we collected qualitative data through semistructured interviews to explain these user personas in more depth and explore the goals and needs of different user personas for future eHealth. Lastly, the quantitative and qualitative findings were integrated during the interpretation phase.

This study has been reported in line with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) checklist for cross-sectional studies [40], the SRQR (Standards for Reporting Qualitative Research) checklist [41], and the GRAMMS (Good Reporting of a Mixed Methods Study) checklist [42].

Quantitative Phase

Setting and Sampling

We recruited a consecutive sample of people living with HIV on arrival at the HIV clinic of the First Hospital of Changsha City, Hunan Province, China, from April 2022 to October 2022. Hunan Province is located in south-central China, with a population of 53,030 people living with HIV at the end of October 2022, similar to the national-level prevalence [43]. The First Hospital of Changsha City is a large designated tertiary hospital for HIV diagnosis and treatment in Hunan Province, which follows about 9000 HIV/AIDS patients, with an annual outpatient volume of about 30,000 visits [44]. Individuals were eligible if they met the following criteria: (1) were aged 18 years or older, (2) had been diagnosed with HIV infection (as confirmed by a diagnosis report), and (3) voluntarily participated in this survey after providing informed consent. Individuals were excluded if they had cognitive or audiovisual impairment assessed by clinicians. We consecutively screened people living with HIV for eligibility to participate in this survey until a sufficient sample size was achieved. Meanwhile, some potential participants were referred by medical social workers. Overall, a total of 600 participants were involved in the survey, and 592 returned completed surveys. A final sample of 572 participants was included for analysis after removing responses with over 10% missing data.

Variables and Measures

Demographic variables included age (years), gender (male=0, female=1), educational level (high school or below=0, higher education or above=1), employment status (unemployed=0, employed=1), monthly household income (<10,000 RMB=0, ≥10,000 RMB=1; a currency exchange rate of RMB 1=US $0.1375 is applicable), and health condition (including comorbidities [no=0, yes=1], latest CD4 count [≥200 cells/mm^3=0, <200 cells/mm^3=1], viral load [not "target not detected (TND)" status=0, TND status=1], and severity of depressive symptoms), with these categories determined by reference to previous literature [26,45-48]. We used the 9-item Patient Health Questionnaire (PHQ-9) to assess the severity of depressive symptoms in the past 2 weeks [49], with a total score range from 0 to 27. Scores of 5, 10, 15, and 20 represent mild, moderate, moderately severe, and severe depression, respectively.

The self-management abilities of depressive symptoms were assessed using the 9-item Chinese version of the Depression-Specific Self-Management Questionnaire (DSSM; a 5-point Likert scale), which has a total score ranging from 9 to 45, with higher scores indicating higher levels of self-management abilities of depressive symptoms [50]. Self-efficacy was assessed using the Self-efficacy for Managing Chronic Disease Scale (SEMCDS; a 10-point scale) [51]. The scale has 6 items, and the total score can range from 6 to 60, with higher scores indicating higher levels of self-efficacy. eHealth literacy was assessed using the 8-item Chinese version of the eHealth Literacy Scale (eHEALS; a 5-point Likert scale), which has a total score ranging from 8 to 40, with higher scores indicating higher levels of eHealth literacy [52,53]. All Cronbach α values were above the cutoff value of .70, indicating good internal consistency [54].

Data Collection

Before the formal survey, we pretested the questionnaire and adjusted the questionnaire wording as necessary to ensure comprehensibility and readability. We trained 4 investigators (graduate nursing students) to distribute and collect questionnaires using a traditional pen-and-paper method. Each participant completed the questionnaire themselves after the investigator demonstrated how to fill in responses. For those who could not read or write, the investigator explained the meaning of each item and completed the questionnaire according to the participant's responses. At the end of the survey, participants were invited to participate in a follow-up qualitative interview. Those who expressed an interest were asked to leave their WeChat contact details.

Data Analysis

All returned questionnaires were double-entered in EpiData software (version 3.1; EpiData Association) to ensure accuracy and integrity. Statistical analysis consisted of 3 parts. First, we conducted descriptive statistics to understand the characteristics of the participants.

Second, we used latent profile analysis (LPA) to identify the latent profiles of user personas among people living with HIV based on responses to the following indicators: the self-management abilities of depressive symptoms, self-efficacy, and eHealth literacy. Participants with similar response patterns were classified into the same profile. To ensure adequate accuracy of the classification, the recommended minimum sample size for LPA studies is at least 500 [55,56], and therefore, the current size of 572 is sufficient.

We used a maximum likelihood estimation with robust standard errors (MLR) to identify the participants' latent profiles [57]. To avoid local maxima, we used 7000 random sets of starting values for the initial stage, 500 iterations for each random start, and the 200 best solutions retained for final-stage optimizations. To identify the optimal number of latent profiles, we evaluated 1- to 5-profile models based on the statistical fit, parsimony, and substantive interpretability [58]. We considered a combination of fit indices, including Akaike Information Criterion (AIC), Bayesian Information Criterion (BIC), sample size–adjusted BIC (saBIC), and entropy [57]. The model with

XSL•FO
RenderX

lower AIC, BIC, and saBIC values had a better fit, while the model with an entropy value closer to 1 had a higher classification accuracy. We also used the adjusted Lo-Mendel-Rubin likelihood ratio test (aLMRT) and bootstrap likelihood ratio test (BLRT) to evaluate model fit [57]. A statistically significant aLMRT or BLRT value indicates that the model with *k* profiles outperforms that with *k-1* profiles. In addition, the percentage of individuals in the smallest profile was set at 5% of the total sample to include at least sufficient individuals (n=30-60) to support the generalizability of the LPA [59,60].

Third, we used the automatic 3-step approach to model the covariates after identifying the optimal number of latent profiles. Specifically, we used the R3STEP command, which assigns individuals to their most likely profiles, to conduct a series of multinomial logistic regressions to examine the effects of covariates on the profile membership [61,62]. This procedure is the recommended method as it accounts for the measurement error in profile classification while modeling the effects of covariates on profile membership [60,61]. All demographic variables were introduced as covariates. In the R3STEP procedure, we used multiple imputation to impute missing values for covariates to minimize bias. A total of 27 imputations were used according to a rule of thumb (ie, the number of imputations should be at least equal to the percentage of incomplete cases) [63]. All statistical analyses were conducted in Mplus software (version 8.4) [64], and a *P* value of <.05 was considered statistically significant.

Qualitative Phase

Sampling

The qualitative phase was conducted using a qualitative descriptive design based on the naturalistic inquiry [65], which is especially appropriate for mixed methods research to provide a rich straight description of the facts from the participants' points of view [66]. From August to October 2022, we recruited 43 participants for the qualitative interviews via a WeChat invitation. We used stratified purposeful sampling to recruit heterogeneous participants with different ages, genders, educational levels, employment statuses, monthly household incomes, or health conditions for each user persona from the quantitative sample [67]. Individuals were eligible if they had completed the quantitative survey of this study and agreed to participate in the qualitative interview. The sample size was determined by the principle of data saturation (ie, no new analytical information arose anymore) [68].

Procedure and Analysis

Three qualitatively trained investigators (female graduate nursing students) used a semistructured interview guide to conduct in-depth interviews. The interview guide consisted of open-ended questions informed by the quantitative findings, a group discussion, and a preliminary pilot study with 5 patients, including the following key topics: (1) how do they self-manage depressive symptoms? (2) what are their attitudes toward using eHealth for the self-management of depressive symptoms? (3) what are their goals and needs toward using eHealth for the self-management of depressive symptoms? Interviews took place in a private room at the HIV clinic, at the participant's home, or in another quiet location, either face-to-face or by telephone, whichever was convenient for participants. The length of interviews ranged from 20 to 82 minutes. No one else was present except the participant and the interviewer. The interviewers had no dependency relationship with any participants.

Each interview was audio-recorded, immediately transcribed verbatim, and member-checked to ensure accuracy. Field notes (eg, verbal and nonverbal cues, "off-the-record" texts) were also used to enrich our results further. Two trained investigators repeatedly reviewed the interview transcripts, immersed themselves in these to obtain a sense of the whole interview, and then independently conducted conventional content analysis using NVivo software (version 12; Lumivero) to identify patterns and categories in an inductive approach. An initial codebook was developed after the first 5 interviews and was iteratively refined in the following interviews until a consensus was reached. Disagreements were resolved through discussion among a 5-member review team having multi-disciplinary backgrounds in nursing, HIV, and mental health.

Mixed Methods Data Integration

We used a mixed methods approach to identify user personas to provide a deeper insight and understanding than either approach [39]. As noted, the quantitative findings informed the sampling frame and interview guide of the following qualitative phase (ie, integration at the methods level) [69]. Second, we used a statistics-by-themes joint display as a visual means to integrate the main quantitative and qualitative findings at the analytic and interpretation levels [70], with the following three possible outcomes: (1) confirmation, where the quantitative and qualitative findings confirm each other; (2) expansion, where the quantitative and qualitative findings diverge and expand insights into user personas; and (3) discordance, where the qualitative and quantitative findings are inconsistent, incongruous, contradictory, or conflicting, or disagree with each other [69]. The integration of quantitative and qualitative findings identified key targets for the design of future eHealth. Multimedia Appendix 1 shows the flow of the overall study.

Ethical Considerations

The study was performed in accordance with the Declaration of Helsinki and received ethics approval from the Institutional Review Board of Xiangya School of Nursing, Central South University (number: E202210). All participants provided verbal informed consent before formal participation in the quantitative or qualitative phase. Pseudonyms were used during data collection, storage, and presentation to maintain anonymization and deidentification (ie, linked only to the study ID). No compensation was provided to participants during the quantitative phase. Upon completing the qualitative phase, participants received US $6.85 for their participation.

Results

Quantitative Findings

Participant Characteristics

A total of 572 valid questionnaires were included in this study (see Multimedia Appendix 2). Participants were between 18 and 72 years old, with a median age of 29 (IQR 25-34.8) years. The majority of participants were male (541/572, 94.6%), had higher education or above (452/572, 79.0%), were employed (472/572, 82.5%), and had a monthly household income of ≥10,000 RMB (≥10,000 Chinese Yuan; 390/572, 68.2%). In addition, 22.2% (127/572) of the participants had comorbidities, but most had a latest CD4 count of ≥200 cells/mm^3 (463/572, 80.9%) and an undetectable HIV viral load (368/572, 64.3%). The PHQ-9 scores of the participants ranged from 0 to 27, with a median score of 6 (IQR 3-11), and 64.3% (368/572) had mild or more depressive symptoms. Detailed descriptive statistics are shown in Table 1.

[e]DSSM: self-management abilities of depressive symptoms.

Model Selection

Table 2 presents fit statistics for 1- to 5-profile structures. As the number of profiles increased, the solutions provided lower AIC, BIC, and saBIC values and statistically significant BLRT values. However, the smallest profile of the 4- or 5-profile solutions contained less than 5% of the total sample. Considering the principle of substantive interpretability, we did not examine these 2 profile solutions further, as these profiles may be spurious [60]. We finally retained the 3-profile solution as the optimal solution because it exhibited lower AIC, BIC, and saBIC values and a higher entropy value than the 2-profile solution, with statistically significant aLMRT and BLRT values, indicating a significant improvement in fit statistics compared to the 2-profile solution. Meanwhile, the smallest profile of the

XSL•FO
RenderX

3-profile solution contained more than 5% of the total sample (35/572, 6.1%), which is the minimum reference standard to support the generalizability of the LPA [59,60]. Average posterior probabilities for individuals assigned to each profile in this solution were 0.898, 0.879, and 0.928, respectively, with all values greater than 0.70, indicating well-separated profiles [71].

Table 2. Fit statistics for 1- to 5-profile structures (N=572).

Profile Characteristics

Table 1 displays the estimated means and SEs for the 3 indicators in each profile. Profile 1 (254/572, 44.4%; *high-level self-managers*) was characterized by relatively higher self-efficacy (mean 51.4, SE 0.7), self-management abilities of depressive symptoms (mean 34.7, SE 0.4), and eHealth literacy (mean 31.9, SE 0.5). Profile 2 (283/572, 49.5%; *medium-level self-managers*) was characterized by relatively medium self-efficacy (mean 35.9, SE 1.1), self-management abilities of depressive symptoms (mean 29.4, SE 0.3), and eHealth literacy (mean 27.9, SE 0.4). Profile 3 (35/572, 6.1%; *low-level self-managers*) was characterized by relatively lower self-efficacy (mean 16.9, SE 2.3), self-management abilities of depressive symptoms (mean 24.7, SE 1.0), and eHealth literacy (mean 24.8, SE 1.3). Figure 1 presents a graphical representation of the 3 profiles based on the z-scores.

Figure 1. Three-profile structure based on z-scores (N=572). DSSM: self-management abilities of depressive symptoms.

XSL•FO
RenderX

Three-Step Approach

The 3-step results for the covariates are shown in Multimedia Appendix 3. Compared with *high-level self-managers*, we found that *medium-level self-managers* and *low-level self-managers* were more likely to have comorbidities and more severe depressive symptoms. Additionally, we found that *low-level self-managers* were more likely to have more severe depressive symptoms than *medium-level self-managers*.

Qualitative Findings

Interview Sample Characteristics

In total, 43 of 572 individuals who completed quantitative surveys volunteered to participate in semistructured interviews, including 23 *high-level self-managers*, 17 *medium-level self-managers*, and 3 *low-level self-managers*. The sample consisted of 37 males and 6 females, with a median age of 29 years (IQR 25.5-37; range 19-70 years). A total of 30 participants had used eHealth for the self-management of depressive symptoms. See Multimedia Appendix 4 for more details.

The findings are summarized by characteristics for the self-management of depressive symptoms, attitudes toward using eHealth, and goals and needs toward using eHealth. See Multimedia Appendix 5 for representative quotes.

Characteristics for the Self-Management of Depressive Symptoms

High-level self-managers were *particularly proactive* in the self-management of depressive symptoms, such as proactively seeking relevant information and social support. High-level self-managers believed that their emotional management plays a critical role in their health conditions and can, in the worst case, be devastating or fatal.

Medium-level self-managers were *proactive* in the self-management of depressive symptoms, but most used distraction techniques, such as playing on their phones. Medium-level self-managers believed that health conditions were the leading cause of their depressive symptoms and thus emphasized the moderating effects of health conditions on their depressive symptoms.

Low-level self-managers were *negative* about the self-management of depressive symptoms. Low-level self-managers often did not know how to make themselves better.

Attitudes Toward Using eHealth

High-level self-managers had a *positive* attitude toward using eHealth for the self-management of depressive symptoms. High-level self-managers often proactively used eHealth to manage their depressive symptoms, including searching for health information, following up on the latest news about HIV, and seeking peer advice.

Medium-level self-managers felt *burdened* toward using eHealth for the self-management of depressive symptoms. Medium-level self-managers usually did not use eHealth to manage their depressive symptoms to avoid potential burdens caused by frequent pushes, such as anxiety, feeling down, or feeling different from others.

Low-level self-managers felt it was *acceptable* to use eHealth for the self-management of depressive symptoms, especially for online guidance from professionals.

Goals and Needs Toward Using eHealth

High-level self-managers desired *access to self-management support for depressive symptoms* from eHealth, including (1) psychological support: psychological counseling, psychological information, peer support, and referral, and (2) HIV-related support: HIV-related information and counseling. Meanwhile, high-level self-managers desired eHealth to have *high usability*, including privacy, a user-friendly interface, personalized content, a positive and healthy atmosphere, and increased fun.

Medium-level self-managers focused on *access to self-management support for HIV* from eHealth, including HIV-related information and counseling, and emphasized the *privacy* of eHealth.

Low-level self-managers desired *access to guidance from professionals*, either psychological or HIV-related. Meanwhile, low-level self-managers desired eHealth with *privacy* and *no cost (free of charge)*.

Integrated Findings

The main quantitative and qualitative findings were integrated into a joint display. See Multimedia Appendix 5 for more details.

High-level self-managers had relatively high levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. High-level self-managers had a positive attitude toward using eHealth for the self-management of depressive symptoms and desired access to self-management support for depressive symptoms from eHealth with high usability.

Medium-level self-managers had relatively medium levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. Medium-level self-managers emphasized the moderating effects of health conditions on their depressive symptoms and felt burdened by using eHealth for the self-management of depressive symptoms. As a result, medium-level self-managers preferred to access self-management support for HIV from eHealth with privacy.

Low-level self-managers had relatively low levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy. Low-level self-managers had an acceptable attitude toward using eHealth for the self-management of depressive symptoms and desired access to professional guidance from eHealth with privacy and no cost (free of charge).

Discussion

Principal Findings and Comparison With Prior Work

This mixed methods study identified 3 types of user personas for eHealth regarding the self-management of depressive symptoms in people living with HIV, including high-level self-managers, medium-level self-managers, and low-level

XSL•FO
RenderX

self-managers. The different user personas reflect different people living with HIV, their characteristics, and their goals and needs for future eHealth. Therefore, developers may need to consider a tailored perspective in the design of eHealth for different user personas.

High-level self-managers were characterized by relatively high levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy, with minimal depressive symptoms. People living with HIV in this user persona attached great importance to the impact of emotional management on their health condition, and thus, they were particularly proactive in the self-management of depressive symptoms. This phenomenon may be explained by the fact that people with high self-efficacy and self-management abilities tend to see difficulties as challenges to overcome rather than to avoid, so they act with more proactive coping efforts in threatening situations [37]. In addition, people with fewer depressive symptoms tend to perceive more benefits and fewer barriers to taking effective measures to manage their depressive symptoms, so they are more likely to engage in self-management proactively [72]. Moreover, considering their positive attitudes toward eHealth, it is unsurprising that high-level self-managers desired access to more self-management support for depressive symptoms from eHealth, which could make them feel more empowered to control their health [25,26]. Notably, high-level self-managers desired eHealth with high usability, including privacy, a user-friendly interface, personalized content, a positive and healthy atmosphere, and increased fun, similar to the findings in previous research [25,26,73]. These findings may be explained by their relatively high levels of eHealth literacy [25], suggesting that future eHealth for high-level self-managers could be designed from a multi-dimensional perspective to provide an ideal interactive feel.

Medium-level self-managers were characterized by relatively medium levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy, with comorbidities and more severe depressive symptoms. People living with HIV in this user persona were proactive in the self-management of depressive symptoms, whereas most tended to use distraction techniques and placed more emphasis on the moderating effects of health conditions on their depressive symptoms. Accordingly, they preferred to access self-management support for HIV from eHealth. This phenomenon may be partly because people with comorbidities may experience more complexity in self-management, such as additional physical or psychological strain [74,75]. As a result, they tend to struggle with self-management and feel less confident to do so [76-78]. Therefore, it makes sense that medium-level self-managers desired access to self-management support for HIV from eHealth. In addition, this phenomenon may be explained by the traditional cultural beliefs and the stigma against depression in Chinese society [79-81], where people tend to keep their mental discomfort to themselves or refer to mental discomfort as physical symptoms to maintain their “face” (dignity, reputation, and public image), which may prevent them from seeking help for mental health [82,83]. Previous research also confirmed that many people living with HIV in China hardly ever use mental health services, including those with persistent depression [8]. Similar phenomena have been found in other geographical areas, such as Europe, South Asia, and South-East Asia [84]. These findings suggest that future eHealth should not only meet the goals and needs of medium-level self-managers but also improve their recognition in the self-management of depressive symptoms to promote behavioral change. Finally, our findings indicated that medium-level self-managers tended to feel burdened by eHealth resources with frequent push notifications, and thus, they used such resources less often, which is in agreement with previous meta-ethnographic findings [25]. These findings suggest that future eHealth for medium-level self-managers should be designed to promote their use of eHealth in the right amount according to the interactive principle of “Not too much. Not too little. Just right.” [85].

Low-level self-managers were characterized by relatively low levels of self-efficacy, self-management abilities of depressive symptoms, and eHealth literacy, with comorbidities and the most severe depressive symptoms. People living with HIV in this user persona were negative about the self-management of depressive symptoms. One possible explanation is that people with low self-efficacy tend to regard their efforts as futile in the face of difficulties and thus quickly give up trying, which, combined with their low self-management abilities, makes it difficult for them to achieve the desired performance in the self-management of depressive symptoms [37]. Another possible explanation is that people with severe depressive symptoms usually experience diminished interest in doing things, loss of energy, reduced ability to think or concentrate, or indecisiveness, and as a result, they often have difficulty in proactive self-management [72,86,87]. However, our findings indicated that low-level self-managers had an acceptable attitude toward eHealth resources and desired access to professional guidance from eHealth with privacy and no cost (free of charge). This finding suggests that future eHealth for low-level self-managers could be designed as a connection point for 2-way communication with an interactive feeling of “minimizing privacy risks and maximizing public benefits.”

Notably, all 3 types of user personas emphasized the privacy of eHealth, such as invitation codes and non-HIV–related names, which may be attributed to HIV-related stigma and discrimination. Although antiretroviral therapy has transformed HIV infection into a manageable chronic health condition [88], people living with HIV worldwide continue to face significant stigma and discrimination at the individual, interpersonal, community, and societal levels, including avoidance, gossip, verbal or physical abuse, social rejection, denial of health or social services, denial or loss of employment or education opportunities, or even arrest [89,90]. As a result, people living with HIV often value privacy to avoid unwanted disclosures and try to live a “normal” life [91,92]. Previous research has also emphasized the privacy concerns regarding eHealth platforms for HIV management, even in developed countries [92-94]. These findings suggest that future eHealth should be designed with adequate consideration of regulatory, privacy, and security protocols, regardless of user personas.

Strengths and Limitations

To our knowledge, this is the first study to construct user personas for eHealth regarding the self-management of depressive symptoms in people living with HIV. We constructed this powerful communication tool based on goal-directed design, providing an effective way for user involvement in the development phase of eHealth [28,95]. In addition, this study used an explanatory sequential mixed methods design, which integrated quantitative and qualitative findings to provide a more in-depth exploration of user personas. Our findings may be of use to gain a better understanding of intended end users and inform the design of future eHealth.

However, this study has several limitations. First, participants were recruited from a single site in the metropolitan area, and thus, our findings might not be generalizable to other areas of China. However, the site is a large designated tertiary hospital for HIV diagnosis and treatment, with a good representation of the diverse patient population in the survey area. Therefore, it can still be assumed that our findings reflect a social trend. Second, most participants were young males, which might be explained by the difficult access to vulnerable people living with HIV (eg, females) [96]. Therefore, the findings should be interpreted with caution. It would be helpful to include more vulnerable people living with HIV in future research to reflect their unique needs. Third, we recruited only 3 low-level self-managers for qualitative interviews, which might have contributed to potential bias. This may be due to the small total number of low-level self-managers and the fact that low-level self-managers usually experienced the most severe depressive symptoms, with diminished interest in interviews. However, we endeavored to ensure the heterogeneity of the participants by stratified purposeful sampling as much as possible, and the qualitative data revealed no new analytical information, so we presumed data saturation. Finally, as the study did not collect data over time, we did not investigate the dynamics of user personas. Future research can examine this vital area to gain more information to guide the design of future eHealth.

Implications for Practice

Our findings provide a practical communication aid, namely user personas, for interdisciplinary collaborations between health researchers and developers, which contributes to the integration of the “art of caring” and the “art of design” in future eHealth to provide personalized support for the self-management of depressive symptoms in people living with HIV [28,97]. Specifically, user personas could help frontline health researchers better play the role of requirement analysts during interdisciplinary collaborations to bring the user voice to the forefront in a clear and easily understandable way, thereby helping developers to keep different types of users and their goals and needs in mind during the early stages of development and continuously throughout the evaluation and implementation phases [95,97]. Furthermore, user personas could help elicit specific advice from health care providers, regulators, and investors by making the intended end users more tangible, which can contribute to addressing broader system and policy constraints [98].

Conclusions

According to goal-directed design, we identified 3 types of user personas for eHealth regarding the self-management of depressive symptoms in people living with HIV: high-level self-managers, medium-level self-managers, and low-level self-managers. The 3 user personas shed light on the possibility of personalized eHealth to support the self-management of depressive symptoms in different people living with HIV. Further research is needed to examine the generalizability of the user personas across study sites.

Abstract

Background: Health systems are rapidly promoting digital cancer care models to improve cancer care of their populations. However, there is growing evidence that digital cancer care can exacerbate inequities in cancer care for communities experiencing social disadvantage, such as Black communities. Despite the increasing recognition that older Black adults face significant challenges in accessing and using health care services due to multiple socioeconomic and systemic factors, there is still limited evidence regarding how older Black adults' access and use digital cancer care.

Objective: This study aims to better understand the digital cancer care experience of older Black adults, their caregivers, and health care providers to identify strategies that can better support patient-centered digital cancer care.

Methods: A total of 6 focus group interviews were conducted with older Black adults living with cancer, caregivers, and health care providers (N=55 participants) across 10 Canadian provinces. Focus group interviews were recorded and transcribed. Through a theory-informed thematic analysis approach, experienced qualitative researchers used the Patient Centered Care model and the synergies of oppression conceptual lens to inductively and deductively code interview transcripts in order to develop key themes that captured the digital cancer care experiences of older Black adults.

Results: In total, 5 overarching themes describe the experience of older Black adults, caregivers, and health care providers in accessing and using digital cancer care: (1) barriers to access and participation in digital care services, (2) shifting caregivers' dynamics, (3) autonomy of choice and choosing based on the purpose of care, (4) digital accessibility, and (5) effective digital communication. We identify 8 barriers and 6 facilitators to optimal digital cancer for older Black adults. Barriers include limited digital literacy, linguistic barriers in traditional African or Caribbean languages, and patient concerns of shifting power dynamics when supported by their children for digital cancer care; and facilitators include community-based cancer support groups, caregiver support, and key features of digital technologies.

Conclusions: These findings revealed a multifaceted range of barriers and facilitators to digital cancer care for older Black adults. This means that a multipronged approach that simultaneously focuses on addressing barriers and leveraging community strengths can improve access and usage of digital cancer care. A redesign of digital cancer care programs, tailored to the needs of most structurally marginalized groups like older Black adults, can enhance the digital care experience for all population groups. Public policies and organizational practices that address issues like availability of internet in remote areas, resources to support linguistic barriers, or culturally sensitive training are important in responding to the complexity of access to digital l cancer care. These findings have implications for other structurally marginalized and underresourced communities that have suboptimal access and usage of digital care.

KEYWORDS

digital care; cancer care; older Black adults; health equity; social determinants of health; access to care; health quality

Introduction

Digital care is defined as "the secure use of information and communication technologies in support of health and health-related fields, including health care services, health surveillance, health literature, and health education, knowledge, and research" [1]. Used in complement with or in lieu of in-person encounters, digital care encompasses a wide array of modalities, including phone calls, videoconferencing, remote monitoring, asynchronous messaging (eg, email and texting), and the use of a patient portal [1]. Digital cancer care has been shown to be effective for pretreatment discussions, the monitoring of adverse events, for counselling purposes, and for long-term cancer care follow-up [2]. However, there is a growing body of evidence that demonstrates inequitable access to digital care services, resulting in a widening health gap between population groups that are able to use digital care versus those that cannot. Reasons for this include an inability to afford the necessary technology, lack of language accessibility within certain applications, lack of infrastructure to support digital connectivity in rural areas, lack of cultural relevance of care provision, and lower levels of comfort in using certain technologies [3-6].

Structurally underresourced [7] and marginalized population subgroups, such as older Black adults, experience barriers specific to their identity, such as physical, cognitive, and sensory limitations or concerns [8]; lack of social or peer support to help with the use of technology [9]; and preference for in-person visits due to limited trust in technology and concerns about privacy [10]. When services are available, acceptability of care [11] is determined by a lack of cultural tailoring of language used in service and technology, such as not adapting the linguistic content of eHealth platforms to the cultural preferences of diverse populations [12], varying views or beliefs for disease management, such as cultural barriers when shifting from traditional in-person care to technology-based intervention platforms [13], and existing historic and societal barriers, such as general distrust of health care providers [14].

While other countries report that cancer disproportionately affects Black people [15], the lack of comprehensive race-based data collection in Canada means that the extent of the care gap affecting Black Canadians is unknown. However, a recent study that used census data to explore patterns of mortality inequities of Black adults in Canada indicates that Black men had an increased risk of dying from prostate cancer (hazard ratio: 1.33) than their White counterparts, and Black women were at an increased risk of dying from stomach cancer (hazard ratio 1.76), corpus uteri cancer (hazard ratio 1.78), and lymphomas and multiple myelomas (hazard ratio 1.26) than their White counterparts [16]. With limited race-based data collection, it is also unclear how race and racism affect digital cancer care use in Canada. It is essential that digital cancer care is delivered in a manner that meets the needs of all communities and does not exacerbate inequities between the most privileged and the most underresourced communities. Knowledge generated in partnership with these communities is essential to developing health care policy and planning that focuses on enhancing equity in access to and quality of digital care. Hence, the purpose of this study was to better understand the digital cancer care experiences of older Black cancer patients, their caregivers, and health care providers. Through this understanding, we sought to identify strategies that can support the delivery of better patient-centered digital cancer care.

Methods

Study Design

Qualitative research methods are appropriate for exploring the lived experiences and perspectives of individuals who are exposed to a social phenomenon like the usage of digital cancer care [17,18]. We used theoretical thematic analysis [17] as a methodology in order to conceptualize, collect, organize, and interpret data for this study. Specifically, we used a codebook approach to thematic analysis [18] that combines structure and reflexivity in methodological choices. In the following subsections of the methods, we describe how we structured our study approach by using 2 theoretical frameworks—the synergies of oppression lens [19] and the patient-centered care model [20]—to create a codebook and using multiple coders to ensure the accuracy of the coding process. The research team's interest in this study stems from a commitment to addressing systemic inequities and amplifying the voices of Black communities. We recognize our positionality influences every stage of the research process, from framing the research question to interpreting findings. Researcher subjectivity was addressed by regular team meetings to discuss and interpret data.

Theoretical Approach

The synergies of the oppression lens [19] is an analytic lens that can be used to illuminate the intersection of multiple systems of oppression that shape the lived or living experiences of older Black patients with cancer as they navigate the health system. Characteristics such as race, age, level of disability, sex at birth and gender, and income levels of individual and social groups are powerful indicators of their access to material and social resources that are necessary to achieve health and wellness. These characteristics (or multiple oppressions) operate in complex synergistic patterns that lead to poor health and have been used previously to unpack and understand inequities in cancer care [21-25]. In this study, we have used the synergies of oppression analytical lens to theorize a combination of oppressions impacting the digital care experiences of older Black patients with cancer. We were also guided by the 7 dimensions of Patient-Centred Care [20] model that outlines the essential components of a patient-responsive health care as (1) aligning the health system's vision, mission, values and quality improvement drivers to patient-centered goals; (2) providing collaborative, coordinated and accessible care at the right time and the right place; (3) providing care that considers physical comfort and emotional well-being; (4) respecting patient and family preferences, values, and cultural traditions

XSL•FO
RenderX

in the organization and delivery of care; (5) integrating family and patients in care teams, and having them fully partake in decision-making at the clinical and system level; (6) encouraging and facilitating the presence of family members in care settings; and (7) supporting informed decision-making by patients and their family by providing complete information in a timely manner. Accordingly, our study questions were as follows: What is the experience of older Black patients who have used digital cancer care? How can we improve the digital cancer care experience of older Black patients with cancer?

We hypothesize that strategies and interventions that will improve the digital cancer care experience of populations that are experiencing the most structural marginalization will improve the digital cancer care experience across all population groups in alignment with Bell Hooks's concept of "centering the margins" [26,27].

Participant Recruitment and Setting

This study was carried out between May 2022 and March 2023. A total of 3 groups of study participants were the focus of this study (Textbox 1).

Textbox 1. Three groups of study participants.

1. Patients: comprised of older Black adults, aged 55 years or older, given the growing health and social challenges of this age group, which includes chronic disease management and barriers in access to high-quality and timely care [28], who had been diagnosed with any form of cancer, including those no longer in active treatment, and had used digital cancer care services across the 10 Canadian provinces.
2. Caregivers: comprised of any individual who provided informal support in activities of daily living to older Black patients with cancer—this included family or paid caregivers.
3. Providers: comprised of health care professionals who regularly delivered clinical care to older Black patients with cancer.

Sampling was carried out through a nonprobabilistic convenience approach. This sampling strategy allowed us to cover various contexts (urban, rural, and remote) and diverse informants who could provide rich data on their experiences in receiving and delivering digital cancer care to older Black patients. The recruitment of potential study participants was supported by the Canadian Cancer Society (CCS), which is the largest cancer charity in Canada. Potential participant recruitment started in August 2022 and ended in January 2023. The CCS posted invitations to participate in the study using their database of patients with cancer, caregivers, and health care professionals. Those who were interested in participating in the study contacted the project coordinator by email—the research team received about 600 responses from potential participants. We sent detailed information letters on the study to all potential participants. In total, 6 groups of participants were created for each focus group, considering time zones and provincial linguistic diversity: (1) patients and caregivers in the Eastern provinces (Newfoundland and Labrador, Nova Scotia, and Prince Edward Island); (2) patients and caregivers in Central or Prairies provinces (Ontario and Manitoba); (3) patients and caregivers in Western or Prairies provinces (Saskatchewan, Alberta, and British Columbia); (4) patients and caregivers in Francophone/Bilingual provinces (Quebec and New Brunswick); (5) health care providers in 8 Canadian provinces; and (6) health care providers in Francophone or bilingual provinces (Quebec and New Brunswick); see Table 1. The final study comprised 55 participants across the 6 groups (Table 1). The final sample of 55 participants was sufficient to achieve code saturation in the qualitative data analysis, ensuring no new themes or codes emerged from the data [29,30].

Table 1. Number of participants in the focus groups.

Focus group	Participants, n
Patients with lived experience and caregivers	
Eastern Provinces (NF, NB, NS, and PEI)	12
Central & Prairie Provinces (ON and MB)	10
Western & Prairie Provinces (BC, AB, and SK)	10
Francophone or bilingual provinces (QC and NB)	8
Health care providers	
English-speaking provinces	10
Francophone or bilingual provinces	5
Total	55

Data Collection

Data were collected through 6 focus group interviews (about 120 minutes duration for each focus group) with the aforementioned groups of participants (Table 1). Focus group interviews were led by 2 Black peer researchers (PW and TM). This was an intentional and important strategy to reduce mistrust of the research process and to increase study participation by leveraging existing relationships between Black communities in Canada. During the focus group interviews, we used 2 distinct interview guides—a patient or caregiver interview guide (Multimedia Appendix 1) and a health care provider interview

XSL•FO
RenderX

guide (Multimedia Appendix 2)—to guide data collection. Both interview guides were developed from the research objectives and targeted literature review. Questions in the interview guides were structured to unpack issues of access and usage of digital cancer care and included probes relating to the roles of various actors in the usage of digital care, preference for various digital care modalities, frequency of digital care use, experiences, and challenges during the usage of digital care. All focus groups were carried out using the Zoom video teleconferencing software, and sessions were recorded with permission. The audio files of the recordings were transcribed externally by CMBusiness & Transcription Services in preparation for data analysis.

Following the focus group interview, a self-reported sociodemographic survey was sent to each focus group participant to better understand the diversity of age, income, and other sociodemographic characteristics that were present in the focus groups. Participation in the sociodemographic survey was optional.

Data Analysis

Qualitative data analysis followed Braun and Clarke's 6-phase thematic analysis approach, as outlined in their original [17] and updated [18] methodological work on codebook approaches to thematic analysis. NVivo 11 software facilitated the organization and coding of data. The analysis began in February 2023 and concluded in May 2023. To ensure familiarity with the data, all authors read and re-read the transcripts. A reflexive stance was maintained throughout the analysis, with the research team acknowledging their positionality, including assumptions and experiences that may influence interpretation. A codebook was initially developed based on the key elements of the patient-centered care model [20]. Line-by-line inductive and deductive coding was conducted independently by 2 researchers (PW and AS), with additional codes iteratively developed and refined during group discussions. Disagreements in coding or categorization were resolved through collaborative reflection and consensus, ensuring confirmability of the coding process. The final coding framework was applied to all transcripts, and excerpts were attributed to relevant codes. Detailed descriptions of each code were developed to deepen understanding of participants lived and living experiences. Themes and subthemes were generated through an iterative process of synthesis and review, prioritizing coherence, internal consistency, and nuanced representation of the data.

For methodological rigor and trustworthiness of our findings, we addressed key dimensions of qualitative research. *Credibility* was ensured through investigator triangulation, as multiple team members were involved in coding and the analysis process, with group discussions validating the consistency and interpretation of the data. To support *transferability*, we provide rich, thick descriptions of participants' experiences and contextual details, enabling readers to assess the applicability of our findings to other settings. *Dependability* was established by systematically documenting each stage of the coding and analysis process, including decisions made during data synthesis, to ensure transparency and reproducibility. Finally, *confirmability* was enhanced through reflexivity, where the research team acknowledged and reflected on their positionality and potential influences on the data interpretation, alongside a collaborative approach to consensus-building during coding and theme development. These steps reinforced the rigor of our analysis and ensured a nuanced, trustworthy representation of the lived and living experiences shared by participants.

Ethical Considerations

Institutional review board approval was provided for this research by the Toronto Women's College Hospital Research Ethics Board (reference 2022-0111-E). The research assistant sent a detailed informed consent form by email to all potential research participants. The researchers and research assistant responded to questions from potential participants by email or by phone conversations before they signed and returned their consent forms prior to the focus group interviews. Privacy and confidentiality of research participants were ensured by removing all identification information during data transcription and analysis; nonidentificatory codes were assigned to focus group interviews that were used in this manuscript. Focus group participants were provided the option to put on or off their camera during the conversation, and we reiterated the need to keep information shared during the conversation confidential at the onset of the focus group. All patients and caregivers who participated in the focus groups were given compensation of CAD $50 (US $35.16) for their time; health care providers were not provided any compensation for participating in the research. Participants had the right to withdraw from the study at any time, without any reasons.

Results

Sociodemographic Results

Of the 55 sociodemographic surveys that were sent to research participants, 24 were completed by patients and caregivers (Table 2). No health care providers completed the survey. All research participants who responded to the survey and whom we identified during the focus groups self-identified as Black people.

About two-thirds of patients and caregivers who participated in the focus group identified as male, and the same proportion of participants were between 50 and 64 years old. Most participants (20/21) had college-level education or higher. More than half of the participants had part-time jobs. There was great diversity in the household income level of participants, with more than half of them earning less than CAD $60,000 (CAD $1=US $0.7) per year.

Thematic Results

The experiences of patients, caregivers, and health care providers on the use of digital cancer care for older Black adults were similar across the 4 patient or caregiver groups and the 2 provider groups. In total, 5 main themes emerged from this qualitative dataset: (1) barriers to access and participation in digital care services, (2) shifting caregiver dynamics, (3) autonomy of choice and choosing based on the purpose of care, (4) digital accessibility, and (5) effective digital communication.

Barriers to Access and Participation in Digital Care Services

Our findings reflected that older Black patients with cancer are not a homogenous group with respect to their lived experience of digital care. They are a heterogenous group composed of individuals with unique needs and lived experiences. Additionally, individuals within this group will have experienced systems of oppression to various degrees, which has shaped the way they experienced digital cancer care. Our data show 4 main challenges that were experienced by older Black patients:

(1) *Multimorbidity* seemed to be the most salient challenge that influenced the capacity of older Black patients with cancer to participate in virtual encounters. Across the 6 focus groups, study respondents often talked about 2 main features of multimorbidity that limited the capacity of patients to effectively engage in virtual encounters. First, the severity of the patient's cancer, marked by clinical symptoms such as intense chronic pain, loss of autonomy in activities of daily living, and persistent mental fatigue, meant that older Black patients were not always capable of fully participating in virtual encounters. Second, another aspect of multimorbidity was related to the adverse effects of chemotherapy, as explained by a caregiver.

> *I think sometimes we have to consider the patient's state of mind, maybe how long the person just finished taking a medication; the amount of time before you could engage them in a virtual meeting […] you have to look at the possibility of the patient being stable before you could engage into any important communication so that you might not end up getting misinformed by the patient just because of the reactions of medications.* [FG 1—Caregiver]

Several respondents pointed out that chemotherapy is exhausting for most patients with cancer. Older Black patients lost appetite, had nausea and vomiting as well as fatigue after rounds of

XSL•FO
RenderX

chemotherapy. These patients could not effectively participate in virtual meetings without assistance.

(2) The *geographic location* of patients emerged as another issue of concern for digital cancer care as explained by a patient:

> *And I will say maybe most times people in the rural areas tend not to have a good stable communication network system.* [FG 4—Patient]

Participants highlighted issues related to internet connection in rural and remote areas. Internet was often unreliable—they may spend days without any connections so they cannot join the virtual meeting; unstable—they may have an intermittent internet connection, so they are often disconnected from the virtual meeting; or low bandwidth—the poor quality of internet meant the connection is very slow.

(3) *Socially isolated* older Black patients were reported as having difficulties in accessing digital care. One respondent talked about a community-based initiative called the African Cancer Support Group that was launched to support socially isolated individuals of African and Caribbean descent in Alberta.

> *I say that because we have these groups called the African Cancer Support Group to help the friends of Africans or Caribbean and Black Canadians going through cancer. […] We're able to provide some patients with computers.* [FG 4—Caregiver]

This support group identified lack of access to digital technologies such as computers, smartphones, and tablets as an obstacle to digital l care for socially isolated Black patients. One way in which they supported this disadvantaged group was by providing computers to enhance access to digital care.

(4) *Linguistic barriers* emerged as a unique challenge to digital care, as explained by a health care provider:

> *Language barrier is kind of something that is digging deep to the Blacks because we have different kinds of languages.* [FG 5—Health care provider]

Our study participants pointed out that some older Black patients with cancer were not fluent in English or French, the official languages of Canada. Health care providers were also concerned that Black seniors seemed to be more proficient in traditional African or Caribbean languages such as Swahili or Patois. These languages are not easily understood by health care professionals, and it was difficult to find trained interpreters that could facilitate communication with these patients.

Shifting Caregiver Dynamics

Across the 6 focus groups, there was increasing recognition of the central role of caregivers in enabling and supporting digital cancer care for older Black patients. Respondents pointed out 4 main aspects of the shifting roles of caregivers as a dynamic process:

(1) Caregivers were critical in supporting patients with limited digital literacy before, during, and after the virtual encounter:

> *But one of the things that was a concern for me was because my mom is elderly and she's not really tech savvy, so I had to take charge of all portals and mail and all of that.* [FG 2—Caregiver]

(2) Caregivers were more involved in direct caregiving to their patient—a role that was traditionally reserved for health care providers. While family caregivers with no prior experience or health care training seemed to be less comfortable in providing direct care, paid caregivers seemed to be more comfortable in providing direct care.

(3) As caregivers were more involved in supporting digital care and providing direct care to Black seniors, there were privacy concerns related to the roles of caregivers. Specifically, some autonomous patients preferred privacy during their virtual meetings:

> *Like I said earlier, he has prostate cancer, and I think most times there are moments he wants to say things that are personal. So, at the moment, I like to understand his privacy and I'll give him that privacy.* [FG 4—Caregiver]

Other patients with cognitive disorders who needed support from caregivers were not concerned about privacy:

> *So, I think in terms of privacy, because already my patient has a little bit of memory loss, so I think without me being there, I think most things would be left untold.* [FG 4—Caregiver]

And family caregivers, like a spouse supporting the partner in digital care, did not consider privacy an issue

> *I'm not worried about privacy, it's my husband. If the patient is the wife, what kind of privacy? And mostly when you are filling the form, you put all the information they're on the form, so they already know everything about you.* [FG 4—Caregiver]

(4) Some older Black patients expressed anxieties about their children who became caregivers. Specifically, the emerging role of caregivers gave rise to a shift in power or influence where caregivers are more involved in decision-making. Some older Black patients were confronted with their children having more influence in their health care—a role that children do not traditionally hold in these cultures and societies.

Autonomy of Choice and Choosing Based on the Purpose of Care

Focus group participants often positioned digital care dualities and in-person care as alternative and complementary means of delivering care for older Black patients with cancer.

(1) By using digital care, patients particularly appreciated the convenience and comfort of receiving care in their homes, as explained by a patient:

> *You can stay at the comfort of your home. And when you have a virtual conversation with your specialist, you feel this level of comfort. And you can tell your specialist how you're actually feeling.* [FG 4—Patient]

Three other benefits of digital care for patients that emerged from our data included easy access to their specialist, feeling safe by not being exposed to the general population during the

XSL•FO
RenderX

COVID-19 pandemic, and older Black adults felt more empowered and confident to participate in their care.

(2) Caregivers and health care providers often talked about and greatly appreciated the flexibility of digital care in adjusting their work schedules.

(3) Despite these benefits, our respondents recognized that digital care was not always realistic or possible in the continuum of cancer care. They explicitly pointed out areas of their cancer care where digital care was impractical. One patient pointed out the need for a physician examination:

> *I'll say that I prefer in person because while I'm communicating in person, there are some physical examinations and some things I may want to explain myself, which I wouldn't be able to do virtually so I prefer in person.* [FG 1—Patient]

(4) Some focus group members argued for more hybrid models of care delivery that integrated digital care and other care modalities like home care and ambulatory care.

Digital Accessibility

Study participants recognized that an important aspect of digital care meant that they had to frequently use information and communication technologies for their routine care needs. While most of our study participants were relatively comfortable with technology, certain areas of concern emerged from the interviews.

Digital literacy was identified as a problem for all participant groups—patients, caregivers, and health care providers. Older Black adults with limited digital literacy had difficulties in understanding and using computers, tablets, or applications. They needed support from caregivers and health care professionals. Interestingly, some caregivers and health care professionals also faced digital literacy issues, as explained by a health care provider:

> *Yes, actually, it was more time intensive, and it was more stressful because I wouldn't say I'm that good at tech myself.* [FG 6—Health care provider]

The limited capacities of participants to use digital technologies could be frustrating in preparing and operating virtual encounters.

Some caregivers and health care providers mentioned that they had to invest time and efforts to improve their digital literacy skills and competencies in order to be ready to effectively support their patients.

> *During the pandemic, I had to learn a lot of technology skills and at the time I was involved with a virtual meeting with my patient, helping him set up virtual care with his GP and with his oncologist and every kind of health professionals involved with my patient.* [FG 2—Caregiver]

Certain health care organizations offered training resources to help health care providers to improve tech skills.

Finally, we noticed that older Black patients often said that they could not easily build their digital literacy skills due to their age and the burden of cancer on their daily lives. This means that the older Black patients were more reliant on their caregivers for their digital care needs. In this situation, patients seemed to value or prefer caregivers that are compassionate and patient in the way they provided support and assistance during virtual encounters:

> *I think for me, say one of the important things that I benefited from my caregiver, she's very patient with me. That is one thing I benefit from her. Because I think at the time, it took me almost a month to be able to navigate using virtual care. She was there for me, and her patience was something that ... I mean, I can't comprehend on the time, because she took the time to put me through, stage by stage, for me to understand what I was doing, and how to do it.* [FG 3—Patient]

Effective Digital Communication

As focus group participants frequently talked about the importance of digital technologies as a medium for good communication and information exchange with their health care team, there were some concerns about confidentiality and privacy. Specifically, we noticed an aspect of privacy where older Black patients were reluctant to share their health information with their children, as explained by a patient:

> *Yeah, when I had my kids around there were times when I was uncomfortable because there were some things I couldn't answer out loud, so I just did mute it when the question was asked and sometimes I would just tell my doctor, not now (inaudible) when we have a physical appointment or something, or maybe later when it's just me and my wife. If it's just my wife, I can say anything I want to say, but when my kids are around I have to limit what I say because I don't want them having this idea that something terrible is going to happen to dad and all that.* [FG 2—Patient]

These older Black patients seemed to be less concerned about sharing information with their spouses.

Our focus group participants also identified other areas where digital technologies could enhance communication, such as (1) having transcripts of conversations after the virtual encounter, (2) live translations for people that speak different languages, or (3) including or using features of technology to improve care for people with visual or hearing impairments:

> *And when it comes to hearing impairment, I think there's something you use in your ear that could help improve your hearing aid. So, when you're looking at things, you have to look at these tools equally so that you don't know whether you're dealing with a patient that has a hearing problem or an eye problem.* [FG 2—Caregiver]

A summary of barriers and facilitators to digital cancer care based on interview findings is shown in Textbox 2.

XSL•FO
RenderX

Textbox 2. Barriers and facilitators to digital cancer care for older Black adults.

Barriers to digital cancer care

- Limited engagement in virtual encounters of patients fatigued by cancer and chemotherapy or radiotherapy
- Difficulties connecting to virtual encounters due to limited and unstable internet connections in rural and remote areas
- Socially isolated older Black patients had limited access to digital technologies
- Difficult communication between patients and providers during virtual encounters due to linguistic barriers in traditional African or Caribbean languages
- Privacy concerns when caregivers supported competent patients during virtual encounters
- Difficulties in using digital care technologies due to limited digital literacy of patients, caregivers and providers
- Concerns of shifting power dynamics when children support their parents for digital cancer care
- Digital care was impractical in emergency situations

Facilitators to digital cancer care

- Community-based cancer support groups provided computers to socially isolated older Black patients
- Caregivers supported patients with limited digital literacy before, during, and after the virtual encounter
- Patients felt comfortable receiving digital cancer care in their homes
- Digital cancer care offered great flexibility to the work schedules of caregivers and health care providers
- Building digital literacy skills of caregivers and providers to provide better support to older Black patients
- Key features of digital technologies, such as visual and hearing aids or the capacity to have transcripts of virtual meetings, motivated actors to uptake digital cancer care

Discussion

Principal Findings

Inequities in cancer outcomes can be linked to higher cancer risk, delayed diagnosis, and unequal opportunities to access timely treatment. This is more significant for certain population groups that experience marginalized social conditions that are shaped by stigma, discrimination, and intergenerational trauma [15,31]. Inequities in cancer care can be further exacerbated at the intersection of social identities with other marginalizing conditions such as unequal access to the social determinants of health, resulting in health inequities that are structured and reinforced by the health care system [23]. One example of this can be the rapid shift of cancer care services from traditional in-person care towards digital cancer care models that arose in response to social distancing measures during the COVID-19 pandemic [32,33]. The implications of this shift—and the resulting impact in terms of access and optimal digital cancer care for populations that experience marginalizing social conditions—are still unknown. In our study, we sought to unpack these issues so that we could inform the redesign of digital cancer care to meet the needs and priorities of underresourced communities—thereby enabling better digital cancer care for everyone.

Prior systematic reviews reveal increasing evidence of the effectiveness of digital cancer care, which is comparable to in-person care, in counseling, and supportive medical care for people with cancer [2] and the increasing adherence of vulnerable populations, including older people and Black populations, to digital care technologies [9,34]. People living with cancer and health care providers were grateful for the convenience of videoconferencing because of reduced travel time to clinics and less travel expenses [2]. There was increasing recognition of digital health literacy challenges for older adults with investments in training older adults on the use of digital technologies and adapting these technologies to the unique needs of this population [2,9,34]. Our findings concur with previous studies on the barriers and facilitators of digital cancer care. Specifically, we identified 8 barriers to an optimal digital cancer encounter, such as linguistic barriers and limited digital literacy, and 6 facilitators that can enhance the digital cancer care experiences of older Black adults, such as community-based cancer support groups and flexible work schedules. Efforts to improve digital cancer care will require a multipronged approach that targets these specific barriers to digital care while creating system-wide policies that encourage these facilitators and influence the distribution of social determinants of health. For instance, policy interventions may be required to improve the stability of internet connections in rural and remote areas, while interpretation resource guides may help health care providers to know what translation and interpretation resources are available to them at the local or provincial and national level to overcome linguistic barriers. While these multipronged interventions will improve the digital cancer care experience for older Black adults, they are also equity-promoting for other underresourced communities and can enhance care for all.

We elaborate on 2 key findings of our study. First, our findings revealed an increasing recognition of the critical role of caregivers in supporting older Black adults in accessing and using digital cancer care. Older Black adults who are fatigued due to cancer multimorbidity, who had limited digital literacy, or who had cognitive disorders due to cancer relied on the support of caregivers before, during, and after virtual encounters.

XSL•FO
RenderX

However, we also noticed that autonomous patients had privacy concerns when supported by caregivers for their digital cancer care needs. This implies that there is an urgent need for guidance at the policy and organizational level on the roles and scope of practice of caregivers in supporting digital cancer care that is tailored to the unique needs of patients with cancer.

Second, previous studies suggest that the cultural background of racialized patients influences their views on symptoms, diagnosis, and treatments that may hinder access to cancer care [31]. Our findings unraveled concerns of older Black patients with cancer who were confronted with their children having more influence in their health care during virtual encounters and who were reluctant to share their health information with their children. These dynamics between older Black patients with cancer and their children have to be taken into consideration during digital cancer care. Framing virtual cancer care in the context of a person's cultural understanding of health requires the health care provider to have an awareness of the community that they serve [31]. This implies that efforts to develop culturally sensitive guides to digital care may be an important step to supporting health care providers to provide culturally appropriate digital cancer care to older Black patients.

Strengths and Limitations

This study has several strengths. The use of the Synergies of Oppression framework [19] provided a robust lens to examine how intersecting systems of oppression influence access to digital cancer care for older Black patients. Including participants from 10 Canadian provinces enhanced the transferability of findings by reflecting diverse regional contexts. The focus on an understudied population—older Black adults—alongside perspectives from caregivers and health care providers offered a multistakeholder view that highlights barriers, facilitators, and opportunities for improving digital care systems. Applying Braun and Clarke's thematic analysis [17,18] ensured a systematic and reflexive analysis, while the findings hold strong policy and practice relevance for advancing equitable, patient-centered care. Reflexivity throughout the research process further strengthened analytical transparency.

However, the study also has limitations. Conducting focus groups virtually may have introduced selection bias, as individuals with limited digital access were unable to participate. While race concordance between facilitators and participants likely fostered trust, discordance in gender, class, and affiliations may have influenced participation dynamics, and the presence of patient-caregiver dyads in the sessions may have constrained the expression of dissenting views. Additionally, regional differences across provinces were not analyzed, and findings may not reflect the full diversity within Black communities given variations in intersecting identities such as gender, class, and migration status.

Data limitations included the lack of completed socio-demographic surveys from health care providers, which restricted exploration of social factors shaping their experiences. Member checking was not conducted, though reflexivity mitigated this by ensuring transparency and neutrality. Lastly, while focus groups facilitated shared insights, they may have limited the discussion of deeply personal topics. Future research using individual interviews and exploring regional and nonusers' experiences would provide further depth.

Despite these limitations, this study provides timely, actionable evidence to enhance digital cancer care for older Black adults. It highlights key barriers and facilitators, offers multistakeholder insights, and lays the groundwork for equitable improvements in digital health care delivery.

Conclusions

Older Black patients face multiple barriers, such as linguistic, privacy concerns, and limited digital literacy, to accessing and using digital cancer care. A multipronged approach that focuses on addressing barriers, encouraging facilitators, and creating culturally sensitive guides to digital care can form the basis of health system efforts to improve access to digital cancer care. A redesign of digital cancer care programs, tailored to the needs of marginalized social groups like older Black patients, can enhance the digital care experience for all population groups. Public policies and organizational practices that address issues like availability of internet in remote areas, resources to support linguistic barriers, or culturally sensitive training are important in responding to the complexity of access to digital cancer care.

Acknowledgments

The authors would like to acknowledge and thank all the participants who agreed to participate in this study for their valuable time and contributions. The authors would like to thank the Canadian Cancer Society for assisting in the recruitment of potential study participants. This study was commissioned by the Canadian Cancer Society, through funding they received from Merck Inc.

Data Availability

The datasets generated and analyzed during this study are not publicly available as they include confidential data, but are available upon request from the corresponding author, including the need of Women's College Hospital ethical vetting.

Authors' Contributions

Abstract

Background: Digital education for outpatient patients with atrial fibrillation (AF) has gradually increased. However, research on digital education for patients undergoing atrial fibrillation catheter ablation (AFCA) is limited.

Objective: This study aimed to develop a novel digital animation-based multistage education system and evaluate its quality-of-life benefits for patients with AFCA.

Methods: This randomized controlled clinical trial included 208 patients with AF who underwent catheter ablation in the Department of Cardiology at Renmin Hospital of Wuhan University between January 2022 and August 2023. The patients were randomly assigned to the digital animation intervention (n=104) and standard treatment (n=104) groups. The primary outcome was the difference in the quality of life of patients with atrial fibrillation (AF-QoL-18) scores at 3 months. Secondary outcomes included differences in scores on the 5-item Medication Adherence Report Scale (MARS-5), Self-rating Anxiety Scale (SAS), and Self-Rating Depression Scale (SDS) at 3 months.

Results: In the digital animation intervention group, the AF-QoL-18 score increased from 38.02 (SD 6.52) to 47.77 (SD 5.74), the MARS-5 score increased from 17.04 (SD 3.03) to 20.13 (SD 2.12), the SAS score decreased from 52.82 (SD 8.08) to 45.39 (SD 6.13), and the SDS score decreased from 54.12 (SD 6.13) to 45.47 (SD 5.94), 3 months post discharge from the hospital. In the conventional treatment group, the AF-QoL-18 score increased from 36.97 (SD 7.00) to 45.31 (SD 5.71), the MARS-5 score increased from 17.14 (SD 3.01) to 18.47 (SD 2.79), the SAS score decreased from 51.83 (SD 7.74) to 47.31 (SD 5.87), and the SDS score decreased from 52.78 (SD 5.21) to 45.37 (SD 6.18). The mean difference in AF-QoL-18 score change between the 2 groups was 1.41 (95% CI 2.42-0.40, *P*=.006) at 3 months. The mean difference in MARS-5 score change was 1.76 (95% CI 2.42-1.10, *P*<.001). The mean difference in SAS score was –2.91 (95% CI –3.88 to –1.95, *P*<.001). Additionally, the mean difference in SDS score was –1.23 (95% CI –0.02 to –2.44, *P*=.047).

XSL•FO
RenderX

Conclusions: Our study introduces a novel digital animation educational approach that provides multidimensional, easily understandable, and multistage education for patients with AF undergoing catheter ablation. This educational model effectively improves postoperative anxiety, depression, medication adherence, and quality of life in patients at 3 months post discharge.

Introduction

Atrial fibrillation (AF) is the most common cardiac arrhythmia and significantly increases the risk of mortality, stroke, heart failure, and dementia, thereby severely impacting patient quality of life (QoL) [1]. It is estimated that by 2050, at least 72 million Asian individuals will be diagnosed with AF [1,2]. The primary goals to treat AF include symptom improvement, heart rate and rhythm control, and stroke risk reduction [3,4]. Currently, catheter ablation has progressively emerged as the primary therapeutic approach for rhythm control in AF, owing to its potential to mitigate AF episodes and enhance patients' QoL [3,5]. However, the efficacy of catheter ablation in reducing AF remains uncertain with regard to its impact on patients' QoL.

Studies have indicated that negative emotions, alcohol consumption, smoking, obesity, and sleep disorders, among other high-risk factors, can expedite AF progression and prognosis, potentially directly impacting the efficacy of atrial fibrillation catheter ablation (AFCA) and postoperative recovery [6]. Additionally, anticoagulation therapy significantly reduces the stroke risk in patients with AF and is emerging as a crucial factor affecting treatment efficacy [7,8]. Therefore, alongside enhancing the safety and QoL benefits of AFCA, strategies focusing on risk factor management and medication adherence to improve ablation outcomes are essential in patients with AF [9,10].

Popular science interventions, such as animations and comics, are a noninvasive, entertaining, emerging approach to disease intervention used to ameliorate patient emotions, sleep, lifestyle, and disease prognosis [11-13]. Patients can vividly comprehend various aspects of AF, including etiology, pathology, surgical procedures, and complications, using vivid and engaging animation content, thereby enhancing their interest and engagement in health management. A recent study suggested that using animation education can enhance patients' understanding of AF and increase their satisfaction with clinical care [14].

With the advancement of internet technology, an increasing number of patients obtain information regarding AF via web-based videos. However, most videos vary in the direction and quality of their focus and offer limited benefits to patients undergoing AFCA [15]. Hence, new and more accessible digital animations are needed, and patients should be provided with digital education during the hospitalization and postdischarge phases of catheter ablation to facilitate management at different stages of AF. In this prospective, randomized, controlled clinical trial, we aimed to evaluate the benefits of multistage education based on digital animation for patients with AF undergoing catheter ablation.

Methods

Study Design

The trial protocol followed the guidelines outlined in the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (Multimedia Appendix 1) for clinical trial reporting. Written informed consent was obtained from all patients. The complete protocol and relevant materials are presented in Multimedia Appendix 2.

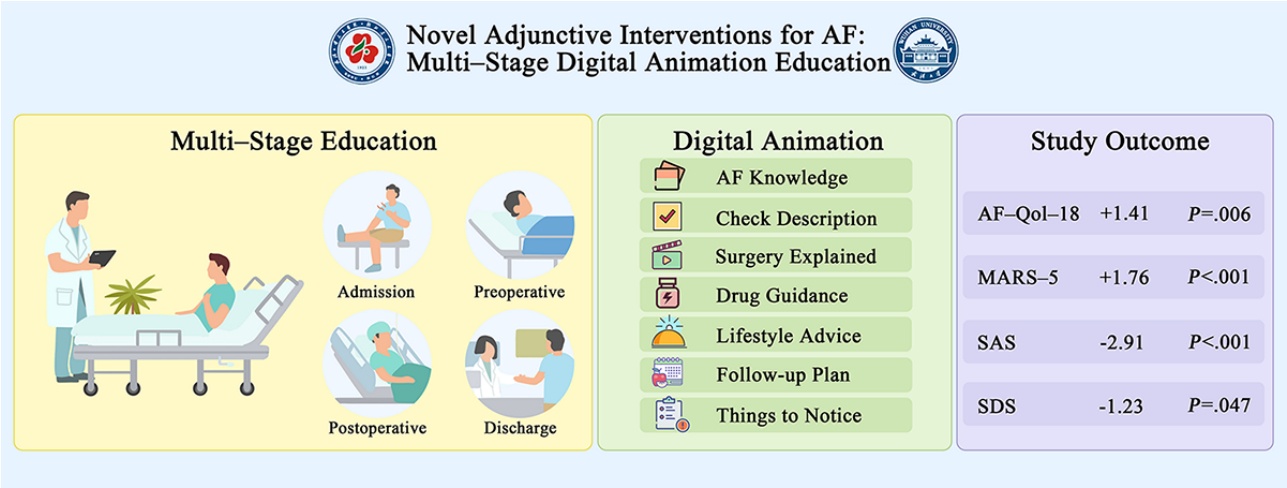
Study Population

This randomized controlled trial enrolled 208 patients with AF who underwent AFCA in the Department of Cardiology at Renmin Hospital of Wuhan University between January 2022 and August 2023. The primary inclusion criteria were as follows: (1) aged between 18 and 90 years, (2) confirmed diagnosis of AF via surface electrocardiogram (ECG) or ambulatory ECG examination, and (3) patients with AF who received AFCA for the first time and were successfully treated during their stay at Renmin Hospital of Wuhan University. The procedures for both groups were conducted by the same AFCA team, ensuring consistency in the ablation techniques used. All the AF diagnosis and treatment criteria strictly adhered to the AF management [16]. Participants failing to meet the study criteria, as determined by the clinical investigator, were excluded if they scored below the designated threshold on the Mini-Mental State Examination or had a medical history of percutaneous coronary intervention or coronary artery bypass grafting. The detailed inclusion and exclusion criteria are provided in Multimedia Appendix 2.

Randomization and Masking

A web-based randomization tool was used to allocate 208 patients undergoing radiofrequency ablation to either the digital animation intervention group or the standard treatment group, with equal probability. Stratification based on gender and age (>60 or ≤60 years) was conducted to ensure a balance in baseline characteristics between the 2 groups. The blinding of participants was unfeasible given the inherent nature of the intervention.

XSL•FO
RenderX



Study Procedures

Participants were assessed at baseline (upon admission) and 3 months post discharge. During the recruitment process, baseline datasets containing sociodemographic characteristics and medical histories were obtained from the digital animation intervention and control groups. Standardized questionnaire surveys were conducted, including the quality of life of patients with atrial fibrillation (AF-QoL-18) [17,18], Self-rating Anxiety Scale (SAS) [19], Self-Rating Depression Scale (SDS) [20] and 5-item Medication Adherence Report Scale (MARS-5) [21,22]. Information regarding at-home medication use was collected from the patients in both groups at the time of discharge. Patients completed the standardized questionnaires at the 3-month follow-up. Patient characteristics and outcomes were collected by reviewing medical records of trained clinical physicians and participant self-reports. Multimedia Appendix 2 contains details of data acquisition in the study protocol.

Study Interventions

Based on the recommendations of the guidelines for treating AF, doctors provided all patients with standardized treatment and knowledge regarding AFCA [16]. In the digital animation intervention group, doctors conducted regular knowledge lectures to patients and used customized digital animations during treatment to educate them, ensuring that patients effectively received relevant information regarding AF treatment at appropriate stages. Figure 1 provides a visual summary of digital animation education for AF.

Figure 1. This study presents a visual summary of a digital animation-based educational framework for AF management, structured into 4 distinct phases. The first phase, admission, involves the initial education of patients about AF. The second phase, preoperative, employs digital animation to elucidate the surgical procedure. The third phase, postoperative, offers comprehensive guidance on medication and lifestyle modifications. The final phase, discharge, focuses on developing a structured follow-up plan. The digital animation comprehensively covers essential topics such as AF Knowledge, Check Description, Surgery Explained, Drug Guidance, Lifestyle Advice, Follow-Up Plan, and Things to Notice. The outcomes of the study demonstrate significant improvements, including AF-QoL-18 (P=.006), MARS-5 (P<.001), SAS (P<.001), and SDS (P=.047). AF: atrial fibrillation; AF-Qol-18: atrial fibrillation effect on quality-of-life scale; MARS-5: 5-item Medication Adherence Rating Scale; SAS: Self-rating Anxiety Scale; SDS: Self-Rating Depression Scale.

In the first phase, physicians provided standardized iPad devices (Apple) to facilitate playback and guided patients in the digital animation intervention group to watch 4 AF-related animations during admission, preoperative, postoperative, and discharge periods. These animations encompassed various aspects as follows: (1) imparting knowledge on cardiac anatomy, mechanisms underlying AF occurrence, and associated risk factors, as well as explaining the necessary examinations before catheter ablation and their significance; (2) discussing the purpose, process, and precautions of catheter ablation surgery; (3) outlining postoperative care requirements during hospital stay following catheter ablation; (4) emphasizing medication adherence upon discharge along with lifestyle recommendations and plans for regular follow-up visits. Furthermore, physicians addressed any queries raised by patients after viewing the animations to enhance comprehension. Patients in the control group solely received routine preoperative discussions without access to digitally animated educational videos at different stages. All patients completed a comprehensive study scale upon admission.

In the second phase, patients in the intervention and control groups were followed up 3 months after discharge by telephone to complete the study questionnaire. Multimedia Appendix 2 provides a detailed description of the intervention activities and their implementations.

All animation contents were directed and produced under the guidance of multiple cardiologists with extensive expertise. This ensured that the animations included important information about the diagnosis and treatment of diseases, surgeries, and crucial aspects of home-based rehabilitation, including improvements in sleep, emotional care, dietary adjustments, medication adherence, and activity recommendations. To minimize barriers to health education dissemination and language obstacles, animations were created based on elementary literacy levels, with audio and subtitles provided in standard Mandarin Chinese. However, each animation was strictly controlled for <5 min. Additionally, regular quality control and feedback mechanisms were implemented to ensure intervention effectiveness.

XSL•FO
RenderX

Regardless of the study group, all patients received standard hospital education from health care professionals and could discuss any questions or concerns regarding AF treatment with their primary physicians. All patients underwent AFCA and were followed for 3 months post discharge.

Measurements

BMI, calculated as weight (kg) divided by height (m^2), was obtained from the self-reported height and weight.

Measures related to psychometrics and psychological aspects, including the AF-QoL-18, SAS, SDS, and MARS-5, were used. The AF-QoL-18 was used to assess QoL in patients with AF. The SAS was used to assess individual levels of anxiety. The SDS was used to measure depression severity. The MARS-5 was used to evaluate patient medication adherence. The details of the QoL scores and related quality controls are listed in Multimedia Appendix 2.

Outcomes

Clinical outcome measurements were obtained at the 3-month follow-up. The primary outcome was the difference in AF-QoL-18 scores at 3 months, while the secondary outcomes included differences in MARS-5, SAS, and SDS scores. The definitions of the clinical outcomes and details regarding quality control are presented in Multimedia Appendix 2.

Ethical Considerations

This randomized controlled clinical study was approved by the Research Ethics Committee of Renmin Hospital of Wuhan University (approval number WDRY2021-K161) and registered with the Chinese Clinical Trial Registry (registration number ChiCTR2400081673). The trial was conducted in accordance with good clinical practice guidelines, the Declaration of Helsinki, and all relevant laws and regulations in China.

Written informed consent was obtained from all participants prior to enrollment. The consent forms detailed the study objectives, procedures, potential risks, and benefits, as well as data use policies. The informed consent documents have been uploaded as part of this submission (Multimedia Appendix 2).

No identifiable images of participants are included in the manuscript or supplementary materials. Identifiable information was removed from the datasets prior to analysis. All study data were anonymized and deidentified to protect participant privacy. All consent forms explicitly authorized the use of anonymized data for research publication.

The study involved only standard clinical care for AFCA and a digital animation-based multistage education program, which is categorized as routine and noninvasive patient education. In accordance with local regulations for low-risk clinical trials and the ethical approval guidelines of Renmin Hospital of Wuhan University, no financial compensation was provided to participants due to the minimal-risk nature of the study.

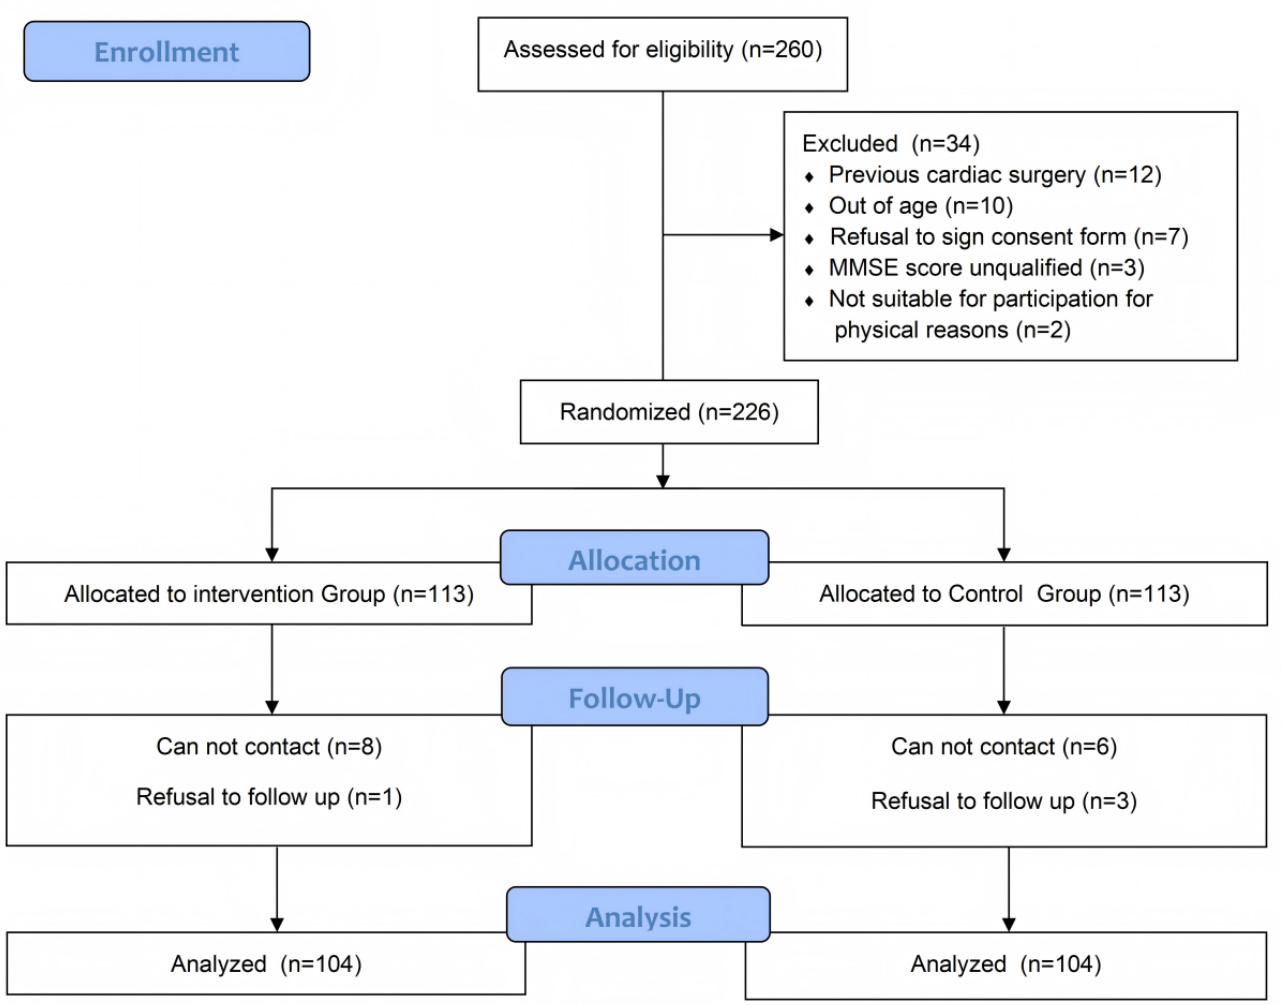
Statistical Analysis

The sample size was estimated by comparing 2 independent proportions with a type I error rate (α) set of 2.5%, an intracluster correlation coefficient of 0.01, and an anticipated retention rate of 80%. A significant absolute difference of 20% in clinical outcomes was detected between the intervention and standard treatment groups, with a statistical power of 90% at a follow-up period of 3 months. Based on our calculations, a minimum sample size of 80 assessable patients per group was required to achieve the desired statistical power.

Statistical analyses were conducted using SPSS (version 23.0; IBM Corp) and R (version 4.2.2; R Foundation for Statistical Computing) software. Data with normal distribution are presented as mean (SD). The 2 groups were compared using the independent sample *t* test. Data with nonnormal distributions are presented as medians and interquartile ranges. The Mann-Whitney *U* test was used to analyze the differences between the groups. Categorical data are expressed as numbers and percentages and compared using the chi-square test or Fisher exact test, as appropriate. To assess the effectiveness of the intervention, the differences between the 2 groups were calculated by subtracting the change from baseline to 3 months in the control group from that in the intervention group. Then, an independent *t* test was used to compare differences between groups before and after the intervention. A $P<.05$ was considered statistically significant.

Results

Figure 2 illustrates participant recruitment and retention. Among 208 patients undergoing catheter ablation (average age of 60.9 years), 68 (32.7%) were female and 140 (67.3%) were male. At baseline, the participants were randomly assigned to the digital animation intervention (n=104) and standard treatment (n=104) groups, both of which had similar characteristics. Table 1 presents the baseline characteristics of the digital animation intervention and the standard treatment groups. Table S1 in Multimedia Appendix 3 reveals significant statistical improvements in the AF-QoL-18, MARS-5, SAS, and SDS scores (all $P<.001$) at 3 months compared with baseline. In the digital animation intervention group, the AF-QoL-18 score increased from 38.02 (SD 6.52) to 47.77 (SD 5.74; $P<.001$; Figure 3A), the MARS-5 score increased from 17.04 (SD 3.03) to 20.13 (SD 2.12; $P<.001$; Figure 3B), the SAS score decreased from 52.82 (SD 8.08) to 45.39 (SD 6.13; $P<.001$; Figure 4A), and the SDS score decreased from 54.12 (SD 6.13) to 45.47 (SD 5.94; $P<.001$; Figure 4B). In the conventional treatment group, the AF-QoL-18 score increased from 36.97 (SD 7.00) to 45.31 (SD 5.71; $P<.001$), the MARS-5 score increased from 17.14 (SD 3.01) to 18.47 (SD 2.79; $P<.001$), the SAS score decreased from 51.83 (SD 7.74) to 47.31 (SD 5.87; $P<.001$), and the SDS score decreased from 52.78 (SD 5.21) to 45.37 (SD 6.18; $P<.001$; Table S1 in Multimedia Appendix 3).



The AF-QoL-18 ($P=.002$), MARS-5 ($P<.001$), and SAS ($P=.02$) scores of the digital animation intervention and conventional treatment groups were significantly different at 3 months. However, the SDS score ($P=.90$) did not exhibit a statistically significant difference (Table S2 in Multimedia Appendix 3). Additionally, the mean difference in AF-QoL-18 score change between the 2 groups was 1.41 (95% CI 2.42-0.40) at 3 months ($P=.006$; Table S3 in Multimedia Appendix 3). The mean difference in MARS-5 score change was 1.76 (95% CI

XSL•FO
RenderX

2.42-1.10, *P*<.001; Table S3 in Multimedia Appendix 3). The mean difference in SAS score was –2.91 (95% CI –3.88 to –1.95, *P*<.001; Table S3 in Multimedia Appendix 3). Furthermore, the mean difference in SDS score was –1.23 (95% CI –0.02 to –2.44), indicating an estimated difference between the digital animation intervention and conventional treatment groups at 3 months (*P*=.047; Table S3 in Multimedia Appendix 3).

At the 3-month follow-up, all patients underwent 12-lead ECGs and 24-hour ambulatory ECG monitoring to assess rhythm control. Our findings indicated that 9 patients in the digital animation intervention group experienced atrial arrhythmic events, including AF, atrial flutter, and atrial tachycardia, compared with 13 patients in the control group. However, the difference in the recurrence rates of these arrhythmic events between the 2 groups was not statistically significant (*P*=.50; Table S4 in Multimedia Appendix 3). Additionally, the mean heart rate was 70.08 bpm in the digital animation intervention group and 70.85 bpm in the control group. The difference in mean heart rate between the 2 groups was also not statistically significant (*P*=.25; Table S4 in Multimedia Appendix 3). Neither group experienced serious cardiovascular events, and no adverse reactions related to the medications were reported in either group.

Figure 2. Screening, randomization, and follow-up flowchart. Our study recruited patients diagnosed with atrial fibrillation who were scheduled for catheter ablation at the Department of Cardiology, Renmin Hospital of Wuhan University, between January 2022 and August 2023. Following a rigorous screening process, eligible participants were randomly assigned to either the digital animation intervention, which received digital animation-based education, or the standard treatment groups, which received standard care. The follow-up period was 3 months. A total of 208 patients with complete data were included in the final analysis. MMSE: Mini-Mental State Examination.

Discussion

Principal Findings

This study demonstrates that multistage education based on digital animation improves the QoL and medication adherence of patients with AF and helps them improve their emotional well-being compared with conventional treatment. Digital animation-based multistage education serves as an adjunctive tool, providing visual cardiovascular disease knowledge and explaining necessary diagnostic procedures, the AFCA process, and treatment-related considerations. It also emphasizes the importance of medication adherence during rehabilitation and provides recommendations for lifestyle and behavioral changes, thereby amplifying the QoL benefits of AFCA.

Comparison With Prior Work

In clinical practice, AFCA has emerged as a critical interventional strategy for rhythm control in patients with AF [5]. This procedure specifically targets and ablates ectopic triggering foci and abnormal electrical conduction pathways that are responsible for the initiation and perpetuation of AF [5]. By effectively disrupting these arrhythmogenic substrates, AFCA aims to restore and maintain normal sinus rhythm, thereby improving patient outcomes [5]. However, some patients experience suboptimal long-term outcomes [23]. This phenomenon may be attributed to a lack of understanding of AF, failure to eliminate risk factors, or poor medication adherence, directly impacting the effectiveness of AFCA and postoperative recovery [24-26]. Patient education regarding AF is crucial for reducing these adverse effects. Digital animation, a form of patient education, offers a more engaging and informative approach due to its audiovisual characteristics. This mode of patient education is more effective than traditional

XSL•FO
RenderX

methods, such as visual brochures or one-on-one verbal conversations [27-29]. Recently, a randomized clinical trial evaluated the impact of video education created by doctors on patients with AF [14]. The results indicated that video education effectively improved AF knowledge and nursing satisfaction among outpatients with AF.

Previous animations used to educate patients with AF primarily focused on AF risk factors, symptoms, complications, and pharmacological and nonpharmacological treatments. However, knowledge regarding the procedural aspects of patients undergoing ablation surgery [30,31]. Unfamiliarity with the surgical environment and lack of understanding of the surgical procedure are important factors contributing to preoperative anxiety among patients [32,33]. This results in preoperative sleep disorders and adversely impacts postoperative efficacy and recovery [34]. Explaining the purpose, process, and precautions of surgery can help alleviate preoperative anxiety during the waiting period. A randomized controlled study demonstrated that combining audiovisual methods to educate patients about preoperative preparation, intraoperative procedures, and postoperative intensive care unit admission effectively reduced preoperative anxiety among patients undergoing coronary artery bypass grafting surgery [35]. Additionally, research using virtual reality devices to provide patients with a first-person perspective of the operating room and surgical procedures found a reduction in preoperative negative emotions and increased postoperative satisfaction [33]. These results indicate that educating patients about surgical procedures can improve their emotional state and benefit them in various aspects, including mental well-being and QoL, during the perioperative period.

In this study, targeted digital animation was designed for patients with AF undergoing AFCA. Compared with traditional audiovisual educational materials for patients with AF, this animation included additional information regarding the purpose, surgical process, intraoperative aspects, and postoperative considerations of catheter ablation. These contents helped reduce patient anxiety during hospitalization, deepen patient understanding of AF, promote changes in unhealthy lifestyles, and improve patient medication adherence, ultimately contributing to QoL enhancement in patients with AF [36-38].

Numerous people have recognized the advantages of video education over traditional educational methods, and numerous studies have produced professional educational videos. However, in clinical practice, most patient education was conducted as a single event during outpatient or inpatient visits [30,31]. Regular and repeated education helps improve patient knowledge of the disease over time. Studies have demonstrated that the relevant knowledge acquired by patients with AF significantly declines 2 weeks after receiving education, while multiple educational sessions help enhance patients' awareness of the disease [14,39,40]. Compared with previous research, this experiment made a preliminary attempt by dividing surgery-related educational materials into preoperative and postoperative stages. Moreover, videos were sent to the patients for reinforced education after discharge. Instead of completing all educational content in a single session, this experiment used a multistage approach, effectively reducing the time required for patients to receive education, with each stage lasting <5 minutes. Patients with AF are mostly older people, particularly those with lower cognitive function, and receiving all educational information in one session can be challenging [41]. The short duration and highly focused nature of these videos ensured that the patients maximized their attention and minimized the opportunity for attentional decline. Furthermore, this staged intervention approach helped patients retain information from different stages of education to some extent, thereby improving medication adherence after discharge.

Limitations

This study has several limitations to consider when interpreting the results. First, the sample size was relatively small (208 patients), and the study was conducted in a single hospital. Therefore, the generalizability of the results to larger populations or different health care settings is limited and requires further investigation. Second, the follow-up period was only 3 months, which may not capture the long-term educational effects and stability of the digital animation intervention. A longer follow-up may provide a more comprehensive understanding of the sustained impact of educational interventions. Third, the perioperative 3-month period, clinically referred to as the "blanking period," is characterized by heightened vulnerability to diverse arrhythmic phenomena. This interval poses significant risks for patients, as electrophysiological instabilities can exacerbate underlying symptoms and compromise daily functional status. Therefore, meticulous monitoring is essential during this phase to optimize risk stratification and guide therapeutic decision-making. Fourth, the use of self-reported measures for medication adherence, anxiety, and depression may introduce response bias, as participants might overestimate their adherence or underreport symptoms due to social desirability. Fifth, while the digital animation system was designed with user-friendliness in mind, variations in individual patient engagement and technological proficiency may have exerted an influence on the efficacy of the intervention. It is important to acknowledge these limitations as they may impact the overall interpretation and generalizability of the findings of the study. Future research with larger and more diverse samples, longer follow-up periods, and objective outcome measures may help strengthen the evidence regarding the educational effectiveness of digital animation for patients with AF undergoing catheter ablation.

Conclusions

Our study introduced a novel approach to digital animation education, providing multidimensional and highly accessible multistage education for patients with AF undergoing catheter ablation. This educational model has demonstrated effectiveness in improving postoperative anxiety, depression, medication adherence, and QoL in patients at the 3-month postdischarge follow-up.

Abstract

Background: Seeking online health information can empower individuals to better understand their health concerns, facilitating their ability to manage their health conditions more effectively. It has the potential to change the likelihood and frequency of health service usage. Although existing literature has demonstrated the prevalence of seeking online health information among different populations, the factors affecting online health information perception and discussions on the associations between seeking online health information and health service utilization are limited.

Objective: We analyzed the associations between online health information seeking behavior and health service utilization, as well as the online health information perception delivery mechanism.

Methods: We analyzed data from the Chinese General Social Survey, the first national representative survey conducted in mainland China. The independent variable was the online health information seeking behavior. The outcome variable was health service utilization by the respondents, and online health information perception was selected as the mediating variable in this analysis. Factor analysis was conducted to obtain online health information perception. Multiple regressions were performed to investigate the effect of online health information seeking behavior on physician visits. Bootstrap methods were conducted to test the mediation effects of online health information perception.

Results: This analysis included 1475 cases. Among the participants, 939 (63.66%) sought online health information in the last 12 months. The mean age of the respondents was 46.72 (SD 15.86) years, and 794 (53.83%) were females. After controlling for other variables, individuals with online health information seeking behaviors showed 0.289 times more outpatient visits (P=.003), 0.131 times more traditional Chinese medicine outpatient visits (P=.01), and 0.158 times more Western medicine outpatient visits (P=.007) over the past year compared to those who did not seek health information online. Additionally, multiple regression analyses revealed statistically significant effects of gender, age, and health status on physician visits. The total effect revealed that seeking online health information significantly influenced the total physician visits (β=0.290; P=.003), indicating a certain correlation between online health information seeking behavior and physician visits. Seeking online health information had a significant positive impact on the perception (β=0.265; P<.001). The mediation effects analysis identified that online health information perception led to a significant increase in physician visits with the increase in the online health information seeking behaviors (β=0.232; P=.02).

Conclusions: The online health information perception of an individual influences the effect online health information seeking has on the frequency of physician visits. The online health information seeking behavior impacts outpatient service utilization both directly and indirectly through online health information perception and significantly increases the frequency of clinic visits

after controlling for other variables. Interventions can be explored to improve the health utilization of residents by increasing their online health information perception.

Introduction

The internet has become an essential part of life around the world. In 2023, the number of internet users reached 5.3 billion globally. Internet penetration rates in Saudi Arabia, Norway, and the United Arab Emirates are approaching 100% [1]. In China, which is the leading market for internet users, the online penetration rate was 78% in June 2024, with 1.099 billion users [2]. There is no doubt that the internet has become the most common resource for health information due to the widespread use of smartphones. Our previous study found that even in rural and remote areas in China, 47.27% of the residents obtained health-related information or services through the internet [3].

Individuals can easily access internet effectively, obtain the relevant medical information available online, and make health care decisions based on their health status. Online health information seeking (OHIS) can empower individuals to better understand their health concerns, facilitating them to manage their health conditions more effectively. Recent studies on OHIS behavior have focused on the population characteristics and associated factors. OHIS behavior in different populations [4] have been discussed, such as college students [5,6], older adults [7,8], adolescents [9,10], mothers [11], and people with various health statuses [12]. OHIS behavior and its influencing factors have also been analyzed in patients with specific diseases such as cancer [13-15], osteoarthrosis [16], type 2 diabetes mellitus [17,18], and rare diseases [19]. The OHIS behavior is influenced by various factors, including demographics, psychological aspects, role-related or interpersonal traits, environmental sources, source-related characteristics, and diseases [13-19]. OHIS can enable individuals to assess their health concerns better, facilitating them to improve their management of health conditions and make more informed decisions about whether to use health services. Therefore, OHIS can potentially change the likelihood and the frequency of health service usage, such as outpatient visits. A systematic review suggested that the current evidence of the association between OHIS and health services is inconclusive [20]. The relationship between internet use and health service utilization is complex and influenced by multiple factors [13,14,21]. Existing empirical studies [21-23] on the effect of internet health information on demand for health care services have shown unclear and inconsistent findings. Some studies [21,22] found that access to online health information enhanced the demand and use of health services by individuals. An empirical analysis based on data from the United States Health Information Trends Survey revealed that OHIS has a positive, relatively large, and statistically significant effect on individual health care demand [21]. Another cross-sectional study [22] of 993 adults in Vietnam drew positive conclusions that the prevalent use of mass media sources, including the internet, for health information was associated with higher rates of health care utilization, even though there were issues such as neglecting the quality of health information. However, a study [23] also found that the behavior of searching for online health information can negatively impact the utilization of health services. A Chinese nationally representative data analysis based on an instrumental variable regression revealed that mobile internet use significantly diminished the inclination of an individual to seek primary health care services [23].

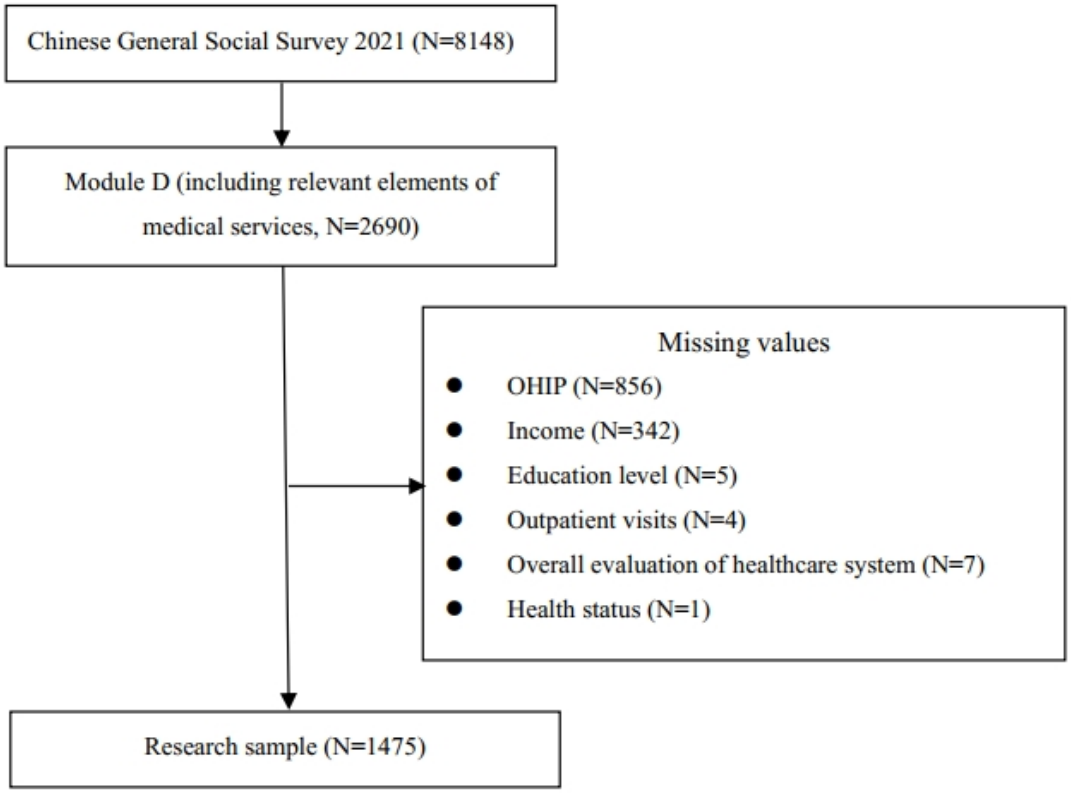
Seeking information on the internet can enhance the knowledge of individuals about health concerns and symptoms, enabling them to better manage their health conditions [24]. However, a vast volume of health information needs to be screened and evaluated, and the perception of people toward health information may influence this process. On the one hand, OHIS fulfills the need of patients for health information or provides opportunities to interact with health providers through the internet, which may decrease the frequency of health consultation visits. In contrast, OHIS draws the attention of patients to health issues, increasing their demand and frequency of visits to health services. Currently, a substantial body of theoretical work has delved into the factors influencing OHIS behavior [25]. Particular emphasis has been placed on the mechanisms by which the attitudes and perspectives of individuals regarding online health information shape their corresponding behaviors [25]. A systematic review integrated the comprehensive model of information seeking, the planned risk information seeking model, and the situational theory of problem-solving and found that the perception and trust of people in online information were the most dominant predictors of OHIS behavior [25]. For patients with chronic conditions, perceived susceptibility and severity can effectively explain perceived risk, helping predict their OHIS behavior. Informational and emotional support can help patients perceive benefits, thereby positively affecting their OHIS behavior [26]. Simultaneously, the OHIS attitude and behavior are dependent on the identity of those who offer opinions online; thus, the advice obtained from others with similar interests is given more weight [27]. A study involving 10,000 participants from mainland China found that perceived information quality mediates the influence of OHIS on health behavior [28].

The abovementioned studies have demonstrated that the impact of OHIS behavior on health service utilization requires considering attitudes, perspectives, and views of people on online health information, which has been confirmed as an important factor for the acceptance of health information [29]. How people perceive the health information available online influences subsequent processes on health behaviors or the use

XSL•FO
RenderX

of health services, for example, if they believe that information on the internet has a positive impact on their health, whether the online information helps them understand the doctor's advice, or whether the doctor provided appropriate advice. Although existing literature [13-19,21-23] has demonstrated OHIS prevalence among different populations and patients as well as the factors that influence OHIS, there has been minimal discussion on the associations between OHIS and health services. Furthermore, even fewer studies have explored the impact of this association [25]. More research is needed regarding the associations among people's attitudes, perceptions, OHIS, and health services.

The above discussion suggests that a step toward a comprehensive understanding of the effects described requires the development of a complex model that considers the simultaneous relationships among OHIS, health service utilization, and the attitude and perceptions of an individual. The research questions of this study focus on how OHIS behavior affects the practice of health service utilization and how the attitudes and perceptions of people toward online health information play a role in this process. We developed a joint model of OHIS, health service usage, and health information belief that considers an individual's unobserved characteristics that are likely to be correlated with health information seeking behavior, individual's health status, and health care utilization.



Methods

Study Participants

This study analyzes data from the Chinese General Social Survey (CGSS), which systematically monitors the changing relationship between the social structure and the quality of life in both urban and rural China. The CGSS is China's first, nationally representative and comprehensive continuous academic survey initiative conducted by an academic institution in mainland China [30]. This project collects data by using a stratified, multistage probability proportional to size method. Data are comprehensively gathered at multiple levels, including society, communities, households, and individuals. CGSS covers 28 provinces, autonomous regions, and municipalities across China. In this study, the latest CGSS2021 survey was selected as the data source for the analysis, which included the context on OHIS and the perceptions of respondents. The details of the sampling scheme and design are available on the official CGSS website [30].

A total of 8148 samples were included in the CGSS2021 data, with 2690 participating in the medical service–related questions (module D). After removing the missing values for the key variables such as online health information perception (OHIP) (n=856), income (n=342), education level (n=5), outpatient visits (n=4), overall evaluation of the health care system (n=7), and health status (n=1), 1475 study samples were obtained. The specific data processing procedures are represented in Figure 1.

Figure 1. Participant screening flowchart. OHIP: online health information perception.

RenderX

Ethics Approval

CGSS was approved by the ethics review committee of Renmin University of China. The study data were anonymous, and the answers were protected by privacy law. The data collection and storage protocols were in full compliance with the personal information protection law of China. All obtained data were anonymized, which means removing any identifiers that can directly or indirectly link the data to individual participants. Each participant signed an informed consent form at the time of participation. There was no requirement for additional ethics approval for approved data users.

Measures

Outcome Variable

The health service utilization by respondents served as the outcome variable for this analysis. This variable was represented by the question "In the last 12 months, how often have you visited a doctor?" The questionnaire was divided into 2 parts: visits to traditional Chinese medicine (TCM) physicians and visits to Western medicine physicians. The numbers 1, 2, 3, 4, and 5 were assigned to the answers never, rarely, sometimes, often, and very often, respectively. The 2 answers were combined to create the outpatient utilization frequency variable ranging from 2 to 10. OHIS behavior was selected as an independent variable in our analysis. OHIS was described by the question, "In the past 12 months, how often have you searched for health or medical information for yourself or others online in various forms?" OHIS was identified as yes if respondents selected several times a day, once a day, or a few times a week/month/year. Other responses (never go online, hardly ever, and cannot choose) were assigned to "no" in the analysis. Afterward, further analysis was conducted after removing individuals with an answer "no" on the OHIS behavior. For those with OHIS behavior, the numbers 1, 2, 3, 4, and 5 were assigned to the answers a few times a year, a few times a month, a few times a week, once a day, and several times a day, respectively.

Mediating Variables

The perceptions of respondents regarding online health information were selected as the mediating variables in this analysis. In the CGSS2021 questionnaire, 4 questions were selected to represent perception: "Do you agree with the following statement that information on the internet has positively influenced my health behaviors?", "Do you agree with the following statement that information on the internet has helped me understand what my doctor has told me?", "Do you agree with the following statement that the internet can help people decide if they need to go to the doctor or not?", and "Do you agree with the following statement that the internet can help to make sure that doctors are giving people the right advice?" The numbers 1, 2, 3, 4, and 5 were assigned to the responses strongly disagree, disagree, cannot tell, agree, and strongly agree, respectively. Factor analysis was conducted to extract the perception of respondents for online information from the 4 questions listed above. The factor with a contribution rate of 0.548 was extracted according to the criterion that the eigen value is greater than 1. The procedure and results of factor analysis are given in Multimedia Appendix 1.

Control Variables

The control variables selected for this study were as follows: gender (female=0, male=1), age, income, residence (rural=0, urban=1), marital status (unmarried=0, married=1), education level (primary or below=0, junior middle school=1, high school or above=1), health status (very poor=0, relatively poor=1, general=2, relatively good=3, good=4), region (western region=0, central region=1, and eastern region=2), and their overall evaluation of the health care system (not at all satisfied=0, very dissatisfied=1, quiet dissatisfied=2, cannot say=3, quite satisfied=4, very satisfied=5, and fully satisfied=6).

Statistical Analysis

Descriptive and univariate analyses were performed for the basic characteristics of respondents. A chi-square test was used for discrete variables, while *t* tests (2-tailed) were applied for normal or 2-sample data. Wilcoxon rank-sum tests were applied for nonnormal or unequal variance continuous variables. Additionally, ordinary least squares regression was conducted to examine the effect of OHIS on physician visits. Bootstrap methods were used to assess the mediation effects of health information perception; 95% CI and *P* values were presented. The weights provided by the CGSS data were utilized for regression models and mediation analysis in this study for ensuring generalizability and reliability. Statistical analysis was conducted using Stata (version 14.0) for Microsoft Windows (Stata Corp).

Results

Sample Characteristics

A total of 1475 cases were selected from the database for the analysis. The mean age of the respondents was 46.72 (SD 15.864) years, 794 (53.83%) were females, 1083 (73.42%) were married, and 562 (38.10%) were living in rural areas. A total of 420 respondents were western region residents, representing 28.47% (420/1475) of the total number of respondents, while 26.31% (388/1475) were central region residents, and 45.22% (667/1475) were eastern region residents. Almost half (728/1475, 49.36%) of the respondents had a high school diploma or more, while one-fifth (289/1475, 19.59%) had only completed primary school or were illiterate. More than half of the respondents (853/1475, 57.83%) were in relatively good or good health conditions. The frequency of physician visits in the last 12 months was 3.883 (SD 1.591); that of TCM visits was 1.787 (SD 0.884) and that of Western outpatient visits was 2.096 (SD 0.957). Among the respondents, 939 (63.66%) sought online health information in the last 12 months.

One-way analysis of the number of total clinic, TCM, and Western physician visits was conducted for the related variables. Preliminary analysis revealed differences among respondents with different health status, genders, and education levels. The female respondents visited physicians more frequently than male respondents in the last 12 months (t_{1473}=–3.411; *P*=.007), as evidenced by the number of visits for TCM outpatients

XSL•FO
RenderX

(t_{1473}=3.040; P=.02) and Western medicine outpatients (t_{1473}=2.842; P=.002). Those with primary school or less education had the highest number of physician visits ($F_{2,1472}$=5.37; P=.04), TCM visits ($F_{2,1472}$=6.46; P=.002), and Western clinic visits ($F_{2,1472}$=3.09; P=.046). As the health condition worsened, the overall number of physician visits increased ($F_{4,1470}$=52.33; P<.001), and the same trend of changes was observed for both TCM ($F_{4,1470}$=55.73; P<.001) and Western clinic visits ($F_{4,1470}$=24.03; P<.001). More details on the sample statistic descriptions are provided in Table 1.

Multivariate Regression

After adjusting for other variables, those with OHIS behaviors increased the frequency of outpatient visits by 0.289 times more during the past year compared to those without OHIS behaviors (*P*=.003). They increased at a rate of 0.131 times in TCM outpatient visits (*P*=.01) and 0.158 times in Western physician visits (*P*=.007). Moreover, multiple regression analyses found statistically significant effects of gender, age, and health status on physician visits. Relative to the female respondents, males decreased their overall physician, TCM, and Western medicine visits by 23% (*P*=.006), 9.3% (*P*=.04), and 13.7% (*P*=.006), respectively. The number of physician visits increased with age. For every 1-year increase in age, the overall physician visits increased by 1.5% (*P*<.001), TCM visits by 0.87% (*P*<.001), and Western medicine visits by 0.7% (*P*<.001). Similar to the results of the univariate analyses, respondents with poorer health had more medical visits, while those in good health had significantly fewer visits to physicians, TCM physicians, and Western physicians (*P*<.001). All the abovementioned factors affected the number of visits in all 3 types. Concurrently, some factors such as marital status, education level, and region of residence influenced one or two types of physician visits. In comparison with respondents who were not married, those who were married had lesser number of overall physician visits by 20.4% (*P*=.03), Western medicine visits by 15.5% (*P*=.008), and TCM visits by 4.8%, with a statistically nonsignificant difference (*P*=.36). In contrast to the respondents in western regions, those in the central and eastern regions had fewer TCM visits by 12.2% (*P*=.06) and 12.6% (*P*=.03), respectively. More details of the multiple regressions are given in Table 2.

Finally, the group that never participated in OHIS was removed. Our findings indicate that a higher frequency of OHIS was associated with a higher frequency of outpatient visits (β=0.127; *P*=.003) and TCM visits (β=0.082; *P*=.001). More details are given in Table 3.

Mediation Effect Analysis

First, the total effect of OHIS behavior on the frequency of physician visits was examined. The results revealed that OHIS had a significant influence on total physician visits (β=0.290; *P*=.003), indicating a certain correlation between OHIS behavior and physician visits. We also tested the effect of OHIS behavior on perception, and results revealed that OHIS had a significant positive impact on perception (β=0.265; *P*<.001). Furthermore, the effect of OHIP on the number of physician visits was conducted, and it was found to have a significant effect on physician visits (β=0.270; *P*=.001). Finally, the effect of perception on physician visits while controlling for OHIS behavior was also assessed. We found that the perception of people regarding online health information had a significantly positive influence on physician visits (β=0.232; *P*=.02). More details are given in Table 4 and Figure 2.

Figure 2. The mediating role of online health information perception between online health information seeking behavior and physician visits. OHIP: online health information perception; OHIS: online health information seeking.

Discussion

Primary Findings

The key findings of this study are summarized as follows. First, the perception of people regarding online health information influences the effect of OHIS on health service usage as predicted. The increased prevalence of OHIS behaviors in the internet era necessitates more awareness and discrimination of health information accessed on the internet. Our findings validated the impact of OHIS on health service utilization outcomes. Second, the effect found through the mediation analysis was partial mediating, which can be divided into 2 parts. On the one hand, respondents' OHIS behavior directly affects the number of physician visits. On the other hand, OHIS behavior affects their perception of the health information available online, which subsequently affects their use of outpatient services. Third, the multivariable linear regression results revealed that OHIS behavior significantly increased the utilization of clinic visits after controlling for other variables. Those with OHIS behavior showed 0.308 times increase in the frequency of total physician visits compared to those without OHIS behaviors. This trend was not only reflected in the total number of physician visits but also in the TCM and Western medicine physician visits. Finally, based on the joint model that was built on OHIS, health care utilization, and OHIP, we clarified the mediator roles of OHIP between OHIS behavior and physician visits and provided new perceptive and explanatory mechanisms to explore the relationship between health information seeking behavior and health service utilization.

Interpretation and Comparison With Existing Literature

Studies exploring the determinants of OHIS have confirmed that perceived usefulness and attitude have a strong positive effect on OHIS [29]. A previous study [31] investigated the psychological mechanisms between OHIS behavior and doctor-patient interactions, concluding the mediating role of eHealth literacy, perceived disease severity, and action benefits. The findings of this study further confirm that a higher perception of health-related information online affects the OHIS behavior and influences the health utilization process. As various studies [14,32] have indicated, OHIS behavior can be a potential tool to improve health literacy improvement and health-related behaviors. Residents consciously accessing health information on the internet can be more knowledgeable about their health and are more likely to identify potential health problems, resulting in higher health demand and higher physician visits.

Based on previous studies, education level is one of the most important factors for health service utilization [33,34]. However, the impact of education level on outpatient services is complex. From one point of view, due to their strong health awareness, people with higher education levels may visit outpatient clinics more frequently for minor discomforts or for the management of chronic diseases. In contrast, individuals with a higher education level are inclined to possess more comprehensive preventive health care knowledge, higher health literacy, and maintain a superior state of physical well-being, which may also lead to a decrease in outpatient visits. We identified significant differences between different education levels and outpatient visits through a primary univariate analysis. Participants with primary or lower education levels had more physician visits. However, this trend disappeared in the multivariate analysis after controlling for other variables. Among educational attainment factors, having a high school diploma or above increased the likelihood of receiving TCM treatment, but this was not reflected in the overall and Western medicine treatments. In our analysis, increasing age indicated increased health service utilization, which is consistent with that reported in previous studies [21,23]. Older adults have various health needs, including medical checkups for chronic diseases, rehabilitation services after illness or surgery, mental health support to combat loneliness and depression, and long-term care assistance with daily activities. All these needs can be partly satisfied through the internet, which provides access to medical information, online consultations, health management, and virtual communities for support and interaction. However, 1 systematic review [7] indicated that older adults confronted 3 types of barriers to conducting OHIS: individual, social, and information and communication technology–related. The findings of this study indicated that shifting the perspective on OHIS can promote OHIS behavior and consequently enhance the rational use of health services. The older adults, being a vulnerable population in terms of health and information and communication technology, require additional support in using web-based services efficiently and reasonably.

Additionally, unauthenticated health information is widely available on the internet. Another study [35] revealed that 96% of the residents use unauthenticated health information to answer

XSL•FO
RenderX

some health-related questions. Patients may not always be able to use effective online search strategies. Studies have indicated that when there is a contradiction between the information on the internet and that provided by doctors, people are more likely to trust the perspective of doctors [36,37]. These results verified that people's positive perceptions and attitudes toward online health information promote OHIS behavior and the use of health services. Health care professionals' recommendations and assistance on reliable information sources and trustworthy websites in patients' search for online health information can be very useful and can improve the rationality of online health information and the seeking of medical treatment.

Implications for Policies and Practice

The findings of this study have important implications for future policies and practices in the health care system. Focusing on the access of individuals to online health information allows health service providers to have a better understanding of their health knowledge, behaviors, and even health attitudes, promoting a more logical use of health services. In the field of health education, the primary health care service system aims to improve the eHealth literacy of residents, including their ability to seek, discriminate, judge, and use internet health information. This is done to promote their ability to access their own or their family's health status and enhance their ability to make timely and appropriate health care decisions. The older adults, who are always considered medically underserved populations, often reported a lack of social support in their OHIS, including informational, organizational, instrumental, intergenerational, and peer support. Interventions can be explored to improve reasonable outpatient utilization by the older adults by improving their perception and attitude toward health information online. Comprehensive support, which encompasses user-friendly devices and software, training, and guidance on efficient internet use, accessible internet connections, and dedicated support services, is necessary for older adults to truly benefit from OHIS and reasonable health services.

Strengths and Limitations

Compared with previous studies, this study is innovative and contributes in the following aspects. First, the research sample included is from CGSS, a large-scale, comprehensive social survey project. On this basis, people's perception of online health information was selected as the mediating factor to explain the mechanism linking OHIS to health service utilization, broadening the research scope. Furthermore, these findings provide new evidence on OHIS behavior and physician visits and verified the partial mediation role of people's perceptions and attitudes toward online health information. Lastly, multiple variables were integrated into participants' perception of online health information based on the factor analysis, which enhanced its efficiency, rationality, and reliability.

Although this study achieved some useful results, there are some limitations. First, our study was conducted using cross-sectional data, which prevented us from determining the causal relationship between variables. Future studies can adopt a longitudinal design to further understand the dynamic relationships among OHIS, OHIP, and health services. Given that a public database was used as a resource, certain limitations were unavoidable. OHIP, selected as the mediating variable, was relatively subjective when compared with eHealth literacy or ability. Nevertheless, it remains significant to know that the attitudes of residents toward online health information have influenced their OHIS and health service utilization.

In the future, the OHIP mechanism can be further explored in more depth, and the influence can be expanded to inpatient and emergency service utilization. Then, the relationships among OHIS, OHIP, and health service utilization can be investigated in different contexts to improve the generalizability of the results. Finally, other research methods such as experimental research and case studies can be combined to gain a more comprehensive understanding of the relationships between variables.

Conclusions

The OHIP of residents influences the effect of OHIS on the frequency of physician visits. OHIS behavior impacts outpatient service utilization both directly and indirectly via OHIP. OHIS behaviors significantly increase the frequency of physician visits after controlling for other variables. Interventions can be explored to improve the health utilization of residents by improving their OHIP.

Abstract

Background: Over the last decade, the health care technology landscape has expanded significantly, introducing new and innovative solutions to address health care needs. The implications of cybersecurity incidents in the health care context extend beyond data breaches to potentially harming individuals' health and safety. Risk perception is influenced by various contextual factors, contributing to cybersecurity concerns that technological safeguards alone cannot address. Thus, it is imperative to study risk perceptions, contextual factors, and technological benefits to guide policy development, risk management, education, and implementation strategies.

Objective: This study aims to investigate the differences in cybersecurity risk perception among various stakeholders in the health care sector in Norway and British Columbia (BC), Canada, and identify specific contextual factors that shape these perceptions. We expect to identify differences in risk perceptions for the explored health care technologies.

Methods: We used a mixed methods approach comprising surveys and semistructured interviews to sample health care–related wearable technology stakeholders, including health care workers, patients (adults and adolescents) and their families, health authorities and hospital staff (biomedical engineers, information technology support, research staff), and device vendors/industry professionals in Norway and BC. Surveys explored information security scenarios based on the Behavioral-Cognitive Internet Security Questionnaire (BCISQ), risk perception, and contextualizing variables. We analyzed both survey data sets to summarize participants' characteristics and responses to questions related to the BCISQ (behavior and attitude) and risk perception. Interviews were analyzed thematically using an inductive-deductive approach to explore risk perception and contextual factors.

Results: Data from 274 survey respondents were available for analysis: 185 from Norway, including 139 (75.1%) females, and 89 from BC, including 57 (64%) females. A total of 45 respondents (31 in Norway and 14 in BC) participated in interviews. The BCISQ showed minor differences between locations; respondents demonstrated generally low-risk behavior and robust information security awareness. However, password simulation demonstrated discrepancies between self-assessed and "real" behavior by sharing or willingness to share passwords. Perceived risk is generally considered low, yet consequences of cybersecurity risks were evaluated as major but unlikely. Risk perception was stronger for assisted living and diabetes technologies than for smartwatches. The most important contextual factors shaping risk perceptions are human factors encompassing knowledge, competence, familiarity, feelings of dread, perceived benefit, and trust, as well as the technological factor of device functionality. Organizational and technological factors had lesser effects.

Conclusions: We found minimal differences in behavior and risk perception among Norwegian and BC participants. Human factors and device functionality were most influential in shaping cybersecurity risk perceptions. Considering the rising need for assisted living technologies and wearables, insights into risk perceptions can strengthen risk management, awareness, and competence building. Further, it can address potential concerns among stakeholders to enable quicker technology adoption.

Introduction

Background

Over the last decade, the landscape of health care technology has expanded significantly, introducing innovative solutions to assist health care needs [1]. These advances have been instrumental in enhancing the efficiency of health care delivery, reducing operational costs, and optimizing timely management. The adoption of artificial intelligence–based solutions in the health care sector has accelerated through applications such as artificial intelligence–supported analysis of X-ray interpretation and blood sample evaluations [2-5]. Moreover, an emerging trend is using technology to facilitate remote patient care outside traditional health care environments such as hospitals [6,7]. This trend introduces multiple challenges, particularly in cybersecurity. Medical devices and assisted living technologies have been the subject of cybersecurity incidents [8-11]. Recently, several hundred insulin pumps were called back by the Food and Drug Administration (responsible for regulating medical devices in the United States) due to software weaknesses, resulting in the battery depletion of insulin pumps [12,13]. Although this was not an intended attack, it demonstrates the vulnerabilities in the technology that could be exploited for malicious purposes. Incidents resulting from intended attacks have also occurred, including attacks on home care services in Ontario, Canada, Norway, and Sweden, which jeopardized patient safety and their data [14,15].

A wide range of remote care technologies are available. These technologies collect and transfer data generated from patients, such as measurements and self-reported data, also known as patient-generated health data (PGHD) [16]. Assisted living technologies (known as "welfare technologies" in Norway) refer to technologies that augment an individual's safety and security, including technology used for remote care. These technologies also manage and transfer PGHD. Assisted living technology, remote care, and disease management technologies have been adopted broadly in Norway and Canada. This adoption is expected to increase drastically in the coming years due to demographic shifts and health care resource constraints [17,18]. The 2 countries differ in geographical size and population, but they share a high degree of trust in public institutions and maintain predominantly publicly funded health care systems. Both also share a decentralization of health care delivery; in Canada, health care services are managed by 10 provincial health authorities and 3 territorial authorities, while in Norway, primary health care is distributed among 356 municipalities, while specialist health care is distributed among 4 regional health care authorities. Moreover, the populations of both countries demonstrate high levels of technological literacy, with an internet penetration rate of 99% in Norway and 92% in Canada [19]. Although technological literacy is high, cybersecurity still poses a challenge.

Cybersecurity can be understood as the "protection of computer systems and networks from attack by malicious actors that may result in unauthorized information disclosure, theft of, or damage to hardware, software, or data, as well as from the disruption or misdirection of the services they provide" [20]. In health care, the implications of cybersecurity incidents extend beyond simple data breaches to encompass critical consequences, potentially harming the health and safety of individuals and compromising PGHD [1,21]. The successful deployment of remote care solutions depends on several elements, including technology accessibility, technological literacy, financial resources, and health care delivery's structural and organizational aspects [22-24]. It involves many stakeholders, including patients, clinicians, public and private health care organizations, technology vendors, and regulatory bodies [25-27]. The stakeholders involved in device use, operation, and management may hold different perceptions of cybersecurity risks.

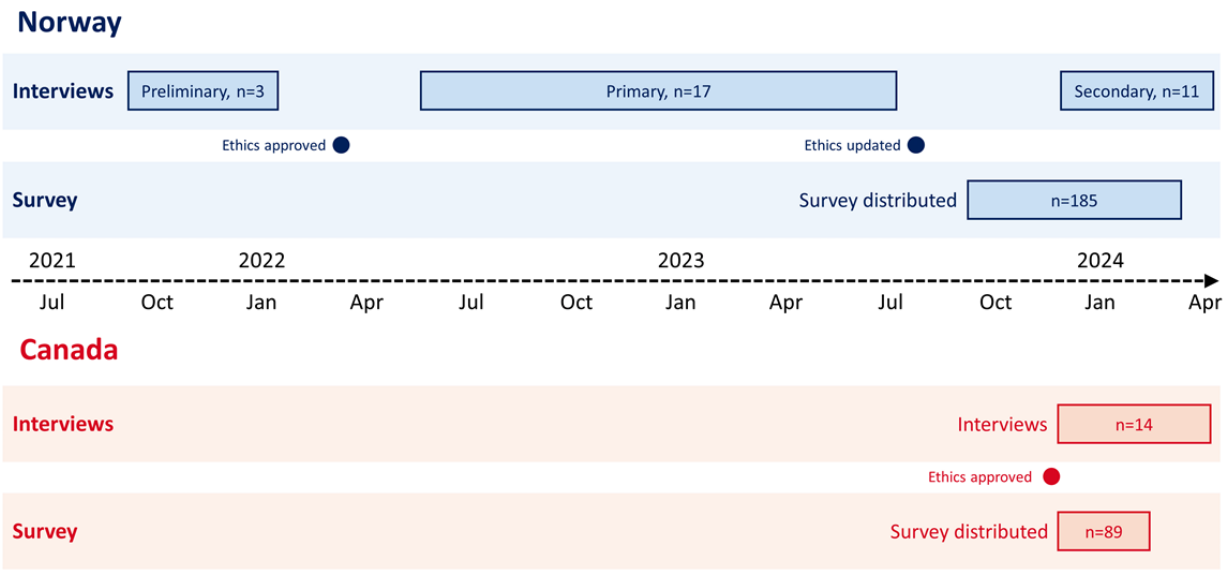
Cybersecurity risk perception may differ between patients and health care workers; a patient using a type 1 diabetes (T1D) device may be more concerned about the immediate threat of denial of service impacting their insulin delivery, while a clinician might focus on the broader implications of compromised data integrity across both T1D devices and wearables for clinical decision-making. Cybersecurity risk perception encompasses concerns about threats and their potential impact on technologies, systems, and data, including incidents such as data breaches, attacks, and hacking, which can compromise confidentiality, integrity, availability, and functionality. Understanding these risks requires technical considerations and the social, cultural, and psychological factors that shape how individuals and organizations perceive cybersecurity threats [28,29].

Various disciplines, such as psychology, engineering, and safety science, have explored risk perception. Common theories in the risk perception field include the social amplification of risk framework and protection motivation theory [30-36]. Factors such as culture, optimism bias, personal fear, dread, familiarity, benefit, trust, and social trust have been explored in previous research on cybersecurity risk perception [30-33,37-45]. The Technology Adoption Model (TAM) and TAM2 are widely accepted in explaining why particular technologies are adopted [46-51]. Previous research highlights a lack of focus on human factors when assessing sociotechnical systems, especially within cybersecurity. A study found that technical factors often receive the most attention, whereas human factors related to awareness, privacy, and trust are frequently overlooked [52]. Addressing these human factors is crucial for a comprehensive understanding of cybersecurity risks in health care. Therefore, we adopted a cybersecurity approach to contextual factors, dividing them into human, organizational, and technological categories [53,54].

XSL•FO
RenderX

Aim

This paper aims to investigate cybersecurity risk perception for assisted living technologies and wearables among stakeholders from Norway and British Columbia (BC), Canada, and identify contextual factors that shape these perceptions. We aim to explore differences in cybersecurity risk perceptions among different stakeholder groups for these technologies and identify the relevant human, organizational, and technological factors that impact these differences. However, due to ethical considerations, we do not compare survey data from the 2 geographical locations; instead, we rely on the interpretation of qualitative data from interviews to identify if differences in risk perception exist.



Methods

Study Design

This study performed an analysis among relevant stakeholders in Norway and BC, Canada, to explore cybersecurity risk perception and contextual factors associated with assisted living technologies. To simplify reporting, we refer to "cybersecurity risk perception" as "risk perception." Our sampling approach in Norway was based on previous research on key stakeholders for assisted living technologies [23,55,56]. In Norway, we focused on 2 specific technologies, medicine dispensers and digital self-reporting forms, as these solutions have been widely adopted. We approached stakeholders to participate as survey respondents and as interviewees. In BC, these same technologies have not been as widely adopted. Hence, we examined other technologies that support an individual in managing their disease remotely: insulin pumps and continuous glucose monitoring (CGM) devices. These technologies are used as examples in the survey and interviews.

The survey was distributed in Norway from September 2023 to March 2024, and interviews were conducted from August 2021 to February 2024. Three preliminary interviews were conducted before ethical approval, which was permitted by Norwegian ethics rules but restricted the ability to gather any identifiable information. However, they enabled the gathering of key insights into the organization and implementation of assisted living technology in the Norwegian health care sector, which were instrumental in the subsequent research design. The survey was distributed in BC from December 2023 to February 2024, and interviews were conducted from December 2023 to April 2024 (Figure 1). This manuscript has been prepared following the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines [57].

Figure 1. Study timeline showing study phases, data collection periods, and ethical approvals.

Participants

Participants were health care workers, patients or device users, and experts involved in the development and implementation of assisted living technologies and wearables. The stakeholder groups enrolled varied slightly between the 2 countries. Specifically, Norwegian participants included health care workers in primary and specialist care, device vendors or industry professionals, health authorities, and cybersecurity experts. The participants from BC were patients (adults and adolescents), families of patients, clinicians or researchers using health care–related wearable technologies or data, biomedical engineers, hospital or research information technology (IT) professionals, and device vendors or industry professionals. We included adolescents to enrich the data material, as they represent a key user group for the T1D technology use case. Thus, it helped to offer a more comprehensive understanding of the cybersecurity risk affiliated with the technology across different demographics.

Recruitment

The survey and interview respondents in Norway were gathered through an initial email to primary health care providers, specialist health care providers, health care authorities, technology vendors, and the expert network at the Norwegian University of Science and Technology. The survey was

XSL•FO
RenderX

distributed by leaders in either primary or specialist health care organizations and a group dedicated to health care technologies in Norway on the social media platform Facebook (Meta Platforms, Inc.). In BC, we recruited adolescents, their parents, and other adults living with T1D using existing lists of participants who had given permission to be contacted for research and additional adult patients through a provincial portal for patient engagement and recruitment: REACHBC [58]. Health care clinicians, researchers, IT professionals, biomedical engineers, and device vendors/industry professionals were contacted via email and newsletters utilizing existing networks; participants belonging to health care institutions were approached via departmental email lists and research institute newsletters.

Survey Instrument

The survey deployed in both countries was built on the Behavioral-Cognitive Internet Security Questionnaire (BCISQ), which uses a 5-point Likert scale to gather data on respondents' behavior and awareness of using solutions based on information and communications technology [59]. Our survey consisted of 3 main parts: the first part gathered background information, including age, gender, and profession; the second part included the BCISQ; and the final part collected insights on risk perception for assisted living technologies or diabetes technology and smartwatches.

The BCISQ measures behavior and perception of information security risk when using the internet in 2 ways: first, by having participants assess and respond to various "risky" situations, and subsequently, by simulating a scenario that asks for the respondent's most commonly used password question. In Norway, the simulation was presented through the open-ended question: "To check the quality of your password, write your most used password." This could not be replicated in BC due to ethical considerations and concerns by institutional research privacy leaders. Instead, we posed the question, "If we asked you to reveal your most used password to evaluate the security of your password, would you reveal it?" with the answer option "yes/no". Two subscales measure the cognitive dimension; the first scale captures an evaluation of information security risk, utilizing the term "likelihood" as per Adams [60] to understand how users evaluate the probability of cyber risk, while the second subscale captures how important users evaluated security mechanisms in managing these risks, following the approach of Velkie and Solic [59] who evaluated the individual's assessment of risk and perceived importance of security mechanisms. For example, the first scale contained questions to evaluate risk, such as "How would you rate the likelihood of someone stealing your identity on the internet (some examples of services that use your personal identity include online banking, social media, and e-mail)?" with options ranging from "very unlikely" to "very likely", while importance was captured by a direct question, such as "How would you rate the importance of updating your smartphone or laptop with the latest software?", with options on a scale of "not very important" to "very important." [59,60].

We extended the survey to encompass questions related to assisted living technologies or diabetes technology and smartwatches to enhance our understanding of risk perceptions associated with specific technologies. Smartwatches were intended to target a technology widely recognized by the general population yet not primarily serving a dedicated health function. This allowed us to explore if risk perception differs between assisted living and diabetes technologies versus smartwatches. The survey sought to capture respondents' evaluations of the likelihood and impact (consequence) of incidents compromising confidentiality, integrity, and availability. Continuing the structure of the BCISQ, responses were collected on the same 5-point Likert scale.

Before deploying the surveys in Norway and BC, we conducted preliminary tests with researchers, mainly from the health care field. These tests led to minor modifications in the question structure and sequence, ensuring clarity and relevance in both contexts. The survey was distributed in Norwegian in Norway and in English in BC. The surveys can be found in Multimedia Appendix 1 (English version) and Multimedia Appendix 2 (Norwegian version).

Interviews

A semistructured interview approach was adopted, and interview guides were prepared in advance. These aimed at gathering comprehensive data on key areas: (1) understanding of assisted living technologies or diabetes technologies; (2) cybersecurity risk understanding; (3) cybersecurity threats and vulnerability specific to these technologies; (4) behavior, attitude, and awareness; and (5) organizational and management practices for technology and security. Because of the varied knowledge and characteristics of the stakeholders, we developed customized interview guides. In Norway, interview guides were tailored to each stakeholder group to reflect their unique perspectives and roles. In BC, an initial interview guide was developed and adjusted according to the specific stakeholder being interviewed. Primary themes were consistent, yet the flexibility in the interview process allowed for follow-up on specific topics based on the interviewee's responses. For instance, health care workers familiar with one of the technologies were asked more detailed follow-up questions regarding their risk perceptions of that technology. Conversely, for those less familiar with specific technologies, discussions were generally focused on risk perceptions of assisted living technologies or smartwatches. The interview guides are attached in Multimedia Appendix 3 (English version) and Multimedia Appendix 4 (Norwegian version).

Analysis

Descriptive statistics were applied to the survey data in both data sets to summarize participants' characteristics and responses to questions related to the BCISQ (behavior and attitude) and risk perception. Variability was assessed using Cronbach α, indicating the internal consistency of the items. A significant challenge in our analysis was comparing the 2 data sets subject to different privacy regulations. The Norwegian data were stored in Norway, and data transfer to other countries, especially outside the European Union, was prohibited. Similarly, the BC data were stored in BC, and transferring data outside Canada was prohibited. The data sets were analyzed separately to overcome these challenges and account for variation in the

XSL•FO
RenderX

specific stakeholder groups participating in the 2 countries. Subsequently, the results of the aggregated data were subjected to further analysis and comparison. We used R statistical software (version 4.3.2; R Foundation for Statistical Computing) and Excel (Microsoft Corporation) to analyze the quantitative data.

Interviews were transcribed and verified against the recordings, followed by analysis using NVivo (Lumivero) for thematic analysis. We used a stepwise deductive-inductive approach. This process began with establishing codes and progressed to linking codes via axial coding, facilitating the identification of relationships between codes [61]. Subsequently, we developed categories encompassing multiple codes, enabling the identification of key concepts and themes. The stepwise inductive-deductive method allowed us to continuously refine our understanding of empirical findings supported by theory [61]. This approach also aligns with the suggested approach for conducting thematic analysis by Braun and Clarke [62]. Throughout the process, the researchers discussed recurring themes to enhance the consistency of the analysis. When analyzing the qualitative data, we completed separate analyses to prevent data transfer and then aggregated and interpreted data on themes and recurring topics between both data sets.

Ethical Considerations

Ethical approval in Norway was obtained from the Norwegian Agency for Shared Services in Education and Research (606692) on March 21, 2022, with updated approval on August 15, 2023, to reflect the data from BC. Ethical approval in BC was granted by the University of British Columbia/Children's and Women's Health Centre of British Columbia Research Ethics Board (H23-01987; date of approval 2023-11-27; principal investigator: MG). Implied informed consent was used for surveys, while electronic consent was used for interviews. Written informed consent was obtained for all interviews. Before each interview, participants were emailed a consent form. As a result of different privacy legislation, the forms were collected in different ways. We used the Research Electronic Data Capture (REDCap) electronic consent framework for BC, while in Norway, the forms were distributed and collected via email, with participants signing and returning the consent form [63].

Privacy and confidentiality protection were priorities in this study. Data were analyzed once samples were deidentified. Norwegian data were stored on an encrypted device with password protection, and the tool used to collect survey data did not collect metadata or IP addresses to prevent the identification of human participants. In BC, data were collected through REDCap, which also did not record IP addresses. Extracted data were stored on research institute network drives, with access restricted to research team members.

Norwegian research participants received no compensation for their participation. In BC, survey participants were entered into a raffle for approximately US $7.50 gift cards, while all the interview participants received an approximately US $15 gift card.

Results

Participation Overview

We received 274 survey responses (Norway, n=185; BC n=89). Participants were predominantly female (139/185, 75.1%, in Norway and 57/89, 64%, in BC) and most respondents were between 21 and 56 years old; 45 interviews were completed (Norway n=31, BC n=14). The median age category was 46-50 years in Norway and 41-45 years in BC (Table 1).

[a]N/A: not applicable.

BCISQ

BCISQ data demonstrated that both respondent groups assessed their behavior as low-risk (Table 2). The groups had a median score of 1 and 1.1 (never). The range of the group demonstrates that few of the respondents ever engage in “risky” behavior, regardless of country. On the cognitive likelihood (risk) scale, both groups demonstrated a neutral to unlikely understanding of the occurrence of an undesired event. However, the range was wider in Norway (range 1.6) versus BC (range 1.0). Norway had a median score of 4 on the cognitive importance scale, while BC had a 3.8 median score.

The last instrument of the BCISQ was the behavioral simulation. In total, 46 out of 185 (24.9%) Norwegian respondents answered the question: 17 out of 185 (9.2%) were deemed to have provided a possible actual password based on password requirements (capital letters, special characters, and password length), while the remaining 29 provided responses that were not deemed to be their actual password. Of the BC respondents, 16 out of 89 (18%) answered that they would provide their password. Moreover, when asked about password strategy, the majority in both groups reported that they only implemented minor password changes when changing passwords (94/185, 50.8%, in Norway and 45/89, 51%, in BC).

XSL•FO
RenderX

Table 2. BCISQ[a] subscale data split by region.

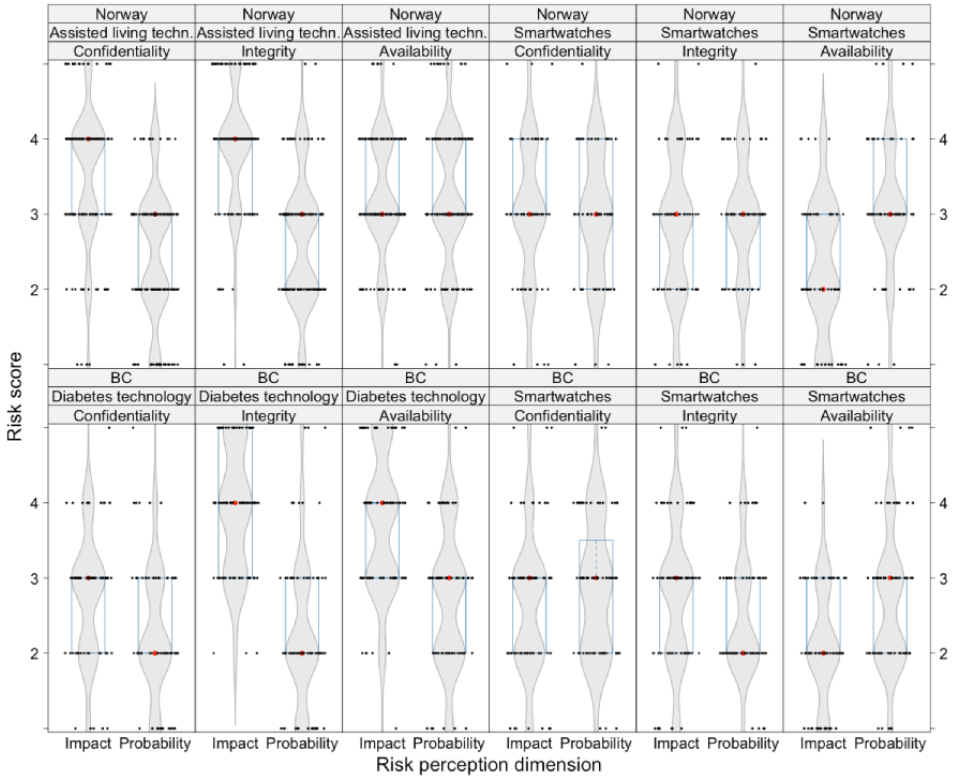
Region	Norway, median (IQR)	British Columbia median (IQR)
BCISQ subscales		
Risky behavior self-assessment scale	1.0 (1.0-1.0)	1.1 (1.0, 1.2)
Cognitive likelihood (risk) scale	3.0 (2.2-3.8)	2.8 (2.2, 3.2)
Cognitive importance scale	4.0 (3.25-5.0)	3.8 (3.0, 4.2)

[a]BCISQ: Behavioral-Cognitive Internet Security Questionnaire.

Reliability Analysis

The Norwegian data sample demonstrated internal consistency with Cronbach α, which was above the acceptable rate (0.7) on the overall questionnaire and the cognitive likelihood and importance scales, but lower on the behavioral scale. The BC responses demonstrated acceptable internal consistency overall and for the cognitive likelihood and importance scales, but the risky behavior self-assessment measurement was not within the acceptable range (Table 3).

Table 3. Cronbach α for the whole BCISQ[a] instrument and each submeasurement, split by region.



Behavioral-cognitive scale	Norway	British Columbia
BCISQ (total)	0.767	0.718
Risky behavior self-assessment scale	0.643	0.446
Cognitive likelihood (risk) scale	0.882	0.745
Cognitive importance scale	0.752	0.746

[a]BCISQ: Behavioral-Cognitive Internet Security Questionnaire.

Risk Perception for Assisted Living Technologies and Diabetes Technologies

For assisted living and diabetes technologies, the likelihood (probability) of confidentiality, integrity, or availability being compromised had a median score of 2 (unlikely) to 3 (neutral) among all respondents (Figure 2).

Figure 2. Risk perception related to the consequences (impact) and likelihood (probability) of cybersecurity-related issues, split by risk dimension, technology type, and location. Data are shown as violin plots (in grey) showing the data distributions, overlaid by boxplots (blue box denoting the first and third quartile, with the red dot denoting the median) with the raw data superimposed as black dots. BC: British Columbia.

XSL•FO
RenderX

Because of a survey logic error, which resulted in optional risk perception questions, the Norwegian sample was limited to 147 out of 185 (79.5%) participants. The range for availability was slightly higher for assisted living technologies (IQR 3-4). Results for consequences (impact) were evaluated higher, between 3 (moderate) and 4 (major), indicating a more serious evaluation of consequence. For diabetes technologies, the range for integrity had the highest consequence, between 3 (major) and 5 (catastrophic). The Cronbach α was 0.679 for the Norwegian data sample and 0.664 for the BC sample.

Risk Perceptions for Smartwatches

For smartwatches, the likelihood (probability) of confidentiality, integrity, or availability being compromised had a median in both populations between 2 (unlikely) and 3 (neutral), with most results at 3 (neutral; Figure 2). The IQR was between 2 and 3 for all measurements. The results for consequences (impact) were between 2 (minor) and 3 (moderate). As a result of a survey logic error, which resulted in optional risk perception questions, the Norwegian sample was limited to 65 out of 185 (35.1%) participants. For the smartwatch risk perception measurement in Norway, Cronbach α was 0.812, and for BC, it was 0.694.

Interview Findings

We conducted 45 interviews (Norway n=31, BC n=14), involving 25 females (Norway n=17, BC n=8) and 23 males (Norway n=18, BC n=5). The initial coding process resulted in 72 codes for Norway and 61 for BC. After aggregating into categories encompassing all codes, we had 10 categories for BC and 10 categories for Norway, which mapped to 3 overarching themes derived from the theory on contextual factors in cybersecurity: organizational, technological, and human factors. As some categories overlapped, this resulted in 14 themes (Textbox 1).

Textbox 1. Contextual factor category and themes and subthemes.

Organizational factor

- Health care organization, systems, and processes
- Regulations, compliance, and ethics
- Risk management, safety, and privacy
- Vendor and third-party relationships
- Goals and objectives
- Cost and accessibility

Technological factor

- Technology, implementation, and effect
- Security and privacy
- Technology perception and data sharing
- Device reliability, criticality, and impact

Human factor

- Stakeholder perspective and responsibility
- Knowledge, competence, and awareness
- Trust
- Benefit and convenience

Organizational Factors

Contextual factors encompass factors specific to organizations, such as organizational structure, culture, and roles and responsibilities, which affect how risks are perceived and managed. In the analysis, we identified themes that included several contextual factors (Table 4).

XSL•FO
RenderX

Table 4. Organizational factors identified from interviews.

Theme and factor	Explanation	Example quotes from participants in Norway (N) and Canada (C)
Health care organization, systems, and processes		
Management of security and technology	This refers to how cybersecurity and technologies are managed within an organization to protect the PGHD[a] and medical devices. This influence risk perception through organizations capabilities and security practices.	• "We talked about silos. Health is no longer just health; it is IT, technological, education. We are so dependent on that collaboration and the flow between them, especially when we start with technology and undergo this digital transformation, it is difficult to sit in separate silos. It is all so interconnected." [N10] • "When it (devices) is kept within the hospital, it is kept there, but when you take out the solutions, they are exposed to new risks, and you have to go slowly to make it safe." [N16]
Organizational structure	Organizational structure refers to how different health care organizations are structured, which can impact the abilities and clarity of security management.	• "(...) we have different layers. [In] primary care, specialist care, and tertiary care, on the other hand, we also see how the organizational aspects are managed and controlled by different authorities, which makes the issue [cybersecurity risk] even more difficult to deal with." [N31] • "Specialist health care is much more competent and centralized, also in terms of competence. I experience that generally from the municipalities, who do not have a lot of competence. They place a lot of trust in us." [N29]
Understanding of responsibility	Refers to how responsibility for security is organized and shared. When responsibility is defined and understood, it indicates that risks are addressed and technologies are safeguarded.	• "One important thing in Norwegian health care is that there are interfaces that will be challenging and have not been addressed. (...) Where is the interface, and how should it be managed? Where should the data go, and who is responsible for the security?" [N15] • "(...) like any personal information that I have responsibility for, but even that is sometimes in conflict with the guidance we get from the hospital or university. Then that creates like this other layer of, I don't know if you want to call it moral distress, I mean, like who am I supposed to listen to?" [C6]
Vendor and third-party relationships		
Vendor expectations	The security expectations of vendors and the belief that vendors have the abilities and capabilities to meet these are also important.	• "(vendors) must be capable of offering solutions that do not fall apart once you start picking (investigating) them." [N30] • "So I trust the Medical Device Company more both in terms of reliability of the device, but also the in terms of it's data security, right?" [C14]
Dependencies	Dependencies can heighten or lower risk perception based on the perceived criticality of dependency. The more dependencies, the more complex a system is, which can introduce vulnerabilities and potential risks.	• "No matter if it is in the health care sector or not, long vendor supply chains are a challenge. One thing is development and drift. Development with a long supply chain can [mean that] those who develop are too far from those using them. There is too big [of a] distance." [N17] • "There have not been any incidents yet at any of our vendors, but there are no guarantees. So that is a major concern. We are very dependent on these vendors." [N25]
Third parties	These refer to external dependencies handling sensitive data or critical operations/components.	• "Of our product, maybe 60-70% of our products are from third parties, such as equipment and software." [N24]

[a]PGHD: patient-generated health data.

Technological Factors

Technological factors include how technologies are implemented, which security mechanisms are integrated, and their functionality. This category refers to the characteristics and capabilities of the technology and how the respondents perceived cybersecurity risk based on their understanding of different technological and system-related factors (Table 5).

XSL•FO
RenderX

Table 5. Technological factors identified from interviews.

Theme and factor	Explanation	Example quotes from participants in Norway (N) and Canada (C)
Technology, implementation, and effect		
Technological dependencies	Describe the perceived reliance on technologies outside of the actor's control, which can heighten risk exposure.	• "...there are so many dependencies on the clients that we can't upgrade quickly enough – it takes a lot of time and a lot of money." [N15] • "We are increasing the digital footprint – the more sensors we get and the more systems we push out will increase the risk that someone can reach something." [N16]
Security mechanisms	The tools implemented to protect data and technology and the confidence placed in their effectiveness impact risk management capabilities and perceived risk.	• "I wouldn't say like a hack, but it's really easy to get information. So you really got to take safety measures if you want to not get your identity stolen or your accounts hacked, and that kind of stuff." [C4] • "Data, accuracy, and security. but you know, like you, you pay a price for it, right? Because devices are very expensive." [C14]
Device reliability, functionality, and criticality		
Reliability	Refers to the perceived trustworthiness of the device, the consistent performance of technology, and the absence of system failures.	• "I'm always a little bit sceptical about, you know, how reliable that data is, and how helpful it is for them to be tracking sometimes, at this micro level." [C6] • "(...) Then I would have to choose accuracy, because that's what I need to know, that what I'm I need to believe that what I'm seeing is real right, and it reflects the state of the patient in front of me. Right?" [C13]
Functionality	The different tasks a system or technology performs affect the user's utility of the technology	• "(worst case)(...) if it just stopped working altogether" [C3] • "I was kind of scared at the beginning. But I'm like, okay, whatever, as long as it works, it works, right?" [C12]
Criticality	This refers to the perceived importance of technology in health care, where failure can result in severe impacts, which would increase perceived risk.	• "Oh, what if you know bad actors kind of interject and you know they give like extra bolus, like, I don't know. Maybe some people might say like, 'Oh, you're, you know, like creating this novel story,' right? But who knows? Right? So those kinds of like it's fear always back up my mind. Like I said. I don't use my phone to bolus." [C12] • "I have been concerned, particularly when thinking about what I talked about before, like a looped system where the pump can control, or you can control both the blood glucose monitor and the pump with the same system." [C4]
Benefit and convenience		
Convenience	The accessibility and ease of use of technology.	• "Because anytime you add encryption, you add security, [but] you added a bit more inconvenience." [C2]
Understanding of the value of data	Understanding of the importance and sensitivity of data. The sensitivity level of data may affect the risks associated with it.	• "If they got a hold of your medical data, could they like - what would they do with it? I'm not aware of, like, what? Why would someone take that, and what to do with it unless it was going to be to blackmail you?" [C11] • "I feel like I expect that my data will be safe and protected." [C4]
Technology perception and data sharing		
Data sharing	Refers to the processes and procedures for data sharing and the attitude toward data sharing.	• "There is a huge security risk when you start talking about data flow and data sharing, that you have so many instances that you must have security at each instance." [N15] • "I think it's continuous. I don't have to like even I remember I had to delete the app (...) But I it seems like it has my information, and it continues to do so." [C12]

Human Factors

The concept of human factors refers to the physiological and behavioral elements that influence how cybersecurity and risks are perceived for systems and technology (Table 6).

XSL•FO
RenderX

Table 6. Human factors identified from interviews.

Theme and factor	Explanation	Example quotes from participants in Norway (N) and Canada (C)
Knowledge, competence, and awareness		
Knowledge	The level of understanding either an individual or organization has about cybersecurity, threats, and risks.	• "If we had more knowledge/competence, then maybe the problem would disappear." [N1] • "I think about this stuff all the time, and I worry about it a lot. In part because I feel like I don't understand it enough." [C6]
Competence	Cybersecurity refers to the skills and abilities one has in cybersecurity, enabling the individual to understand and manage cybersecurity and how cybersecurity incidents are managed.	• "I think everyone understands that this (cybersecurity) is important; however, there is a lack of competence." [N24] • "No, I believe it is humans. It is without a doubt that and lack of competence." [N29]
Awareness	The degree to which one recognizes the importance of cybersecurity and affiliated risk and how the individual behaves based on this.	• "It's not a question of if (an attack will occur), but when." [N30] • "I don't know if I've ever thought about it being altered like sort of like, nefariously or maliciously." [C6]
Stakeholder perspective and responsibility		
Fear and severity of consequence	The dangers or severity affiliated with the potential consequences of a cybersecurity incident.	• "I just sleep through my low blood sugars. That's scary. I might not be able to wake up in the morning right? (...) Usually the pump usually peeps so I'm usually like be able to treat myself, but at that time I don't know what happened, and so I was sleeping through (...)." [C12] • "If you think about the worst-case scenario, it could be that users are sitting at home who believe these alarms work, and they become ill for some reason and trigger this alarm, but it doesn't work as they expect it to. So, in the worst case, it could result in death." [N3]
Potential risk scenarios and concerns	The perceived incidents that could occur.	• "I don't know what the feasibility of is like somebody hacking someone's insulin pump and overdosing or underdosing (...) because I suppose it would be hacking the CGM and telling the insulin pump to do so like." [C15] • "A data breach is very serious because it involves very sensitive data for patients, and we have seen that it is very serious for the municipalities. It could greatly affect what people think about our organization's solutions, so I think that's actually the maximum consequence." [N24]
Trust		
Trust in technology	The confidence placed in the technology to be reliable and secure.	• "I think my trust. Yes. Although it's really a case of going from a state of no knowledge or no experience, and therefore may be no trust to yeah using this as a reliable trend monitor and saying, 'Yeah, this is fine,' you know, and if I need to verify it, I will do." [C13] • "I'm just hoping and trusting that the technology, the companies making these products. They have some kind of security at their end." [C9]
Trust in institutions/in organizations	The confidence placed in institutions or organizations to be reliable and secure in their management of systems, technology, and data.	• "I would say I trust them, and I trust that they keep my data private and they don't share it with anybody (...)." [C3] • "The fact that one (municipalities) just trusts the vendor (blindly) is not very good." [N29] • "(...) you are heavily influenced by the atmosphere of trust, so people trust each other." [N31]
Benefit and convenience		

XSL•FO
RenderX

Theme and factor	Explanation	Example quotes from participants in Norway (N) and Canada (C)
Perceived benefit	The advantages related to the use of technology or specific devices.	• "Because I know that it's helped my management a lot, so I think I would probably take risks for that." [C11] • "Just think, what the devices bring to the table is so life-changing that it would have to be really a risk that had it had been clearly identified that it was super high for anybody to really take much notice." [C9]
Cost/benefit	The trade-offs made between risk and benefits.	• "...it's really a balance between how the convenience of use and the level of protection you can provide" [C2]. • "So you know, like most decisions in medicine, are sort of either risk, benefit, or cost-benefit equation (...) where better is defined as whatever better is defined as, right? It may be a trade-off right?" [C13]

Discussion

Principal Findings

For assisted living technologies, cybersecurity risk was perceived as reasonably low. Yet, there were variations in how confidentiality, integrity, and availability were assessed between technologies. Findings from the BCISQ demonstrated similar behavior and awareness among respondents, but risk perceptions for different technologies varied. For assisted living technology, integrity and confidentiality were prioritized, whereas, for diabetes technology, availability was viewed as more critical. Moreover, our survey and interview findings indicated that risk perception is stronger toward assisted living and diabetes technologies than smartwatches. This nuance was further explored in interviews, where both groups acknowledged availability as a crucial aspect of device functionality. Although few respondents considered data or device manipulation likely, they expressed significant concern about the potential consequences if such events occurred. Risk perceptions of the respondents are significantly affected by contextual factors in the area of human factors, namely, knowledge, competence, familiarity, dread/security of consequence, perceived benefit, and trust. The technological factor of "functionality and criticality" was also found to affect risk perception, as demonstrated in the differences between "high-risk" and "low-risk" devices. These are the factors evaluated to have the greatest implications for risk perception. Organizational factors such as health care sector organization were identified to have an effect, but based on the interviews, less than the others.

Risky Behavior and Information Security Awareness

The results from the BCISQ demonstrated that our respondents assessed their behavior as secure, with a more unlikely than likely chance of being exploited. Security measures were evaluated as high in importance, which indicates a strong awareness among respondents. There were only minor variations in the data between the included participants, indicating that respondents have similar behavior and awareness about cybersecurity. However, a discrepancy was identified between how respondents self-assessed their behavior and how they behaved: 17 out of 185 (9.2%) Norwegian respondents and 16 out of 89 (18%) BC respondents were willing to engage in risky behavior by revealing their passwords to check password quality. In addition, 94 out of 185 (50.8%) Norwegian respondents and 45 out of 89 (51%) respondents reused passwords, which is viewed as risky behavior and bad practices within cybersecurity.

Comparison With Prior Work

Organizational Factors

In our study, factors such as organizational structure, roles and responsibilities, and expectations toward vendors influenced how risks were perceived. This is supported by previous research, which found that organizational factors can contribute to increase (amplify) or decrease (attenuate) perception of risks [35]. Moreover, previous research has found that cross-cultural differences can affect risk perceptions [34,35]. Our survey suggested minimal differences among respondents from Norway and BC in behavior, awareness, and view of risks for health care technology and smartwatches. Similarly, our interviews found similarities in risk perceptions between the participants, indicating that region (cross-cultural differences) has a minimal effect on risk perception in this case [44,45].

Technological Factors

We found similar understandings of the risks of assisted living and diabetes technologies based on the consequences if confidentiality, integrity, or availability were compromised. A minor difference was found where availability risks were evaluated higher in consequence for insulin pumps and CGMs (4=major), while integrity and confidentiality risks were evaluated higher for medicine dispensers and digital self-reporting (4=major).

Smartwatches were included to investigate if respondents perceived risks differently for "low-risk" compared with "high-risk" devices, as risk perception has previously been connected to the severity and fear of consequences [39,42,44,48,64,65]. Our survey identified differences in risk perception, where "high-risk" devices included assisted living technologies and diabetes technologies, and "low-risk" included smartwatches. The probability and consequences were evaluated higher for "high-risk" devices than "low-risk" devices (Figure 2). In interviews, the perceived consequences of a closed-loop insulin control system were viewed as potentially fatal, which was a consideration for adopting such technologies. Manipulation of data, compromising data integrity, could lead to devastating consequences, such as wrong insulin/medication dosage. This indicates that the function and criticality of the

XSL•FO
RenderX

device affect risk perception and technology adoption, which aligns with previous research [39,64,66,67].

Human Factors

Previous research has demonstrated that human factors such as knowledge, behavior, and emotions are essential for understanding cybersecurity risk [52]. Risk perception theory highlights that understanding, competence, and familiarity with both hazards and risks affect risk perception. Yet, the TAM views familiarity as an enabler for technology adoption [29,44,47,50,51,65,66]. Findings from our study agree with previous studies, where increased familiarity and knowledge of a technology resulted in a change in risk perception. Thus, the perceived severity of consequences affected risk perception, agreeing with previous research emphasizing that the severity level will increase or decrease risk perception [30-32,45]. The concept of dread has been investigated thoroughly within risk perception theories [66,68]. Dread associated with potential harm affects risk perception: in both interviews and our survey, consequences were evaluated as more severe, with potentially fatal consequences. Within TAM and risk perception studies, it has been found that perceived usefulness is important for technology adoption and that the benefits of technology lead to greater risk acceptance, followed by a lower risk perception [42-44,67]. Similarly, we found that respondents were willing to accept risk up to a certain level due to the perceived benefits of the devices. This indicates that convenience and benefit also shaped how risks were perceived, resulting in a lower risk perception.

The implication of trust on risk perception has been debated in previous work [40]. In our study, trust was an essential factor influencing risk perception. Our respondents expressed trust in health care institutions and medical device companies to ensure that technology is secure, previously conceptualized as social trust [42]. Trust is also placed on individuals, whereas if a user trusts others interacting with technologies, risks are perceived to be lower [43,44]. Lastly, there is also trust dedicated to technologies, as respondents perceived these as trustworthy due to a lack of incidents, which resulted in lower perceived risk for assisted living technologies and diabetes technologies.

Limitations

The starting point of this study was to investigate cybersecurity perceptions among stakeholders in 2 different countries. The first limitation concerns the inherent differences between these 2 countries. Although we recognize these differences, we can compare risk perceptions due to a focus on technologies deployed in the health care sector. We recognize differences between users of assisted living technologies and diabetes technologies; however, the findings provide valuable insight into cybersecurity risk perception. A limitation in the Norwegian data sample is the exclusion of patients, which should be addressed in future studies to provide a more comprehensive perspective. In continuing this research, including patients as part of the Norwegian sample would be advisable to capture their concerns about cybersecurity risks.

Next, due to a survey logic error that resulted in optional risk perception questions, the Norwegian sample was limited to 147 out of 185 (79.5%) participants for assisted living technologies and 65 out of 185 (35.1%) participants for smartwatches. This significantly reduces the power of the Norwegian sample in this dimension; nevertheless, we believe the observations still provide valuable insights.

Expanding the sample to include a wide range of patients in both countries would also allow a deeper exploration of how patient-specific factors, such as age, condition, or digital literacy, influence risk perception. Further, women are overrepresented in both samples (139/185, 75.1%, for Norway and 57/89, 64%, for BC). Although a more equal gender distribution would be desirable, it reflects the workforce composition in the health care sector in both regions [69,70]. Future research should aim for equal gender representation to ensure that one gender's perspectives do not disproportionately shape the findings. Recruitment strategies could be adjusted to target more men or other underrepresented groups in the sample. Additionally, we did not perform a subgroup analysis by age category to explore if age is a factor that can explain some of the variability observed in risk perception, which should also be considered in future work, including more diverse populations and larger sample sizes.

Additionally, we could not combine the data sets for further statistical analysis, which restricts the depth of our analysis. The technologies used as examples in the study (assisted living or diabetes technology) serve different purposes and groups, which may lead to varying risk perceptions. This variability must be considered when interpreting the results, as it may influence stakeholders' views on risk differently. Future research should aim to collect a larger sample, possibly through collaborations with multiple health care institutions. Additionally, future studies could consider longitudinal designs to identify changes in risk perceptions over time.

This study did not perform a subgroup analysis of survey responses by participant type, such as patients and clinicians. However, differences among patients and clinicians were observed in the interviews and, therefore, included in the discussion. Future research should investigate the effects of participant type in interpreting the survey data to more comprehensively explore the potential differences in risk perception by participant type or organizational role.

Next, the first author (AS) conducted the thematic analysis of interviews. This approach introduces the potential for bias, as a single researcher's perspective can influence the interpretation of qualitative data. To mitigate this, the themes and key findings were discussed among the researchers. Future studies should aim for multiple researchers to engage in the thematic analysis process, ensuring a more balanced analysis. Furthermore, the reliance on self-reported data from surveys and interviews inherently carries the risk of response bias, where participants might provide socially desirable answers or have recall bias.

Suggestions for Further Research

The BC cohort should be used to investigate differences between participant groups and user characteristics further. Including patients from the Norwegian population would also be interesting, as this could provide a more comprehensive

XSL•FO
RenderX

understanding of risk perceptions and enable the comparison between patients in Norway and BC. A comparative analysis of Norwegian and BC patient populations could reveal how factors such as health care infrastructure, cultural attitudes, and patient demographics influence cybersecurity risk perception. This broader understanding could also inform more tailored approaches to risk communication and management in different health care contexts.

This study has examined cybersecurity risk perception related to specific individual health devices, yet they are often combined—a technological complexity that should be explored further. Further research should explore these complexities by investigating how interoperable systems manage cybersecurity risks, such as CGMs and insulin pumps working in tandem. This would involve assessing the technical vulnerabilities introduced by their interaction and understanding how users perceive or experience those risks in real-world settings. It may also be worthwhile to explore whether various vendor or operating system considerations (eg, Android vs iOS for smartphones) impact users' risk perception.

Another promising direction would be to combine technological analysis of systems with human and behavioral studies, providing a comprehensive system-level perspective on cybersecurity risks in health care. Such research could offer insights into balancing cybersecurity's technical aspects with user experiences, ultimately contributing to more secure health care technology ecosystems. In addition, future studies should incorporate mixed method approaches, such as triangulating self-reported data with observational data or objective measures (eg, usage logs or system performance data), to validate and complement the findings. This would provide a more comprehensive understanding of risk perceptions and reduce the potential bias in self-reporting.

Practical Recommendations

Implementing technology is not straightforward, and one could argue it is even more challenging in health care due to patient safety and security considerations. Ensuring transparency about potential risks and threats is critical for fostering trust, as subjective perceptions of risk vary among interested parties, as identified in this study. For instance, when rolling out new devices such as closed-loop systems for diabetes management (T1D), health care workers and technology developers could hold regular informational sessions or consultations directed toward both care receivers (patients and end-users) and caregivers. Based on the identified needs, one could focus on explaining the security features of and fail-safe mechanisms implemented in these systems. Enabling ongoing risk communication could help reduce skepticism and perceived risk.

Moreover, a structured risk management process, including regularly updated risk and threat assessments, is essential. The study found that respondents were generally willing to accept a certain degree of risk when the perceived benefits and convenience of their device outweighed the potential risks. The balance between risk and benefit/convenience is a crucial driver of technology acceptance. For example, although users may have concerns about data privacy when using wearables, many still choose to use them because of the convenience and value of the health insights these devices provide—such as real-time glucose monitoring or medication assistance—as these are essential in managing their health.

In addition, strengthening the knowledge and competence of all relevant parties—developers, care receivers, and health care workers—is essential, as cybersecurity risks and threats can be challenging to understand, especially for novices. Awareness is a security measure that can mitigate risks derived from humans' interaction with technology, and education is another area that should not be neglected to increase cybersecurity understanding. Practical steps such as security awareness programs could be integrated into the onboarding process for new technologies. For example, when introducing T1D technology (insulin pump or CGM) or assisted living technology (digital medication dispenser or digital self-reporting forms) to new users, as a part of the adoption process, one could introduce training sessions that cover key security areas such as password management, recognizing phishing attempts, and fail-safe mechanisms of the platforms. Such initiatives should be developed in close cooperation with the developers and vendors of the technology, as they often hold more detailed information about the system's security features.

Conclusions

We found minimal behavior and risk perception differences among the participants from Norway and BC. Human factors and device functionality were most influential in shaping cybersecurity risk perceptions. Considering the expected reliance on assisted living technologies and remote care solutions for disease management in the coming years, insight into risk perceptions can assist in reducing fears among relevant parties so that technologies can be adopted more broadly. Understanding risk perceptions can strengthen risk management and awareness, and understanding how to develop mitigating strategies to improve cybersecurity risk management is essential. Different inhibitors and drivers exist in technology adoption, so it is essential to understand the needs and capabilities of specific technology users. Building competence, knowledge, and trust can be essential steps in this endeavor. For future technological innovation and development, security should be considered as a prerequisite rather than an afterthought—it should be a license to operate.

Acknowledgments

The authors thank the participants for their time and for sharing their insights, and Drs Holly Longstaff and Tibor van Rooij for their feedback on the Canadian study design. The study was supported by a 2020 BC Children's Hospital Research Institute External Salary Recognition Award (to MG). MG holds a Michael Smith Health Research BC scholar award (SCH-2020-0494)

and is supported by a Natural Sciences and Engineering Research Council of Canada (NSERC) Discovery Grant (RGPIN-2021-02833). Philanthropic funding from the BC Children's Hospital Foundation enabled the project.

Generative artificial intelligence tools were not used in this manuscript's writing, editing, or development. The authors verified all content generated by the Zoom transcription service.

Data Availability

Some data are available. Ethical approval in BC permits us to share deidentified survey data with other researchers upon request from the corresponding author, but not the interview transcripts. Approval in Norway does not permit us to share survey or interview data publicly.

Authors' Contributions

AS contributed to the conceptualization, methodology, formal analysis, investigation, data curation, writing (original draft and review and editing), and visualization. MG contributed to conceptualization, investigation, formal analysis, funding acquisition, writing (review and editing), and supervision. NW contributed to conceptualization, investigation, project administration, visualization, and writing (review and editing).

Abstract

Background: Digital health technology (DHT) has the potential to revolutionize the health care industry by reducing costs and improving the quality of care in a sector that faces significant challenges. However, the health care industry is complex, involving numerous stakeholders, and subject to extensive regulation. Within the European Union, medical device regulations impose stringent requirements on various ventures. Concurrently, new reimbursement pathways are also being developed for DHTs. In this dynamic context, establishing a sustainable and innovative business model around DHTs is fundamental for their successful commercialization. However, there is a notable lack of structured understanding regarding the overarching business models within the digital health sector.

Objective: This study aims to address this gap and identify key elements and configurations of business models for DHTs in the European Union, thereby establishing a structured understanding of the archetypal business models in use.

Methods: The study was conducted in 2 phases. First, a business model taxonomy for DHTs was developed based on a systematic literature review, the analysis of 169 European real-world business models, and qualitative evaluation through 13 expert interviews. Subsequently, a 2-step clustering analysis was conducted on the 169 DHT business models to identify distinct business model archetypes.

Results: The developed taxonomy of DHT business models revealed 11 central dimensions organized into 4 meta-dimensions. Each dimension comprises 2 to 9 characteristics capturing relevant aspects of DHT business models. In addition, 6 archetypes of DHT business models were identified: administration and communication supporter (A1), insurer-to-consumer digital therapeutics and care (A2), diagnostic and treatment enabler (A3), professional monitoring platforms (A4), clinical research and solution accelerators (A5), and direct-to-consumer wellness and lifestyle (A6).

Conclusions: The findings highlight the critical elements constituting business models in the DHT domain, emphasizing the substantial impact of medical device regulations and revenue models, which often involve reimbursement from stakeholders such as health insurers. Three drivers contributing to DHT business model innovation were identified: direct targeting of patients and private individuals, use of artificial intelligence as an enabler, and development of DHT-specific reimbursement pathways. The study also uncovered surprising business model patterns, including shifts between regulated medical devices and unregulated research applications, as well as wellness and lifestyle solutions. This research enriches the understanding of business models in digital health, offering valuable insights for researchers and digital health entrepreneurs.

Introduction

Background

In recent years, digital health technologies (DHTs) have seen significant advancements, with some apps becoming prescribable by physicians and reimbursable by health insurers, thus making them accessible to patients at no additional cost via their smartphones [1]. Germany has pioneered this approach, and several other countries have since adopted similar measures [2]. This development marks a significant step forward in DHT adoption. However, the potential value of DHTs extends beyond mobile apps. They can support physicians in diagnostic and treatment decisions, streamline administrative tasks, or support clinical trials, among other functions [3,4]. With health care systems worldwide struggling with sustainability issues [3] due to aging populations and increasing numbers of chronic diseases [5], DHTs play a crucial role in delivering value, enhancing the quality of care, and reducing rising health care costs [6].

DHTs encompass systems that integrate computing platforms, connectivity, software, and sensors for health care and related use [7]. These digital technologies primarily consist of stand-alone software solutions. Despite their promise, integrating DHTs into health care systems presents significant challenges due to the complexity and stringent regulations of these systems. The European Union (EU) recently introduced new, more stringent medical device regulations [8]. Medical devices for human use in the EU are now governed by Regulation (EU) 2017/745 on medical devices (MDR) or Regulation (EU) 2017/746 on in vitro diagnostic medical devices (IVDR) [8,9]. These regulations aim to ensure high standards of quality and safety for medical devices [8]. Consequently, some DHTs are classified as medical devices, while others do not meet this criterion [7]. In addition, various countries in the EU are establishing new reimbursement pathways specific to DHTs [2], such as the fast-track approach for digital health apps in Germany mentioned previously [1]. This development opens new revenue options for DHT businesses. The complexity of health care systems is further compounded by the broad stakeholder landscape that includes health insurers, health care providers, and patients, among others [10]. New ventures in the emerging DHT segment face substantial challenges in bringing their solution to market [11]. These challenges include meeting the stringent requirements of the medical device regulations, such as the need to build a quality management system and collect clinical evidence [9]. These activities demand significant additional time and costs [8]. Furthermore, the revenue model poses a challenge because consumer willingness to pay is often low, with many accustomed to free health care services [12]. Reimbursement pathways for digital health are often unclear and vary between several EU countries [2]. Moreover, high-quality, real-world evidence is often required to secure reimbursement [1].

To overcome these challenges and realize the full potential of DHTs, establishing a well-defined and sustainable business model is one of the crucial elements for success [13]. A DHT business model can help to cocreate and formulate a set of critical success factors [5]. Although start-ups have limited resources, they can leverage their structural flexibility to explore new market segments, thereby playing a pivotal role in introducing and adopting innovative business models [14]. This innovation is particularly important because, although medical technologies are constantly introduced to the market, they rely on less inventive business models [15]. Consequently, emerging business models built on DHTs can address the shortcomings of traditional medical technologies, overcoming barriers to commercialization. Therefore, a structured understanding can help identify sustainable and innovative DHT business model types. This understanding can also support the development process of business models at different stages [16]. However, there is a significant gap in the structured understanding of the business models within the DHT domain. In addition, there is a lack of research on how medical device regulations impact digital business models despite these regulations having a considerable influence [17].

Objectives

This study aims to identify key elements and configurations of business models for DHTs and, by doing so, provide a structured understanding of the archetypal business models in use. Given the variations in medical device regulations across countries, this study focuses on the EU with a common medical device regulatory framework. To achieve this goal, we formulated 2 research questions (RQs):

- RQ1: What are the key observable elements of DHT business models in the EU?
- RQ2: Which archetypes of DHT business models in the EU can be identified?

To answer these RQs, we developed a DHT business model taxonomy based on the digital health business model literature, data from real-world start-ups, and expert interviews. Subsequently, we derived DHT business model archetypes through cluster analysis. This approach provides a systematic classification of DHT business models and a simplified overview that establishes a common language. In addition, this study contributes to business model theory in complex domains by describing key components, the influence of the regulations, and drivers for business model innovation. In practical terms, this clear structure, real-world cases, and archetypal descriptions can assist digital health entrepreneurs in identifying suitable business models for their DHTs. It may also aid venture capitalists and investors in systematically analyzing digital health ventures.

The remainder of this work is structured as follows: the next subsection provides an overview of current research on business models in digital health. The Methods section outlines the research methodology followed, which is based on 2 main research phases. The Results section presents the developed business model taxonomy and archetypes. Finally, the Discussion section discusses the results and concludes the study.

Related Work

Digital health has emerged as an umbrella term to describe the practice of using information and communication technology to address health care needs [18]. The main components of digital health include eHealth, which encompasses internet and

XSL•FO
RenderX

web technologies used in health care delivery; mobile health (mHealth), which focuses on mobile devices to administer health care services; and telemedicine, which involves remotely connecting physicians and patients [19,20]. The digital technologies used in the context of digital health are referred to as DHTs. DHTs, which are regulated as medical devices, are known as software as a medical device [7]. The term *software as a medical device* refers to software intended to be used for at least 1 medical purpose that is performed without being part of a hardware medical device [21]. The intended medical purpose, declared by the medical device manufacturer, qualifies a DHT as a medical device [9]. The EU definitions of a medical device, in vitro diagnostic medical device, medical purpose, and other relevant definitions in this context are provided in Table S1 in Multimedia Appendix 1.

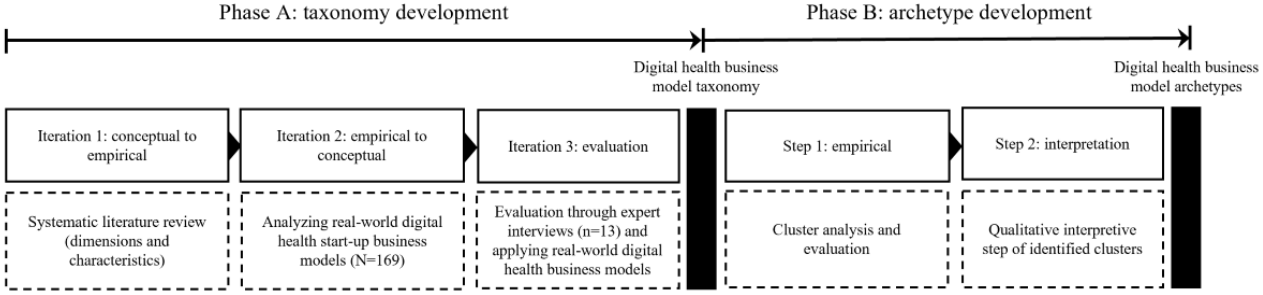
A business model can be described as the mechanism by which a business creates, delivers, and captures customer value [22]. Osterwalder [23] defines the business model as a strategic plan translated into a conceptual blueprint, positioning the strategy as one layer removed from the business model itself. In this context, the business model lies between the business strategy and the business processes and can be used as a tool of alignment through explicit depiction of the business logic [13]. It implements strategies and reflects the realized strategy [24]. The broad scope of business model research includes several subareas, such as research on business model components, development tools, and taxonomies [16]. Among development tools, the business model canvas is widely used to support the development process [25].

Existing literature discusses business models of digital health and related subcategories, such as telemedicine, eHealth, and mHealth. Some conceptual work exists in this domain [14,26-28]; for instance, Pascarelli et al [28] and Velayati et al [27] conducted systematic literature reviews to identify key components of digital health and telemedicine business models. Much of the research is empirical, describing elements of business models in digital health, telemedicine, and eHealth [29,30]. Some studies use the business model canvas to frame their empirical research [31-34], while others present their own frameworks [35,36]. Sterling and LeRouge [30] identified value proposition, key processes, key resources, and the profit formula as key components, while Gehde et al [4] focused on the technologies used to distinguish between business models.

Classification is the broad concept of organizing knowledge [37]. Under this scope, taxonomies create a structure and organization of a knowledge field and can help to navigate it [38]. While taxonomies are typically built inductively from empirical data, the term *typology* often denotes deductively derived classifications [16], although these concepts are sometimes used interchangeably [38].

Some taxonomies exist in the realm of digital health [39-42]. These taxonomies primarily emphasize technical aspects and lean toward telemedicine, but they also provide some useful criteria in the context of business models, such as technology [40], care sectors [41], or data types [42].

Business model taxonomies categorize business models based on their unique features [16] and aim to formulate ideal types of businesses [43]. These types of taxonomies have recently seen increased attention [16]. A few studies have focused on digital health business model taxonomies; for instance, a validated taxonomic business model description for telemedicine highlights the dimensions of value proposition, value cocreation, value communication and transfer, and value capture [44]. Three patterns of business models were identified. Other specific business model taxonomies include those for specialized mHealth segments such as maternal and baby care [45] or Middle Eastern telemedicine [46].



In conclusion, the focus and results of the studies vary depending on the digital health domain and research methods used. While some research has explored the components of digital health business models, a comprehensive and systematic classification that accounts for unique features, such as medical device regulations, and is based on extensive empirical data remains lacking.

Methods

Overview

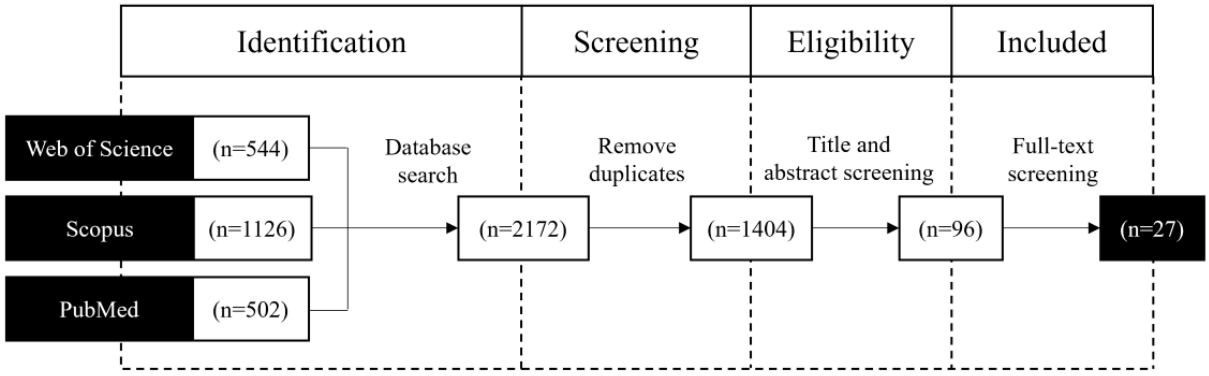
Our research design comprises 2 phases, as illustrated in Figure 1. These phases include the development of the taxonomy followed by the archetype development. This research design is inspired by similar work on business model taxonomy development [47-49].

Figure 1. Overview of the research design, which was organized into 2 main phases: taxonomy development and archetype development. Each phase encompassed multiple iterations and steps.

XSL•FO
RenderX

Phase A: Taxonomy Development

Overview



In the initial phase, we followed the iterative taxonomy development process proposed by Nickerson et al [38], incorporating recent enhancements by Kundisch et al [50]. The systematic process developed by Nickerson et al [38] is well established for its ability to integrate both empirical (inductive) and conceptual (deductive) approaches, allowing for iterative refinement until specified ending conditions are met [38]. Therefore, taxonomy design can be systematized, producing comprehensive and robust results. Kundisch et al [50] extended the taxonomy development process proposed by Nickerson et al [38] with more emphasis on taxonomy evaluation. Therefore, we focus on the approach of Nickerson et al [38] and integrate the suggestions for evaluation proposed by Kundisch et al [50], similar to previous taxonomy development [49].

Following the recommendations of Nickerson et al [38], our first step was to define a meta-characteristic to guide the taxonomy design. We selected "key observable and unique elements of DHT business models in the EU" as our meta-characteristic. Furthermore, our ending conditions were based on the work of Nickerson et al [38] and can be found in Table S2 in Multimedia Appendix 1. We selected the V4 business model dimensions developed by Al-Debei and Avison [13] as a theoretical lens for the taxonomy design, which is a common approach in business model taxonomy development [43]. Consequently, we categorized all identified taxonomy dimensions into 4 meta-dimensions: value proposition (offering value structure), value architecture (technological and organizational architecture), value finance (financial setups and return), and value network (business and customer actors web) as defined by Al-Debei and Avison [13]. Building on these foundations, we set out to develop the taxonomy in 3 iterations. The first iteration followed a deductive, conceptual-to-empirical approach grounded in a literature review. By contrast, the second iteration adopted an inductive, empirical-to-conceptual approach and relied on real-world observations, while the third iteration focused on evaluating the taxonomy through expert interviews. Throughout these iterations, we were mindful of potential biases related to our methods. Systematic literature reviews can be prone to publication selection biases, while qualitative research may introduce interpretive biases. To mitigate the risks of individual methods, we used a mixed methods approach and discussed results within the team to enhance objectivity. This process enabled us to incorporate diverse perspectives, resulting in a more comprehensive and robust taxonomy [38].

Iteration 1: Systematic Literature Review

The first iteration of the taxonomy development was based on a systematic literature review [51,52] to identify initial taxonomy dimensions and characteristics. A systematic literature review is a transparent and reproducible methodology for identifying relevant scientific work in a field [51]. This process involves planning the review, identifying and evaluating studies, extracting and synthesizing data, and disseminating the review findings [51]. An overview of the publication selection process is illustrated in Figure 2. To identify relevant publications, we conducted a comprehensive search in February 2024 across 3 major databases: Web of Science, Scopus, and PubMed. We applied an extensive search string to titles, abstracts, and keywords: ("digital health*" OR "mobile health*" OR "mhealth*" OR "m-health*" OR "ehealth*" OR "e-health*" OR "telemedicine*" OR "tele-medicine*" OR "telehealth*" OR "tele-health*" OR "software as a medical device*" OR "digital therapeutic*") AND ("business model*" OR "taxonom*" OR "archetyp*"). We did not limit the search period. This approach yielded a total of 2172 potential publications. After removing duplicates, titles and abstracts were scanned, and 3 inclusion criteria were applied: publications must (1) mention potential business model dimensions of digital health, (2) be written in English, and (3) be peer reviewed. Applying these inclusion criteria to the 2172 potential publications resulted in 96 (4.42%) publications. A subsequent full-text screening of these 96 publications narrowed this down to 27 (28%) final publications [4,6,19,26,28,30,32-36,39-42,44-46,53-61]. Almost half of the papers (13/27, 48%) use qualitative or conceptual research methods. A comprehensive list of the included publications, along with their study objectives, research methods, and key dimensions, is presented in Table S3 in Multimedia Appendix 1.

Figure 2. Visualization of the publication selection process as part of the systematic literature review, which involved searching 3 databases, applying a targeted search string, and using inclusion criteria to identify relevant studies.

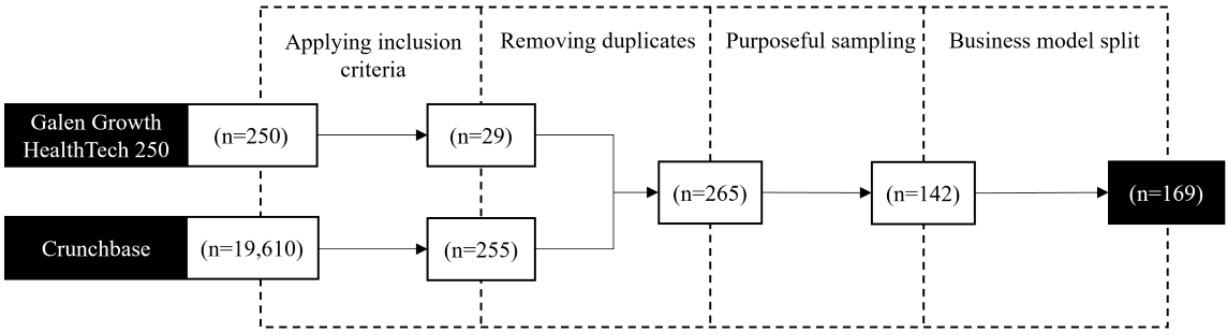
XSL•FO
RenderX

The knowledge gained from these publications was incorporated as a theoretical foundation into the subsequent analysis. Common themes were identified and then conceptualized as dimensions and characteristics based on the V4 meta-dimensions [13].

The meta-dimension *value proposition* was frequently highlighted as a central element of the business models in digital health [28,44], with the most commonly mentioned dimensions being the *main purpose* [4,44,45] and the *target user*, referring to the primary customer of a digital health company [6,33].

Under the meta-dimension *value architecture*, digital technology [44] and regulations [36,45] were identified as key business model elements. In addition, data often drive digital business models [26,33], leading us to introduce the dimensions *enabling technology*, *regulations*, and *data type*. These dimensions incorporate key resources [30] and dominate key activities [28,34] relevant to the business model. Recognizing the importance of embedding a business model into the health care system, we created the dimension *medical specialty level* [35,41] as the final dimension of *value architecture*.

For the third meta-dimension, *value finance*, we incorporated *paying entity* [44,45] to distinguish between users and payers, often different health care entities. Health care–specific reimbursement options were mentioned in the literature, where health insurers cover costs for digital health solutions [28,35]. This led to the establishment of the dimension *reimbursement*. In addition, *funding* was established as a further dimension [6,28].



In the final meta-dimension, *value network*, partnerships along the value chain were identified as part of the business model [26,28], prompting us to introduce the dimension *value chain partnerships*. Furthermore, digital health also plays a crucial role in connecting users through digital platforms [35,44,45], leading to the establishment of the dimension *platform interaction type*.

These initial dimensions were frequently cited in the literature; however, some variability between studies was observed, likely due to differences in research methods and the specific focus areas of the studies.

Iteration 2: Real-World Digital Health Business Models

Transitioning from the conceptual-to-empirical step, we adopted an empirical-to-conceptual approach for the second iteration of taxonomy development by analyzing real-world DHT business models. A fruitful approach is to analyze start-up business models because they often have novel digital business models and good availability and narrowness of data [43]. We used the HealthTech 250 list by Galen Growth [62] and the business intelligence platform Crunchbase to identify suitable start-ups to build our dataset. The HealthTech 250 list comprises 250 early-stage digital health ventures. On Crunchbase, by setting the industry group to “health care” and limiting the Crunchbase Rank, which is a measure of a company’s prominence [63], to 100,000 companies, we received an initial 19,610 results. To refine these results and focus on start-ups, inclusion criteria were established. First, the start-ups should be located in the EU and target this market. As medical device regulatory frameworks vary between countries, the EU enables the study of a common regulatory framework. Second, the solution developed by the venture should fit into the scope of DHTs. Third, the company should not be older than 10 years [64]. Next, the maximum number of employees should not exceed 250, aligning with the EU’s commonly defined upper limit for small- and medium-sized enterprises [65]. Finally, the company must be privately held and should not have merged with, or been acquired by, another entity. These criteria, which should ensure that the companies have a clear, identifiable business model and can be considered start-ups, were applied to both the HealthTech 250 list and the Crunchbase search. Afterward, we removed duplicates and performed purposeful sampling to create a balanced dataset and avoid overrepresenting specific business model types [66]. The complete list of companies, with relevant metadata, is shown in Table S4 in Multimedia Appendix 1. Next, we randomly scanned companies from our sample by reviewing their websites and other publicly available information to verify existing dimensions and characteristics and identify additional ones based on our meta-characteristic. If more than 1 applicable business model was identified for a company, each business model was considered separately, as depicted in the last step in Figure 3.

Figure 3. A summary of the selection process for real-world digital health technology business models, incorporating 2 primary sources for ventures and applying specific inclusion criteria.

XSL•FO
RenderX

This process led to the identification of 12 dimensions and 64 characteristics. Finally, theoretical saturation was achieved after no new business models were identified for >20 companies in a row, and the second taxonomy development iteration was concluded.

Iteration 3: Qualitative Evaluation

It has been emphasized that the evaluation of a taxonomy is a crucial element of the taxonomy design that should not be ignored [50,67]. On the basis of this understanding, we extended the taxonomy development process proposed by Nickerson et al [38] with a third iteration, with the goal of triangulating the previous quantitative research approach with a qualitative one. Hence, we evaluated the previously developed taxonomy qualitatively through semistructured expert interviews. Interviews allow the collection of detailed and context-rich data, offering deep insights into a research topic [68]. We built our qualitative evaluation on commonly mentioned and applied criteria for taxonomy evaluation: completeness, simplicity, understandability, and robustness [50]. On the basis of these criteria and following the questions proposed by Szopinski et al [67] for taxonomy evaluations, we prepared an interview guideline. Thirteen experts from both academia and industry, with relevant expertise in digital health, business models, or taxonomy development were selected to participate. Each interview was conducted using videoconference software and was recorded and transcribed. An overview of the experts' roles, expertise, and interview durations (total duration: 407 min) is presented in Table 1.

Table 1. Overview of the interviewed experts' roles, expertise, and interview durations.

ID	Role	Expertise	Duration (min)
E1	Research group leader	Digital health and taxonomies	25
E2	Senior consultant	Taxonomies and business models	30
E3	Start-up consultant	Digital health and business models	47
E4	Cofounder	Digital health and business models	37
E5	Cofounder	Digital health and business models	28
E6	Cofounder	Digital health and business models	35
E7	PhD student	Digital health and business models	25
E8	Chief strategy officer	Digital health and business models	26
E9	Pharmaceutical industry consultant	Digital health and business models	38
E10	Venture capitalist	Digital health and business models	37
E11	PhD student	Digital health and business models	20
E12	Junior professor	Taxonomies and business models	25
E13	PhD student	Taxonomies and business models	34

The transcripts were inductively analyzed using the Gioia methodology [69]. On the basis of this analysis, we used the taxonomy operators *adding*, *renaming*, *merging*, and *removing* to rework dimensions or characteristics [50]. A table with the detailed changes after conducting the expert interviews can be found in Table S5 in Multimedia Appendix 1. We applied the updated taxonomy to our previously derived sample of DHT start-ups, resulting in no further changes to the taxonomy. To validate our findings, 2 additional raters coded a subsample (10%) of the real-world cases. The resulting Fleiss κ value of 0.79 indicates substantial agreement with the original classification [70]. This concluded the taxonomy development, with all ending conditions met (refer to the Results section for the final taxonomy version).

Phase B: Archetype Development

In the second phase, a cluster analysis was performed to develop archetypes of DHT business models. This method groups observations based on their similarities [71] and is the dominant mechanism for generating business model archetypes [43]. It is an objective and data-driven approach, thereby reducing potential biases. In addition, several clustering methods are available that enable fine-tuning and ensure that the clusters reflect meaningful and interpretable business model archetypes. Various approaches and methods for cluster analysis exist, raising questions regarding which similarity or dissimilarity measure to choose and which algorithm to use [72]; for instance, iterative partitioning methods such as k-means are considered superior to hierarchical algorithms [72], but they require predefined cluster numbers, which hierarchical algorithms do not require [72]. To overcome this limitation, we followed the 2-stage clustering approach proposed by Punj and Stewart [72].

In the first stage, we used the method proposed by Ward [73] to perform agglomerative hierarchical clustering. We used the simple matching coefficient as a similarity measure suitable for binary datasets [48]. The resulting clusters were visualized in a dendrogram (Figure S1 in Multimedia Appendix 1). Clusters that merge at greater heights in the dendrogram are more dissimilar. Therefore, cluster numbers were deemed reasonable in the range of 2 to 6 because the height differences between merge points dropped significantly beyond 6 clusters.

In the second stage of the cluster analysis, we performed k-means clustering with various cluster numbers to identify the optimal number [47]. The elbow rule indicated that 6 clusters were an optimal solution (Figure S2 in Multimedia Appendix

XSL•FO
RenderX

1). In addition to k-means, we conducted a similar analysis using algorithms such as k-modes, which are suitable for binary datasets. On the basis of these analyses, we examined the number of cases per cluster and discussed the interpretability and explanatory power of the clusters within the team. The 6-cluster solution of the k-means algorithm was identified as the strongest, with each cluster being well separated and interpretable (Table S6 in Multimedia Appendix 1). The average silhouette score of the solution was 0.35, suggesting a rather weak but substantial cluster structure in the data [74]. Social science data frequently lack strong natural groupings [75], and similar results have been observed in previous business model taxonomy research [48]. Therefore, we interpret the result as a good clustering outcome for the diverse and complex configurations of DHT business models observed in our study.

Finally, we conducted a qualitative interpretive step to interpret the results and the corresponding clusters by inspecting the frequency distributions of each characteristic within the clusters [75]. The frequency distributions for each cluster are presented in Table S7 in Multimedia Appendix 1.

Ethical Considerations

The qualitative data in this study, collected through interviews, have been deidentified to protect participant privacy and confidentiality. All interviewees provided informed consent for the use of deidentified data in this scientific publication. The research was conducted in accordance with the relevant ethics guidelines, and it was exempt from human participant ethics review.

Results

A Taxonomy of European DHT Business Models

The resulting taxonomy is presented as a morphological box in Figure S3 in Multimedia Appendix 1. In total, 11 dimensions were identified. Some dimensions are exclusive, allowing only 1 characteristic to be assigned, while others are nonexclusive, allowing multiple characteristics to be assigned. All characteristics in Figure S3 in Multimedia Appendix 1 are sorted alphabetically. The key elements of the taxonomy, based on 4 meta-dimensions, are discussed herein. A detailed description of each dimension and characteristic is presented in Table S8 in Multimedia Appendix 1, and an example of how a DHT business model can be categorized within the taxonomy is presented in Table S9 in Multimedia Appendix 1.

The *value proposition* meta-dimension outlines how a company offers value [13]. In DHT business models, 9 *main purposes* have been identified, indicating the type of value delivered. These purposes are divided into 2 main groups: those with a medical purpose and those without (refer to Table S1 in Multimedia Appendix 1 for the definition of *medical purpose*). Characteristics with a medical purpose include *diagnosis or prediction*, *monitoring support*, and *treatment or interventional purpose*. All these characteristics are related to specific medical conditions. The *treatment or interventional purpose* characteristic also encompasses preventive and rehabilitation interventions [76,77]. Characteristics without a medical purpose include *administrative support* and *information delivery or education*, among others. DHT business models can have multiple *main purposes*, including combinations of medical and nonmedical purposes. It is crucial to identify the primary source of value when selecting the *main purpose*. Another dimension of the *value proposition* meta-dimension is the *target user*, encompassing *patients or private individuals* and stakeholders directly involved in health care delivery, such as *health care providers*. Another target user is *indirect health care commercial firms*, such as pharmaceutical and medical technology companies or even *non–health care commercial firms*. Finally, some companies collect data to provide clinical and nonclinical *evidence*. Here, some companies base their evidence on established medical literature, while others provide real-world evidence, for example, through randomized controlled trials.

The *value architecture* meta-dimension describes the technical and organizational infrastructure of the business model [13]. This meta-dimension encompasses the integration of the business model into health care systems, considering the *level of care*, such as *primary*, *secondary*, or *tertiary care* [78,79]. This describes whether the value is generated through integrating solutions at the initial points of contact with health care systems or, alternatively, within highly specialized care settings. In addition, this meta-dimension includes the EU *medical device regulatory framework*, which comprises the *medical device regulation* covering most regulated DHTs with a medical purpose and the *in vitro diagnostic medical device regulation* for DHTs with a medical purpose using primarily biological data derived from human biological materials [9]. In addition, it recognizes the existence of *nonmedical devices* without a medical purpose. Digital business models are fundamentally driven by data as a key resource and often are built on an *enabling technology*. In total, 9 *data types* were identified, ranging from *medical imaging data* derived through x-ray imaging or magnetic resonance imaging to *physiological parameter data* captured using sensors to measure bodily functions. Some of the data are reported directly by patients or involve tracking user behavior, summarized under the dimension of *user activity or patient-reported data*. Examples of enabling technologies include *artificial intelligence*, *cloud or network technology*, and *sensor technology*.

Value finance is the part of the business model that focuses on financial setups and returns [13]. Therefore, the taxonomy includes the *paying entity*, which can be the *patient or other private individuals* such as caregivers, *health care providers*, or even companies indirectly involved in health care delivery. *Reimbursement* plays a vital role in the revenue model, with *health insurers and governments* covering expenses for DHTs, depending on the country-specific *reimbursement* pathways [2].

Finally, the *value network* is defined as the web of business and customer actors [13]. A key aspect is the *user interface*, which shapes how users interact with the solution. In addition, the business model taxonomy covers stakeholder interactions. Digital platforms can engage both internal and external actors [80], as illustrated in the dimension of *stakeholder interaction type*. This category examines network effects, focusing on user and company interactions facilitated by the solution. It assesses whether users engage with each other through the solution and

XSL•FO
RenderX

how the companies themselves interact with their customers using the solution.

Archetypes of DHT Business Models

Overview

Six archetypes of DHT business models were identified. The number of business models in these clusters ranges from 18 (10.7%) to 36 (21.3%) out of 169 business models. The frequency distribution for all characteristics of the archetypes is shown in Table S7 in Multimedia Appendix 1. Through an interpretive step, we analyzed the archetypes and assigned the following labels: administration and communication supporter (A1), insurer-to-consumer digital therapeutics and care (A2), diagnostic and treatment enabler (A3), professional monitoring platforms (A4), clinical research and solution accelerators (A5), and direct-to-consumer wellness and lifestyle (A6). Table 2 provides an overview of the archetypes, and the subsections that follow offer a comprehensive summary of the main findings for each cluster.

XSL•FO
RenderX

Table 2. Concise descriptions of the 6 business model archetypes identified through cluster analysis, along with corresponding examples.

ID	Archetypes	Distinguishing characteristics	Examples of underlying DHTs[a]
A1	Administration and communication supporter	• Business models around tools assisting with administrative tasks (eg, scheduling and report writing) and patient interactions • Not medical devices; often using cloud, network technology, and artificial intelligence; efficiency evidence not typically provided • Health care providers pay for these nonreimbursable solutions; interfaces are mainly mobile apps and web applications	Automated medical report writing, appointment management tools, and telehealth video consultation
A2	Insurer-to-consumer digital therapeutics and care	• Business models around supporting digital treatment of medical conditions, used mainly by patients and private individuals • Regulated as medical devices under the MDR[b], providing mostly high clinical evidence (peer-reviewed studies) • Focus on primary and secondary care, rely on health insurer reimbursement, and incorporate multimedia and patient-reported data; some act as support channels with the provider	Mobile app for treatment support of leaky gut, depression, or overweight
A3	Diagnostic and treatment enabler	• Business models for solutions assisting physicians in diagnosis or treatment planning, sometimes including administrative support • Regulated as medical devices under the MDR (medical imaging and physiological data) or the IVDR[c] (data derived from human biological materials) • Used and paid for by health care providers; use artificial intelligence; feature mobile apps or web applications; do not facilitate stakeholder interaction	Radiological imaging tools, treatment planning software, and in vitro diagnostic software to support the diagnosis
A4	Professional monitoring platforms	• Business models based on digital platforms to monitor patients' medical conditions, connecting health care providers with patients and private individuals • Classified as medical products under the MDR, supported by clinical evidence • Facilitate interuser interaction; integrate administrative support, telecommunication, and education; primarily paid for by health care providers, sometimes reimbursable	Physician platform to monitor progression of Parkinson disease based on mobile app and therapeutic exercise–monitoring platform
A5	Clinical research and solution accelerators	• Business models around the acceleration of clinical research or the provision of raw technology for pharmaceutical companies, medical technology companies, and research institutions • Some solutions are classified as medical devices under the MDR, while research applications are not regulated • Paid for by indirect health care firms and research institutions, may or may not facilitate stakeholder interaction and include developer tools as well as mobile apps and web applications	Diagnostic tools based on artificial intelligence that medical technology companies can integrate and software to support clinical trial execution through data collection
A6	Direct-to-consumer wellness and lifestyle	• Business models enabling information delivery and education for patients and individuals, with some telecommunication features and marketplaces • Not classified as medical devices • Include coaching through mobile apps and web applications; sometimes provided by medical clinics; targeting self-pay markets and corporate wellness; some are reimbursable and report nonclinical evidence	Mobile app for meditation, pregnancy support apps, and health and sports coaching mobile app

[a]DHT: digital health technology.

[b]MDR: Regulation (EU) 2017/745 on medical devices.

[c]IVDR: Regulation (EU) 2017/746 on in vitro diagnostic medical devices.

XSL•FO
RenderX

Administration and Communication Supporter (A1)

The first archetype comprises business models built on software tools designed primarily to assist health care providers with administrative tasks such as appointment scheduling, automated report writing, job matchmaking, professional education, and claims management. These administrative solutions are often combined with telecommunication modules that facilitate interactions between health care providers and patients or private individuals. Therefore, they also target private individuals. As the underlying solutions do not serve a medical purpose, they are not classified as medical devices, and companies typically do not provide evidence to support their efficacy. These business models operate across all levels of care. Communication is primarily enabled through cloud and network technology, with some solutions incorporating artificial intelligence. The revenue model predominantly involves health care providers who use and pay for these solutions, making them generally nonreimbursable for patients. The user interfaces are mainly mobile apps and web applications, and the solutions often connect health care providers with patients.

Insurer-to-Consumer Digital Therapeutics and Care (A2)

The second type of business model comprises software solutions that primarily support digital treatment and care through interventions for medical conditions. These business models target mainly patients or private individuals. Some of the business models additionally enable telecommunication with employees of the solution provider itself. They typically provide a high level of clinical evidence, such as through published peer-reviewed studies. The focus lies predominantly on primary and secondary care. Due to their medical purpose, solutions under this archetype are regulated as medical devices under the MDR. They incorporate multimedia data for educational purposes and capture user activity and patient-reported data. Most of the business models in this archetype rely on reimbursement through health insurers to generate revenue. For cases that are not reimbursed, patients or private individuals are payers.

Diagnostic and Treatment Enabler (A3)

Similar to the first archetype, the third business model archetype is mainly used and paid for by health care providers, specifically professionals such as physicians. In a few cases, these professional tools are reimbursed through health insurers or are paid for by patients and private individuals. They primarily assist physicians in the diagnosis or treatment of medical conditions. Although they sometimes include additional administrative support, they are regulated as medical devices under the MDR or the IVDR for their medical purpose. Business models under the MDR are substantially driven by medical imaging data, physiological parameter data, or medical laboratory results. By contrast, business models under the IVDR primarily use data derived from human biological materials, such as genomics and microscopic cell images. The business models are built on solid clinical evidence. This category also includes business models built on diagnosis software for patients and private individuals that share the same main purpose regarding diagnosis and prediction as professional tools and are nonreimbursable. The business models are often enabled through artificial intelligence, feature mobile app or web application interfaces, and do not facilitate stakeholder interaction.

Professional Monitoring Platforms (A4)

This archetype focuses on business models with the purpose of monitoring patients and their medical conditions through digital platform solutions that connect health care providers with patients or private individuals. Both the platforms for health care providers and the patient-side applications vary in complexity. Depending on the business model, several other purposes are integrated with the monitoring, such as diagnosis and prediction, administrative support, telecommunication, or information delivery and education. Monitoring is often achieved through the collection of user activity or, in many cases, through the collection of patient-reported data (mostly patient-reported outcome measures). The underlying solutions are classified as medical devices under the MDR and are supported by clinical evidence. Typically, the business model focuses on secondary or tertiary care applications. These platform business models facilitate interuser interaction by connecting patients and health care providers. Health care providers primarily bear the cost, but sometimes solutions are reimbursable.

Clinical Research and Solution Accelerators (A5)

The fifth archetype primarily targets indirect health care commercial firms, such as pharmaceutical or medical technology companies, as well as research institutions. The underlying solutions do not provide direct health care but serve as tools to accelerate drug discovery and clinical research by offering digital tools for study execution. This application occurs outside of direct medical care. In addition, some business models are built on offering raw technology that can be used by medical technology companies as part of their solutions. While some solutions are classified as medical devices under the MDR, others are not, because research applications do not fall under the MDR or the IVDR. The payers in this archetype are indirect health care commercial firms and research institutions. Some business models do not involve solution-side stakeholder interaction, while others facilitate interuser interaction, for example, through contact with study participants for clinical research. A distinctive feature of these business models is that the raw technologies are not only provided as mobile apps and web applications but also as developer tools.

Direct-to-Consumer Wellness and Lifestyle (A6)

The last archetype proposes value through information delivery and education for patients and private individuals. These can be simple, user-facing applications for general well-being, such as those providing guided meditation. Another type of value that is delivered by some of these business models is telecommunication, and a few offer marketplaces targeting patients and private individuals. A unique aspect of some of these wellness and lifestyle solutions is the interaction between the solution provider and users, where employees of the solution provider connect with users and coach them through mobile apps and web applications. Sometimes, the contact can be through a solution provider–operated medical clinic. Solutions

XSL•FO
RenderX

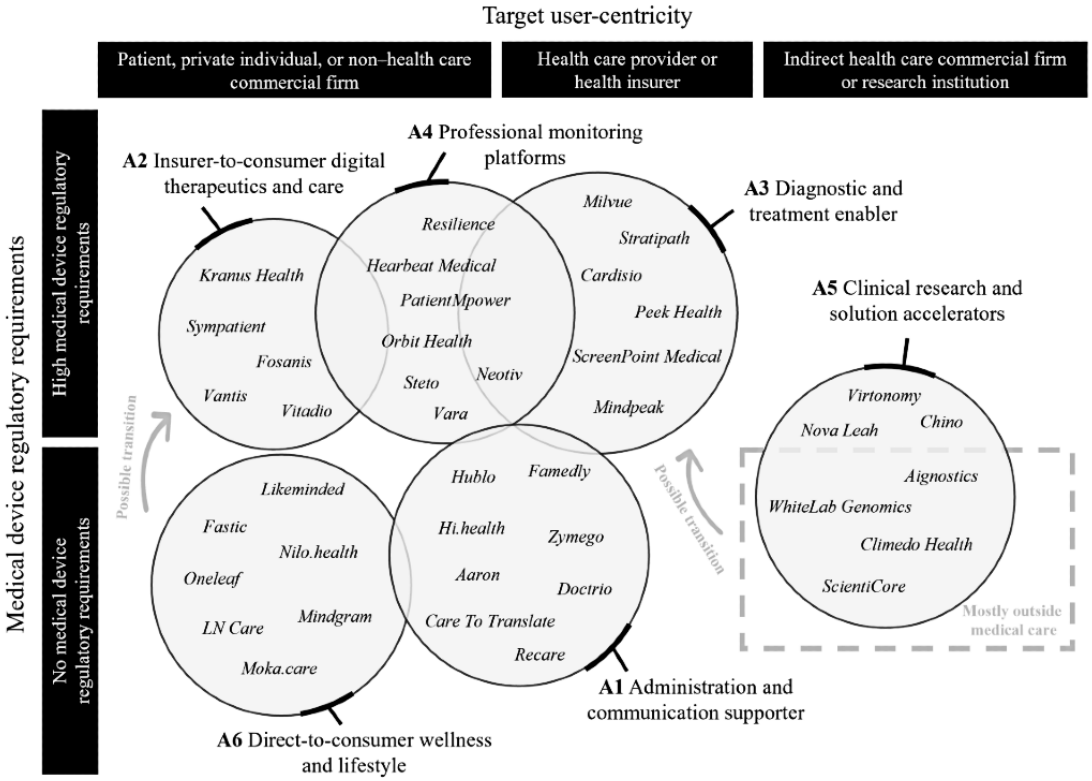
related to this business model archetype do not mention specific medical purposes and are not classified as medical devices. While some solutions aim at the self-pay market, others target non–health care commercial firms that are interested in corporate wellness, making them reimbursable for patients and private individuals. In addition, some companies report nonclinical evidence from their solutions, which might help to convince health insurers to reimburse costs.

Discussion

Principal Findings

The objective of this study was to identify key elements of business models for DHTs, aiming to develop a structured understanding of the archetypal business models used in the industry. This goal was achieved through a 2-phase process. In the first phase, we developed a taxonomy of DHT business models [38,50]. The taxonomy was based on a systematic literature review and an analysis of 169 real-world business model cases. It was evaluated qualitatively through 13 expert interviews. In the second phase, we conducted a cluster analysis based on hierarchical and iterative partitioning clustering methods [72], which resulted in the identification of 6 archetypal clusters. These clusters were subsequently evaluated and interpreted. This resulted in interesting findings regarding the dominant business models used for DHTs and enabled the study of business model innovation in the DHT domain.

Primarily, we want to mention the cascading effect observed for the *medical device regulatory framework* dimension. Medical device regulations significantly impact the business model design if a company delivers a value proposition based on a medical purpose, which applies mainly to archetypes A2, A3, and A4. Through this, these regulations have a strong influence, requiring ventures to adapt their strategies based on available resources due to the additional time, costs, and potential partnerships needed. Many medical device companies in our sample of digital health start-ups (49/142, 34.5%) showcased proof of clinical evidence because the medical device regulations require demonstrating sufficient evidence. Some of the companies (7/142, 4.9%) based their evidence on the state of the art, while others (42/142, 29.6%) presented results from their own clinical studies. Furthermore, clinical partnerships and other quality and security certifications were listed on the company websites. Therefore, medical device regulations exert a strong influence on business models. While medical device regulations have the largest impact, other EU and local regulations also contribute to the cascading effect; for instance, the Artificial Intelligence Act recently adopted by the EU is relevant if the business model relies on artificial intelligence technologies that pose risks deemed sufficiently high. Thus, some companies must navigate a complex regulatory landscape to ensure compliance and sustainability when designing their business models.



Second, we identified 3 key drivers of business model innovation within the DHT domain. The first driver of business model innovation pertains to the dimensions of users and payers. Unlike traditional medical technology companies, which often develop business models centered around hardware-intensive technologies operated by health care providers, DHT business models can directly engage patients, private individuals, and even corporate employers. This is facilitated by the integration of mobile interfaces with cloud and network technologies, promoting innovative business models, particularly in archetypes A2, A4, and A6. The second driver is the advent of artificial intelligence and the rise of digital technologies, which enable unprecedented value delivery. These advancements facilitate the creation of business models that were previously unimaginable, significantly driving archetypes A4, A5, and A6. The third driver of business model innovation is the revenue model, customized to the target countries' specific conditions. The self-payer market is more attractive in some regions, whereas others have established reimbursement pathways allowing cost coverage by 1 health insurer or multiple health insurers [2]. It has been observed that certain reimbursement pathways are exclusively available to medical devices or specific DHTs; for example, the reimbursement pathway for digital health applications in Germany [1] is limited to digital medical devices. This fosters new business models and drives innovation in archetypes A2 and A6. Companies in the study sample (26/142, 18.3%) engage in selective contracts with individual health insurers or use other pathways that facilitate the reimbursement of health care expenses. Therefore, the revenue model constitutes a critical element of DHT business models and must be tailored to the national context while ensuring alignment with other business model components. Start-ups should consider reimbursement pathways and possible related medical device requirements early in their strategy development.

Finally, the relationships among the identified business model archetypes reveal interesting connections. To discuss these relationships, we categorize the 6 identified archetypes of business models based on their compliance with medical device regulations and their primary target users, as depicted in Figure 4. The solutions underlying the business model archetypes A2, A3, A4, and some in A5 are regulated as medical devices. Notably, A3, A4, and some A2 business models face stringent medical device regulatory requirements because they provide critical tools for health care providers and patients. A3 stands out because it is the only archetype that includes in vitro diagnostic medical devices regulated under the IVDR. It was noted that these business models often emerge from academia as transfer projects. While most health care providers typically use and cover the costs of these solutions, 1 particular business model stands out and deserves mention: in this model, patients pay for enhanced diagnoses through professional software, and health care providers receive a share of this payment as additional revenue. By contrast, the underlying solutions of A6 and A1 are not classified as medical devices. Notably, some companies within these archetypes, as well as A2 companies, operate at the intersection of regulated medical devices and unregulated wellness and lifestyle products [81]. This implies that these companies might initially adopt an A6 business model (no medical purpose and not subject to medical device regulations) and gradually transition to an A2 business model as they gather more real-world evidence (medical purpose and subject to medical device regulations). A5 business models play a unique role because they operate outside of direct medical care and are not subject to medical device regulations as research

XSL•FO
RenderX

applications. Similar to the archetype A6, some companies adopting A5 business models can decide to progressively evolve into A3 business models over time as more real-world evidence is collected. In addition, a common approach is to combine A2 or A6 with A4. This combination involves a digital therapeutic, care application, or wellness and lifestyle solution that the patient uses, paired with a professional monitoring platform on the health care provider's side, enabling monitoring through the patient-side applications. In such cases, patients, health care providers, or health insurers might be payers.

Figure 4. A visual representation of the 6 business model archetypes, each accompanied by example ventures organized by target user–centricity and relevant medical device regulatory requirements.

Comparison With Prior Work

We developed a comprehensive taxonomy for business models based on 11 dimensions, following the V4 business model dimensions framework [13]. This taxonomy covers the broad space of DHT business models. Compared to prior studies in the field, which focused on specific subdomains of digital health, such as telemedicine [44] or maternal and baby segments in mHealth [45], our work confirms some of the previously identified dimensions, such as *target user*, *paying entity*, or *enabling technology*, as key resources. These dimensions are commonly used across various sectors to describe business models through taxonomies [44,45]. In addition to these dimensions, previous work has highlighted some taxonomy characteristics specific to the subdomains of digital health, such as medical devices under an mHealth category dimension [45], and overall purpose characteristics, such as diagnosis and therapy [44]. In our study, we describe the broad field of DHT business models. We have identified several new dimensions and characteristics that are highly relevant and specific to the field that had not been mentioned in previous business model taxonomy research. Notably, the *main purpose* dimension in our taxonomy enables the description of complex combinations of medical and nonmedical purposes related to the value proposition. In addition, the *medical device regulatory framework* has emerged as a critical dimension. This framework significantly impacts the entire business model, from value proposition to value architecture and value network. By focusing on the EU, we precisely delineated emerging business models shaped by medical device regulations and those that evolve around unregulated DHTs. Another dimension specific to DHT business models is the *evidence* dimension. In the context of DHTs, it is mandatory for medical devices to provide clinical evidence to enter the market. Interestingly, we found that even some nonregulated DHT business models provide evidence (in the form of nonclinical evidence) to facilitate reimbursement with health insurers and prove their value within the ecosystem. Developing reimbursement pathways specifically for digital health applications opens new revenue models. Consequently, the *reimbursement* dimension is also highly relevant for DHT business models. Finally, the health care *level of care* introduces an important consideration that has been previously overlooked: the necessity for business models to integrate into the existing health care system. An intriguing finding was that some business models focus on research applications within traditional research institutions and pharmaceutical companies. As these operate outside of medical care, their solutions do not need to comply with medical device regulations.

Our work is the first to delineate archetypes of DHT business models based on real-world observations in the EU while also considering medical device regulations. While some research has reported overarching areas of activities in digital health [4], typical value propositions in mHealth [29], or categorizations

XSL•FO
RenderX

of patient needs that are addressed through different solutions [14], our work creates a clear image of archetypal business models used for stand-alone software in health care. The archetypes we identified align with the findings of Gehde et al [4]. The 13 areas of activity mentioned in their work are congruent with our findings and are covered by our archetypes. In addition, we mention here the work of the Digital Therapeutic Alliance [82], which, in partnership with Health Advances classified DHTs based on a technological perspective, identifying 8 major categories of DHTs. While the aforementioned work does not focus on the business models behind these solutions, our work offers suitable business models for the DHTs identified in that study. The DHT business models are inherently complex and exhibit some overlap. However, our archetypes effectively balance the need to simplify these complexities while still delivering valuable insights essential for designing business models in digital health.

Limitations

Our research is not without limitations. First, the DHT business model landscape is rapidly evolving, with new start-ups emerging, new technologies being developed, and regulatory changes occurring. Our study provides a snapshot of the current business models used in the field. However, regulatory environments and business models are subject to change. Furthermore, our focus on observable business model elements of DHTs to derive our archetypes necessitated the exclusion of dimensions such as key partnerships, pricing strategy, and funding. However, these are fundamental to DHT business models as described in the literature and discussed in the expert interviews. In this context, we developed an empirically driven taxonomy to study business model archetypes. We argue that a taxonomy has limited capabilities to describe complex stakeholder and partnership configurations. The same applies to funding, which has a highly relevant temporal component. Finally, the taxonomy focuses on digital business models in the EU, which means we do not describe business models of hardware medical device manufacturers and have not incorporated other business model aspects that might be relevant in other continents.

Contribution and Further Research

Theoretically, our work contributes to the systematic understanding of business models in the emerging DHT domain. By delineating common dimensions and characteristics of the field, we create a common language that paves the way for further research and helps scholars, such as those in business and management, health sciences, and information systems, to position their work within this landscape. The archetypes provide high-level descriptions of business models in this domain, offering a foundational framework for future studies. Furthermore, our dataset, which relies primarily on publicly available information from DHT companies, can serve as a basis for additional research.

On the practical side, the taxonomy we developed can assist entrepreneurs and start-ups in understanding key dimensions and characteristics relevant to DHT business models. An early informed understanding of the intricacies of a sustainable business model is fundamental for later success. In addition, the archetypes and strategic interpretation clarify the business models used in this domain, aiding entrepreneurs in identifying viable strategies based on common patterns. The data on the companies compiled in this work can serve as a starting point for competitor analysis or inspiration for developing their own business models. In addition to start-ups, established medical technology and pharmaceutical companies can benefit from a systematic understanding as they continually explore business model innovations to bring new solutions to the market. Investors, venture capitalists, and health insurers can also leverage this work to identify and validate viable business models. Finally, policy makers can use these insights when shaping new regulations.

Further research could delve deeper into the implications of funding and partnerships for the business model. In addition, the research could investigate business model configurations in other continents or even specific countries because reimbursement policies are specific to each country. Finally, further research could focus on business models of software and hardware combinations, such as software in a medical device.

Conclusions

Digital health is a rapidly evolving field that is attracting increasing attention. In our work, we provide the first overview of business models for DHTs with a focus on the EU. We systematically describe business models in the field and elaborate on the influence of medical device regulations on the entire business model. Furthermore, we created a business model taxonomy based on a systematic literature review and real-world cases, which we evaluated qualitatively. In addition, we identified 6 archetypes of DHT business models through cluster analysis, describing key strategies and differences for each cluster. This allowed us to identify drivers for business model innovation in the DHT sector. These contributions offer a systematic understanding and common language to facilitate analyses and comprehension in this domain. Our findings could assist decision makers, especially start-ups, in positioning themselves and building sustainable business models in this evolving field.

Abstract

Background: Some scholars who are skeptical about open-access mega journals (OAMJs) have argued that low-quality papers are often difficult to publish in more prestigious and authoritative journals, and OAMJs may be their main destination.

Objective: This study aims to evaluate the academic quality of OAMJs and highlight their important role in clinical medicine. To achieve this aim, authoritative journals and representative OAMJs in this field were selected as research objects. The differences between the two were compared and analyzed in terms of their level of disruptive innovation. Additionally, this paper explored the countries and research directions for which OAMJs serve as publication channels for disruptive innovations.

Methods: In this study, the journal information, literature data, and open citation relationship data were sourced from Journal Citation Reports (JCR), Web of Science (WoS), InCites, and the OpenCitations Index of PubMed Open PMID-to-PMID citations (POCI). Then, we calculated the disruptive innovation level of the focus paper based on the local POCI database.

Results: The mean Journal Disruption Index (JDI) values for the selected authoritative journals and OAMJs were 0.5866 (SD 0.26933) and 0.0255 (SD 0.01689), respectively, showing a significant difference. Only 1.48% (861/58,181) of the OAMJ papers reached the median level of disruptive innovation of authoritative journal papers (MD_{AJ}). However, the absolute number was roughly equal to that of authoritative journals. OAMJs surpassed authoritative journals in publishing innovative papers in 24 research directions (eg, Allergy), accounting for 40.68% of all research directions in clinical medicine. Among research topics with at least 10 authoritative papers, OAMJs matched or exceeded MD_{AJ} in 35.71% of cases. The number of papers published in authoritative journals and the average level of disruptive innovation in each country showed a linear relationship after logarithmic treatment, with a correlation coefficient of –0.891 (P<.001). However, the number of papers published in OAMJs in each country and the average level of disruptive innovation did not show a linear relationship after logarithmic treatment.

Conclusions: While the average disruptive innovation level of papers published by OAMJs is significantly lower than that of authoritative journals, OAMJs have become an important publication channel for innovative research in various research directions. They also provide fairer opportunities for the publication of innovative results from limited-income countries. Therefore, the academic community should recognize the contribution and value of OAMJs to advancing scientific research.

Introduction

Henry Oldenburg, the founding editor of the journal Philosophical Transactions of the Royal Society, noted that the purpose of scholarly journals is to provide a forum for researchers to transfer knowledge to each other and contribute to perfecting the grand design of all the philosophical arts and sciences. However, due to technical limitations, printed journals have been the only form of journal publication since the first journal was introduced in the 17th century. Therefore, researchers must usually wait for 10 to 12 months or more before publishing a paper [1]. The appearance of web-based publications has solved the limitations of page size and publishing cycles. Readers can access the latest research more quickly through online publishing and distribution, which provides a more flexible and efficient way for knowledge dissemination and sharing. This transformation significantly enhanced content deliverability, but accessibility has not kept pace. The urgent need to address this issue has fueled the rise of the open-access (OA) movement and the development of OA journals. Simultaneously, the rapid development of science and technology, combined with the pressure of "publish or perish," has created an increasing demand for efficient, timely, and cost-effective publication methods. Furthermore, the rapid increase in the number of publications has imposed a growing financial burden on academic institutions and researchers seeking access to scholarly literature. Providing a platform that can accommodate the rapid publication and huge volume of emerging research while facilitating academic exchange and reducing the economic strain of accessing academic resources has become a widespread concern for the scientific community.

Open-access mega journals (OAMJs) may currently be one of the most effective solutions, offering faster publishing speeds, higher acceptance rates [2], and support for the initial exploration of new fields [3]. These advantages align well with the needs of authors [4]. Additionally, many OAMJs provide readers with value-added functions that most traditional journals still lack [5].

Since the establishment of the Public Library of Science (PLoS) in 2001, numerous traditional academic publishers have launched their own OAMJs to expand their product lines [6]. This has positioned OAMJs as increasingly important players in facilitating academic exchanges [7]. However, the evaluation criteria of most OAMJs only pay attention to *research rationality* [8]. Coupled with the financial incentives of OA publishers to publish widely, concerns have arisen about the quality of research published in OAMJs, which have a higher publishing error rate [9] and possibility of predatory publishing [10].

Most OAMJ papers have received a significant number of citations [11], which often exceed the average citation level [12]. However, the evaluation processes of authoritative journals cannot guarantee the accuracy of the research [13]. Despite this, prejudice still exists among some scholars [14], and the complex attitudes within different academic groups have not significantly improved [15].

It is unfair to view OAMJs solely as a negative development. As Professor John Ioannidis of Stanford University [16] points out, several features of OAMJs align with desirable scientific practices. For instance, OAMJs enhance the visibility of academic papers and their broader academic impact. Furthermore, OAMJs reduce selective publication biases by accommodating results that are considered undesirable in traditional professional journals, thus fostering the diversity of perspectives and challenging orthodoxy.

Since 1972, the mainstream evaluation system has relied on citation metrics [17], which means indicators such as the Journal Impact Factor (JIF) have been widely used in academic review, promotion, and tenure evaluation. However, it is important to note that citation metrics primarily reflect the impact of journals rather than their academic innovativeness. Related research has shown that relying on these impact indicators introduces biases against innovation [18], often resulting in flawed decisions in research assessment and evaluation [19].

Disruptive innovation is defined as the process by which a new product, service, or technology transforms an existing market by creating a new market or significantly altering an existing one. This is one of the core driving forces for developing productivity. Therefore, conducting a scientific and reasonable evaluation of the innovation levels in OAMJ papers is crucial for determining their value. Given that clinical medicine is the primary focus of OAMJ papers [5], this paper selects the authoritative journals and the representative OAMJs related to this field as its research subjects. This study compares and analyzes the differences in disruptive innovation levels between these 2 groups and examines the countries and research directions for which OAMJs serve as publication channels for disruptive innovations.

Methods

Research Objects

The objects of this study include 2 groups of journals, representing authoritative journals in the field of clinical medicine and OAMJs. The selection criteria for authoritative journals were as follows: (1) JIF ranks high in the field; (2) selected journals are not review journals; and (3) academic authority is widely recognized. The selection criteria for representative OAMJ journals were as follows: (1) OA peer-reviewed journals that charge publication processing fees; (2) an annual average of more than 2000 OA research papers published on clinical medicine topics; (3) a 3-year impact factor within Q1 or Q2.

Through a search of relevant journals in the field of clinical medicine, we discovered that the impact factors of the British Medical Journal (BMJ), the New England Journal of Medicine, The Lancet, and the Journal of the American Medical Association (JAMA) ranked among the highest in impact factors between 2017 and 2019, with widely recognized academic authority [20-25]. We also found that BMJ Open, PLoS ONE, and Scientific Reports published more than 2000 open-access research papers on clinical medicine topics annually, establishing a certain degree of academic influence.

XSL•FO
RenderX

Based on these criteria, this study selected BMJ, New England Journal of Medicine, The Lancet, and JAMA as the authoritative journals and BMJ Open, PLoS ONE, and Scientific Reports as the representative OAMJs.

Because there is no disruptive innovation in review articles, and because Bornmann et al [26] suggest that the disruption index should only be calculated for research papers with at least 10 references, this study exclusively focused on clinical medical research papers with more than 10 references from the aforementioned journals.

Data Sources

The data required for this study included journal information, literature information, and citation relationship information, obtained through Journal Citation Reports (JCR), Web of Science (WoS), InCites, and the OpenCitations Index of PubMed open PMID-to-PMID citations (POCI), respectively. POCI, a data set sourced from the National Institutes of Health, comprises over 700 million citations and 29 million bibliographic resources. In POCI, citations are regarded as first-class data entities with 7 attribute fields, including the citation time span. To evaluate disruptive innovation, we selected focus papers and used their PMIDs along with POCI data identifiers to calculate the disruptive innovation level for each paper.

Data Acquisition and Processing

First, we logged into JCR, WoS, and InCites to retrieve the journal information and literature information of the selected journals and save them. Then, we logged into opencitations.net, entered the download page, selected the POCI data set, and downloaded the dump data in CSV format via the Figshare platform. Next, we used Navicat software (PremiumSoft CyberTech Ltd) to import all data into the local SQLite database and process the downloaded POCI data. Finally, in the local database based on the POCI data transformation, we used the PMID numbers extracted from the full records of the focus literature to identify the citation relationship associated with the focus papers. We established relevant data tables for the subsequent calculations.

The disruption index calculation was highly dependent on the time window chosen. The findings of Liu et al [27] confirm that the stabilization time window for the disruption index varies across different disciplines. We believe this is partly due to the different stages of development in various disciplines. Bornmann and Tekles [28] suggest that a time window of 3 years or more is an important prerequisite for ensuring the validity of the calculation results. Given the complexity of the disruption index calculation, the large volume of data [29], and our lack of access to extensive commercial citation data resources, we used the open citation data provided by OpenCitations for the calculation. To guarantee the accuracy of the results of the paper's innovation measurement while minimizing the computational workload, the citation time window in this study was set to 3 years.

Evaluation Indicators

Since Christensen [30] of Harvard Business School posited the theory of disruptive innovation in 1996, it has become an important paradigm in the field of innovation research. Based on this theory, Wu et al [31] put forward the disruption index (often referred to as the D Index for short), which can be used to measure disruption by calculating the citation substitution of focus papers in the citation network. Based on the disruption index, Bornmann et al [26] discussed the effectiveness of the convergence of this index and the variants that may improve the measurement effect. Ruan et al [32] analyzed the application limitations of the disruption index for measuring progress in the fields of science and technology.

Considering the process of metric calculation, F-type citations reflect that the focus paper disrupts the reference, B-type citations indicate that the focus paper is a development of the reference, and R-type citations reveal that the focus paper inherits the reference. Liu et al [33] argued that the disruption Index is a “relative” concept because it measures disruption based on the relative size of N_F (F-type citations) and N_B (B-type citations). They defined the disruption index, which is only reflected by F-type citations, as the “absolute disruption index.” Additionally, Liu et al [27,34] empirically studied the stabilization time window for the disruption index in different subject areas and resolved mathematical inconsistencies in its traditional formation (eg, N_R not satisfying monotonicity).

Based on this disruption index, Bornmann et al [35], Horen et al [36], Sullivan et al [37], Meyer et al [38], Jiang and Liu [39], and others have mined disruptive papers in the fields of scientometrics, craniofacial surgery, pediatric surgery, synthetic biology, and energy security respectively. On this basis, Jiang and Liu [40] proposed a method for calculating the Disruption index using open citation data during previous research. They carried out evaluations at both the literature and journal levels [41-45], contributing to a mature framework for evaluating disruptive innovation.

In equations (1) to (3), N_F refers to the literature that only cites the focus paper (FP); N_B refers to the literature that cites both the focus paper and at least one reference (R) of the focus paper; N_R refers to literature that only cites at least one reference (R) of the focus paper but not the focus paper; n is the number of articles contained in the journal; and D_{Zi} is the absolute disruption index (D_Z) of the i^{th} article in the journal.

Results

Comparative Analysis of the Journals’ Disruptive Innovation Levels

Annual changes in JIF, JDI, and the number of published articles for the 7 journals selected in this study between 2017 and 2019 are shown in Table 1. The key findings are as follows. First, the average JDI of the selected authoritative journals is 0.5866, while the average JDI of OAMJs is 0.0255, indicating a significant difference. Second, the JDI values of the authoritative journals are higher than those of OAMJs. Third, JDI does not necessarily increase with a higher JIF.

XSL•FO
RenderX

Additionally, to better measure the difference in disruptive innovation level between OAMJ papers and authoritative journal papers, this study defined 2 parameters: the median D_Z of authoritative journals (MD_{AJ}) and the median D_Z of OAMJs (MD_{OAMJ}), which were 0.289 and 0.0019, respectively. The findings indicated that (1) the disruptive innovation level (94.60 %) of authoritative journal papers was higher than MD_{OAMJ} and (2) only 1.48% (861/58151) of OAMJ papers had a disruptive innovation level higher than MD_{AJ}. However, the number of OAMJ papers (n=861, 1.48%) was close to half of the number of authoritative journals (n=1128 of 2222).

Table 1. Annual changes in JIF[a], JDI[b], and number of articles for the 7 selected journals.

Journal	JIF			JDI			Number of articles				Number of COCI[c] articles

Comparative Analysis of Disruptive Innovation Level Across Fields of Paper

Due to the complexity and diversity of clinical medical research, this study summarized statistics based on the classification results of InCites to assess the disruption of OAMJ papers and authoritative journal papers across various research fields. The findings, shown in Table 2, revealed several key insights.

There were differences in the average levels of disruptive innovation among OAMJ papers published in different research fields. The highest level was observed in the research field of immunology (0.1965), while neuroimaging had the lowest level (0.0049).

Similarly, there were differences in the average levels of disruptive innovation in authoritative journal papers, with reproductive biology showing the highest level (15.7902) and sport sciences (0.0031) showing the lowest level.

Across all fields, authoritative journal papers outperformed OAMJ papers in terms of disruptive innovation at the overall level. In 24 research directions such as allergy—accounting for 40.68% of all clinical medicine research areas—the number of OAMJ papers with disruptive innovation levels exceeding MD_{AJ} surpassed half the number of authoritative journal papers. Among the topics with no less than 10 authoritative papers published, the topics in which the number of papers published by OAMJ with a level of disruptive innovation exceeding MD_{AJ}'s was no less than half of the number of papers published in authoritative journals accounted for 35.71% of the total.

[a]OAMJ: open-access mega journal.

[b]D_Z: absolute disruption index.

[c]MID: median.

[d]MD_{OAMJ}: median D_Z of the OAMJ papers.

[e]MD_{AJ}: median D_Z of the authoritative journal papers.

[f]Not applicable.

Comparative Analysis of Disruptive Innovation Level of Papers Across Countries

The disruptive innovation levels of OAMJ papers and authoritative journal papers published by different countries are shown in Tables 3 and 4, which include data for countries with records in both types of journals. To better describe the relevant results, this study used the following criteria. First, the number of authoritative journal papers is used as a measure of national scientific research strength. A higher number of published authoritative papers reflects stronger national scientific research capabilities. Second, the difference in the disruptive innovation levels between published OAMJ papers and authoritative journal papers serves as a measure of the recognition of OAMJs by scholars in different countries. A smaller difference indicates a higher degree of recognition. Third, the ratio of OAMJ papers to authoritative journal papers measures the degree of favoritism scholars from different countries show toward OAMJs. A larger ratio suggests a higher degree of favoritism toward OAMJs by scholars from a particular country.

From Tables 3 and 4, we observed several key insights. First, there was a difference between the average disruptive innovation level of OAMJ papers across countries, with South Korea ranking the highest (0.5476) and Serbia ranking the lowest (0.0043). Similarly, the average disruptive innovation level of authoritative journal papers also varied across countries, with Peru ranking the highest (35.6125) and Serbia ranking the lowest (4.7261).

[f]MD_{AJ}: median D_Z of the authoritative journal papers.

* P<.01

**P<.001

There was a linear relationship between the number of authoritative journal articles and the average disruptive innovation level of each country after logarithmization (as shown in Figure 1), with a correlation coefficient of –0.891, which indicated that authoritative journals did not consistently recognize the work of scholars from different countries. However, for OAMJ papers issued by each country, the average level of disruptive innovation did not show a linear relationship after logarithmic processing (as shown in Figure 2).

Scholars from different countries also had varying levels of recognition for OAMJs and tendencies to publish them. A higher recognition of OAMJs correlated with a higher likelihood of publishing papers in these journals (0.553). This was significantly correlated with the disruptive innovation levels of both authoritative journal papers (–0.461) and OAMJ papers (0.878). Moreover, the proportion of OAMJ papers meeting the MD_{AJ} threshold was significantly and positively correlated with the tendency to publish papers in OAMJs (0.689).

Among all countries, those that published more than 10% of OAMJ papers with a level of disruptive innovation above MD_{AJ}, while maintaining an average annual publication count of at least 1 in the selected journals, included Argentina, Turkey, Chile, Colombia, Pakistan, Philippines, Bangladesh, and Egypt.

Discussion

Principal Results

Differences Between the Disruptive Innovation Levels of OAMJ and Authoritative Journals

In this study, the disruptive innovation levels of OAMJs were lower than those of authoritative journals. A plausible explanation is that OAMJs require more rationality than innovation during the review process. Therefore, OAMJ papers were more focused on incremental innovation and proximity innovation, while authoritative journals were more likely to publish papers with breakthrough innovation.

OAMJs As Important Publishing Platforms for Innovative Research Across Fields

In this study, the overall disruptive innovation levels of authoritative journal papers were higher than those of OAMJ papers across all clinical medical research fields. However, the number of OAMJ papers with a higher level of disruptive innovation than MD_{AJ} was close to half of the number of authoritative journal papers. Moreover, in almost half of the research directions examined, the number of OAMJ papers with a higher level of disruptive innovation than MD_{AJ} exceeded half of the count for authoritative journal papers.

This phenomenon indicates that the contribution of OAMJs to the overall development of science rivals that of authoritative journals. While OAMJs must continue to emphasize overall quality control, their contribution to scientific development should not be overlooked [46].

Additionally, OAMJ papers involve some research directions that are not covered by authoritative journal papers. Therefore, it is unreasonable to judge the level of disruptive innovation of a paper based solely on the source journal without distinguishing the research direction. Thus, we must evaluate the contributions of OAMJs fairly and scientifically [47].

OAMJs Provide a Fair Publishing Channel for Innovative Achievements from Limited-Income Countries

Research has confirmed that national bias exists in the peer-review process [48], and specific journals have preferences for their authors' countries of origin [49]. Therefore, authoritative journals demonstrate varying degrees of recognition for the research results of scholars from different countries. This phenomenon was also evident in this study, where notable differences were observed in the disruptive innovation levels of authoritative journal papers published by scholars from different countries. Furthermore, the disruptive innovation levels in authoritative journals from each country were linearly and negatively correlated with the volume of publications.

A reasonable explanation for this is the first-mover advantage of high-income countries in the field of science and technology. These nations benefit from a group of senior scholars in various fields whose work often receives recognition that exceeds its quality in the current peer-review process [50]. This recognition also extends to the young scholars they collaborate with [51]. On the other hand, this study also found that OAMJs play an important role in promoting innovation diffusion in limited-income countries. Therefore, OAMJs may provide fairer publishing opportunities, and in tandem with postpublication peer review [52], may contribute to the accelerated development of science and technology.

Limitations

This study has some limitations that must be acknowledged. First, participating authors with different ranks were treated as equal contributors, disregarding variations. Second, all focus papers were categorized under a single subject classification, without considering their inherent interdisciplinary properties. Third, only the knowledge diffusion of focus papers within the scope of periodical literature was considered, ignoring other venues. These limitations must be explored in future research based on natural language processing technology, and more accurate results can be obtained by jointly using multiple types of citation data sources.

Conclusions

The disruptive innovation levels of OAMJs were different from those of authoritative journals. However, OAMJs have become an important publication channel for innovative results in several research directions, providing fairer opportunities for researchers from limited-income countries to publish their work. Therefore, the academic community should acknowledge and appreciate the contributions of OAMJs to scientific research.

Abstract

Background: Medical journals are critical vanguards of research, and previous years have seen increasing public interest in and engagement with medicoscientific findings. How findings propagate and are understood and what harms erroneous claims might cause to public health remain unclear, especially on publicly contentious topics like COVID-19 vaccines. Gauging the engagement of the public with medical science and quantifying propagation patterns of medicoscientific papers are thus important undertakings. In contrast to misinformation and disinformation, which pivot on falsehood, the more nuanced issue of malinformation, where ostensibly true information is presented out of context or selectively curated to cause harm and misconception, has been less researched. As findings and facts can be selectively marshaled to present a misleading picture, it is crucial to consider this issue and its potential ramifications.

Objective: This study aims to quantify patterns of public engagement with medical research and the vectors of propagation taken by a high-profile incidence of medical malinformation.

Methods: In this work, we undertook an analysis of all altmetric engagements over a decade for 5 leading general-purpose medical journals, constituting approximately 9.8 million engagements with 84,529 papers. We identify and examine the proliferation of sentiment concerning a high-profile publication containing vaccine-negative malinformation. Engagement with this paper, with the highest altmetric score of any paper in an academic journal ever released, was tracked across media outlets worldwide and in social media users on Twitter (subsequently rebranded as X). Vectoring media sources were analyzed, and manual sentiment analysis on high-engagement Twitter shares of the paper was undertaken, contrasted with users' prior vaccine sentiment.

Results: Results of this analysis suggested that this COVID-19 scientific malinformation was much more likely to be engaged and amplified with negative by vaccine-negative Twitter accounts than neutral ones (odds ratio 58.2, 95% CI 9.7-658.0; $P<.001$), often alluding to the ostensible prestige of medical journals. Malinformation was frequently invoked by conspiracy theory websites and non-news sources (71/181 citations, 39.2%) on the internet to cast doubt on the efficacy of vaccination, many of whom tended to cite the paper repeatedly (51/181, 28.2%).

Conclusions: Our findings suggest growing public interest in medical science and present evidence that medical and scientific journals need to be aware of not only the potential overt misinformation but also the more insidious impact of malinformation. Also, we discuss how journals and scientific communicators can reduce the influence of malinformation on public understanding.

Introduction

The growing dominance of social media as a news source has resulted in not only widespread engagement with science but also a perpetuation of medical misinformation in fields ranging from dementia [1] to cardiology [2] and cancer [3,4] and beyond. Vaccines have been a topic of misinformation for centuries [5], with antivaccine propaganda being a leading contributor to declining vaccine uptake worldwide [6], and in 2019, the World Health Organization named vaccine hesitancy a top threat to public health, with COVID-19 vaccines being a recent major focus for an abundance of misinformation [7,8].

Misinformation undermines trust in medical science [9], leading to calls for medical journals to be more proactive in combatting health fiction, pseudoscience, and misconceptions. Armstrong and Naylor [10] argue that medical journals have a critical role in addressing medical misinformation by containing the dissemination of misinformation, identifying falsehoods and their purveyors, and striving to avoid false balance and legitimization of false information. They suggest that medical journals have a unique role in debunking myths and facilitating health-specific inoculation and education. Medical journals, as repositories of trustworthy information, have a central role to play, as "...the ability to credit information from scientific journals, and...to discredit information without such sources, is perhaps the most conventional countermeasure to misinformation" [11]. Directing the public to reliable sources of information, including medical journals, has been identified as an urgent undertaking in combatting COVID-19 misinformation [12].

Medicoscientific journals are not only trusted gatekeepers for reliable findings but are also far from infallible. Moreover, peer-reviewed medical science is no longer read and propagated solely by medical scientists but is widely disseminated by social media influencers and the wider public. The pandemic era has witnessed several high-profile retractions resulting from flawed analysis or even outright fabricated data. As Toth et al [13] note, "Medical journals not properly 'vetting' and eventually publishing high-impact papers that turn out to be based on unverified data can misguide providers as well as the public. Information on the disease that was previously restricted to medical professionals is now available to the broad public by the swipe of a screen, just like any other newsreel." Accordingly, findings can be used in misinformation, disinformation, and malinformation, as defined in Table 1.

Table 1. Council of Europe definitions [14].

Term	Definition	Characteristics
Misinformation	"Information that is false, but not created with the intention of causing harm"	False information spread inadvertently or intentionally.
Disinformation	"Information that is false and deliberately created to harm a person, social group, organization or country"	False information introduced and spread with the intent to mislead or confound.
Malinformation	"Information that is based on reality, used to inflict harm on a person, organization or country"	Nominally true information is misleadingly presented or curated with the intention to deceive or mislead.

Unlike misinformation and disinformation, malinformation does not depend on false information, but instead leverages plausible and accurate—or at least arguably accurate—information presented either without context or in an incorrect context to lead those encountering it to false or misleading impressions and conclusions. When encountered without cognizance of crucial background or context, malinformation can create perceptions at odds with reality and cause harm to individuals, organizations, and collective understanding. In medical journals, malinformation can emerge through several mechanisms.

- Authors curate information out of context, with the net result of presenting a misleading impression of findings that are undetected by peer reviewers and editorial staff.
- Distortion of published research findings by third-party vested interests to cherry-pick or misrepresent legitimate published medical science to create a narrative at odds with the scientific evidence base.
- The synergy between these mechanisms.

To date, there has been comparatively little research done on quantifying engagement with medical science or the problems of malinformation in a medical context. Altmetrics measure the broader impact of scholarly works by analyzing social media and media engagement beyond traditional citations. They track mentions on social media, news, blogs, policy documents, and academic tools like Mendeley. Data are gathered using persistent identifiers (typically DOIs), which are weighted by source to generate composite altmetric scores. Altmetrics provide immediate insights into public and academic attention, complementing traditional metrics, a barometer of how research is understood and engaged with by the public on social and conventional media [15]. As they yield data complementary to citation-based metrics, tracking social media engagement, press coverage, and social media discussion, we took a novel approach of analyzing altmetrics as an indicator of engagement with medical science and the spread of potential malinformation, providing insight into how claims in medical journals are consumed in context and potential public health impacts.

Methods

Quantifying Engagement Metrics

Raw historical altmetric records for 5 leading medical journals (*New England Journal of Medicine*, *The Lancet*, *JAMA*, *Annals of Internal Medicine*, and *British Medical Journal*) for all papers published between April 2012 and April 2022 were exported from Altmetric Explorer. The CSV files for each journal included altmetric attention scores and publication dates for all papers in the 10-year interval, which were extracted and imported into MATLAB (MathWorks) on May 10, 2022. These journals were selected as a representative sample of respected broad-interest medical journals as opposed to more specialist offerings [16-18] to capture the typical dynamics of public engagement with general medical science over a long interval. Data were subsequently pooled and sorted to produce a hierarchical ranking of all altmetric scores. From this, the Lorenz curve and Gini coefficient were derived to ascertain the relative importance ranking of papers in terms of public engagement. Mathematical outlines are provided in Multimedia Appendix 1, and the process is illustrated in Figure 1A.

Figure 1. (A) Extraction of altmetric data for papers published over 10 years for 5 major journals, yielding approximately 9.8 million engagements with 84,529 papers. (B) Deep analysis of identified malinformation, including tweets and media citations.

Identification and Quantification of Potential Misinformation or Malinformation

A specific breakdown of the detailed altmetric mentions in a full analysis of a single medical journal publication from November 2021 [19] was also undertaken. For this paper, which garnered the highest altmetric score ever achieved in any scientific journal in any field published to the date of extraction, specific altmetric data were extracted, including all media mentions, outlet names, and linking tweets. At the time of data extraction, direct Twitter (subsequently rebranded as X) engagement with the paper yielded 165,720 tweets from 81,861 users with an upper bound of 11,094,945 followers, 181 media mentions, and a total altmetric score of 45,844. This investigative piece suggested that Pfizer vaccine trials were compromised by the unblinding of subjects and data falsification. Serious issues with this reporting were detected almost immediately after publication by independent fact-checks [20], medical press [21], and medical writers [22]. Criticisms focused chiefly on the paucity of evidence presented to support the statements in the paper, which were largely speculative and extrapolated unverified reported problems at one contract research organization center in Texas to all 153 centers worldwide.

No evidence was presented for the incendiary charge of data falsification, and ostensible problems at a single site were

XSL•FO
RenderX

extrapolated to the entire clinical trial 24 times in the paper. Several other problems in the reporting and framing were identified, outlined in Multimedia Appendix 1. As the paper's assertions, based on unfounded extrapolation, were likely harmful to public perception of Pfizer and of vaccine science more broadly, the European Council's definition of malinformation ("information that is based in reality, but is used to inflict harm on a person, organization or country" [14]) appears most fitting here, given that real potential issues with a single contract research organization being contracted by Pfizer were used as a basis for unevidenced claims that Pfizer "falsified data" and "unblinded patients," despite such assertions being at best speculative extrapolation. This could arguably be deemed misinformation too, a point expanded upon in the *Limitations* section. As this paper has by far the highest altmetric score of any paper in a biomedical journal (or any other scientific work in any field) ever published, extended altmetric analysis was performed to analyze its propagation and reception, including a breakdown of media sources, described in the later section and illustrated in Figure 1B.

Propagation Analysis (Media Outlets)

For the extended analysis, all media mentions were systematically exported from Altmetric Explorer. Mentions with the header "News Story" were extracted into MATLAB. Sources were categorized as news stories (recognized media outlets and investigative media organizations) and aggregators, collectively deemed news sources. Mentions from non-news conspiracy theories or propaganda sites were also counted, as were sources from Russian state media outlets and blogs, collectively deemed non-news sources (objective criteria for demarcation are provided in Multimedia Appendix 1). A nonparametric right-tailed Wilcoxon rank sum test was performed to investigate the hypothesis that non-news sources cited the paper with greater frequency than reliable outlets.

Sentiment Analysis (Social Media)

To ascertain how this paper was understood in a wider context, a Twitter search strategy was implemented for manual sentiment analysis for tweets relating to the paper in question. These were taken from the altmetric data and from an additional search containing the primary terms "Pfizer" and "BMJ," with any of the secondary terms ("whistleblower," "whistle," "fraud," "trials," and "Ventavia"). All tweets with greater than 50 engagements were selected for manual sentiment analysis. For any account hosting such tweets, an advanced search was conducted on their username for all tweets with the terms "vaccine," "vaccines," "COVID," "Pfizer," "hoax," or "lies." The 100 most recent tweets for each user under these criteria were exported. Users whose mention of vaccines in this set was solely negative or propagated discredited antivaccine propaganda were deemed as having vaccine-negative attitudes, while users whose set included mixed or positive vaccine stances were deemed non-negative. When the sentiments were ambiguous, cases were recorded as non-negative. Follower counts, engagement, and reach were also computed, with full data given in the Multimedia Appendix 1. A 2×3 Fisher exact test was used to test the hypothesis that vaccine-negative accounts were far more likely to embrace the paper as evidence against COVID-19 vaccination than non-negative accounts. All raw data are available in Multimedia Appendix 1.

Ethical Considerations

This study involved analysis of publicly accessible tweets, which are considered public behavior data not requiring ethical or institutional board review. No informed consent was sought, as data analyzed are publicly available and no interaction with the authors of the tweets occurred. The data were handled in compliance with ethical guidelines for research using publicly available data, with anonymized tweets—to ensure that individuals cannot be reidentified—available in Multimedia Appendix 1 and unredacted versions available to reviewers and editors. No identifiable images or data from individual users are included in this paper or Multimedia Appendix 1. Where tweet content is cited verbatim, usernames and identifying details have been removed or generalized to protect privacy. An exception was made for a tweet authored by Robert F Kennedy Jr, a public figure, as it represents a public statement made in his capacity as a public advocate.

Results

Quantifying Engagement Metrics

Figure 1A depicts altmetric trends for 5 major medical journals in the decade from April 26, 2012, to April 26, 2022, for 85,529 papers, depicting growing public interest with time. It is worth noting, however, that interest is greatly skewed. Figure 1B depicts the Lorenz curve and derived Gini coefficient of 0.835, demonstrating that altmetrics are driven by a small proportion of papers, quantified in Table 2. For all 5 included journals, the median altmetric scores of papers were also calculated (Figure 2A). As the safety and efficacy of COVID-19 vaccines were a worldwide topic of interest both on social media and traditional media, Table 3 gives the altmetric scores from the most highly discussed research works on vaccine efficacy trials for Moderna, Pfizer, and AstraZeneca vaccines.

Table 2. Altmetric statistics (medical papers).

Percentile of papers (%)	Proportion of total altmetrics (%)
Top 1	34.2
Top 0.5	25.6
Top 0.1	11.1
Top 0.01	2.37

(B) Lorenz curve for medical altmetrics (Gini coefficient=0.835). Ann Intern Med: Annals of Internal Medicine; BMJ: British Medical Journal; MAS: median altmetric score; NEJM: New England Journal of Medicine.

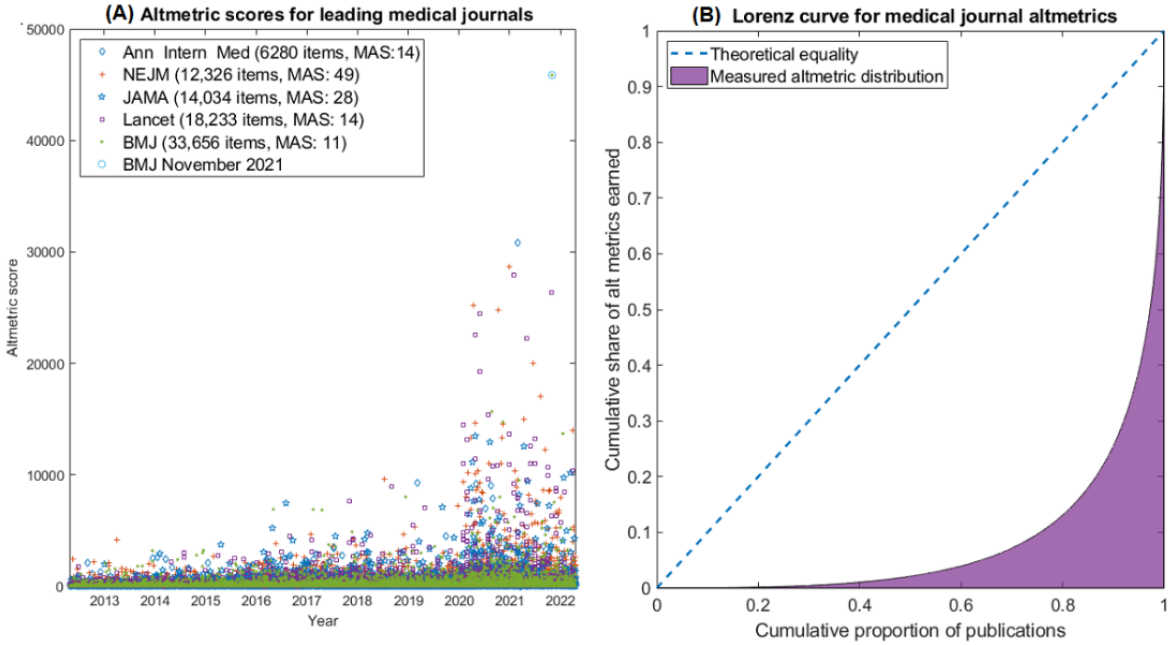

Table 3. Altmetric scores for COVID-19 vaccine studies.

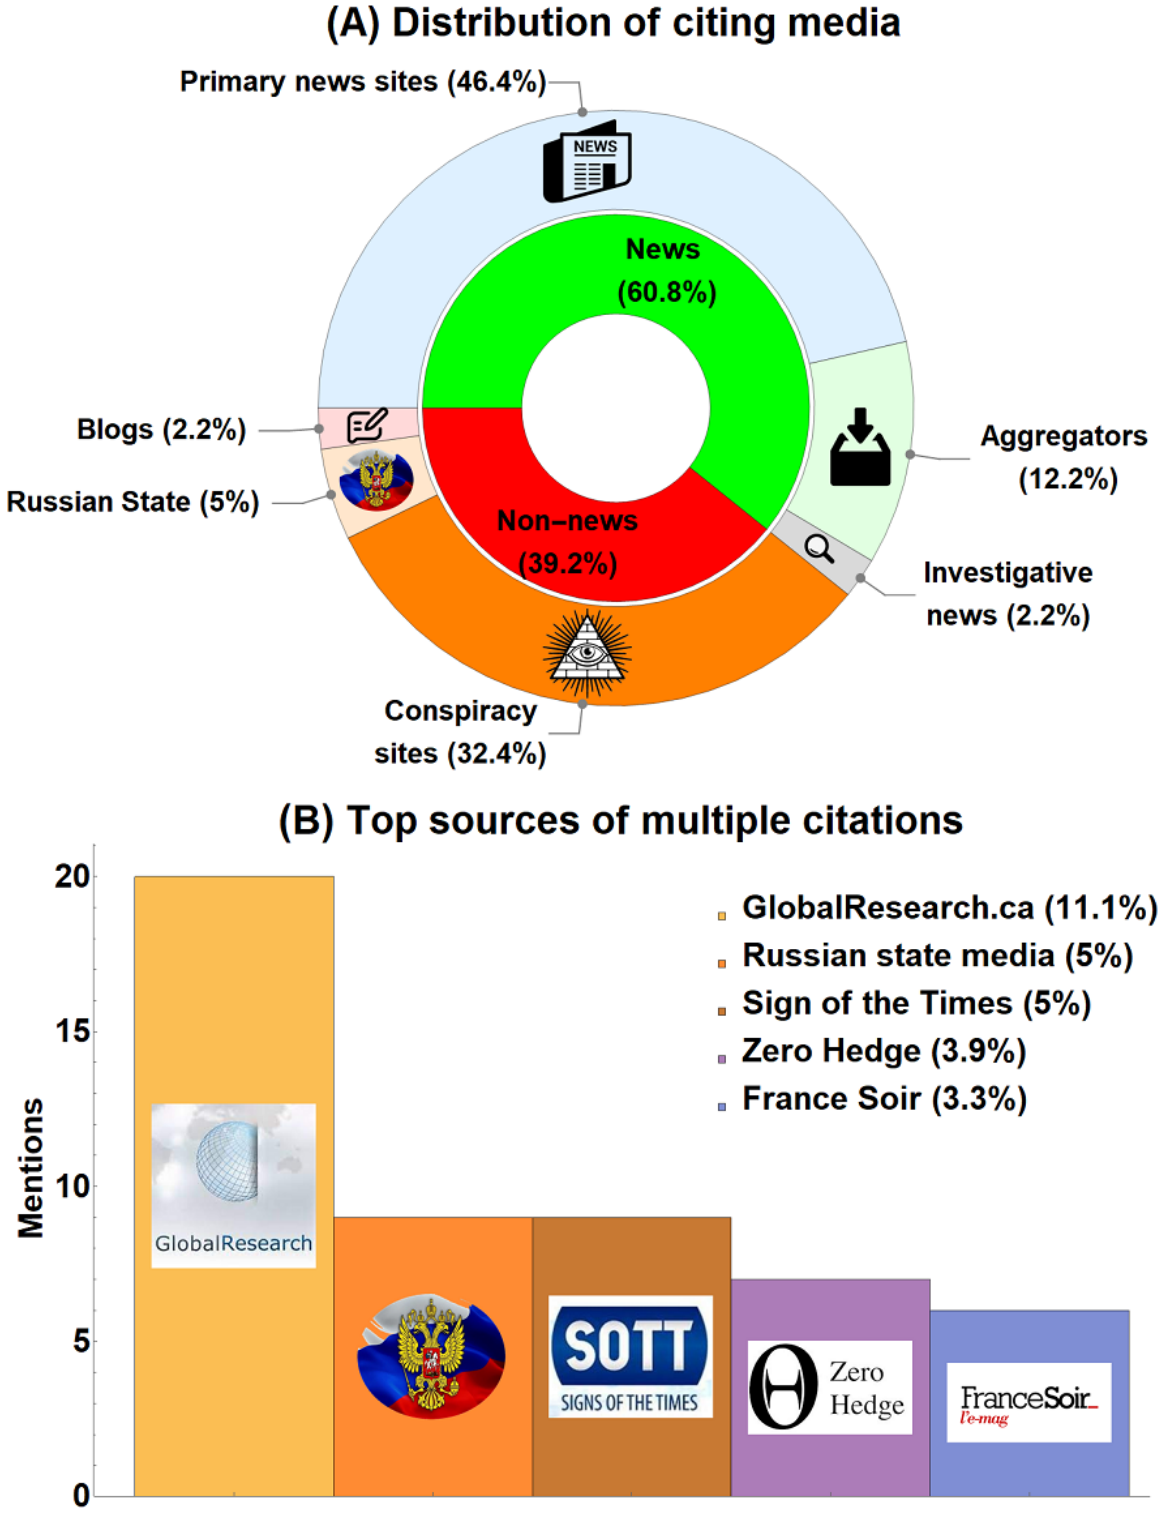
Date	Vaccine	Title	Journal	Altmetric score
July 2020	Moderna	An mRNA Vaccine against SARS-CoV-2—preliminary report	*NEJM* [a]	14,325
August 2020	AstraZeneca	Safety and immunogenicity of the ChAdOx1 nCoV-19 vaccine against SARS-CoV-2: a preliminary report of a phase 1/2, single-blind, randomized controlled trial	*Lancet*	15,254
December 2020	Pfizer	Safety and efficacy of the BNT162b2 mRNA Covid-19 Vaccine	*NEJM*	29,151
November 2021	Pfizer	Covid-19: Researcher blows the whistle on data integrity issues in Pfizer's vaccine trial	*BMJ* [b]	45,844

[a]NEJM: New England Journal of Medicine.



[b]BMJ: British Medical Journal.

Propagation Analysis (Media Outlets)

Figure 3A depicts the media distribution of the paper from publication to April 26, 2022, where 71 (39.2%) out of all 181 media citations of the paper came from non-news sites. Figure 3B shows the cumulative mentions from the 5 sources that cited the paper multiple times, all of which were non-news media and conspiracy site sources, with explicit classification means of reporting sites given in Multimedia Appendix 1. These 5 outlets accounted for 51 (28.2%) of the 181 total media mentions alone. A nonparametric right-tailed Wilcoxon rank sum test was performed to investigate the hypothesis that illegitimate non-news sources cited the paper with greater frequency than reliable outlets; for both cases where all Russian outlets were individually counted or pooled as a single entity, the result was highly significant (P<.001). This strongly suggests the paper was disproportionally embraced by partisan outlets with documented histories of antivaccine sentiment rather than conventional media.

XSL•FO
RenderX

Figure 3. (A) Quantification of news-related altmetrics for case study from publication to April 26, 2022, inclusive. (B) Sources with the highest frequency of paper mentions. Legend indicates what proportion of total media citations for which these sources account.

Sentiment Analysis (Social Media)

Our Twitter search strategy yielded 75 tweets from 68 unique users, of which vaccine-negative accounts (52/68, 76%) yielded an upper-bound direct audience of 3,701,281, whereas non-negative accounts (16/68, 24%) had an upper-bound direct audience of 979,198, a 3.78-fold reach difference. Vaccine-negative accounts included the Russian state Sputnik vaccine account (more than 1 million followers, denoted as a vaccine-negative account despite its ostensible purpose due to its disparagement of other vaccines and spreading conspiracy theories about them) and Robert F Kennedy Jr's account (420,900 followers at the time of analysis, widely criticized for vectoring virulent antivaccine propaganda). The non-negative account with the greatest number of followers was the journal's official Twitter account (489,800 followers).

XSL•FO
RenderX

Table 4 depicts the sentiment of high-engagement tweets, distinguishing between shares of the story without caveats or with negative editorialization (including terms like "fraud," "criminal," "corruption," "enemy," "fake," and "scandal") versus those which reported without negative editorialization with caveats or actively rebutted the paper. A Freeman-Halton extension of the Fisher exact test for 2×3 case yields $P<.001$, strongly supporting the hypothesis that vaccine-negative accounts were far more likely to embrace the paper as evidence against COVID-19 vaccination than non-negative accounts. Vaccine-negative accounts were far more likely to share the paper with negative editorialization (odds ratio 58.2, 95% CI 9.7-658.0).

Table 4. Sentiment division on paper.

Preexisting vaccine sentiment	Neutral or caveated presentation	Negative editorialization	Refutation
Non-negative	8	2	6
Negative	5	47	0

Discussion

Principal Findings

The results of our analysis suggest a growing public interest in medical science and highlight a clear instance of how even a dubious finding in medical journals can readily be propagated, buoyed by the veneer of legitimacy that comes from being published in a respected journal. In some respects, this finding is not unexpected. The now infamous case of Andrew Wakefield's fraudulent *Lancet* paper in 1998 led to an enduring confidence crisis over the measles-mumps-rubella vaccine [23], and more recently, dubious claims in medical journals about the efficacy of ivermectin [24] and hydroxychloroquine [25] in treating COVID-19 wrongly led millions to ineffective treatments for the condition; in the case of ivermectin, it even led people to purchase the drug from veterinary suppliers. In these cases, however, the primary information itself was incorrect; malinformation is more nuanced and likely to mislead precisely because the primary information may not be incorrect but selectively presented.

Lewandowsky and Cook [26] proposed a tactic for combatting conspiratorial thinking, misinformation, and disinformation that they characterize as "inoculation" or "prebunking," with two distinct aspects: (1) an "explicit warning of an impending threat of being misled" and (2) "refutation of the misinformation's arguments," noting that fact- and logic-based inoculations have been successful in prebunking a 9/11 conspiracy theory [27]. Malinformation is more difficult to inoculate against because it is more difficult to predict how legitimate stories, studies, and information will be weaponized as malinformation than it is to delineate the general characteristics of misinformation and disinformation, particularly when based on conspiratorial thinking. However, we would counter that it is useful to publicly document instances of malinformation to elucidate why they constitute malinformation, as once articulated it can be applied to other stories of this sort.

How journals contribute to malinformation remains poorly understood, but editors need to be aware of how legitimate (or seemingly legitimate) stories and studies can be turned into malinformation. Accordingly, we suggest that in the age of social media, it is imperative that peer review, editorial oversight, and fact-checking go beyond just the issue of whether individual facts and findings reported in a paper are accurate and consider the overall context (or lack thereof) in which the "facts" are arranged to produce a narrative, a point expanded upon in Multimedia Appendix 1. There is increasing recognition that much of what is published in medical journals may not be reproducible and that biased, or outright fabricated results, taint biomedical literature [28-30], an alarmingly common occurrence [31]. Inevitably, dangerous falsehoods and polemics can sometimes appear in literature. It is vital that reviewers and editors are aware of these issues and skeptically evaluate potentially dubious claims. While some guidelines exist [32], wider awareness is urgently required.

In the pre–social media era when medical journals were read predominantly by clinicians and scientists, the failure of peer reviewers and editors to identify malinformation like this story would likely have had only a minor impact on the public perception of vaccine safety and efficacy, with studies like Andrew Wakefield's fraudulent research in *The Lancet* being very exceptional cases that reduced vaccine confidence [23,33]. Unfortunately, the situation has changed markedly in the social media era. Now, the inability on the part of peer reviewers and editors to recognize malinformation before it is published under the imprimatur of a respected medical journal can have major repercussions because, as demonstrated in this analysis, such malinformation can be amplified widely.

It is crucial that scientific publications strive to communicate vital findings while also being aware that the audience for scientific work now extends far beyond the confines of academia. It is thus inevitable that highly uncertain or nuanced findings in medicoscientific journals will be stripped of context by malicious actors seeking to undermine public health and understanding. While findings can and should be debated by scientists, it is very naive to ignore the reality that these specialized debates will also transpire in the public sphere, driven by the characteristic context collapse of social media. This new normal has ramifications for how scientific publishers and scientists frame their work and their responsibilities after publication. Journals and authors need also be mindful of how their work is interpreted after publication, including issuing clarifications and correctives to address situations in which their publications are weaponized as malinformation.

Potentially controversial findings, when they arise, should not be censored, but rigorously evaluated and reported in proper context, ideally including independent lay summaries to stave off potential distortion in the public arena. If journal editors and peer reviewers are not trained to recognize potential

XSL•FO
RenderX

malinformation when they see it, peer-reviewed biomedical journals can all too easily inadvertently become powerful sources and amplifiers of malinformation, rather than what they should be—bulwarks against it.

Limitations

While our analysis showed that antivaccine sources were most likely to propagate the offending piece, it was not possible to quantify the proportion of receptive audiences who already had vaccine-negative attitudes and how much it might remain within an already committed echo chamber. Even so, there is already ample evidence that mere exposure to antivaccine sentiment induces vaccine hesitancy [6]. The volume of vaccine disinformation available online and offline creates a lingering public perception that vaccines might be harmful due to the psychological phenomena of the illusory truth effect, the observation that a statement is more likely to be deemed true after repeated exposure, regardless of intrinsic veracity [34]. As fiction is spread more efficiently across social media than corrective information [35], it is reasonable to conclude that the high publicity this piece garnered, reflected in its staggering altmetric score, was likely to induce novel vaccine hesitancy and undermine public health.

There is also some unavoidable ambiguity in defining the precise border of what constitutes malinformation. In scientific publications, erroneous claims that are perpetuated under usual circumstances might be deemed misinformation. However, as outlined in the potential mechanisms of malinformation in this work, the marshaling of claims produces a misleading and harmful picture without adequate context and is typically better described as malinformation. Moreover, even completely accurate works can be weaponized by vested interests and used as malinformation, despite no error or intention on the authors' part. There can also be synergy between the 2 mechanisms; dubious claims can be adopted and championed by bad-faith actors, amplifying harmful effects. The results of this analysis suggest that this facet may have been evident in this instance, but it is important to recognize that such distinctions will be context-specific in many cases.

There have been many hundreds of papers on COVID-19 misinformation and disinformation since the pandemic began, and only a small number have been concentrated on altmetrics of misinformation, tracing, for example, engagement with retracted papers [36]. Potential sources of confusion with the altmetric data have included in particular numerous changes to Twitter (now X) since 2022 that have reduced transparency and an exodus of users, which could have caused altmetrics to change with time. This analysis circumvents these issues by virtue of having been performed prior to these drastic access changes, with tweets included (Multimedia Appendix 1), but will likely make future approaches using this methodology limited in scope. The use of manual sentiment sorting was time-intensive, and future iterations might take a natural language processing approach or use large language model–based artificial intelligence, but the by-hand verification of the relatively small number of high engagement tweets on the subject combined with the analysis of users' prior vaccine positions should make conclusion in this work relatively robust.

Conclusions

Vaccine malinformation was far more likely to be shared with negative editorialization by vaccine-negative accounts and repeatedly cited by media sources opposed to vaccination. This work highlights how malinformation is an issue that should be considered in scientific communication in the social media era to avoid the propagation of misleading and harmful narratives.

Acknowledgments

The authors would like to thank Altmetric for allowing access to the discovery platform so that the data for this cross-sectional analysis could be compiled.

Data Availability

All raw tweet data analyzed during this study are included in this published paper and its supplementary information files in redacted form. The altmetric dataset and full tweet history analyzed and the raw code generated during this study are not publicly available due to potentially identifying information but are available from the corresponding author on reasonable request.

Authors' Contributions

DRG and DHG were responsible for the concept, writing, and editing. DRG undertook data curation, methodology, and formal analysis. Both authors composed, edited, and reviewed the final manuscript.

Conflicts of Interest

DRG is a popular science author who contributes to numerous outlets worldwide on health disinformation and vaccine hesitancy, occasionally receiving fees for these pieces. He also receives royalties from his books on critical thinking (multiple editions) and reports receiving Wellcome Trust research funding (grant 214461/A/18/Z). He has also been a public advocate for the human papillomavirus vaccine in Ireland and Europe, receiving zero industry funding for this advocacy. DHG is a long-time editor and author on Science-Based Medicine, a website for discussions of medicine and pseudoscience, which has been critical of the British Medical Journal's reporting on this issue. Neither author is in receipt of any funding whatsoever from vaccine manufacturers, nor have they been financially compensated by the pharmaceutical industry for any of this work.

Abstract

Background: Social determinants of health (SDoH), such as financial resources and housing stability, account for between 30% and 55% of people's health outcomes. While many studies have identified strong associations between specific SDoH and health outcomes, little is known about how SDoH co-occur to form subtypes critical for designing targeted interventions. Such analysis has only now become possible through the *All of Us* program.

Objective: This study aims to analyze the *All of Us* dataset for addressing two research questions: (1) What are the range of and responses to survey questions related to SDoH? and (2) How do SDoH co-occur to form subtypes, and what are their risks for adverse health outcomes?

Methods: For question 1, an expert panel analyzed the range of and responses to SDoH questions across 6 surveys in the full *All of Us* dataset (N=372,397; version 6). For question 2, due to systematic missingness and uneven granularity of questions across the surveys, we selected all participants with valid and complete SDoH data and used inverse probability weighting to adjust their imbalance in demographics. Next, an expert panel grouped the SDoH questions into SDoH factors to enable more consistent granularity. To identify the subtypes, we used bipartite modularity maximization for identifying SDoH biclusters and measured their significance and replicability. Next, we measured their association with 3 outcomes (depression, delayed medical care, and emergency room visits in the last year). Finally, the expert panel inferred the subtype labels, potential mechanisms, and targeted interventions.

Results: The question 1 analysis identified 110 SDoH questions across 4 surveys covering all 5 domains in *Healthy People 2030*. As the SDoH questions varied in granularity, they were categorized by an expert panel into 18 SDoH factors. The question

XSL•FO
RenderX

2 analysis (n=12,913; *d*=18) identified 4 biclusters with significant biclusteredness (*Q*=0.13; random-*Q*=0.11; *z*=7.5; *P*<.001) and significant replication (real Rand index=0.88; random Rand index=0.62; *P*<.001). Each subtype had significant associations with specific outcomes and had meaningful interpretations and potential targeted interventions. For example, the *Socioeconomic barriers* subtype included 6 SDoH factors (eg, *not employed* and *food insecurity*) and had a significantly higher odds ratio (4.2, 95% CI 3.5-5.1; *P*<.001) for depression when compared to other subtypes. The expert panel inferred implications of the results for designing interventions and health care policies based on SDoH subtypes.

Conclusions: This study identified SDoH subtypes that had statistically significant biclusteredness and replicability, each of which had significant associations with specific adverse health outcomes and with translational implications for targeted SDoH interventions and health care policies. However, the high degree of systematic missingness requires repeating the analysis as the data become more complete by using our generalizable and scalable machine learning code available on the *All of Us* workbench.

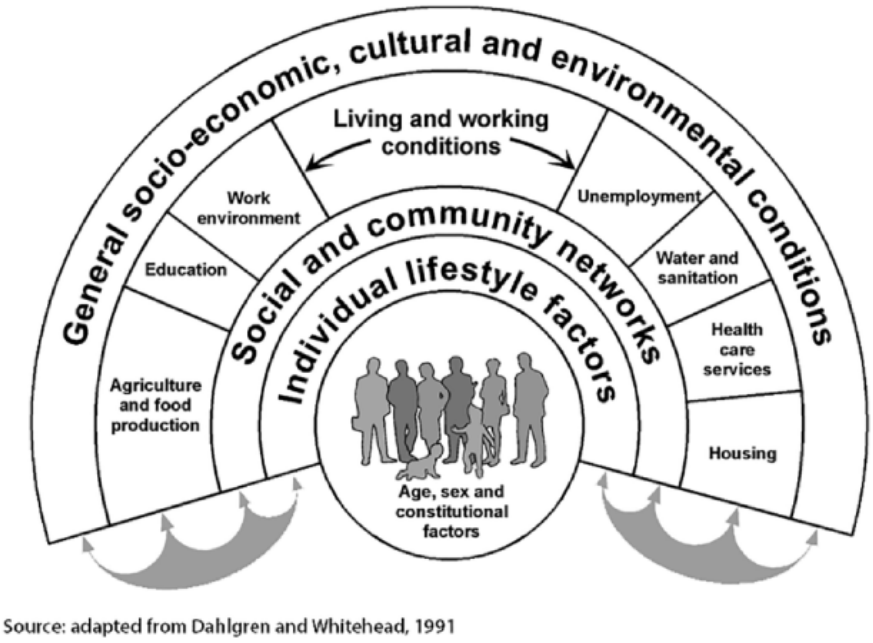
Introduction

Background

Social determinants of health (SDoH), such as financial resources [1] and housing stability [2], account for between 30% and 55% of people's health outcomes [3]. While many studies have identified strong associations between specific SDoH and health outcomes, most people experience multiple SDoH concurrently in their daily lives [4-8]. For example, limited access to education, unstable employment, and lack of access to health care tend to frequently co-occur across individuals, leading to long-term stress and depression [8]. Such complex interactions among multiple SDoH make it critical to analyze combinations of SDoH versus single factors. However, analysis of such co-occurrences and their risks of adverse health outcomes requires the integration of personal, clinical, social, and environmental information, critical for designing cost-effective and targeted interventions. Unfortunately, the lack of databases containing such multiple datatypes from the same individuals has resulted in a fragmented understanding of how SDoH co-occur and impact health, which is critical for designing targeted interventions.

The *All of Us* program [9-11] provides an unprecedented opportunity to address this fragmented view of SDoH. This program aims to collect data from multiple sources related to 1 million or more individuals, with a focus on populations that have been traditionally underrepresented in biomedical research. These data sources include electronic health records (EHRs), health surveys, whole-sequence genome data, physical measurements, and personal digital information. Critically, *All of Us* provides several survey modules containing a wide range of SDoH-related questions, which, in combination with other data sources, could transform our understanding of high-risk combinations of SDoH [9].

However, little is known about the range of and responses to SDoH questions in *All of Us* and how they co-occur to form subtypes, which are critical for designing targeted interventions. To address these gaps, we characterized 110 SDoH in *All of Us*, which guided the methods we used to analyze how they co-occur to form subtypes and their risk of adverse health outcomes. The results helped highlight the opportunities and challenges for conducting subtype analysis in *All of Us*, which integrates multiple datatypes through the use of scalable and generalizable machine learning methods aimed at designing targeted interventions.



Models and Research Related to SDoH

The World Health Organization defines SDoH as the "non-medical factors that influence health outcomes" [3]. Specifically, these include the conditions in which people are born, grow, work, live, and age. Furthermore, such conditions are shaped by a wider set of forces, such as economic and social policies, and systems, such as discriminatory laws and structural racism.

Several models have proposed the factors and mechanisms involved in SDoH [4,12]. These models were motivated by the concept of *social gradient* [13], an empirical phenomenon observed within and across nations [14,15] consistently showing that the lower an individual's socioeconomic position, the worse their health. To help explain the factors underlying the social gradient, the model by Dahlgren and Whitehead [4,16] proposed several interconnected layers of social determinants that influence health. As shown in Figure 1 [4,16], the innermost layer comprises demographic and genetic factors, which are largely unmodifiable. In contrast, the outer layers are modifiable to different degrees, such as lifestyle (eg, exercise and smoking); social and community networks (eg, contact with supportive friends and family); living and working conditions (eg, access to health care and employment); and broader socioeconomic, cultural, and environmental conditions (eg, crime in the neighborhood). While this model was not intended to provide explicit testable hypotheses [4], the factors within each layer are expected to co-occur and impact each other in addition to responding to external forces such as systemic racism and capitalism when it is focused on financial profits at the expense of societal benefits.

XSL•FO
RenderX

Figure 1. The Dahlgren-Whitehead conceptual model aimed at visually showing the interrelated layers of social determinant of health domains that influence health (reproduced from Dahlgren and Whitehead, 2021).

These early SDoH models motivated numerous studies [17] that analyzed associations among specific SDoH (eg, immigration status and home density [7]), their association with health outcomes (eg, education and mortality [18]), and how they manifest within subpopulations (eg, patients with diabetes [19]). More recently, organizations such as the Centers for Disease Control and Prevention and *Healthy People 2030* (HP-30) have classified these empirical results into SDoH domains that roughly map to the Dahlgren-Whitehead model. For example, HP-30 organized SDoH empirical studies into five SDoH domains: (1) economic stability, (2) education access and quality, (3) health care access and quality, (4) neighborhood and built environment, and (5) social and community context. Furthermore, the PhenX program (which provides well-established measurement protocols for use in biomedical and translational research) has identified SDoH data collection protocols to enable more systematic data collection and analysis [20-22].

While the aforementioned findings and categorizations have greatly improved our understanding of SDoH and their impact on health, they have been mostly analyzed based on snapshots of associations between a few factors and health outcomes. In contrast, SDoH models and recent empirical studies suggest that multiple SDoH tend to co-occur and impact each other. For example, during the pandemic, Hispanic and Black or African American individuals not only had a higher exposure to COVID-19 due to their frontline jobs and overcrowded living conditions but also had a higher risk of serious infections due to previous health conditions not addressed due to lack of health care access [4]. Similarly, undocumented immigrants with lower incomes living in neighborhoods with high pollution, combined with the stress of deportation, have an increased risk of multiple chronic conditions such as depression and lung cancer [7]. Such studies have resulted in the Centers for Medicare and Medicaid Services emphasizing that SDoH are a multilevel construct that includes both individual and contextual factors that have complex interactions [23]. Furthermore, a distinction has been made between the aforementioned SDoH at the community level and social needs at the individual level [24]. However, while this distinction is critical when designing care pathways, there is growing consensus [25] that SDoH is an umbrella term that covers both levels, and it is an approach that has been adopted by both the PhenX Toolkit [21] and the *All of Us* surveys on SDoH widely used for analysis [9-11]. Therefore, we use *SDoH* to include all levels of nonmedical factors that impact health and well-being.

The aforementioned co-occurrences of multiple SDoH and their impact on health directly reflect the interconnected layers of the Dahlgren-Whitehead model shown in Figure 1. However, analysis of such co-occurrences and their health outcomes requires large datasets with multiple datatypes that have only recently been made available through the *All of Us* program.

All of Us: Multiple Datatypes Across a Large Cohort of Underrepresented Americans

The *All of Us* research program [9-11] (*All of Us*), funded by the National Institutes of Health since 2015, aims to accelerate biomedical research to enable discoveries leading to individualized and equitable prevention and treatment. Such research is currently hampered due to the *limited range* of

XSL•FO
RenderX

personal, clinical, social, and environmental variables available for the same individuals; *limited representation* in research datasets of socially marginalized populations; and *limited access* to individual-level data due to privacy laws.

To overcome these hurdles, *All of Us* provides three critical features: (1) a data repository that is projected to contain 1 million or more participants with data from multiple sources, including EHRs, health surveys, whole-sequence genomic data, physical measurements, and personal digital information such as from Fitbit trackers; (2) a cohort targeted to include 75% of participants from populations underrepresented in research (race, ethnicity, gender, sex, sexual orientation, and disability) oversampled from the US population; and (3) strictly enforced rules to prevent reidentification of participants by disallowing the download of any participant data or reporting of research results for subgroups of <20. These rules allow for analysis of the *All of Us* data to be categorized as non–human subjects research, which, combined with training and personal authentication by researchers, has resulted in a substantial reduction in administrative hurdles.

As of December 30, 2022 (Controlled Tier; version 6), *All of Us* contained 372,397 total participants, with 8.6% who had attempted all 9 health surveys (7 related to demographics and general health and 2 related to COVID-19) and 26.5% who had genomic data. Critical to this study is the recent addition of a survey specifically targeted to SDoH questions, which has been attempted by 15.5% in the *All of Us* cohort. A preliminary analysis revealed that SDoH appear to be distributed across multiple health surveys and EHR codes, with participants providing those data at different times on a rolling basis. However, little is known about the range of and responses to SDoH questions in *All of Us* and how SDoH co-occur to form subtypes, a critical step for selecting the methods to identify and interpret SDoH subtypes.

Computational Methods to Identify and Interpret Subtypes

A wide range of studies [26-34] on topics ranging from molecular to environmental determinants of health have shown that most humans tend to share a subset of characteristics (eg, comorbidities, symptoms, and genetic variants), forming distinct subtypes (also referred to as *subgroups* or *subphenotypes* depending on the condition and variables analyzed). A primary goal of precision medicine is to identify such subtypes and infer their underlying disease processes to design interventions targeted to those processes [27,35]. Methods to identify subtypes include (1) investigator-selected variables such as race for developing hierarchical regression models [36] or assigning patients to different arms of a clinical trial, (2) existing classification systems such as the Medicare Severity Diagnosis Related Group [37] to assign patients to a disease category for purposes of billing, and (3) computational methods such as classification [38-40] and clustering [30,41] to discover subtypes.

Several studies have used computational methods to identify subtypes, each with critical trade-offs. Some studies have used *combinatorial* approaches [42] (eg, identify all pairs, all triples, and so on), which are intuitive but which can lead to a combinatorial explosion (eg, enumerating combinations of the 31 Elixhauser comorbidities would lead to 2^{31} or 2,147,483,648 combinations), with most combinations not incorporating the full range of symptoms (eg, the most frequent pair of symptoms ignores what other symptoms exist in the profile of patients with that pair). Other studies have used *unipartite* clustering methods [40,41] (clustering patients or comorbidities but not both together), such as k-means and hierarchical clustering, and dimensionality reduction methods, such as principal component analysis, to help identify clusters of frequently co-occurring comorbidities [42-48]. However, such methods have well-known limitations, including the requirement of inputting user-selected parameters (eg, similarity measures and the number of expected clusters) in addition to the lack of a quantitative measure to describe the quality of the clustering (critical for measuring the statistical significance of the clustering). Furthermore, because these methods are unipartite, there is no agreed-upon method to identify the patient subgroup defined by a cluster of variables, and vice versa.

More recently, bipartite network analysis [49] (see Multimedia Appendix 1 [48,50-55] for additional details) has been used to address the aforementioned limitations by automatically identifying *biclusters* consisting of patients and characteristics simultaneously. This method takes as input any dataset, such as *All of Us* participants and their SDoH, and outputs a quantitative and visual description of biclusters (containing both participant subgroups and their frequently co-occurring SDoH). The quantitative output generates the number and members of the biclusters, in addition to the statistical significance of the biclusteredness [50-52], and the visual output displays the quantitative information of the biclusters through a network visualization [53-55]. Therefore, bipartite network analysis enables (1) the automatic identification of biclusters and the significance of their biclusteredness and (2) the visualization of the biclusters critical for their clinical interpretability. Furthermore, the attributes of participants in a subgroup can be used to measure the subgroup risk of an adverse health outcome, develop classifiers for categorizing a new participant into one or more of the subgroups, and develop a predictive model that uses that subgroup membership for measuring the risk of an adverse health outcome for the classified participant.

However, while several studies [52,56-63] have demonstrated the usefulness of bipartite networks for the identification and clinical interpretation of subgroups, there has been no systematic attempt to identify SDoH subtypes, mainly because of the lack of large cohorts containing a wide coverage of SDoH. The *All of Us* program provides an opportunity to use bipartite networks for the identification and interpretation of SDoH subtypes using a wide range of variables in a large cohort and for analyzing their risk of adverse health outcomes, a critical step in advancing precision medicine.

Methods

Research Questions

Our analysis was guided by two research questions targeting the *All of Us* dataset:

XSL•FO
RenderX

1. What are the range of and responses to survey questions related to SDoH?
2. How do SDoH co-occur to form subtypes, and what are their risks for adverse health outcomes?

Expert Panel

The selection of the research questions, variables, cohort, methods, and results and their interpretation were guided by an expert panel consisting of SDoH researchers with a professional background in applied demography, gerontology, and rehabilitation who worked closely with the machine learning and biostatistics researchers. The overall project and manuscript were examined by an ethicist for bias, stigma, and perpetuation of stereotypes. Therefore, the examination of each step in the project was aligned with the human-centered artificial intelligence approach [64-66].

Data Description

Study Population

For question 1, we analyzed the full *All of Us* cohort (N=372,397) and characterized their responses to all the SDoH questions identified by the expert panel (described in the *Variables* section). For question 2, we analyzed all participants (n=12,913) who had valid responses to the SDoH questions identified in question 1 and used them to identify subtypes and their risks of specific outcomes.

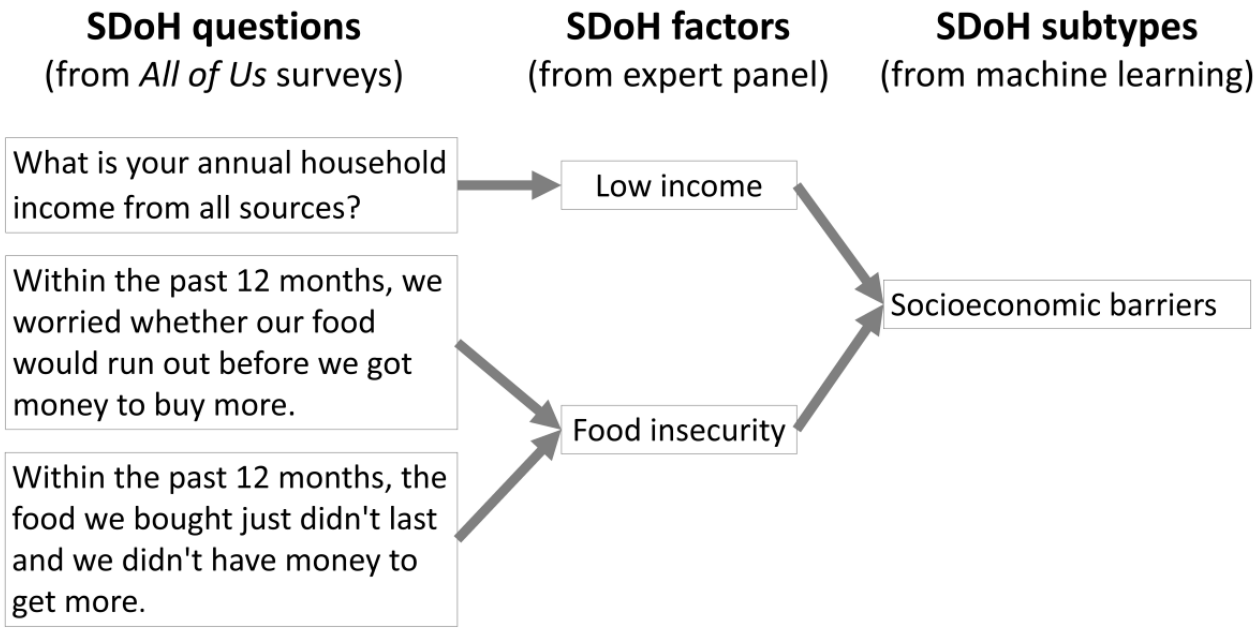
Variables

For question 1, the expert panel was asked to review all 1113 questions across 6 *All of Us* non–COVID-19 health surveys, each of which was attempted once per participant (*The Basics*, *Lifestyle*, *Overall Health*, *Personal/Family Health History*, *Health Care Access and Utilization*, and *SDoH*), and the 2843 Systematized Medical Nomenclature of Medicine (SNOMED) codes related to SDoH [67]. The expert panel arrived at a consensus for the SDoH across the surveys and the SNOMED codes. As the SDoH-related SNOMED codes in the EHRs had very low use (see Multimedia Appendix 2 for a characterization), they were not further analyzed.

For question 2, to identify and analyze the SDoH subtypes, we used the following variables:

1. Independent variables included the SDoH factors identified from question 1.
2. Covariates included 3-digit zip code (to determine whether participants in each subtype came from a state that accepted Medicaid expansion, providing greater access to health insurance) and demographics (eg, age, sex, and race).
3. A total of 3 outcomes were included: *depression*, *delayed medical care*, and *emergency room (ER) visits in the last year*. *Depression* was selected as it is a common health outcome when individuals encounter SDoH in their daily lives, such as long-term stress resulting from racism [68], and the dysregulation of the hypothalamic-pituitary-adrenal axis [69]. Depression was defined as having a positive response to both of the following questions in *The Basics* survey—"Are you still seeing a doctor or health care provider for depression?" and "Has a doctor or health care provider ever told you that you have Depression?"—or having SNOMED codes related to depression in their EHRs (35489007, 36923009, 370143000, 191616006, or 66344007). *Delayed medical care* was selected as it often results from the lack of medical insurance, which can impact the use of medical care when needed, leading to poorer health outcomes [70]. Delayed medical care was defined as having one or more positive responses to 9 survey questions (delayed care due to transportation, rurality, nervousness, work, childcare, copay, older adult care, out-of-pocket costs, and deductible costs) in the *Health Care Access* and *Utilization* survey. *Emergency room (ER) visits in the last year* was selected because lack of medical insurance often results in individuals not seeking early medical care when needed, leading to an exacerbation of conditions precipitating one or more ER visits [71]. As the survey questions that we used for SDoH subtyping were based on outcomes in the previous year, we defined ER visits for a participant as having one or more ER visits (current procedural terminology 99281-99285) 1 year preceding the date when the SDoH survey was completed.

Analytical Approach



Question 1: What Are the Range of and Responses to Survey Questions Related to SDoH?

Identification and Coding of SDoH

To analyze the range and responses to the survey questions, we first characterized all SDoH in *All of Us* at two levels of granularity—(1) SDoH questions based on the surveys used to collect the data and (2) SDoH factors, which were categories of the SDoH questions to form a coarser-grained classification (see Figure 2, which explains SDoH questions, factors, and subtypes).

XSL•FO
RenderX

Figure 2. Examples showing how the social determinants of health (SDoH) questions from the *All of Us* surveys that differed in their levels of granularity were transformed by the expert panel into SDoH factors with uniform granularity to ensure consistency for analysis and interpretation and clustered into SDoH subtypes through machine learning. The SDoH questions and factors were subsequently analyzed for coverage across the 5 Healthy People 2030 domains.

To identify the SDoH questions, members of the expert panel independently used their domain knowledge about SDoH to identify and code the SDoH questions and examine their range with respect to the 5 HP-30 domains using the following steps: (1) reviewed all 1113 questions across 6 health surveys (excluding 2 related to COVID-19) and extracting all SDoH questions that were relevant, (2) transformed all positive or value-free questions into negative phrases and abbreviating them for interpretability in the graphs (eg, *How often do you have someone help you read health-related materials?* was changed to *No one to help read health materials*), (3) reverse coded and dichotomized the abbreviated SDoH questions (eg, always or often=1 and never, occasionally, or sometimes=0), and (4) categorized the SDoH questions into 1 of the 5 HP-30 SDoH domains (economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context). The expert panel subsequently met and collaboratively resolved any differences among their coding schemes to arrive at a consensus (see Multimedia Appendix 3 for the 110 SDoH questions and their consensus coding by the expert panel).

To characterize the SDoH factors, the expert panel arrived at a consensus to categorize one or more of the aforementioned SDoH questions in *All of Us* into SDoH factors and examined their range with respect to HP-30 using the following steps: (1) reviewed the subgrouping labels of questions in the *All of Us* surveys and integrating them to categorize the SDoH into factors, (2) coded a participant as having a "1" for an SDoH factor if they answered one or more of the questions within that factor with a "1," and (3) categorized the SDoH factors into 1 of the 5 HP-30 SDoH domains (economic stability, education access and quality, health care access and quality, neighborhood and built environment, and social and community context; see Multimedia Appendix 3 for the 110 SDoH questions, their consensus coding into 19 SDoH factors, and mapping to the 5 SDoH domains from HP-30).

Analysis of the Range and Responses to SDoH Questions and Factors

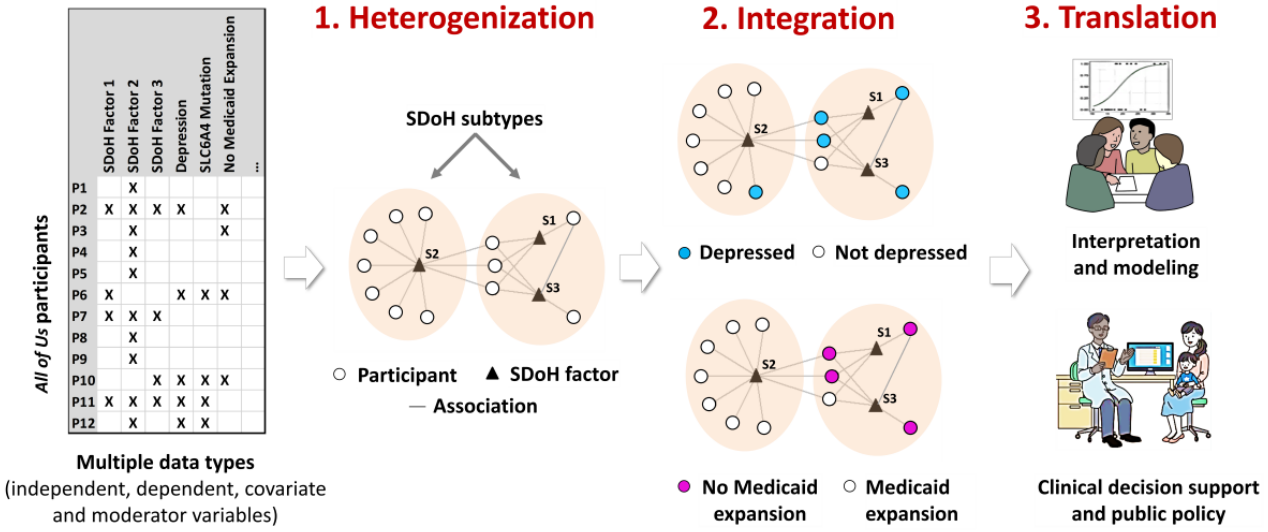
The aforementioned knowledge-based classification of SDoH questions and SDoH factors was analyzed to examine their range (with respect to the 5 HP-30 domains) and their responses (across all participants in *All of Us*) using the following four methods: (1) bar graph displaying the number of participants who had valid answers (all responses other than "skip" or "choose not to answer") to each of the SDoH questions, sorted by survey based on mean response, and then sorted by raw response within each survey. Finally, to analyze their range, each bar was colored to denote one of the 5 SDoH domains defined by HP-30; (2) Venn diagram showing how many participants had cross-sectionally valid responses to all identified SDoH questions or factors; (3) table describing the number and proportion of race, ethnicity, sex, gender, and age between those who answered the SDoH questions or factors and those who did not have valid responses; and (4) frequency distribution of the number of SDoH questions or factors across participants who had valid responses for all the SDoH questions. The aforementioned plots are shown in the *Results* section.

Question 2: How Do SDoH Co-Occur to Form Subtypes, and What Are their Risks for Adverse Health Outcomes?

Data

We used the cohort identified in question 1 (participants who had valid answers to all the SDoH questions). However, examination of the SDoH questions revealed that some of them (eg, *cannot afford dental care* and *cannot afford prescriptions*) had a finer level of granularity compared to others (eg, single household). As the questions with a finer level of granularity

XSL•FO
RenderX



tend to be more strongly corelated to each other in comparison to other coarser-grained questions, they also tend to cluster together more strongly, confounding the interpretation of the subtypes. In contrast, as the SDoH factors had a more uniform granularity and were at a level of abstraction that was appropriate to guide referral to the proper social services, we used them to identify the SDoH subtypes.

Analytical Model

Overview

To identify SDoH subtypes, their associations with outcomes and covariates, and their future translation into precision medicine and public policies, we used a 3-part analytical framework called heterogenization, integration, and translation (HIT). As shown in Figure 3, the *heterogenization* step was used to identify the subtypes through the use of bipartite modularity maximization [50-52] (see Multimedia Appendix 1 for more details), the *integration* step was used to measure the association of each subtype with multiple datatypes [72], and the *translation* step was used to qualitatively interpret the subtypes [72] with the goal of developing in the future a decision support system to translate the subtypes into clinical practice and the design of public policies. The following sections describe the specific methods used in each of the HIT steps.

Figure 3. The three steps of the heterogenization, integration, and translation framework to analyze social determinants of health (SDoH): (1) heterogenization of the data to identify subtypes, (2) integration of multiple datatypes such as from electronic health records (eg, depression) and information on state of residency (eg, to determine Medicaid expansion) to determine the risk and enrichment of each subtype, and (3) translation of subtypes through interpretation and predictive modeling with the goal of designing clinical decision support systems and public policy. SLC6A4: Serotonin Transporter Gene Polymorphism.

Heterogenization: Identification of Subtypes

As there were many participants who did not have valid answers to the SDoH questions, dropping them resulted in differences in the proportion of demographic variables compared with the full *All of Us* cohort. Therefore, the data needed to be adjusted to better reflect the overall *All of Us* participants. To adjust the demographic distribution of the cohort to match the full *All of Us* cohort, we used inverse probability weighting (IPW) [73,74]. IPW calculates weights to proportionally boost the values of participants who are underrepresented in a cohort with respect to a comparison, such as the full *All of Us* dataset, using a method similar to that of an earlier study on *All of Us* [75] (Multimedia Appendix 4). Next, we multiplied the IPW-generated weights with the original binary values for each participant in our cohort and used the min-max method to range-normalize those weights within each SDoH factor. Finally, to test the replicability of the SDoH factor biclustering, we randomly divided the dataset into a training and a replication dataset.

We identified subtypes in the training dataset and tested the degree to which the SDoH factor co-occurrences were replicated in the replication dataset using the following steps: (1) modeled participants and SDoH factors as a weighted bipartite network (step 1 in Figure 3) where nodes were either participants (circles) or SDoH factors (triangles) and the associations between participant–SDoH factor pairs were weighted edges (lines) generated from IPW (the inclusion of IPW-generated weights enabled the network to represent the demographic distribution of the full *All of Us* dataset), (2) used a bipartite modularity maximization algorithm [50-52] (which takes edge weights into consideration) to identify the number of biclusters and their members and measure the degree of biclusteredness through bicluster modularity (Q, defined as the fraction of edges falling within a cluster minus the expected fraction of such edges in a network of the same size with randomly assigned edges), (3) measured the significance of Q by comparing it to a distribution of the same quantity generated from 1000 random permutations of the network while preserving the network size (number of nodes) and the distribution of weighted edges for each participant, (4) used the Rand index (RI) to measure the degree to which SDoH occurred and did not co-occur in the same cluster in the training and replication datasets, and (5) measured the significance of the RI by comparing it to the mean of a distribution of the same quantity generated by randomly permuting the training and replication datasets 1000 times while

XSL•FO
RenderX

preserving the size of the networks and the distribution of weighted edges for each participant.

Integration: Risk and Enrichment of Subtypes

We used logistic regression to measure the odds ratio (OR) for each subtype compared pairwise to each of the other subtypes for the 3 outcomes (depression, delayed medical care, and ER visits in the last year) and for living in a state with no Medicaid expansion. To adjust for the difference in demographics due to the missingness, we used weights generated from IPW for each participant, and the comparisons were adjusted for demographics (eg, age, sex, and race) and corrected for multiple testing within each outcome using false discovery rate. As 13.07% (1688/12,913) of the participants did not have 3-digit zip code information, we used IPW to measure the weights of the cohort and used them to account for potential sample selection bias.

Translation: Interpretation of Subtypes

The subtype interpretation was done using the following steps: (1) used the *Fruchterman-Reingold* [53] and *ExplodeLayout* [54,55] algorithms to visualize the bipartite network along with the risk of each of the outcomes; (2) asked the expert panel to independently label the subtypes, infer the mechanisms that increase the risks in each subtype for the 3 outcomes (depression, delayed medical care, and ER visits in the last year) with potential strategies to reduce those risks, and then collaboratively come to a consensus; and (3) asked an ethicist to examine the results and their interpretations for bias, stigma, and perpetuation of stereotypes.

Ethical Considerations

The original data collection by the *All of Us* program was approved by an institutional review board as described on the web [76].

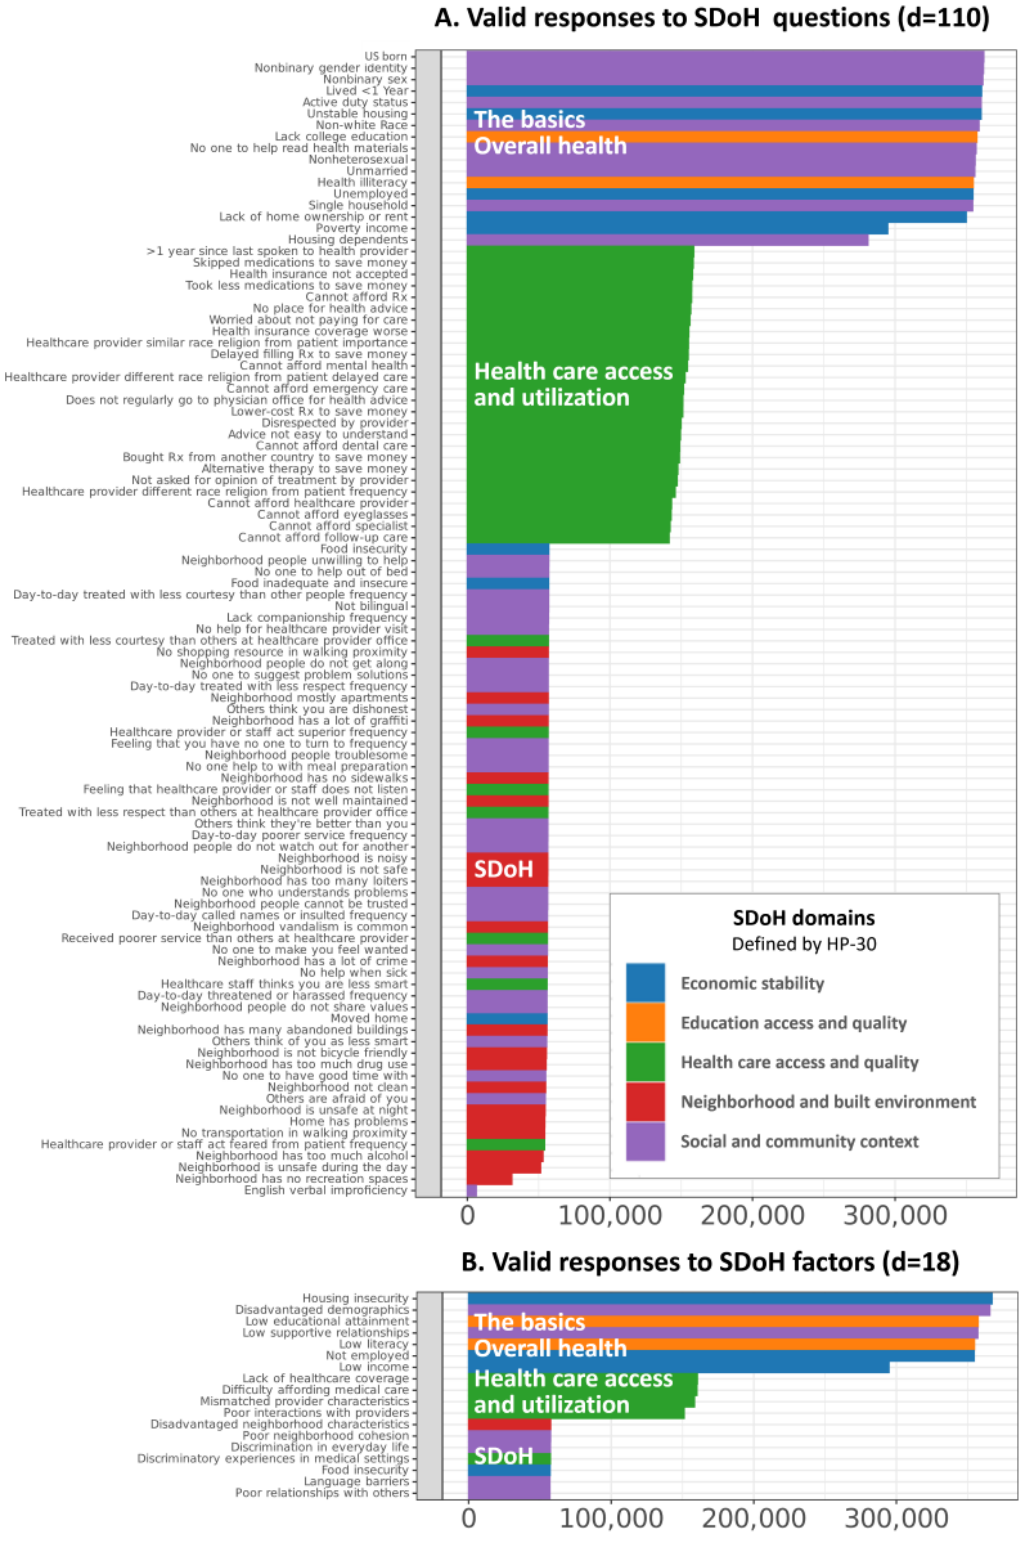
The secondary analysis of the *All of Us* data conducted in this work did not receive approval or exemption from an institutional review board. Such an approval or exemption is not required as described on the web [77].

Therefore, the authors had permission to conduct a secondary analysis of the data.

Results

Question 1: What Are the Range of and Responses to Survey Questions Related to SDoH?

Identification and Coding of SDoH Questions and Factors



The expert panel identified 110 questions from 4 surveys (*The Basics*, *Overall Health*, *Healthcare Access and Utilization*, and *SDoH*). Of these 110 questions, 110 (100%) were abbreviated, and 48 (43.6%) were negatively worded and coded (Multimedia Appendix 3). The 110 SDoH questions were further categorized into 19 SDoH factors (one of these was *Delayed medical care*, which was used as an outcome).

Responses to SDoH Questions and Factors

As shown in Figure 4A, the number of valid responses to each of the 110 SDoH questions was largely dictated by the surveys in which the responses were solicited. SDoH from 2 surveys (*The Basics* and *Overall Health*) had the most valid responses (mean 349,434, SD 23,556), followed by *Healthcare Access and Utilization* (mean 149,898, SD 6146) and, finally, the *SDoH* survey (mean 55,960, SD 1083). This pattern of responses matched how answers to each of the surveys were solicited—at enrollment, all participants are required to do *The Basics* and *Overall Health* surveys, and then, on a rolling basis, responses to the other surveys are solicited. The *SDoH* survey was the last survey that was solicited, which explained it having the lowest number of responses. As shown in Figure 4B, this pattern of missingness held for the responses at the SDoH factor level, which was not unexpected as the SDoH factors were aggregations of the SDoH questions. However, as shown in Figures 4A and 4B by the uneven number of valid responses within each survey block, there were several SDoH questions that had invalid responses (“skip” or “choose not to answer”) at both levels of granularity: *The Basics* (339,254/5,655,412, 5.99%), *Healthcare Access and Utilization* (341,516/5,587,957, 6.11%), *Overall Health* (32,669/744,126, 4.39%), and *SDoH* (83,699/3,206,035, 2.61%). Furthermore, the proportion of valid to invalid responses among them was significantly different for the SDoH questions (N=365,237, χ^2_2=57.5; *P*<.001) and for the SDoH factors (N=372,063, χ^2_2=75.6; *P*<.001).

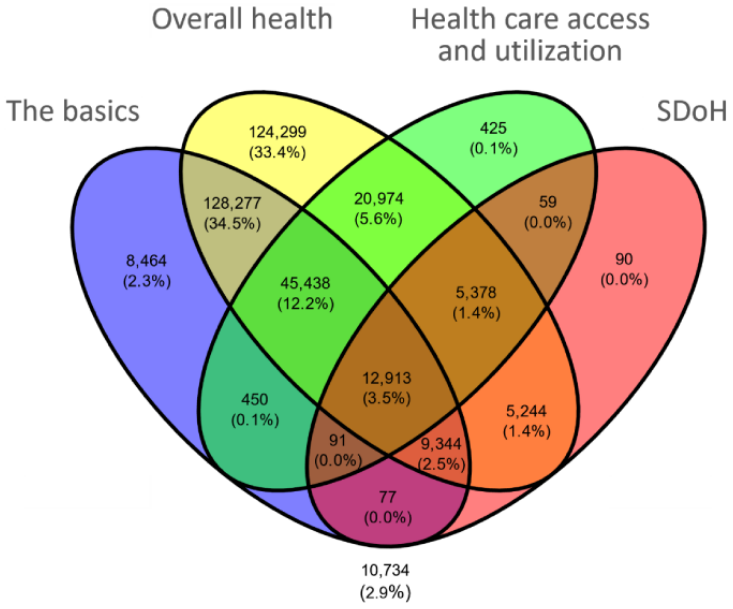
Figure 4. The number of valid responses for (A) 110 social determinants of health (SDoH) questions and (B) 18 SDoH factors. The colors denote how the SDoH in each were categorized based on the 5 Healthy People 2030 (HP-30) domains. Rx: prescription medication.

Range of SDoH Questions and Factors

As shown by the colored bars in Figure 4, the surveys spanned the full range of the 5 SDoH HP-30 domains. The SDoH questions in *The Basics* and *Overall Health* surveys were predominantly related to economic stability (blue) and social and community context (purple), those in the *Healthcare Access and Utilization* survey were all related to that topic (green), whereas those from the *SDoH* survey were a mix of all 4 domains. Overall, the 4 surveys contained 110 SDoH questions that together had 100% coverage of the 5 HP-30 domains (social and community context: n=38, 34.5%; neighborhood and built environment: n=19, 17.3%; economic stability: n=10, 9.1%; education access and quality: n=2, 1.8%; health care access and quality: n=42, 38.2%). This characterization suggests that, while the SDoH in *All of Us* have broad domain coverage across the



XSL•FO
RenderX

surveys, analysis of them requires access to all 4 surveys, each of which has different levels of completion and valid responses.

Cohort With Maximized Valid Responses

Given the large degree and systematic nature of missingness in 2 of the 4 surveys, we could not use multiple imputation to estimate the values. Therefore, we had to find a subset of participants who had valid responses to all the SDoH questions. An examination revealed that 2 SDoH questions had <10% of responses (*English verbal frequency*: 6193/371,942, 1.67%; *Neighborhood has no recreation spaces*: 31,152/371,942, 8.38%), accounting for the largest loss in cohort size with valid responses. Therefore, these questions were dropped from further analysis. Furthermore, one question required a branched response (*Living situation* branching to *Did not live in a house*), and these responses were merged. Finally, as we used *Delayed medical care* as an outcome, 8.2% (9/110) of the questions related to that topic were removed, resulting in a total of 98 SDoH questions. As shown in Figure 5, a Venn diagram of the overlap among the valid responses across the surveys revealed that 3.47% (12,913/372,397) of the participants had valid responses to all 98 SDoH questions.

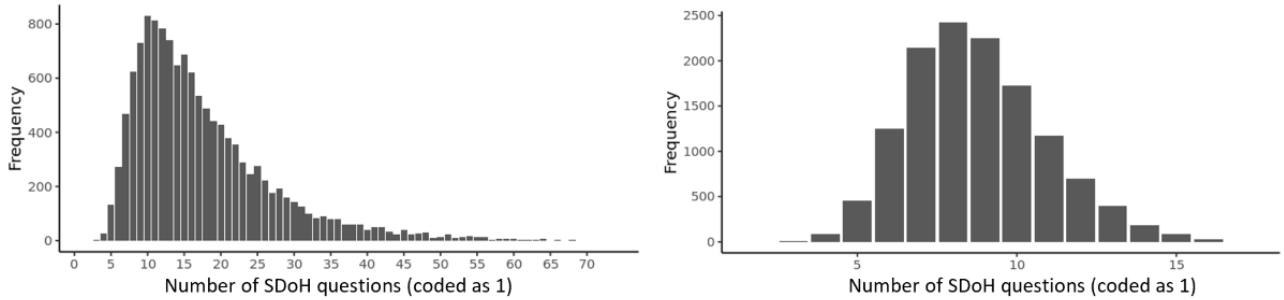


Figure 5. Venn diagram showing 3.47% (12,913/372,397) of participants of the full cohort who had valid responses to all 98 social determinants of health (SDoH) questions.

Co-Occurrence of the Number of SDoH Across Responders

As shown in Figure 6, participants had a median of 15 SDoH question co-occurrences and a median of 9 SDoH factor co-occurrences. Furthermore, participants of racial and ethnic minority groups who had valid responses to the 110 SDoH questions had a significantly higher median number of co-occurring SDoH compared to the equivalent White population (median 20 for participants of racial and ethnic minority groups; median 14 for White participants; P<.001). These results show the high co-occurrences of SDoH at both levels of granularity, with a significant difference in median co-occurrences between the White participants and the participants of racial and ethnic minority populations with valid responses.

Figure 6. Frequency distribution of (A) number of co-occurring responses to social determinant of health (SDoH) questions across the 12,913 participants with valid answers to the 98 SDoH questions and (B) number of co-occurring SDoH factors across 19 SDoH factors.

RenderX

Participant Demographics With Valid Responses to SDoH Questions

As the cohort size dropped to 3.47% (12,913/372,397), we analyzed how that impacted the demographic distribution compared with the overall *All of Us* dataset. As shown in Table 1, there were statistically significant differences in race (N=372,397, χ^2_5=2073.1; *P*<.001) and ethnicity (N=372,397, χ^2_9=6292.2; *P*<.001) between the 2 cohorts after multiple testing correction, with a higher proportion of White participants having valid answers than participants of racial or ethnic minority groups. Furthermore, there was a statistically significant difference in age between the participants who had valid answers and those who did not (*H*1=148.08; *P*<.001). These results show the demographic differences between the cohort with complete and valid answers to the SDoH questions and the full *All of Us* dataset, necessitating the use of IPW–generated weights to address those imbalances, as discussed in question 2.

Table 1. The demographic differences between the total *All of Us* (AoU) participants and those who had valid answers to all 110 social determinant of health (SDoH) questions (N=372,397). Participant counts of <20 are shown as a count of 20 based on the AoU reporting rules.

Demographics	Total AoU participants	Total AoU participants with valid[a] SDoH answers (n=12,913)

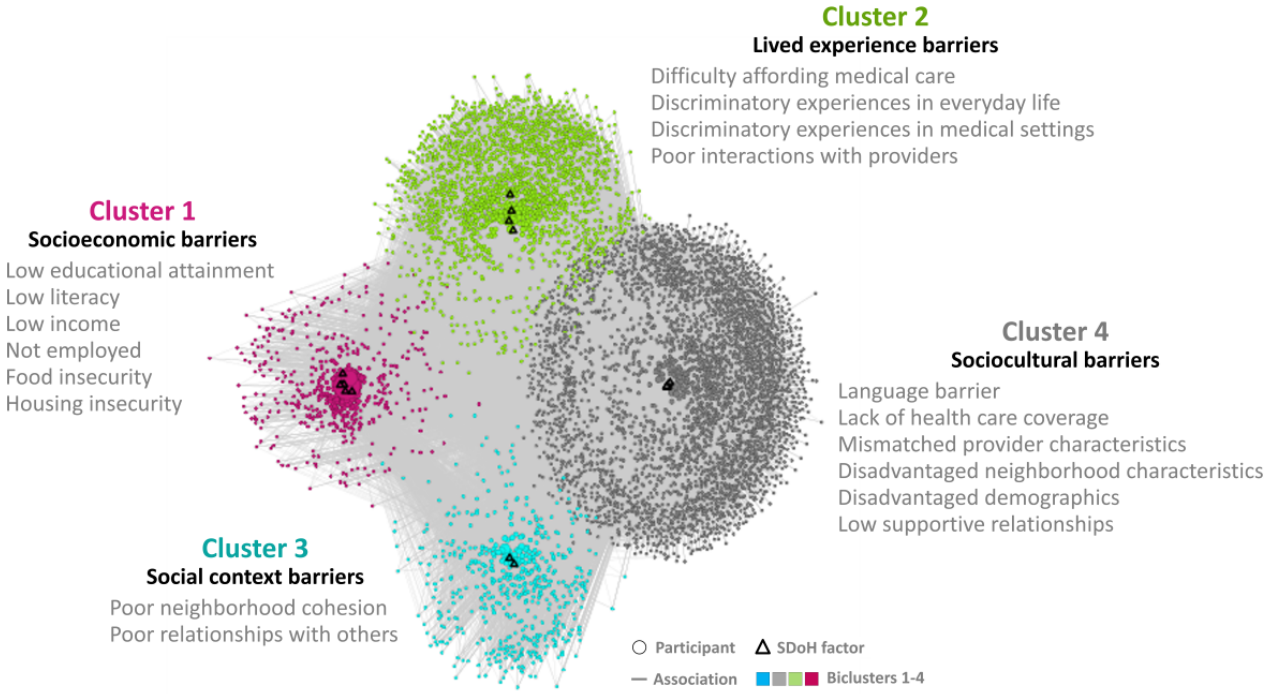
Question 2: How Do SDoH Factors Co-Occur to Form Subtypes, and What Are Their Risks for Adverse Health Outcomes?

Overview

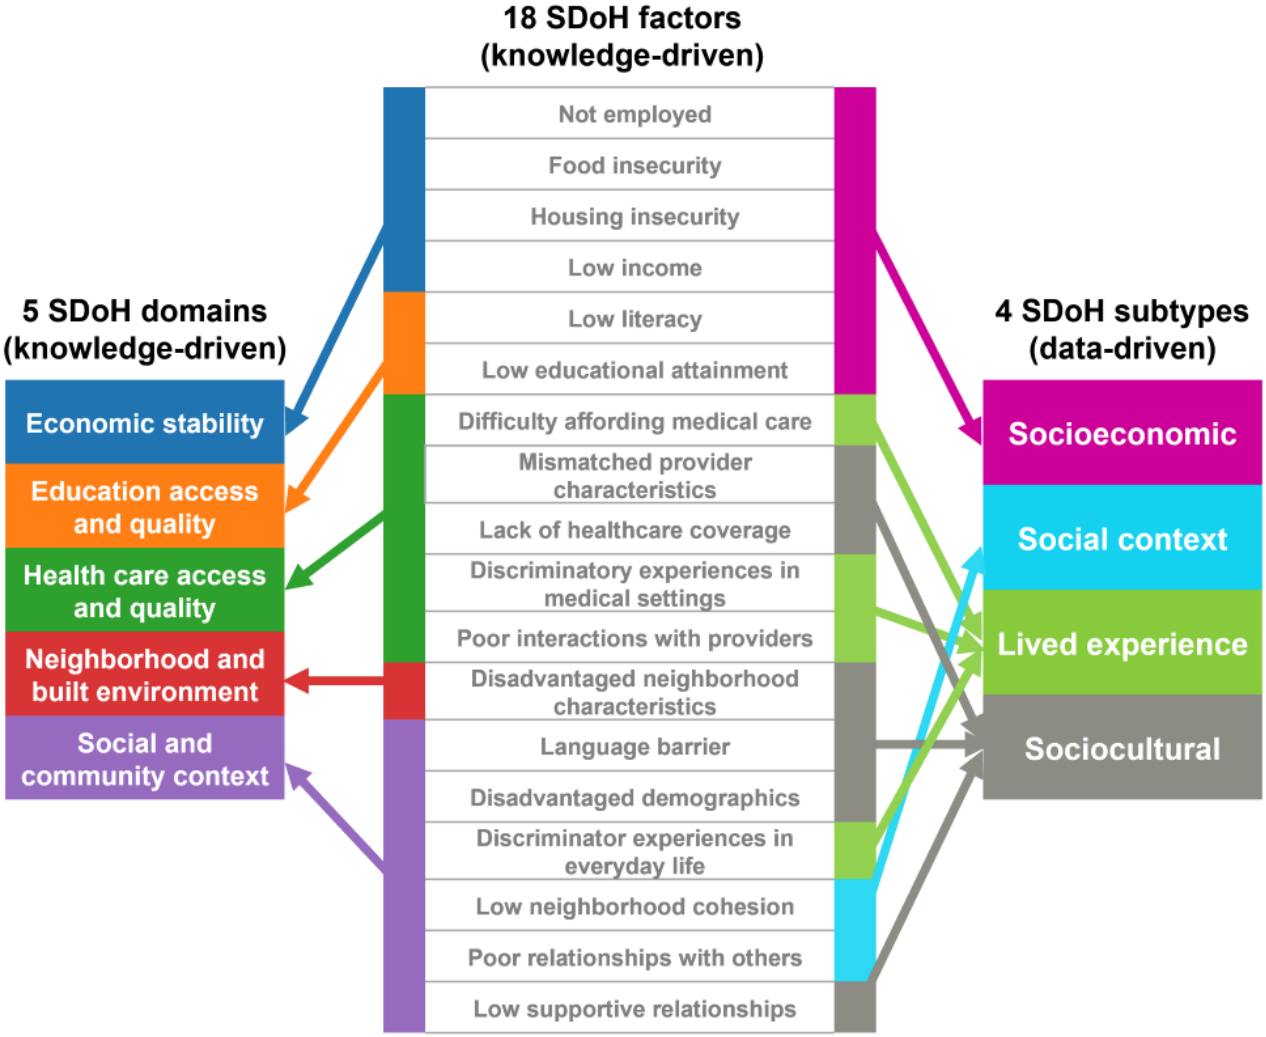
The cohort used to identify the subtypes consisted of 12,913 participants, of whom 12,886 (99.79%) had valid IPW–generated weights. The latter cohort was split randomly into the training and replication datasets, each with complete data for 18 SDoH factors (identified in question 1) in addition to the 3 outcomes (depression, delayed medical care, and ER visits in the last year) and covariates (demographics). The results are organized based on the 3 parts of the HIT framework described in Figure 3.



Heterogenization: Identification of Subtypes

The subtypes were identified by using a bipartite network where the edges were weighted using the IPW-generated weights to account for the imbalance in demographics between our cohort and the full *All of Us* dataset. The weighted bipartite network of the training dataset (n=6492) and the 18 SDoH factors revealed 4 biclusters with statistically significant bicluster modularity (*Q*=0.13; random-*Q*=0.11; *z*=7.5; *P*<.001). As shown

XSL•FO
RenderX



in Figure 7, there were 4 clusters with participant subgroups and their most frequently co-occurring SDoH factors (*Cluster 1 [pink]*: low educational attainment, low literacy, low income, not employed, food insecurity, and housing insecurity; *Cluster 2 [green]*: difficulty affording medical care, discriminatory experiences in everyday life, discriminatory experiences in medical settings, and poor interactions with providers; *Cluster 3 [blue]*: poor neighborhood cohesion and poor relationships with others; and *Cluster 4 [gray]*: language barrier, lack of health care coverage, mismatched provider characteristics, disadvantaged neighborhood characteristics, disadvantaged demographics, and low supportive relationships). These co-occurrences of SDoH factors were significantly replicated in the replication dataset (real RI=0.88; random RI=0.62; $P<.001$). As shown in Figure 8, while the 18 SDoH factors have a hierarchical relationship with the 5 *knowledge-driven* HP-30 domains (shown on the left), those same SDoH factors have a more complex relationship with the 4 *data-driven* biclusters (shown on the right).

Figure 7. A total of 4 biclusters in the training dataset consisting of subgroups of participants (n=6492) and their most frequently co-occurring social determinant of health (SDoH) factors (d=18).

XSL•FO
RenderX

Figure 8. A total of 18 social determinant of health (SDoH) factors (center) have a hierarchical relationship with the 5 SDoH domains defined by Healthy People 2030 (HP-30; left), both of which are knowledge driven. In contrast, the data-driven analysis shows that SDoH factors have a complex relationship with the SDoH subtypes (right) identified through machine learning (ML), reflecting how they co-occur in the real world and aligned with models such as the Dahlgren-Whitehead model.

Integration: Risk and Enrichment of Subtypes

Table 2 shows the association of each subtype with the 3 outcomes. As shown by the italicized row, Cluster 1 (low educational attainment, low literacy, low income, not employed, food insecurity, and housing insecurity) had a significantly higher OR for each of the 3 outcomes than Cluster 4 (mismatched provider characteristics, disadvantaged neighborhood characteristics, lack of health care coverage, disadvantaged demographics, low supportive relationships, and language barriers). Furthermore, within the Depression outcome, each of the clusters had a significantly higher OR than one other cluster, forming a ranking of risk among all the 4 clusters (1>3>2>4). In contrast, Delayed medical care had 2 other significant associations (2>1 and 3>4), with ER visits in the last year having only 1 significant pairwise association that fit into the overall trend.

As shown in Table 3, this trend continued in the enrichment analysis of association with living in a state with *No Medicaid expansion*. As shown, Cluster 1 had a significantly higher OR than Cluster 4 in addition to having a significantly OR than the other clusters. The overall results suggest that Cluster 1 and Cluster 4 form “book ends” representing the high and low ends of the risk spectrum among the clusters.

XSL•FO
RenderX

Table 2. Cluster comparisons to measure the risk across all 3 outcomes. Cluster 1 had a significantly higher risk than Cluster 4 for all 3 outcomes (shown in italics). The depression outcome had a distinct ranking of risks, whereas the other 2 outcomes had a subset of that ranking. All *P* values shown are corrected for multiple testing.

Cluster comparison	Outcomes					
	Depression		Delayed medical care		ER[a] visits in the last year	
	OR[b] (95% CI)	*P* value	OR (95% CI)	*P* value	OR (95% CI)	*P* value

Translation: Interpretation of SDoH Subtypes and Design of Potential Interventions

The expert panel examined the co-occurrences of SDoH factors within each bicluster shown in the network visualization (Figure 7) and integrated them with the quantitative ORs in Tables 2 and 3. The consistent "book ends" result where Cluster 1 had significantly higher ORs than Cluster 4 across all 4 variables was of strong interest and interpreted as follows: (1) Cluster 1 was labeled *Socioeconomic barriers* as it comprised multiple high-risk SDoH. These co-occurring SDoH could have resulted from cascades over time, such as low educational attainment, potentially leading to lower rates of employment and lower income with higher rates of food and housing insecurity. Such cascading factors can be perceived as being relatively unmodifiable, leading to a higher risk of chronic stress and depression. Furthermore, the strong association of this subtype with the outcomes *Delayed medical care* and *ER visits in the last tear* and the fact that participants in this subtype were more likely to be from a US state with *No Medicaid expansion* provided a more comprehensive understanding of this high-risk SDoH subtype; (2) Cluster 4 was labeled *Sociocultural barriers* as it contained a combination of SDoH related to disadvantaged neighborhood characteristics and low supportive relations in addition to language barriers and mismatched provider interactions. In contrast to the socioeconomic barriers in Cluster 1, many of the sociocultural barriers could be perceived as potentially modifiable, resulting in a lower risk of depression, delayed medical care, and ER visits. Participants who matched this profile could be screened for language and communication barriers, useful for providing culturally competent care, identifying providers who better match the profile of the individuals, and providing resources to facilitate contact with matching nationality or cultural groups in the vicinity or on the web.

While Clusters 1 and 4 formed the "book ends" of risk across the 3 outcomes, potentially caused by relative differences in the unmodifiability of their frequently co-occurring SDoH, Cluster 2 was flagged as critical and labeled *Lived experience barriers*. The SDoH in this cluster included discriminatory experiences in everyday life and in medical settings in addition to poor

XSL•FO
RenderX

interactions with providers and difficulty affording medical care. These frequently co-occurring SDoH could explain why this subtype had a significantly higher OR for *Delayed medical care* than Cluster 1. Finally, Cluster 3 was labeled *Social context barriers* as the SDoH were related to poor neighborhood cohesion and relationships with others. While not as critical as Clusters 1 and 2, this cluster still had a significantly higher OR for Depression than Cluster 4. Together, the 4 clusters could explain how different degrees of unmodifiability in frequently co-occurring SDoH might impact health outcomes.

The expert panel and the ethicist concluded that clinicians treating patients who match each subtype profile could be alerted of specific risks and, consequently, motivate a discussion about mental health and consequences of delayed medical care with the goal of collaboratively exploring options and solutions with the patients. The results could also be useful for resource planning in hospitals to ensure that there is adequate staff to address the needs of the populations they serve, and for proposing health care policies to address the critical connection between specific combinations of SDoH and their impact on public health. For example, many health equity policies categorize Americans based on sociodemographic variables like race and income, which are proxies of need rather than the needs themselves. Instead, such policies could categorize Americans based on SDoH subtypes and their risks to more precisely allocate resources based on combinations of real-world needs.

Furthermore, the subtypes did not have a one-to-one mapping to the 5 SDoH domains defined by HP-30. As shown in Figure 8, these data-driven clusters have a complex relationship with the SDoH domains and factors. While one subtype belonged to a single domain (the *Social context* subtype belonged to the *Social and community context* domain), 3 of the 4 subtypes belonged to ≥2 domains (eg, the *Socioeconomic barriers* subtype belonged to the *Economic stability* and *Education access and quality* domains). Such interdomain relationships reflect how SDoH co-occur in the real world, reflecting the complex cross-domain interactions described in the Dahlgren-Whitehead model (Figure 1). These relationships could be useful for refining conceptual models to explain the complex association between SDoH and adverse health outcomes and build more accurate SDoH models for predicting adverse health outcomes.

Discussion

Principal Findings

The mechanisms through which SDoH precipitate adverse health outcomes are complex, consisting of many interacting factors and feedback loops among individual and environmental and contextual factors. While this phenomenon has been studied for >3 decades, critical hurdles for researchers have included the *limited range* of datatypes, *limited representation* of populations that have been socially marginalized, and *limited access* to individual-level data at scale due to privacy laws. Recognizing that *All of Us* has well-articulated plans and resources to overcome these limitations but is still in a rapidly evolving stage, we conducted a systematic characterization of >100 SDoH survey questions available in *All of Us* and used them to identify SDoH subtypes with the future goal of designing targeted interventions.

For question 1, we identified 110 SDoH questions across 4 surveys, which covered all 5 domains in HP-30. However, the results also revealed a large degree of missingness in survey responses (1.76%-84.56%), with later surveys having significantly fewer responses than earlier ones, and significant differences in race, ethnicity, and age of participants among those who completed the surveys with SDoH questions compared to those in the full *All of Us* dataset. Furthermore, as the SDoH questions varied in granularity, they were categorized by an expert panel into 18 SDoH factors. For question 2, the subtype analysis identified 4 biclusters with significant biclusteredness and significant replication. Furthermore, there were statistically significant associations between specific subtypes and the outcomes, as well as with Medicaid expansion, each with meaningful interpretations and potential targeted interventions. Finally, the identified subtypes spanned one or more HP-30 domains, revealing the difference between the current knowledge-based SDoH domains and the data-driven subtypes.

While the results revealed the nature of and responses to SDoH questions in *All of Us* and significant and interpretable SDoH subtypes, the analysis revealed critical opportunities and challenges related to data, methods, and theory. Such insights are useful for future researchers conducting similar analyses on *All of Us* and, therefore, are discussed in the following sections.

Data: Missingness and Granularity

Missingness

The analysis revealed 3 types of missingness. The first was *rollout missingness*. This type of missingness was largely dictated by how the surveys were rolled out to participants. As all participants at enrollment are required to do *The Basics* and *Overall Health* surveys, these surveys had the highest number of responses, followed by the later solicited *Healthcare Access and Utilization* and *SDoH* surveys rolled out more recently in 2022. This order of rollout was the main source of missingness, resulting in a precipitous reduction in cohort size for those who had answers to all the SDoH questions. The second type was *valid answer missingness*. As participants can choose not to answer any survey questions, the data contained “skip” and “choose not to answer” responses. However, these responses accounted for a much smaller reduction in cohort size for complete data than rollout missingness. The third type was *low use missingness*. Although there were 259 SDoH SNOMED codes, only 93 (35.9%) had such information for >20 participants that are allowed to be reported. This could be because most clinicians currently do not screen for SDoH as it is typically done by a social worker. Furthermore, we also attempted to use 3-digit zip codes to determine which subtypes had a significant association with living in a state that did not offer Medicaid expansion. However, 13.07% (1688/12,913) of the participants did not have zip code information (which was adjusted by using IPW).

Together, the aforementioned 3 types of missingness impacted the size of the resulting cohort that had valid answers in the

XSL•FO
RenderX

following 2 ways, which is the minimum number of participants that are allowed to be reported by *All of Us*. First, there was a drastic reduction in cohort size by 93.5%. However, because of the size of the overall dataset (N=372,397), we were still left with a large cohort (n=12,886), which, to the best of our knowledge, is the largest set of individuals to be analyzed for such a wide range of SDoH. Second, there were significant differences in the proportion of race, ethnicity, and age in the aforementioned cohort when compared to the overall *All of Us* population. Specifically, the cohort with valid answers had significantly more White, non-Hispanic, or older participants when compared to the overall cohort. This could potentially be because, once a participant has been enrolled, there is a 90-day delay in sending subsequent solicitations to complete surveys, a policy that is currently being reassessed due to its impact on missingness. Therefore, we had to correct this imbalance in demographic proportions by using IPW with the goal of identifying subtypes that were representative of the overall *All of Us* cohort.

Granularity

Because our goal was to use machine learning methods to identify SDoH subtypes, we encountered uneven granularity in the SDoH questions. Some questions were fine grained and highly correlated and, therefore, would cluster more strongly because of the nature of the granularity of the questions, not because of the SDoH mechanisms. To address this uneven granularity and make the results more interpretable, we used SDoH factors that had a coarser but more consistent level of granularity. We chose this approach because SDoH factors had already been defined; were understood by the expert panel, enabling high domain fidelity; and appeared to be at the right level of abstraction useful for clinical applications, such as referring a patient to the appropriate social services. However, because the use of coarse-grained variables loses information, future research could explore aggregating only those SDoH questions that are highly correlated while preserving the rest at the finer level of granularity and explore computational methods to merge SDoH questions into SDoH factors.

Method: Scalability, Generalizability, and Extensibility

We designed the HIT analytical framework to be scalable, enabling its use for the growing size of the data in *All of Us*; generalizable across cohorts and conditions; and extensible for including additional methods as needed in the future. Testing the HIT framework on the *All of Us* dataset provided insights into the strengths and limitations of the framework and the *All of Us* workbench where the analysis was conducted.

Scalability

We used 3 types of code to conduct the analysis for both research questions. The first was automatically generated code to extract the cohort, produced by *All of Us* once a cohort was selected using the point-and-click interface. This code was adequately scalable and generalizable and so will not be discussed further. The second was customized code to extract specific parts of the data. For example, the analysis of co-occurrences required customized code in R (R Foundation for Statistical Computing) to plot the diagrams in Figures 4–6. As expected, these tasks required strong programming skills, but fortunately, we did not encounter any coding or execution problems using the R or Python (Python Software Foundation) programming languages. However, there were significant server issues that hampered our analysis. Although the workbench instructions stated that code running on the workbench for >2 weeks would be terminated and all intermediate results would be deleted, we frequently encountered our work disappearing at shorter intervals. These disruptions resulted in a higher consumption of the free server time credits resulting in fewer analyses that could be conducted. The third type of code was machine learning code that we had previously developed and disseminated on Comprehensive R Archive Network [78-80] to conduct the bipartite network analysis and the significance testing and visualize the network. As this code was designed to be generalizable and scalable, we did not encounter any issues in the execution of our code (in addition to the same server issues mentioned previously). Finally, the visualization of our networks worked as expected, and we used them to help interpret the patterns in the data.

Generalizability

Our code for the first 2 steps of the HIT framework is in Project Jupyter notebooks and has been used to analyze other cohorts that were filtered for age and previous conditions. For example, we extracted a cohort (n=4090) of participants with diabetes aged ≥65 years with complete data on 18 SDoH variables selected through consensus by 2 experienced health services researchers and guided by the Andersen behavioral model. The analysis [81,82] revealed 7 SDoH subtypes with statistically significant modularity compared with 100 random permutations of the data (*All of Us*=0.51; random mean 0.38 SD 0.0065; z=20; P<.001) and that were not only clinically meaningful but also significant in different degrees for the outcome. Our subsequent attempt at increasing the number of SDoH variables from 18 to 110 for participants with diabetes who had valid answers led to an extremely small cohort size (n=926; Multimedia Appendix 5) due to the missingness that we described previously. While this reduction resulted in our current strategy of analyzing all participants regardless of condition or age, these experiments demonstrate that our approach is generalizable to other subsets of the data.

Extensibility

The HIT model is designed to be extensible to include other methods. For example, the model could use other biclustering (eg, nonnegative matrix factorization [83]) and causal modeling methods and different types of classification (eg, deep learning [84]) and prediction methods (eg, subgroup-specific modeling [40]) to build the decision support system in the translational step (Figure 2). Furthermore, the model can integrate a wide range of datatypes to enable analysis of how each subtype is associated with them, resulting in a layered interpretation of the SDoH subtypes, as we have demonstrated. For example, as the percentage of participants who have genomic information increases (currently, >25% of our cohort have missing genomic information), our pipeline will be able to integrate such information into our analysis. Finally, the integration of different datatypes required a diverse team consisting of experts in

XSL•FO
RenderX

machine learning, biostatistics, programming, clinical care, health services research, gerontology, and ethics to enable a 360° analysis and interpretation of the subtypes that was, therefore, aligned with the human-centered artificial intelligence approach [64-66]. Furthermore, the use of the workbench to share results through visualizations operationalized *team-centered informatics* [85] designed to facilitate multidisciplinary translational teams [86] working more effectively across disciplinary boundaries with the goal of analyzing subtypes and designing targeted interventions.

Theory: Model Building and Translational Implications

The identification of SDoH subtypes has strong implications for model building in addition to translational applications. As shown in Figure 8, while the current classification of 5 SDoH domains has a hierarchical relationship with the SDoH factors, the data-driven clusters have a more complex association with the same SDoH factors. This reflects the complexity of how SDoH occur in the real world while at the same time being interpretable for purposes of translation.

Future studies should develop prediction models using the data-driven subtypes to determine whether they improve the accuracy of predicting adverse health outcomes when compared to models that do not use those subtypes. Because the subtypes were clinically interpretable, they could be used to build classification and prediction models and used with an interface to develop a clinical decision support system that helps triage patients to critical services. For example, the St Vincent's House [87] in Galveston, Texas, United States, provides several services to address SDoH, including free walk-in clinical care, nurse practitioners with reduced insurance co-payments, English- and Spanish-speaking free mental health counseling, free dental health clinic, utility and rental assistance, case management, financial literacy, expanded food pantry, weekly free home delivery of pantry groceries, snack pack for people experiencing homelessness, free transportation to clinician's appointments, immigration legal services, and spiritual counseling. Given the availability of this wide range of services in many communities across the United States, a decision support system could help classify an individual based on their SDoH profile into one or more of the subtypes and measure their risk of an adverse health outcome. Such information could be used by clinicians to collaboratively explore solutions with the patient to consider one or more of such local services based on the membership strength to a subtype and the associated risk (Figure 2, step 3). At a population level, understanding health risks associated with clusters may assist institutions and organizations in developing more effective prevention programs.

Notebooks for *All of Us* Community Use

Because the missingness in SDoH variables is expected to decrease, their characterization and subtyping will need to be repeated and verified for different cohorts. Therefore, we have made the following 2 sets of code available for general use by the *All of Us* researcher community (accessible after creating a free account on *All of Us* and completing the required training).

SDoH Valid Answer Tracker

This set of notebooks generates four plots that can be used by other researchers on *All of Us* to characterize any cohort: (1) valid response plot to show how many participants have data with valid responses and colored by SDoH domain, (2) Venn diagram showing how many participants have valid responses for all questions within each survey, and (3) frequency distribution plot showing co-occurrence of SDoH across the selected cohort. This set of tools should enable researchers to characterize SDoH across different cohorts to help determine methods that are appropriate to adjust for missingness in those cohorts.

SDoH Subtyper

This set of notebooks can be used to conduct the following analyses: (1) bicluster modularity of a cohort with the 18 SDoH factors to identify the number and members of biclusters and the measure Q representing the quality of the biclustering, (2) visualization of the bipartite network, and (3) significance of the network with respect to null models.

Limitations

This study has 2 main limitations. The first emerges from the large amount of missingness in the survey data, precluding the use of imputation methods that assume a random distribution of missingness. Therefore, we could use only complete data, which led to a large drop in cohort size and which also introduced a bias in the demographics requiring a rebalancing through IPW. While such rebalancing is typically done for large datasets, the IPW method requires judgment to decide which variables to include in the model and, therefore, could have introduced additional unknown biases. Therefore, the model should be refined to determine which variables to include in the regression models that estimate the IPW-generated weights. However, because the clustering was similar between the unweighted and IPW-weighted networks, we believe that the current subtypes are stable and meaningful and represent the demographic composition of the full *All of Us* dataset, but this needs to be verified by redoing the analysis as the data become more complete. The limitation of missingness in the surveys is expected to be addressed as *All of Us* has recently removed the requirement of waiting 90 days before a subsequent survey is given to an enrollee in the program, potentially reducing the degree of missingness. The second limitation is due to the high computational cost of empirically determining the significance of the biclustering. As such analysis is computationally expensive and time-consuming, it limited the experiments we could do to test different cohorts and models. Therefore, we look forward to the *All of Us* workbench providing the ability to run batch processes more efficiently and uninterruptedly for extended periods (exceeding the current time window), which together could help alleviate this computational hurdle in the future.

Conclusions

How SDoH impact health is a complex phenomenon involving many interconnected social, biological, and environmental factors that have yet to be fully elucidated. While this phenomenon has been studied for >30 years, the analyses have

XSL•FO
RenderX

been hampered by the lack of large cohorts representing diverse populations with a wide range of SDoH variables measured, multiple datatypes, and easy access by researchers. *All of Us* provides an unprecedented opportunity to directly address these limitations with the goal of doing justice to early conceptual models such as the social gradient and the Dahlgren-Whitehead model, both of which drew international attention to the complex ways in which individual and contextual SDoH factors impact health. The *All of Us* dataset is also timely because of the extensive health disparities that were revealed during the pandemic, which highlighted the critical need to address SDoH in the public and policy realms. However, because *All of Us* is still rapidly evolving to meet its target of 1 million participants or more, we conducted a systematic characterization of SDoH variables in *All of Us* and used the results to guide the analysis of SDoH subtypes. The identified subtypes, along with their risks, could be used to design data-informed interventions, resource-planning strategies, and public health policies aimed at reducing the risks of adverse health outcomes. However, careful consideration would be required to ensure that the identification of high-risk subtypes is not used in a way that stigmatizes subpopulations.

Our first goal of characterizing the data revealed the nature of the missingness in SDoH and the uneven granularity in the SDoH questions. Both of these results led us to select the IPW method to address the missingness and to analyze subtypes using SDoH factors to address the uneven granularity. Our second goal of identifying SDoH subtypes led not only to statistically significant biclusteredness but also to their statistically significant replication and meaningful domain interpretations. These results set the stage for further investigations to build and evaluate classification and prediction models for designing decision support systems that alert clinicians of specific risks that their patients face due to a combination of SDoH factors. Furthermore, the SDoH subtypes could be used to design public health care policies that are multifactorial and need based, enabling more targeted interventions compared to policies that are based on a few sociodemographic factors such as race and income.

The results also led to the design, use, and dissemination of general-purpose tools currently available on *All of Us* for other researchers, which will be useful to reanalyze the *All of Us* dataset as it grows over the next few years to directly address the high rate of missingness. These collaborative advances should position *All of Us* to revolutionize research for analyzing complex phenomena such as how SDoH impact health and beyond, with the goal of enabling a more equitable future that all of us deserve.

Acknowledgments

The authors thank Gautam Vallabha, PhD, for his assistance in refining the analysis and the manuscript. This study was supported in part by the Artificial Intelligence and Machine Learning Consortium to Advance Health Equity and Researcher Diversity (1OT2SD03258102293), the Clinical and Translational Science Award (UL1 TR001439) from the National Center for Advancing Translational Sciences at the National Institutes of Health, the University of Texas Medical Branch Claude D. No part of this manuscript was generated using large language models.

Data Availability

The datasets analyzed in this study are publicly available from the *All of Us* program after registering for access [88].

Authors' Contributions

SKB and BD conceived the overall design of the analysis and wrote the manuscript. WZ, DB, and AB wrote the analytical code to analyze the data. BD designed the method for handling the missing data, identified sources for social determinants of health (SDoH), and guided the overall design of the analysis. SV identified frameworks for SDoH and guided the overall design of the analysis. YFK provided statistical guidance for the analysis. BD, SS, and TR guided the identification and granularization of the SDoH questions from the *All of Us* surveys. SS, MRP, TR, BD, and MR interpreted the subtypes and inferred the mechanisms and potential interventions, and VA and RH refined those interpretations. ES provided guidance on the ethical aspects of the analysis and interpretation. SV and BD had equal contribution for guiding the overall project. All authors reviewed the final manuscript.

Abstract

Background: Electronic health records (EHRs) consist of both structured data (eg, diagnostic codes) and unstructured data (eg, clinical notes). It is commonly believed that unstructured clinical narratives provide more comprehensive information. However, this assumption lacks large-scale validation and direct validation methods.

Objective: This study aims to quantitatively compare the information in structured and unstructured EHR data and directly validate whether unstructured data offers more extensive information across a patient population.

Methods: We analyzed both structured and unstructured data from patient records and visits in a large Dutch primary care EHR database between January 2021 and January 2024. Clinical concepts were identified from free-text notes using an extraction framework tailored for Dutch and compared with concepts from structured data. Concept embeddings were generated to measure semantic similarity between structured and extracted concepts through cosine similarity. A similarity threshold was systematically determined via annotated matches and minimized weighted Gini impurity. We then quantified the concept overlap between structured and unstructured data across various concept domains and patient populations.

Results: In a population of 1.8 million patients, only 13% of extracted concepts from patient records and 7% from individual visits had similar structured counterparts. Conversely, 42% of structured concepts in records and 25% in visits had similar matches in unstructured data. Condition concepts had the highest overlap, followed by measurements and drug concepts. Subpopulation visits, such as those with chronic conditions or psychological disorders, showed different proportions of data overlap, indicating varied reliance on structured versus unstructured data across clinical contexts.

Conclusions: Our study demonstrates the feasibility of quantifying the information difference between structured and unstructured data, showing that the unstructured data provides important additional information in the studied database and populations. The annotated concept matches are made publicly available for the clinical natural language processing community. Despite some limitations, our proposed methodology proves versatile, and its application can lead to more robust and insightful observational clinical research.

Introduction

Electronic health records (EHRs), originally designed for clinical documentation and administration, are now increasingly used in observational research [1,2], supporting various types of studies, including case studies, patient cohort characterizations, and clinical prediction modeling. EHR data are generally recorded in 2 forms: structured and unstructured data. Structured data includes clinical codes for documenting clinical events, such as diagnoses, medications, procedures, and measurements. Structured data is particularly suitable for observational research due to its consistent meaning, tabular format, and standardized vocabulary of codes. Unstructured data consists of free-text clinical notes, which can provide detailed descriptions capturing the nuances of patient care, such as physician observations, patient histories, diagnostic impressions, and discharge summaries. Although rich in contextual information, unstructured data poses challenges for direct analysis because of its variability and lack of standardization [3,4]. Consequently, extracting meaningful information from unstructured data requires significant investment in manual labor, computational resources, and time.

It is commonly assumed that the text data contains more detailed and extensive information than structured data, based on the often-reported claim—grounded in business-related data [5]—that 80% of EHR data is unstructured [3,4,6-8]. While this assumption may hold, its validity is influenced by factors like documentation quality and clinical context. For example, intensive care data is characterized by a high frequency of measurements, while psychiatric care relies more on textual narratives. Many studies explored the added value of information from text by comparing analyses with and without it [9-15], indirectly validating this assumption. However, even if the assumption holds, it initially remains uncertain to what extent the information in the text data matches or complements the structured data.

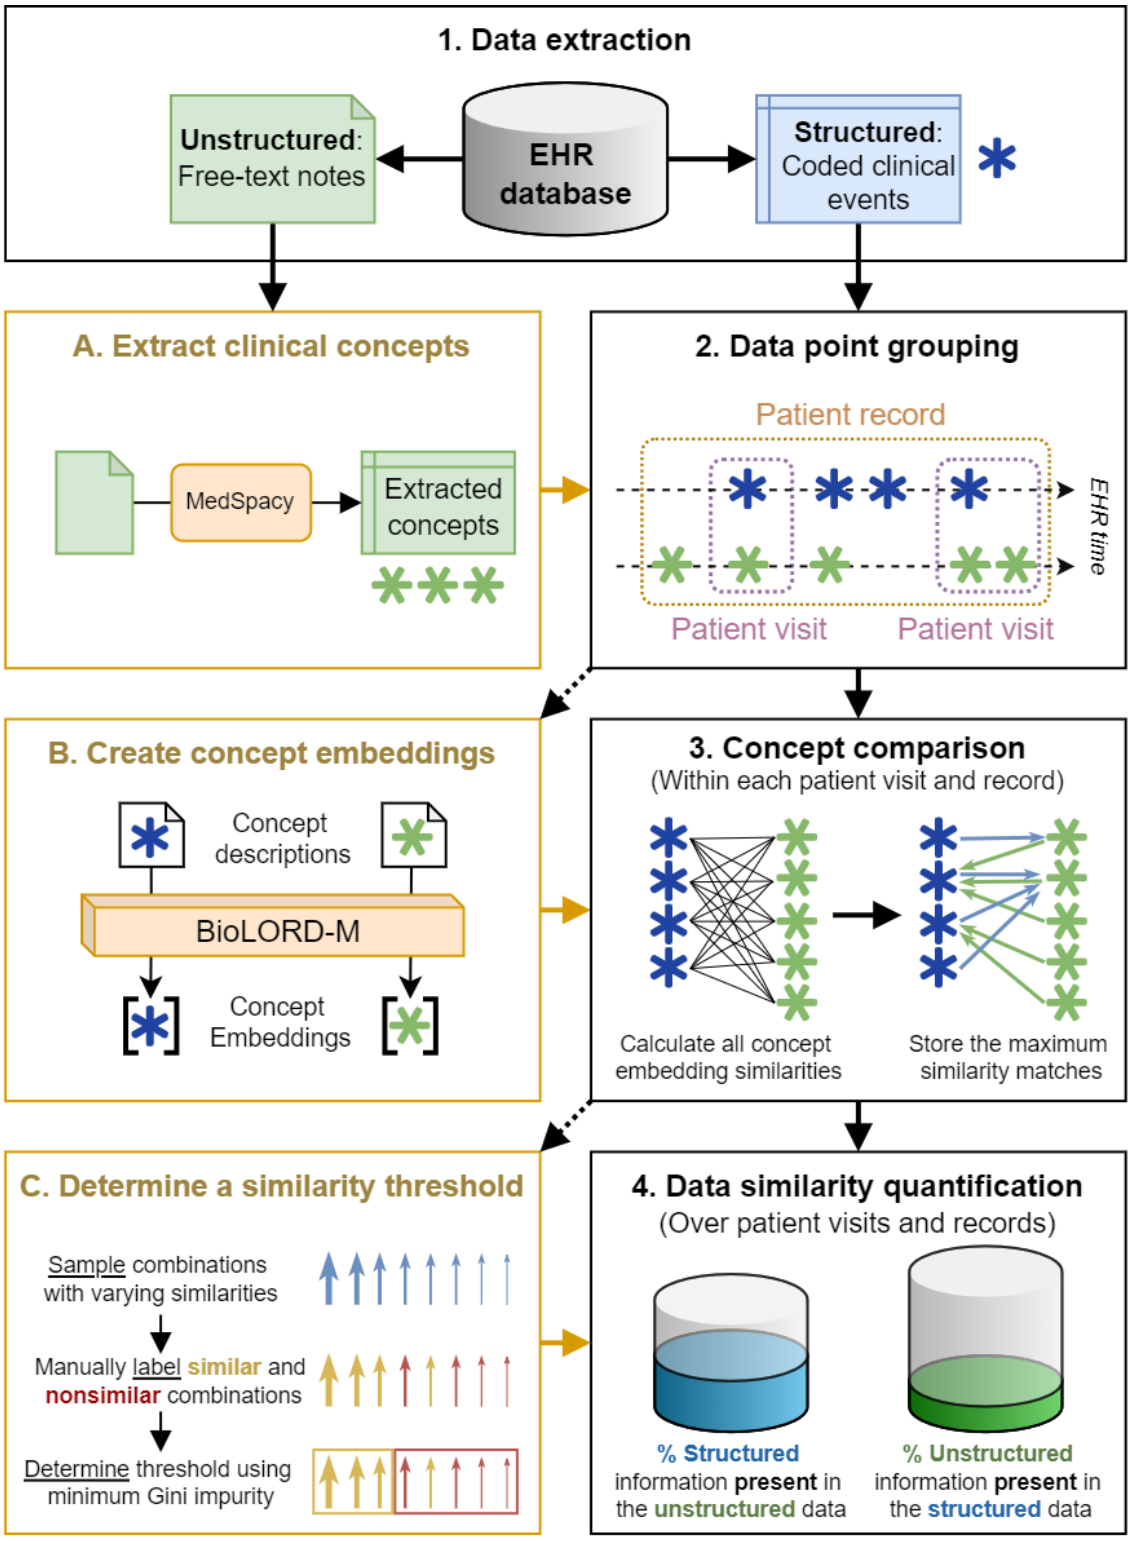
Understanding the quantity and differences in the information available in structured and unstructured data for a specific database offers several advantages for observational clinical research. First, it aids study design by identifying the most abundant and reliable data types, enabling researchers to formulate feasible hypotheses and research questions. Second, it allows for more effective allocation of human and computational resources by focusing efforts where they are most needed. Third, knowing the balance between structured and unstructured data helps researchers prioritize according to the study's specific needs. Finally, it highlights gaps or unique aspects of the data, facilitating the exploration of underused research opportunities.

Comparing the information from structured and unstructured data involves various measures, such as quantity and content. While structured data points can be counted and unstructured data quantified by individual words or extracted concepts, comparing content similarity is more challenging. The core meaning of both structured codes and unstructured text lies in their semantic content. Evaluating the information distance between 2 concepts or texts requires comparing their semantic meanings, a task commonly addressed in natural language processing through semantic similarity measures. Modern approaches often use word embedding models to generate concept embeddings, which are used in applications like biomedical ontology matching [16,17] and concept normalization [18-20]. Specialized embedding models, such as SapBERT [21] and BioLORD [22], have been developed for this purpose and provide the opportunity to measure the information difference between structured and unstructured data.

Several studies have compared structured and unstructured data for specific clinical variables, such as social and behavioral determinants of health [23,24] and smoking history [25,26]. However, to our knowledge, no research has directly assessed the information differences between structured and unstructured data across all clinical events in a database. Our study aims to quantitatively compare the information coded by general practitioners (GPs) with the information documented in free-text notes, using data from a large Dutch GP database. We extracted clinical concepts from unstructured text and used concept embeddings to calculate their similarity with the structured concepts. After determining a similarity threshold, we estimated the difference and overlap of information between structured and unstructured data.

Methods

Database and Setting



This study used the Integrated Primary Care Information (IPCI) database [27], a longitudinal EHR database of Dutch GPs. IPCI contains records of 2.9 million patients with a median follow-up of 4.8 years, spanning from 1993 to 2024. The database is standardized using the Observational Medical Outcomes Partnership Common Data Model [28]. Eligible participants in our study dataset included all patients recorded in the database from January 2021 to January 2024. The study received approval from the IPCI governance board under code 2023-04.

Methodological Setup

The methods consist of 4 main parts, visualized in Figure 1, each described in detail in the following sections. First, we extracted both structured and unstructured data for each eligible patient and applied a concept extraction framework to extract clinical concepts from the free-text notes. Second, we applied 2 different data grouping methods to the population. Third, we used pretrained multilingual concept embeddings to calculate the similarities between the structured and extracted concepts. Finally, we annotated a sample of concept similarity matches to determine a similarity score threshold and quantified the data similarity in the database.

XSL•FO
RenderX

Figure 1. Visualization of the methodological setup. Steps 1-4 outline the primary process, including data extraction, data point grouping, concept comparison, and data similarity quantification. Steps A, B, and C detail additional processes, specifically the extraction of clinical concepts, the creation of concept embeddings, and the determination of a similarity threshold. EHR: electronic health record.

Data Extraction

We extracted all structured and unstructured data points for each eligible patient (step 1 in Figure 1). Structured data includes conditions, procedures, prescriptions, measurements, and observations. The coding systems used, such as the International Classification of Primary Care-1, are listed in Table S1 in Multimedia Appendix 1. Unstructured data consists of 3 types of notes: subjective, objective, assessment, and plan notes from consultations; referral and communication notes with secondary care; and other notes from free-text fields in the EHR system, primarily accompanying condition codes.

Clinical Concept Extraction

Structured coded clinical events are considered single data points, while free-text notes can contain multiple pieces of

XSL•FO
RenderX

information embedded in the narrative. To compare these, we extracted individual data points from unstructured text using clinical named entity recognition and linking, generally known as clinical concept extraction (step A in Figure 1). We used MedSpacy [29], a toolkit that extracts clinical concepts based on a reference thesaurus such as the unified medical language system (UMLS) and detects contextual modifiers using language-specific rules. We used a version of MedSpacy adapted for Dutch [10,30], incorporating all Dutch vocabularies from UMLS and replacing the English Systematized Nomenclature of Medicine Clinical Terms with the Dutch translation [31]. We used Dutch context rules to detect qualifiers such as negation, temporality, and experiencer. These rules were previously validated with an annotated corpus [32]. The extracted UMLS concepts were mapped to concept domains such as observation, condition, measurement, drug, and procedure in the Observational Medical Outcomes Partnership standardized vocabulary, which contains the majority of UMLS vocabularies, for easy comparison with the structured data.

Data Point Grouping

Given the longitudinal nature of GP EHR data, we used 2 grouping methods for comparison: by patient visit and by patient record (step 2 in Figure 1). Grouping by visit considers data points recorded simultaneously during a patient visit, providing a natural basis for comparison, while grouping by record includes additional information recorded outside visits, such as lab results and secondary care communications, allowing for a broader comparison.

Concept Comparison

Each structured or extracted data point is represented by a single clinical concept. We compared the Cartesian product of structured and extracted concepts within each group (step 3 in Figure 1). For example, a visit with 1 coded condition and 1 prescription, along with a subjective, objective, assessment, and plan note containing 5 extracted concepts, results in 10 comparisons. While we could count exact concept matches, 2 issues arise. First, the compared concepts can be very similar but not identical, for example, the International Classification of Primary Care-1 code “Fracture: hand/foot bone” (L74) and the Systematized Nomenclature of Medicine Clinical Terms concept “Closed fracture of hand” (704005005). Second, the concept vocabularies differ, as the GPs choose from a limited set of codes, while concept extraction uses the complete UMLS.

To overcome these issues, we used concept embeddings for fuzzy matching, enabling us to measure semantic similarities and recognize similar concepts. Cosine similarity, which measures the angle between 2 embedding vectors, was used to calculate similarities, ranging from –1 (strongly opposite) to 1 (very similar). For each structured and extracted concept, we stored only the highest similarity match, as we are only interested in finding the most similar concept in the other data type.

Concept Embeddings

We used the BioLORD-2023-M pretrained sentence transformer model [22] to generate the multilingual concept embeddings, as visualized in step B of Figure 1. BioLORD-2023-M is designed to produce meaningful representations for biomedical concepts across multiple languages, including English and Dutch, and its cross-lingual performance has been evaluated by the authors [22]. By inputting the concept description, from either UMLS for the extracted concepts or from the source vocabulary for the structured concepts, the model generates a dense 768-dimensional vector, allowing us to create embeddings for both structured and extracted concepts. For concepts with multiple descriptions or synonyms, we calculated an embedding for each and averaged them to create one comprehensive concept representation. For structured observations and measurements, we included the unit and value in the description to enrich the embedding. The model's multilingual capability enabled us to embed concept descriptions in both Dutch and English within the same latent space.

Similarity Threshold Determination

To quantify the information difference between structured and extracted concepts, we needed to define a threshold for concept similarity. Since concept similarity depends on the nature of the embeddings, we developed a systematic method to determine this threshold, as visualized in step C of Figure 1. First, we randomly selected concept pairs at various similarity levels, ranging from a similarity score of 0.35 to 1, with samples taken at 0.05 intervals. This sampling was done for both structured and extracted concepts across patient visits and records, ensuring each concept domain was represented by sampling 5 concepts per domain. Next, we manually annotated the concept pairs as either similar or nonsimilar. Using these annotations, we determined the threshold at which the weighted Gini impurity [33] of the split between similar and nonsimilar matches was lowest.

Data Similarity Quantification

Using a similarity threshold and the most similar counterpart for each structured and extracted concept, we determined the number of structured concepts found in free-text (structured-to-unstructured) and the number of extracted concepts that were coded in the structured data (unstructured-to-structured), as shown in step 4 of Figure 1. It is important to note that these counts are not reciprocal since we consider the maximum similarity per concept. For example, multiple extracted concepts from a patient visit text may be highly similar to a single structured concept, but we only compare the structured concept to its most similar extracted counterpart to determine its presence in the text, not the frequency. We calculated these counts and their percentages across the entire set of concepts, as well as within different concept domains, to explore domain-specific differences. For extracted concepts, we only included those without context modifiers to focus on the core unmodified concepts, which ensures a higher degree of certainty and a more straightforward, reliable comparison.

Subpopulation Comparison

While observing data similarity across the entire population or all GP visits is insightful, applying this method to smaller subpopulations may provide further detail. We defined 3 subpopulations based on different types of clinical events: visits

XSL•FO
RenderX

for chronic disorder (type 2 diabetes mellitus), acute event (COVID-19 vaccination), and psychological disorder (depression), as detailed in Table S2 in Multimedia Appendix 1. We then quantified the similarity between structured and unstructured data for these subpopulations, similar to the full population.

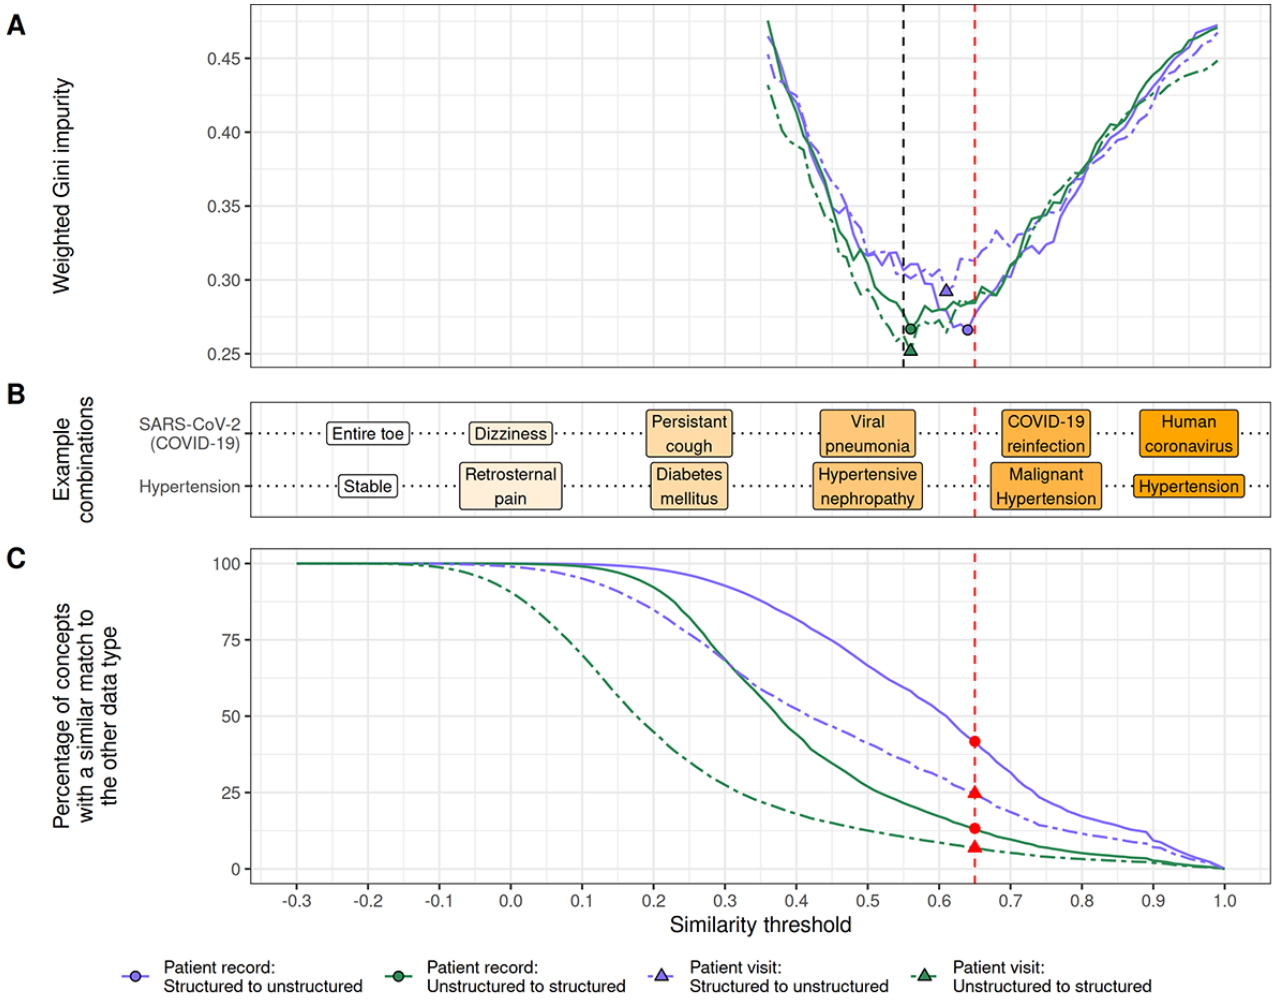
Results

Population and Data Characteristics

Table 1 presents the population and data characteristics for patient records and visits, including details per observation. Additionally, characteristics are listed for 3 subpopulations. Key differences between patient visits and records are evident. First, each patient has one complete record but can have multiple visits. Second, the total number of structured events and their median values indicate that many events are recorded outside GP visits, as their total numbers are roughly 3 times higher in records. Similarly, the total number of clinical notes is twice as high in records compared to visits alone. Third, more extracted concepts per structured event are generally found in patient visits, but the median number of concepts per note is the same.

Table 1. Population and data characteristics for patient records, patient visits, and 3 subpopulation-specific visits.

Characteristic	Patient records	Patient visits	COVID-19 vaccination visits	Depression visits	Diabetes visits
Total numbers					
Number of patients	1,794,209	1,507,473	62,724	20,519	51,032
Number of observations	1,794,209	13,995,524	84,484	63,957	324,698
Ratio number of observations/number of patients	1	9.28	1.35	3.12	6.36
Number of structured events	132,287,566	41,232,407	281,606	118,351	4,513,756
Number of free-text notes	95,790,377	47,915,131	188,318	216,449	1,253,418
Number of extracted concepts	635,232,943	245,052,660	688,420	1,374,430	5,329,978
Ratio extracted concepts/structured events	4.80	5.94	2.44	11.61	1.18
Statistics per observation					
Percentage male, %	49	49	45	33	51
Median age (years)	39	39	62	49	68
Median number of structured events	33	2	2	1	6
Median number of free-text notes	35	3	2	3	3
Median number of extracted concepts	172	12	5	15	12
Median number of concepts per note	3	3	2	3	3



Characteristics for visits across different clinical events also show clear contrasts. As expected, visits regarding diabetes presented the most visits per patient, while for COVID-19 vaccination, the number of visits per patient was the least. Furthermore, diabetes visits contain much structured and unstructured data, whereas depression visits rely mostly on unstructured data with a large median number of extracted concepts per visit and few structured events. Demographic differences are also notable: diabetes and vaccination populations are similar, but the depression population consists of younger females.

Determining the Similarity Threshold

We annotated 1764 matches in 4 concept samples: structured-to-unstructured and unstructured-to-structured in both patient record and visit populations. For transparency and reproducibility, the annotated samples are available in Table S3 in Multimedia Appendix 2. Figure 2B visualizes some example extracted concepts matched with increasing similarity to the structured concepts SARS-CoV-2 (COVID-19) and hypertension. The weighted Gini impurity calculated over the binary annotated matches at different similarity thresholds is presented in Figure 2A. We found the minimum impurity of each of the 4 samples between thresholds of 0.55 and 0.65. To be conservative, we set the threshold at 0.65 for data similarity quantification.

XSL•FO
RenderX

Figure 2. Analysis across similarity thresholds. (A) The weighted Gini impurity measures the level of impurity in the annotated concept combinations in the 4 samples over the different thresholds. The points indicate the minimum impurity in each sample, and the dashed lines represent their lower bound (0.55) and upper bound (0.65). (B) Examples of extracted concepts matched to the structured concepts of SARS-CoV-2 (COVID-19) and hypertension across different similarity thresholds. (C) The percentage of structured concepts matched the extracted concepts (blue) over the range of similarity thresholds and vice versa (green) for both patient records and visits. The red dashed line in all figures depicts the determined similarity threshold value of 0.65.

Similarity of Structured and Unstructured Data

The percentage of structured concepts that have a similar match to an extracted concept and vice versa over various similarity thresholds is visualized in Figure 2C for both patient visits and records. At the similarity threshold of 0.65, indicated by the red line in Figure 2, 42% (55.1 million of 132.1 million) of structured concepts in patient records are similar to a concept extracted from text, compared to 25% (9.3 million of 37.8 million) for visits. In contrast, only 13% (66.9 million of 501.9 million) of extracted concepts are similar to a structured concept in patient records, and 7% (11.3 million of 155.7 million) in visits (Figure 3A). This indicates that information in the structured data is more likely to be present in the unstructured data than vice versa. The difference between patient records and visits can be explained by the number of available concepts for matching the entire record versus a single visit.

XSL•FO
RenderX

Figure 3. Comparison of structured and extracted concepts in patient records and visits. (A) Total number of structured (left) and extracted concepts (right), along with the number of concepts matched at a similarity threshold of 0.65 (blue for structured to unstructured data, green for unstructured to structured). The percentage of matched concepts is listed in the chart for each data type. (B) The proportion of each concept domain contributed to the total number of structured (left) and extracted concepts (right), along with the proportion of concepts in each domain matched to the other data type.

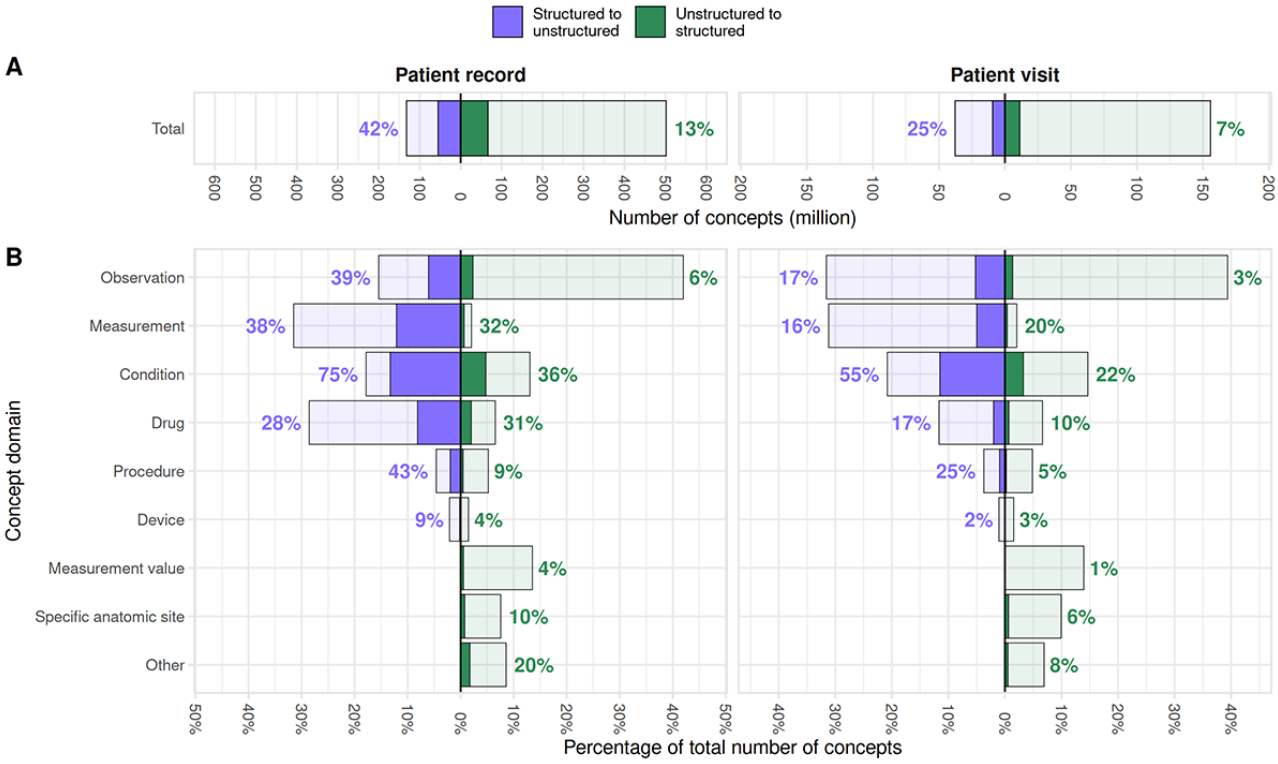


Figure 3B presents the counts and overlap percentages for different domains of structured and extracted concepts. Primarily structured conditions are often also in the text, with 75% (17.6 million of 23.6 million) for patient records and 55% (4.3 million of 7.8 million) for visits. Similarly, extracted condition concepts are also most often matched with structured concepts, with 36% (23.9 million of 65.6 million) in patient records and 22% (5.1 million of 22.8 million) in visits. Other concept domains, such as measurements and drugs, show a relatively high overlap in both structured and unstructured data as well.

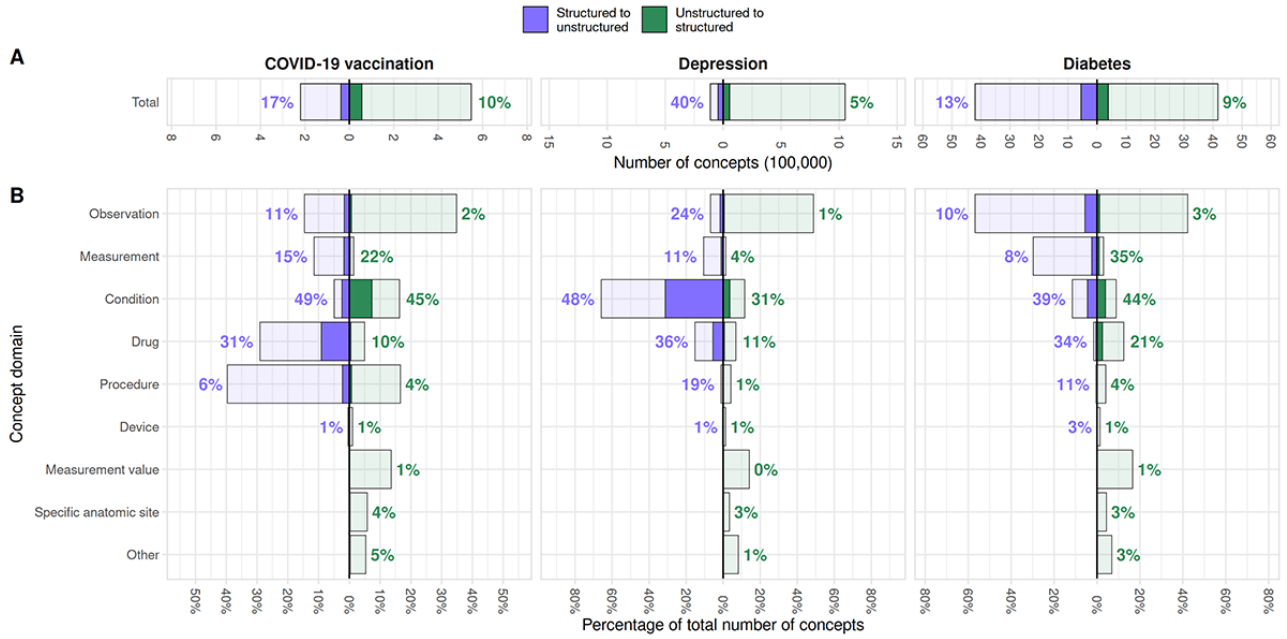

Interestingly, differences in concept domain numbers between patient visits and records are larger for structured concepts than extracted concepts. For example, the proportion of structured observation concepts is 31% (11.9 million of 37.8 million) in patient visits but 15% (20.4 million of 132.1 million) in patient records, and the reverse is true for drug concepts. However, this difference is not observed in extracted concepts.

Differences Between Subpopulations

Figure 4A presents the total concept overlap at the selected threshold for the 3 subpopulations, showing ratios of structured and extracted concepts as seen in Table 1. While the proportion of structured data overlapping with unstructured data and vice versa is similar for the vaccination and diabetes populations, the depression population shows a much higher proportion of structured data matched to concepts in the text (43,934/110,317, 40%) and a lower proportion of extracted concepts matched to structured concepts (55,921/1,051,186, 5%). Figure 4B shows different proportions of concept domains in the structured data across the 3 populations. However, in the extracted concepts, the proportions are relatively similar. The data similarity results are consistent with the total population, with conditions, drugs, and measurement concepts showing the highest overlap between structured and unstructured data.

XSL•FO
RenderX

Figure 4. Comparison of structured and extracted concepts in the 3 subpopulation visits. (A) Total number of structured (left) and extracted concepts (right), along with the number of concepts matched at a similarity threshold of 0.65 (blue for structured to unstructured data, green for unstructured to structured). The percentage of matched concepts is listed in the chart for each data type. (B) The proportion of each concept domain contributed to the total number of structured (left) and extracted concepts (right), along with the proportion of concepts in each domain matched to the other data type.

Discussion

Comparing Structured and Unstructured Clinical Data

This study explored the feasibility of quantifying the information difference between structured and unstructured data in a large primary care EHR database. We used concept embeddings to measure the similarity between structured clinical event concepts and concepts extracted from free-text narratives. By systematically determining a similarity threshold, we found that a substantial proportion of structured information is also present in unstructured data, while only a small portion of unstructured information is reflected in structured data. This indicates that most concepts in one data type do not match those in the other, suggesting that the information in structured and unstructured data is highly complementary. The difference between the data modalities can be attributed to certain types of information being exclusively structured, such as measurements made at the general practice, while other information, like observations reported in unstructured communication of a hospital to a GP, is often not captured in the structured data of the GP record.

Furthermore, we observed that condition concepts had the largest overlap between structured and unstructured data, followed by measurements and drug concepts. These results were consistent across different data point grouping methods, by patient record or visit. We also quantified the information difference in smaller subpopulations of patients with specific diseases or procedures. Differences in overlap proportions were evident between these subpopulations, but the concept domains with the largest overlap were the same as in the full population. Overall, our findings validate the often assumed notion that unstructured data contains more extensive information than structured data in this specific database. Most importantly, we prove the feasibility of quantifying the information difference in an EHR database by using a combination of clinical concept extraction methods [29], high-dimensional clinical concept embeddings for similarity measurement [22], and annotating a small number of matched concepts to determine the appropriate similarity threshold.

Strengths and Limitations

The study was conducted on a large, private dataset, which limits public reproducibility. However, our approach to compare and quantify differences between structured and unstructured data is dataset-agnostic. With the detailed pipeline and methodology, the work is adaptable and replicable to any EHR dataset containing both data types. There are several limitations to our methodology. The results depend heavily on 3 factors: the type and quality of concept extraction, the type of concept embeddings used for determining concept similarity, and the chosen similarity threshold. First, the performance of named entity recognition and entity linking is crucial for extracting all relevant information from unstructured data. Imperfect extraction can lead to missed concepts (false negatives) that cannot be matched to structured concepts and wrongly extracted concepts (false positives) that distort the results. The MedSpacy extraction framework used in this work was validated for different languages and demonstrates good performance [29,30]. It was chosen for its availability in Dutch, its versatility with ontologies, and its extraction speed. Second, different types of word and concept embeddings may vary in their ability to distinguish between similar and nonsimilar clinical concepts, affecting the distribution of similarity scores. While other, more complex embeddings might improve similarity discrimination, we only tested the multilingual BioLord-2023-M embedding model [22], as it was specifically trained to produce meaningful representations for clinical sentences and biomedical concepts across different languages, making it perfectly suited to our application. Third, the chosen similarity threshold impacts the results. Setting this threshold can be subjective and heavily depends on the concept embeddings. Therefore, we used a

XSL•FO
RenderX

systematic approach using the minimization of the Gini impurity to determine the threshold, and we published the annotated concept matches for transparency. Lastly, data grouping and the ordering of data points in time pose a challenge. We used 2 grouping methods that ignored the time aspect within each group to explore the differences. However, more sophisticated approaches might be necessary depending on the research question. For instance, data recorded outside patient visits may be assigned to the nearest visit, or more advanced sliding time windows could be used to group the data points.

Overall, the strength of this study lies in enhancing our understanding of the information overlap between structured and unstructured clinical data within a large GP EHR database covering 1.8 million patients. Our methodology of using concept embeddings to calculate the similarity between clinical concepts offers a versatile and language-independent solution, demonstrated here for Dutch, ensuring accurate comparisons by capturing nuances in clinical terminology.

Future Work

Future research in quantifying the data similarity or difference between different data types could explore more advanced concept extraction and embedding techniques or alternative similarity measurements beyond cosine similarity. Our study focused on individual concepts for comparison, but combining multiple concepts might yield higher similarity matches. Investigating the use of concept n-grams and further incorporating context modifiers of the extracted concepts could be beneficial. We applied concept extraction before embedding to retain the granular meaning of individual events within a document. This approach ensures that specific events—such as symptoms, prescriptions, and procedures—are not lost in broader document or sentence embeddings. Future research could explore directly comparing structured concepts and free text without prior clinical concept extraction to enhance the method's reliability and applicability.

We used a single similarity threshold across all concept domains and populations. Future work could involve establishing separate thresholds for each concept domain and population for a more refined comparison. Additionally, considering distinct thresholds for Dutch-to-Dutch and Dutch-to-English concept comparisons might be beneficial, as cross-lingual similarities may vary. The potential applications of our methodology extend beyond the clinical domain. With the appropriate information extraction framework and embedding model, our approach could be adapted to various settings. Conducting specific clinical case studies to demonstrate the benefits of leveraging the data-type differences would be a logical next step for research.

Conclusions

Our study aimed to assess the feasibility of quantifying the information difference between structured and unstructured data in EHR databases. Within a large Dutch primary care EHR database, we successfully demonstrated that unstructured data provides more extensive information than structured data, quantitatively validating this prevailing assumption. By leveraging concept embeddings to measure semantic similarity between structured concepts and those extracted from free-text narratives, we found that a significant portion of structured information is present in unstructured data, while the reverse occurs much less frequently. Notably, concept domains such as conditions, measurements, and drugs exhibited the largest overlap. Despite limitations related to the performance of concept extraction, the type of embeddings used, and the determination of similarity thresholds, our methodology is versatile and was applied across different data grouping methods and subpopulations. The exploration of more sophisticated techniques could further enhance the accuracy and applicability of this approach. We suggest that structured and unstructured data should be used together, as their combined information exceeds that of each data type separately. Understanding the extent and nature of information in structured and unstructured data within a database can enhance study design, research exploration, resource allocation, and data prioritization, ultimately leading to more robust and insightful observational clinical research.

Abstract

Background: Body image issues are prevalent among individuals diagnosed with cancer, leading to detrimental effects on their physical and psychological recovery. eHealth has emerged as a promising approach for enhancing the body image of patients with cancer.

Objective: The purpose of this study was to evaluate the effectiveness of eHealth interventions on body image and other health outcomes (quality of life, physical symptoms, and emotional distress) among patients with cancer. In addition, the acceptability, engagement, and challenges of eHealth interventions were also assessed.

Methods: A total of 11 databases were searched, encompassing PubMed; Embase; Web of Science; MEDLINE (via Ovid); Scopus; the Cochrane Library; CINAHL (via EBSCO); OpenGrey; and 3 prominent Chinese repositories: China National Knowledge Infrastructure, China Wanfang Database, and China VIP Database. The search dates were from the inception of the database to September 25, 2024. The inclusion criteria for this study encompassed research that used randomized controlled trials (RCTs) and quasi-experiments (QEs) to examine the effectiveness of eHealth interventions for patients with cancer. The methodological quality of RCTs and QEs was evaluated using the Cochrane risk of bias tool and the Joanna Briggs Institute Critical Evaluation Checklist, respectively. The review adhered to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and was registered with PROSPERO.

Results: There were 3548 studies reviewed, and 7 studies were selected. Three studies were RCTs and 4 were QEs, involving a total of 512 patients. Evidence of efficacy for eHealth interventions targeting body image and other health outcomes (physical symptoms and emotional distress) was mixed. Nevertheless, our findings indicate that there was no notable enhancement in quality of life resulting from eHealth interventions. A total of 5/7 (71%) studies reported the acceptability of eHealth interventions among patients with cancer, and patients perceived eHealth interventions as acceptable. However, the difficulty of operating the software, determination of the most effective course of treatment, and time constraints emerged as the primary challenges associated with electronic interventions.

Conclusions: The implementation of eHealth interventions has the potential to enhance body image, physical symptoms, and emotional distress in patients with cancer. Researchers should undertake more rigorous experiments in the future to elucidate the effectiveness of eHealth and address pertinent concerns.

Introduction

Cancer is an escalating global public health issue. Worldwide, the number of cancer diagnoses is swiftly increasing, projected to rise from 19.3 million in 2020 to approximately 21.6 million by 2030 [1,2]. Fortunately, with the innovations of technologies in early diagnosis and cancer treatment, it is more likely that patients with cancer will live longer and have a better prognosis [3]. However, cancer and subsequent treatments may lead to a range of physical changes including, but not limited to, cosmetic changes (eg, hair loss, scarring, and swelling), sensory changes (eg, pain and numbness), and dysfunction (eg, dysphagia, dysarthria, and impotence), which can severely affect the patients of body image [4].

It has been widely acknowledged that an individual's body image is a complex construct encompassing perceptions, thoughts, feelings, and behaviors related to the entire body [4]. Body image disturbance in adult patients with cancer manifests as self-perceived dissatisfaction with physical alterations, functional impairments, and psychological distress resulting from changes in appearance or functionality [5]. According to the American Cancer Society, it is estimated that between 31% and 67% of the approximately 3.1 million survivors of breast cancer in the United States have experienced distress related to body image issues [6]. The prevalence of body image disturbance in patients with head and neck cancer has been reported to be as high as 74% [7]. A study has demonstrated that body image concerns are not limited to patients with breast, head, and neck cancer. These concerns significantly affect a substantial proportion of patients with cancer and persist throughout their long-term survival [4]. These findings are concerning, as prospective research has indicated that poor body image can result in elevated levels of anxiety, depression, and sexual and intimacy concerns, as well as an increased risk of mortality [8,9].

Therefore, there is a growing concern about the importance of body image in the diagnosis and treatment of patients with cancer. According to a report published by Breast Cancer Care, a prominent UK charity, there was an urgent need for increased support for women undergoing breast cancer treatment to address their body image concerns [10]. The international skincare and make-up workshop, "Look Good, Feel Better," offers instructional sessions on makeup techniques to address eyebrow loss and eyelash loss in women [11]. However, traditional face-to-face intervention may struggle to achieve the ideal intervention effect due to time constraints, geographical barriers, lack of medical resources, and high costs. The emergence of eHealth may overcome the shortcomings of these traditional interventions.

eHealth is an accessible health information delivery strategy that provides information and health services through the internet and related technologies [12-14]. eHealth interventions are recognized for their numerous advantages. First, the privacy and confidentiality of patients are ensured during the implementation [15]; second, multiple patients can attend simultaneously and repeatedly, and the fidelity of the intervention is not affected by time constraints and different interveners [15]; and finally, eHealth interventions can be considered as a less time-consuming and cost-effective method of delivering interventions.

Given the diverse advantages of eHealth interventions, it has been gradually applied to address body image issues among patients with cancer, but the findings were still controversial. Sherman et al [16] revealed that web-based psychological intervention, a structured writing exercise, significantly improved body image distress among patients with breast cancer. However, Høyer et al [17] found that teleconferencing did not improve the body image of patients with breast cancer undergoing radiotherapy. A recent investigation indicated that the group using a smartphone app for exercise did not demonstrate a significant improvement in body image among patients with cancer when compared to the traditional exercise group [18]. Therefore, the purpose of this study was to evaluate the effectiveness of eHealth interventions for improving body image among patients with cancer, considering the methodological quality of the most recent clinical trials on the topic, and other secondary outcomes (quality of life, physical symptoms, and emotional distress) were also investigated. Finally, the acceptability, engagement, and challenges of relevant eHealth interventions were discussed.

Methods

Overview

This systematic review has been registered on the PROSPERO platform (CRD42023388898). It was performed in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [19] (protocol for conducting systematic reviews) and following the population, intervention, comparison, outcomes, and study (PICOS) design [20].

Search Strategy

A total of 11 databases were searched, encompassing PubMed; Embase; Web of Science; MEDLINE (via Ovid); Scopus; the Cochrane Library; CINAHL (via EBSCO); OpenGrey; and three prominent Chinese repositories: China National Knowledge Infrastructure, China Wanfang Database, and China VIP Database. The search dates were from the inception of the database to September 25, 2024. The reference lists of pertinent systematic reviews were scrutinized to identify any additional studies that could be incorporated [11,21-26]. The search form included the truncations and synonyms for the following terms: neoplasms, cancer, onco*, internet-delivered, app, eHealth, mHealth, smartphone, telephone, text message*, body image, self-image (Multimedia Appendix 1 provides a comprehensive search strategy for each database).

Inclusion and Exclusion Criteria

The studies that met the following criteria were included in this review: (1) the study population comprised adults aged 18 years and older, who had been diagnosed with cancer and were either undergoing or had completed cancer treatment; (2) the intervention in the studies were related to eHealth interventions, which encompassed various modes of communication such as SMS text messaging, phone, email, app, web, smartphone app,

XSL•FO
RenderX

and videoconferencing; (3) the comparison groups were standard care or control intervention (access to the internet without specific guidance from intervention personnel); (4) the primary outcome of the study was body image, which was assessed using standardized, scientifically validated, and reliable psychometric instruments; (5) the studies design included randomized controlled trial (RCT) or quasi-experimental (QE) studies; and (6) the language of the study was Chinese or English.

Studies were excluded for the following reasons: (1) the experimental group involved a combination of eHealth and face-to-face interventions; (2) body image was used as a secondary outcome; (3) the study included study protocols without outcomes, review, nonclinical study, meta-analysis, and so on; (4) the full text cannot be obtained; and (5) studies were repeated publications.

Study Selection

The research team deliberated and reached a consensus regarding the search terms. Literature was retrieved by 2 researchers (GH and RW) and subsequently imported separately into the document management software NoteExpress (Beijing Aiqin Haile Technology Co, Ltd). Title and abstract screening and full-text screening were performed independently by 2 investigators (GH and RW) in accordance with the same inclusion and exclusion criteria. Any disagreements were initially addressed and resolved by 2 researchers. Otherwise, a third researcher (XX) was involved to ensure agreement was reached. Finally, GH reviewed all studies to determine inclusion or exclusion.

Data Collection Process

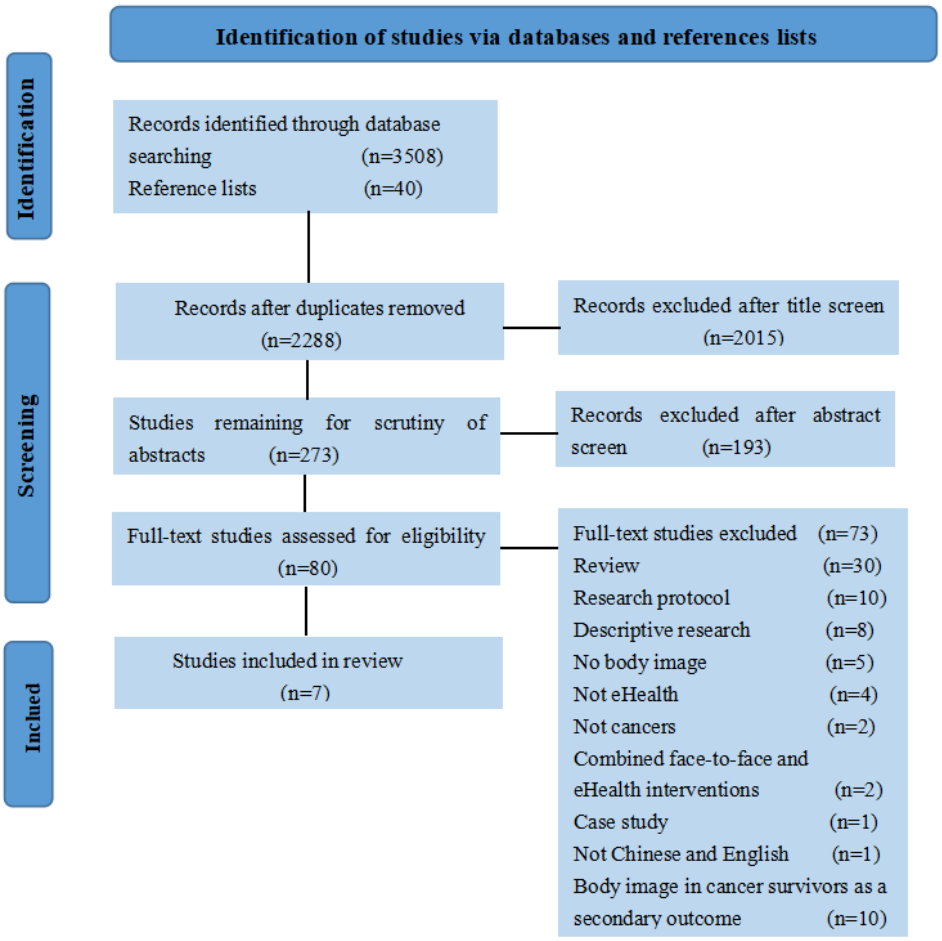
Excel data extraction tables were developed according to PRISMA guidelines [19]. The information mainly included (1) general research information: author, year, country, participants, design type, study duration, mean age, and sample size; (2) intervention and control group details: intervention platform, method, intervention, and follow-up time; and (3) outcomes: evaluation tool and primary and secondary outcomes.

Quality Assessment

The methodological quality of each included RCT was evaluated using the Cochrane Risk of Bias (RoB) Tool [27]. Quasi-randomized studies were assessed for RoB using the Joanna Briggs Institute (JBI) Critical Appraisal Checklist [28]. RoB was independently assessed by authors RW (3 studies) and XX (3 studies). The JBI tool was independently evaluated by authors RZ (3 studies) and XC (3 studies). Discrepancies were addressed through collaborative discussion by the review team. Finally, GH checked all assessments to ensure accuracy.

Data Synthesis

The heterogeneity in methods and outcomes precluded the use of meta-analysis. Instead, a narrative overview of the findings from the included studies was presented alongside a tabular summary of the extracted data. Study outcomes were divided into primary outcomes (body image) and other health outcomes (quality of life, physical symptoms, and emotional distress).



Results

Study Characteristics

After eliminating duplicates and conducting a screening process, 7 full-text studies were identified (Figure 1), including a total of 512 participants. The general characteristics of each study are reported in Multimedia Appendix 2 [16,29-34]. In terms of research methodology, 3 (43%) out of the 7 studies were RCTs and the rest (n=4, 57%) were QE studies.

XSL•FO
RenderX

Figure 1. PRISMA flowchart describing study identification and selection process. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Based on the study population, 4 out of 7 studies were conducted on women diagnosed with breast cancer, accounting for 57% of the total number of studies [16,29-31]. As for study location, the included studies were conducted in Europe (n=1, 14%) [32], the United States (n=2, 29%) [31,33], Australia (n=2, 29%) [16,34], or Asia (n=2, 29%) [29,30].

Overview of eHealth Interventions

A total of 3 (43%) studies were conducted through a website or web-based app [16,30,34]. All others were conducted by SMS text messages, telephone, or video intervention [29,31-33]. The intervention methods included psychological intervention (n=5, 71%) [16,30,32-34], health education intervention (n=1, 14%) [29], and physical exercise intervention (n=1, 14%) [31]. The duration of intervention ranged from 30 minutes to 3 months. The practitioners involved in the intervention involved doctors [16], oncologists [29,34], peer mentors [31], psychologists [29,30,32,33], and health education specialists [29].

Due to the extensive inclusion criteria and resultant heterogeneity of outcomes, we reported outcomes involving 4 subject-related categories under eHealth interventions: body image [16,29-34], quality of life [32], physical symptoms (fatigue [29,31] and sexual function [31]), and emotional distress (anxiety and depression [16,30-32], self-efficacy [30], and self-compassion [16]).

Primary Outcome

All of the study outcomes measured patients' body image [16,29-34]. Nine body image measures, validated in patients with cancer, were used: Body Image Concern Inventory [29], Body Image Scale [16,30-32], Body Mindfulness Questionnaire [32], Body Image States Scale [34], Body Image Coping Skills Inventor [33], IMAGE-HN (Inventory to Measure and Assess image disturbance—Head and Neck) [33], Body Appreciation Scale [16], the Body Appreciation Scale-2 Short Form [34], and Multidimensional Body-Self Relations Questionnaire [34]. The intervention methods included psychological intervention via the internet, app, videoconference, telephone- or text-based health education intervention [16,29,30,32-34], physical exercise intervention using activity monitors, and videoconference [31]. A total of 6 (86%) studies reported a significant effect of the intervention [16,29-31,33,34]. A 3-month, internet-based, peer-moderated physical activity (PA) intervention (Pink Body Spirit) for young patients with breast cancer showed that participants reported an improvement in body image at 3 months after the intervention [31]. A 1-week, web-based brief writing intervention for patients with cancer demonstrated that participants reported a significant improvement in body image 1 week after the intervention [34]. A 7-week app health education intervention was conducted for patients with breast cancer. The results showed that the body image of the intervention group was significantly improved after 7 weeks of intervention [29]. A 6-week, internet-based, mindfulness-based

XSL•FO
RenderX

stress reduction intervention for patients with breast cancer showed significant improvement in body image at 6 weeks after the intervention [30]. A 3-month, internet-based structured writing intervention for patients with breast cancer showed a significant reduction in body image concerns within the intervention group after 3 months [16]. A brief cognitive behavioral intervention based on a video telemedicine platform was conducted for patients with head and neck cancer for 3 months. The results showed that body image was significantly improved after 3 months of intervention [33]. Of them, 4 studies [16,31,33,34] tracked the effects of the intervention at multiple time points (≥2 time points), but not all of these studies achieved the intended.

Other Health Outcomes

Quality of Life

Quality of life was assessed as a secondary outcome in 14% (n=1) of studies. This study used a quality-of-life scale that has been validated in patients with cancer: the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30, with higher scores reflecting better quality of life. This study was based on smartphone-based group physical and psychological therapy, and the treatment effect on quality of life at 5 weeks after the intervention was statistically insignificant [32].

Physical Symptoms

In total, 2 (29%) studies investigated physical symptoms, including fatigue and sexual function. Two studies showed significant reductions in fatigue, including one video remote intervention [31] and one eHealth education intervention [29]. A study focusing on female sexual function indicated that a PA intervention using remote video peer support did not yield improvements in sexual function among young patients with breast cancer [31].

Emotional Distress

A total of 4 (57%) studies investigated the outcome of emotional distress, including anxiety and depression, self-compassion, and self-efficacy [16,30-32]. The results from 4 separate studies evaluated the prevalence of anxiety and depression. Notably, 2 studies indicated that a remote, video-based, peer-led intervention focused on exercise detection and an internet-based, mindfulness-based stress reduction intervention were effective in reducing anxiety symptoms; however, they did not produce significant enhancements in depressive symptoms [30,31]. In contrast, the remaining study reported that the intervention was successful in improving both anxiety and depression levels for participants with breast cancer and lymphedema [16]. Yet another study indicated that smartphone-based physical and psychological interventions did not improve anxiety and depression [32]. A study reported significant improvements in self-compassion with a structured web-based writing exercise intervention [16]. The Internet-Mindfulness-Based Stress Reduction intervention greatly improved self-efficacy [30].

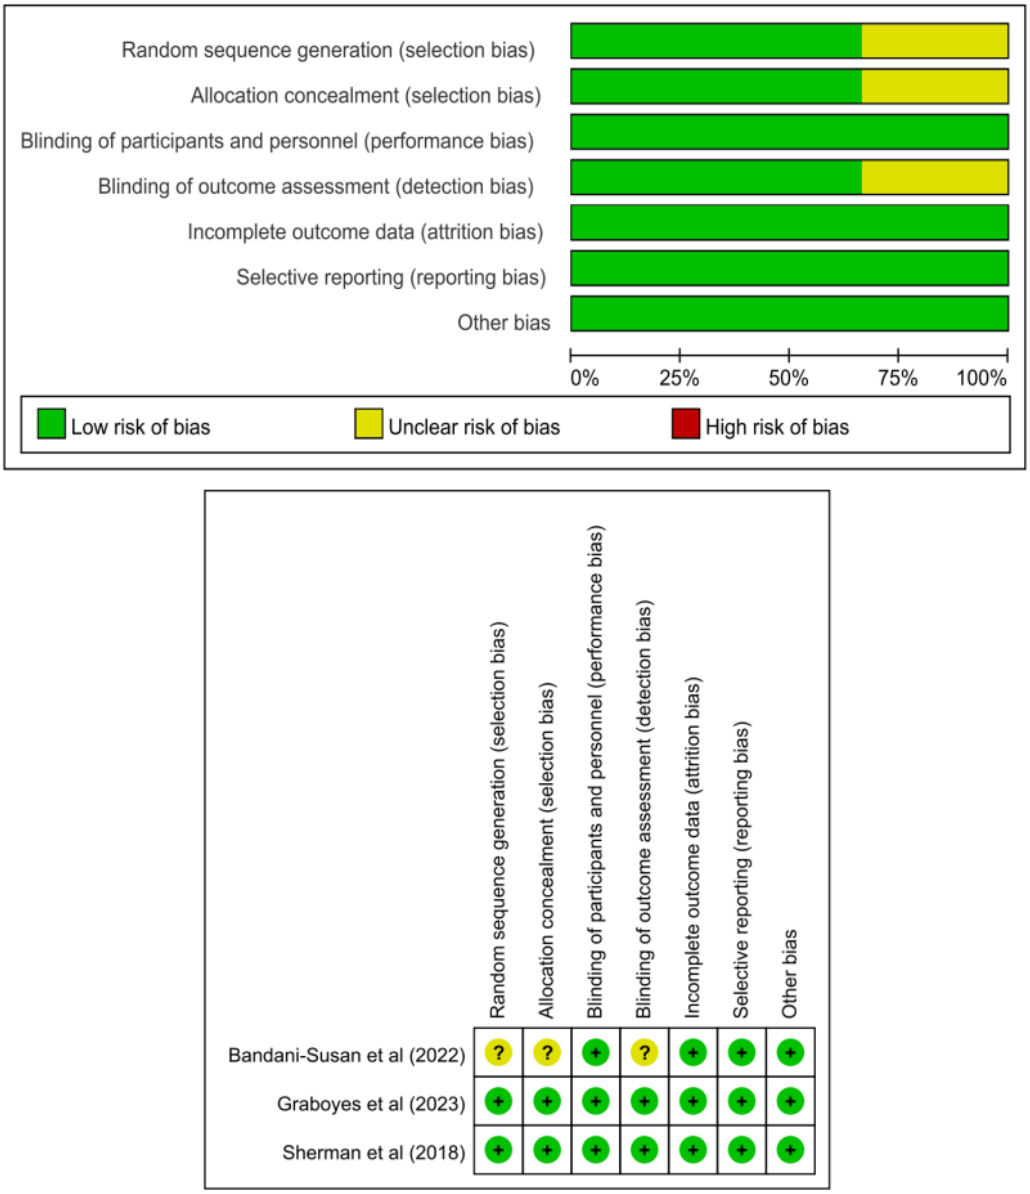
Acceptability

A total of 5 (71%) studies reported the acceptability of eHealth interventions among patients with cancer [16,30-32,34]. Participants rated videoconferencing as acceptable and promising [31]. Participants reported that internet-based teaching methods allowed them to feel more relaxed [30]. A total of 88% of respondents felt that internet-based interventions were worthwhile [16]. Alternatively, participants perceived the intervention via the internet as beneficial [34]. A study indicated that 92.5% of participants expressed a higher level of satisfaction with psychosomatic therapy delivered via smartphone [32].

Engagement

A total of 3 (43%) studies evaluated participants' involvement with the intervention through the completion of modules and use tracking [16,31,32]. A study revealed that 88% of participants in the intervention group completed all 6 components of the web writing intervention [16]. Another study showed that 92.5% of participants participated in at least 4 video sessions of 15 physical smartphone-based interventions [32]. Weiner et al [31] found that more than 85% of people wore an exercise monitoring device on at least 75% of intervention days.

Challenges



A total of 3 (43%) studies reported challenges faced during the intervention process [16,30,31]. A psychosocial intervention program delivered via the internet has indicated that certain older patients with cancer encountered challenges in using the software, such as difficulties in accessing courses and experiencing audio issues during course playback [30]. An RCT reported that the web-based My Changed Body psychosocial intervention was delivered only once, and therefore, it could not be concluded that the optimal number of administrations of the writing for maximum benefit [16]. At the same time, participants in another study said that videoconferencing may take more time to coordinate than email and SMS text messaging because of the potential time conflicts involved in dealing with daily events [31].

RoB Assessment

This study used the Cochrane Collaboration's RoB assessment tool, as well as the JBI tool for quality assessment of RCTs and quasi-randomized studies, respectively. The final results are shown in Figure 2 [16,29,33] and Table 1. Two studies within the RCT were assessed and found to exhibit a low RoB across all 6 evaluated dimensions [16,33]. Selection bias was evaluated as unclear in a study due to insufficient information [29]. Moreover, one study had some detection bias due to a lack of blinding [29]. In addition, regarding quasi-randomized studies, the comparability of baseline data was not clearly articulated for most studies (n=3, 75%) [30-32]. As for the two groups of interventions, only one study explicitly stated that all other measures received by each group were the same [30]. Regarding multivariate measures of outcome indicators, most of the studies (n=3, 75%) implemented diversified measures of outcome indicators before and after the intervention [31,32,34]. With respect to the treatment of follow-up data, all studies reported missing data; however, only one study failed to address this issue with statistical methods [30]. For further details, please refer to the Multimedia Appendices 3 and 4. In addition, the study was performed in accordance with the PRISMA guidelines (Multimedia Appendix 5).

[a]Is it clear in the study what is the "cause" and what is the "effect" (ie, there is no confusion about which variable comes first)?

[b]Were the participants included in any similar comparisons?

[c]Were the participants included in any comparisons receiving similar treatment/care other than the exposure or intervention of interest?

[d]Was there a control group?

[e]Were there multiple measurements of the outcome both before and after intervention/exposure?

[f]Was follow-up complete and if not, were differences between groups in terms of their follow-up adequately described and analyzed?

[g]Were the outcomes of participants included in any comparisons measured in the same way?

[h]Were outcomes measured in a reliable way?

[i]Was appropriate statistical analysis used?

[j]Y: yes.

[k]NC: not clear.

[l]NA: not applicable.

[m]N: no.

Discussion

Principal Findings

In light of the growing prevalence of eHealth interventions, their application in patients with cancer has been on the rise. To our knowledge, this study was the first systematic review to evaluate the effects of eHealth interventions on body image in individuals diagnosed with cancer. This study aimed to scrutinize published research on eHealth interventions for body image in patients with cancer and critically evaluate the effectiveness of these interventions. In addition, other secondary outcomes (quality of life, physical symptoms, and emotional distress) also were explored. Finally, the acceptance, engagement, and challenges faced by patients with cancer during eHealth intervention were also assessed.

From the perspective of research characteristics, the majority(4/7, 57%) of studies involved female patients with breast cancer, possibly attributed to the higher incidence rate of breast cancer in women or their generally heightened concern toward appearance and body image compared to men [35]. Recently, body image interventions in patients with prostate cancer and head and neck cancer have also emerged [36,37], indicating that body image problems in patients with other cancer types are also receiving scholars' attention. We observed that the majority(5/7, 71%) of the studies incorporated in this review were conducted in high-income countries, probably because high-income countries have a higher penetration of smartphones and computers and more stable networks, which was more conducive to the development of research. According to 2023 International Telecommunication Union statistics, there has been a noticeable increase in mobile network use in low- and middle-income countries [38]. Therefore, it is not difficult to carry out research based on eHealth interventions in limited-income countries in the future.

The intervention outcomes, encompassing body image, physical symptoms, and emotional distress, yielded mixed results. The eHealth-based interventions in this study included psychological intervention [16,30,32-34], health education intervention [29], and physical exercise intervention [31]. Our analysis revealed that a majority (6/7, 86%) of the eHealth intervention studies demonstrated substantial effects on body image. In previous studies, face-to-face or group psychotherapy, psychoeducation, and PA have shown positive effects on the perception of body imagery among patients with cancer, but limitations in time, medical resources, and geographic location make it difficult to implement widespread interventions [11,39]. However, these problems were well addressed using electronic information interventions [40]. Although this study found that eHealth-based interventions can have a positive effect, the effect of the interventions waned as the duration of follow up increased. Given the availability of resources, it is recommended that future research explore the most serious time points of body image distress in patients with cancer and that targeted interventions may achieve the best results at the lowest possible economic cost. In addition, we demonstrated that a group-based physical and psychological intervention significantly enhances the appreciation of body awareness among survivors of cancer [32]. Therefore, we suspect that resources permitting, future studies may achieve better results if multiple intervention modalities are implemented simultaneously. Given that only a single study within the reviewed literature assessed the quality of life, the findings indicated that the enhancement in quality of life resulting from eHealth interventions did not reach statistical significance [32]. The limited follow-up period may be a contributing factor to the lack of significant differences observed

XSL•FO
RenderX

in the study. Given that the duration of an intervention is a crucial determinant of its effectiveness, it is essential to carefully consider this aspect during the design phase of the program. A large, cross-country RCT study demonstrated the significant benefits of remote monitoring in mitigating symptom management and emotional distress in patients with cancer [41]. However, in this study, the outcomes of interventions targeting physical symptoms and emotional distress had mixed results. These studies did not specify which component was most influential in alleviating symptoms. The effective intervention of emotional distress was mainly based on the positive perspective to provide psychological support for patients [30,31].

From the viewpoint of attitudes toward eHealth interventions, a majority(37/40, 92.5%) of patients with cancer expressed satisfaction, acceptance, and perceived value and welcomed these interventions. However, only 3 studies reported patient participation in intervention completion [16,31,32], and none of the included studies examined the economic costs of the intervention. This suggests that future research should delve into strategies for sustaining the appeal of intervention programs while ensuring patient participation, taking into account economic costs. In addition, the study explored the challenges of eHealth interventions, including the difficulty of operating the software, determination of the most effective course of treatment, and time conflicts. Some implications for future research can be obtained. First, it is suggested that multidisciplinary cooperation is needed in eHealth intervention to evaluate the physical and mental conditions of patients with cancer and formulate reasonable and scientific intervention programs. Second, eHealth interventions may pose a challenge for patients with cancer in areas with poorly developed network communications. Therefore, robust technical support and patient education provided by professional staff are essential. Finally, considering the time constraints that patients with cancer often encounter, eHealth interventions can offer greater flexibility, enabling patients to engage in them during their leisure time.

Study Limitations

The study findings were meticulously reviewed and reported in strict adherence to the PRISMA guidelines. However, the study does have certain limitations. First, although we conducted a comprehensive search as much as possible, some studies may have been missed due to language limitations. Second, the heterogeneity in intervention methods, frequency, timing, and assessment tools among the included studies precludes the application of a meta-analysis program for synthesizing their results. Consequently, narrative data synthesis was deemed to be the most suitable approach. Finally, among the 7 studies included in this study, 4 studies were QEs, and the sample sizes of 2 studies were relatively modest, which may affect the research conclusion.

Conclusions

In conclusion, this research indicates that eHealth interventions may be beneficial for improving body image, physical symptoms, and emotional distress in individuals with cancer. To further validate their effectiveness, future high-quality RCTs are warranted. In the future, more multidisciplinary teams are needed to explore the availability, acceptability, effectiveness, and cost of different eHealth interventions to improve the health outcomes of patients with cancer.

Abstract

Background: Lifestyle behaviors, including physical inactivity, sedentary behavior, poor sleep, and unhealthy diet, significantly impact global population health. Wearable activity trackers (WATs) have emerged as tools to enhance health behaviors; however, their effectiveness and continued use depend on their user experience.

Objective: This study aims to explore changes in user experiences, preferences, and perceived impacts of WATs from 2016 to 2023.

Methods: We conducted a cross-sectional online survey among an international cohort of adults (n=475, comprising 387 current and 88 former WAT users). Results were compared with a 2016 cross-sectional online survey (n=237, comprising 200 current and 37 former WAT users) using descriptive statistics and chi-square tests. The survey examined brand preference, feature usefulness, motivations, perceived health behavior change, social sharing behaviors, and technical issues.

Results: In 2023, Apple (210/475, 44%) and Fitbit (101/475, 21%) were the most commonly used devices, compared with the 2016 survey where Fitbit (160/237, 68%) and Garmin devices (39/237, 17%) were most common. The median usage duration in 2023 was 18 months, significantly longer than the 7 months reported in 2016, with most users planning ongoing use. Users in both survey years reported greater improvements in physical activity than diet or sleep, despite lower improvement in physical activity in 2023 compared with 2016, contrasted with greater perceived improvements in diet and sleep. Social media sharing of WAT data notably rose to 73% (283/387) in 2023 from 35% (70/200) in 2016. However, reports of technical issues and discomfort increased, alongside a decrease in overall positive experiences. There was also a noticeable shift in discontinuation reasons, from having learned everything possible in 2016 to dissatisfaction in 2023.

Conclusions: The study highlights significant shifts in WAT usage, including extended use and evolving preferences for brands and features. The rise in social media sharing indicates a deeper integration of WATs into everyday life. However, user feedback points to a need for enhanced design and functionality despite technological progress. These findings illustrate WAT's potential in health promotion, emphasizing the need for user-focused design in diverse populations to fully realize their benefits in enhancing health behaviors.

Introduction

Lifestyle behaviors such as physical inactivity, sedentary behavior, poor sleep quality, and unhealthy dietary habits collectively contribute significantly to global morbidity and mortality [1-4]. Current estimates suggest that 1.4 billion adults, accounting for 27.5% of the global adult population, do not adhere to recommended physical activity guidelines [1], increasing the risk of major noncommunicable diseases, including coronary heart disease, stroke, type 2 diabetes, cancers, and mental illness [5]. Sedentary behavior, which is considered a distinct health risk factor, also contributes to adverse health outcomes [6]. In addition, inadequate sleep [7] and suboptimal dietary patterns [8] are recognized as critical determinants of poor health, influencing both physical and mental well-being. Together, these lifestyle factors form a quartet of behaviors that significantly impact global health, underscoring the need for effective interventions and public health strategies. Observation of daily living research emphasizes the importance of individual's understanding of their everyday activities and their impact on their health [9]. Wearable activity trackers (WATs) are one method of tracking activity, providing health insights and highlighting the potential for targeted interventions to improve health and well-being.

WATs have emerged as promising tools for enhancing health behaviors. The WAT market is experiencing rapid growth, valued at US $53.94 billion in 2023, and is projected to grow from US $62.03 billion in 2024 to US $290.85 billion by 2032 [10]. These devices, often worn on the wrist, are designed to positively influence daily lifestyle behaviors by providing users with a variety of health-related data, including metrics such as step count, calories burned, heart rate, sleep patterns, stairs climbed, and sedentary time. Assessment of physical activity using WATs tends to perform better in terms of validity and reliability than self-report assessment [11,12], pointing to their potential to improve activity surveillance and understanding of how activity can impact health. Beyond tracking data, WATs also incorporate behavior change techniques like goal setting, feedback on progress, action planning, review of behavior goals, the discrepancy between current behavior and goal, self-monitoring of behavior, biofeedback, commitment, social support, and rewards for achieving daily objectives, all designed to promote healthier behaviors [13].

The effectiveness of WATs in increasing physical activity levels and improving health across all age groups and in both healthy and clinical populations is well-documented. An umbrella review encompassing 719 primary studies demonstrated that WAT-based interventions significantly improved physical activity, daily step count, time spent in moderate to vigorous physical activity, body composition, blood pressure, and fitness among 163,992 participants [14]. There is also emerging evidence regarding WAT's role in sleep improvement, with a meta-analysis of 20 randomized controlled trials suggesting significant improvements in sleep quality parameters [15]. Furthermore, extensive research has been conducted on the reliability and validity of WATs [16,17].

However, there has been relatively less focus on users' perceptions and experiences of WATs. A 2016 study with 133 participants recruited through Amazon Mechanical Turk explored the well-being implications of these devices, revealing that WATs could impact users' daily life experiences beyond behavior change, providing psychological benefits and fostering a sense of relatedness [18]. Our group conducted a cross-sectional survey in 2016 with 237 Australian adults, examining user experiences with WATs, including usage patterns, social media data sharing, perceived behavior changes, and technical challenges [19]. We also investigated the emotional and psychological responses of users to their activity trackers, finding that most users felt empowered and motivated, while some experienced negative emotions such as anxiety or frustration [20]. Systematic literature reviews of studies conducted up until 2017 [21], 2019 [22], and 2020 [23] have examined various themes related to acceptability and user experience using quantitative and qualitative methods. They identified key issues in WAT user experience, including preferred WAT features [23], how user motivation impacts user experience [23], and how acceptance and usability research provide important design implications [21]. Since these studies, WATs have become more prevalent, and more diverse populations may now be using them. With the regular release of new models featuring advanced capabilities, user experience with WATs is likely to have evolved.

This study aims to understand current and former users' experiences of WATs in 2023 and compare these with our 2016 survey findings. Specifically, we will explore (1) patterns of use (eg, length of use, features used), (2) perceived motivation and behavior change, (3) practices and reasons underpinning data sharing through social media, and (4) technical issues and other barriers to use. By comparing these results with our previous survey [19], we hope to provide insights that will assist clinicians in supporting patients through observation of daily living, as well as aid researchers in exercise physiology, physical activity, and digital health considering WAT use in clinical or general populations.

Methods

Overview

Survey Instrument Development

An online survey instrument (Multimedia Appendix 1) was developed to address the research objectives and was delivered through Qualtrics. To allow for comparison, the survey items were based on the Maher et al [19] 2016 survey, which was developed in consultation with experts and showed test-retest bivariate correlation coefficients ranging between r=0.30 and 0.81 for survey sections [19]. A total of 7 items were added or edited to reflect recent advances in WAT features, such as meditation, workouts, phone call or text messaging, contactless payments, and calendar reminders. WATs were defined in the survey as any bodily-worn device that objectively measures physical activity and provides feedback [24]. The test-retest reliability of the 2023 survey was evaluated with a sample of 19 individuals (14 females, 4 males, and 1 nonbinary or third gender) recruited through Facebook over a 7 to 21-day interval,

XSL•FO
RenderX

yielding bivariate correlation coefficients between r=0.45 and 0.79 across sections.

Participants

Overview

Participants were adults aged 18 and over who were either current or former WAT users within the past 3 years and had used the device for at least 1 month. Exclusion criteria included the use of health-related smartphone applications or software without an associated WAT, WATs not measuring or providing physical activity feedback, and WATs not interacting with a smartphone or computer.

To recruit a diverse, international participant pool, voluntary response sampling was used using 2 platforms:

1. Amazon Mechanical Turk (MTurk): An Amazon-hosted crowdsourcing service that offers rapid access to a varied participant base. For this study, the Qualtrics survey link was posted on MTurk.
2. Facebook: The survey was disseminated through various community groups, the university research center's social media pages, and the research team's profiles. To encourage broader sharing, Facebook users who shared the post were entered into a draw to win one of 2 Aus $100 (US $62.83) retail gift vouchers.

Demographic Characteristics and WAT Usage

Participants' basic demographic information, including sex, age, country of residence, and education level, was collected through 4 items. They were asked about their current or former use of a WAT, leading to respective survey variations. Questions also covered the make and model of their WAT (open-ended), duration of usage, and, for current users, the intended continuation period.

Perceptions of Features

A total of 28 items asked current users about the frequency and perceived usefulness of common WAT features like active minutes, steps, stairs, sleep, heart rate, energy burned, energy consumed (food), meditation, workouts, calls or texts, contactless payment, calendar reminders, device connectivity, and data sharing. Responses were recorded on a 5-point Likert scale.

Behavior Change

Participants' perceptions of health behavior change due to WAT use were explored through 4 items. A total of 3 items on a 5-point Likert scale measured agreement on improvements in eating habits, physical activity, and sleep. In addition, 1 item presented 4 graphical physical activity patterns for participants to identify their own physical activity changes while using a WAT.

Motivation for Wearing a WAT

Participants chose their main motivation for using a WAT from 8 options, including fitness improvement, health monitoring, appearance, activity tracking, social sharing, competition, technology interest, or other (open-ended).

Data Usage and Sharing

A total of 2 items used a 5-point Likert scale to explore the usefulness of WAT data for short-term and long-term self-monitoring. Participants were asked what social networks they share their activity data in and could select from 6 options (tick all that apply), including "Facebook," "Twitter," "Instagram," "Within the activity tracker's software," "I don't share my activity data," or "Other (please specify)." Participants were then asked why they share their data and could choose from 6 options (tick all that apply), including "To share progress," "To compete with friends," "To get encouragement from others," "To motivate others," "I didn't share my data," or "Other (please specify)."

Practical Issues

A total of 3 questions explored practical issues related to using WATs. Both current and former users were asked if they had any complaints about their WAT and were asked to select all that applied from a multiple choice question, with responses including "Technical issues," "It falls off," "It doesn't fit," "It is uncomfortable," "Lost it," "Low battery life," "General wear and tear," "It often doesn't match my outfit," "Problems with the screen," "Problems uploading the data to supporting software," "Problems interpreting the data," "Problems with navigation of supporting website and technology," "Inaccurate at recording data," and "Other (please specify)." Participants were asked to rate the extent to which they agreed their experience using a WAT had been positive. Finally, former users were asked to specify their reasons for discontinuing WAT use from a list including device malfunction, insufficient use, technical difficulties, unmet goals, personal dislike, psychological impacts, and others (open-ended).

Data Quality Checking

After data collection, signs of internet bot activity were detected in the MTurk responses, notably identical and nonsensical answers to open-ended questions (eg, responding "GOOD" to a question asking what brand and model of WAT they use). To ensure data integrity, we implemented quality-check processes as recommended by Griffin et al [25]. This involved removing responses with a Qualtrics reCAPTCHA score below 0.5, indicating a higher risk of bot activity (on a scale of 0-1, where 1.0 indicates a low risk of bots, and 0.0 indicates a high risk of bots [26,27]). Furthermore, responses completed unrealistically quickly (less than 5 minutes) were excluded, considering the average completion time was 17 minutes. In addition, responses with less than 5% survey completion were removed. These quality-check processes filtered out all the participants initially suspected of being nongenuine.

Analysis

Data were downloaded into SPSS (version 26; IBM Corp) for analysis. Categorical variables and ordinal variables were analyzed using the frequency of responses and percentages, while continuous variables were analyzed using medians, means, and ranges. Comparison between 2023 and 2016 WAT users were examined using chi-square tests, with an alpha of .05 used to denote statistical significance.

XSL•FO
RenderX

Ethical Considerations

Ethical approval for this cross-sectional, descriptive online survey study was provided by the University of South Australia Human Research Ethics Committee (204908). Data collection took place from February to May 2023. As per ethical requirements, the cover page of the survey contained detailed information about the study, and completion of the online survey was regarded as informed consent. Survey data were de-identified.

Results

Demographic Characteristics and WAT Usage

A total of 827 survey responses were received. However, 338 were excluded with suspected bot activity (reCAPTCHA scores below 0.5 [n=208] and responses completed in less than 5 minutes [n=130]), and a further 14 responses were excluded for having less than 5% of the survey completed. Consequently, the analytic sample comprised 475 participants (280 recruited through MTurk and 195 recruited through Facebook), with 387 (82%) current users and 88 (18%) former users, which is similar to the 2016 survey proportions of 84% (200/237) current and 16% (37/237) former users among 237 participants.

Table 1 presents the participants' characteristics. The majority (219/475, 46.1%) were aged 25-34 years, and 60.8% (289/475) were male. This contrasts with the 2016 survey, where the majority were aged 18-24 years (75/237, 33.8%), and a greater proportion (168/237, 70.9%) were female. The 2023 survey was international, with 62% (292/475) of respondents from the United States, 26% (122/475) from Australia, and 12% (61/475) from other countries including Albania, Armenia, and India. In contrast, the 2016 survey was national, with all participants from Australia.

Table 1. Demographic characteristics of participants.

Demographic characteristics	2023 survey (n=475), n (%)	2016 survey (n=237), n (%)	*P* value	Chi-square (*df*)
Gender			<.001	64.6 (2)
Male	289 (60.8)	69 (29.1)		
Female	185 (38.9)	168 (70.9)		
Nonbinary or third gender	1 (0.2)	—[a]		
Age (years)			<.001	47.8 (5)

Postgraduate degree (eg, Master's degree)	73 (15.4)	48 (20.3)		

[a]Not available.

The 2023 survey results showed that Apple (210/475, 44%) was the most popular WAT brand, followed by Fitbit (101/475, 21%), Garmin (92/475, 19%), Samsung (47/475, 10%), and other brands (22/475, 5%). This was a significant change from 2016, where Fitbit dominated (160/237, 68%), followed by Garmin (39/237, 17%), Apple (8/237, 3%), Samsung (4/237, 2%), and other brands (26/237, 11%; *P*<.0001). The primary method of acquisition in both years was purchase by the users themselves (2023: 232/475, 49%; 2016: 134/237, 57%) or as gifts from family members (2023: 136/475, 29%; 2016: 103/237, 44%).

In terms of usage duration, current 2023 users reported using their WATs for a median of 18 months, while former users had

XSL•FO
RenderX

used them for a median of 9 months. In 2016, current users had a median usage duration of 7 months, and former users had used theirs for 5 months.

When current users from the 2023 survey were asked how long they planned to use their WAT in the future, the most common response was “indefinitely” (82/475, 21%). Similarly, current users of the 2016 survey were also asked how long they planned to use their WATs; the most common response was >36 months, which was the maximum duration response option in that survey. Among former 2023 users, when asked if they would be inclined to ever use a WAT again, 45% (39/88) somewhat agreed, and 40% (34/88) were neutral.

Motivation and Behavior Change

In 2023, the most commonly cited motivations for using WATs were improving health (239/475, 50%), monitoring activities (221/475, 47%), and enhancing fitness (180/475, 38%; Table 2). The same 3 motivations were common in the 2016 survey, though in a different order, with 2016 participants prioritizing monitoring activity patterns (85/237, 36%), improving fitness (65/237, 27%), and improving health (43/237, 18%). Nearly one-third of 2023 respondents (147/475, 31%) reported improving their appearance as a motivation for using a WAT, compared with <1% in 2016. During analysis of the motivation data, we noticed that the 2023 survey allowed multiple responses for motivation, differing from the 2016 survey’s single-choice format. Given this discrepancy, direct comparisons using chi-square tests were not undertaken.

Table 2. Participant motivations for wearing a wearable activity tracker.

Primary motivation	2023 survey (N=475), n (%)	2016 survey (N=237), n (%)
To improve health	239 (50.3)	43 (18.1)
To monitor activities	221 (46.5)	85 (35.9)
To improve fitness	180 (37.9)	65 (27.4)
To improve appearance	147 (30.9)	2 (0.8)
To share my activity	126 (26.5)	—[a]
To compete with family or friends	60 (12.6)	7 (2.9)
To keep up with new technology	45 (9.5)	4 (1.7)
Other	15 (3.9)	15 (6.3)

[a]Not available.

Table 3 presents the comparison of participants’ ratings (percentage of participants responding somewhat agree or agree strongly) for the usefulness of various WAT metrics in 2023 versus 2016. Notably, the perceived usefulness of the step count feature significantly decreased from 94.5% (189/200) in 2016 to 65.9% (255/387) in 2023. Similar declines were seen in the perceived usefulness of activity minutes (151/200, 75.5% in 2016 to 252/387, 65.2% in 2023), and stairs climbed (115/200, 57.5% in 2016 to 189/387, 48.9% in 2023). Conversely, the usefulness rating for energy intake rose from 36% (72/200) in 2016 to 49.6% (192/387) in 2023. The heart rate feature also showed a nonsignificant trend for increased perceived usefulness, from 63% (126/200) in 2016 to 70.5% (273/387) in 2023. In fact, it was the top-rated useful feature in 2023. Ratings for sleep features fell slightly (232/387, 59.9% in 2023 vs 132/200, 66% in 2016) while energy burned remained fairly stable.

Table 3. Participant rating of usefulness of features (percentage reporting somewhat agree or agree strongly).

Feature	2023 survey (n=387), n (%)	2016 survey (n=200), n (%)	*P* value	Chi-square (*df*)
Heart rate	273 (70.5)	126 (63)	.06	3.4 (1)
Steps	255 (65.9)	189 (94.5)	<.001	58.5 (1)
Active minutes	252 (65.2)	151 (75.5)	.01	6.6 (1)
Sleep	232 (59.9)	132 (66)	<.001	16.6 (1)
Energy burned	227 (58.6)	113 (56.5)	.61	0.09 (1)
Energy consumed	192 (49.6)	72 (36)	<.001	9.8 (1)
Stairs	189 (48.9)	115 (57.5)	.04	3.9 (1)

Current WAT users in 2023 generally agreed on the usefulness of updated WAT features, with high ratings for workouts (290/387, 75% somewhat or strongly agree), device connectivity (263/387, 68%), receiving calls or text messages (249/387, 64%), contactless payment (200/387, 52%), calendar reminders (214/387, 55%), data sharing (193/387, 50%), and meditation (193/387, 50%).

Respondents were asked their opinions on the usefulness of real-time monitoring and long-term monitoring features. While the majority of 2023 participants somewhat or strongly agreed

XSL•FO
RenderX

that both real-time monitoring and long-term monitoring were useful (57% and 58% agreement, respectively), the agreement ratings have fallen since 2016, when the ratings for real-time and long-term monitoring were 84% and 72% agreement, respectively.

Participants were asked whether they had changed their lifestyle behaviors as a result of using a WAT (Table 4). In both the 2023 and 2016 surveys, physical activity was the behavior respondents were most likely to report having changed due to their WAT. However, there was a slight reduction over time in the perceived impact of WATs on enhancing physical activity, from 77% (182/237) agreement in 2016 to 63% (300/475) agreement in 2023. In contrast, the perceived positive impact on diet increased from 36% (85/237) in 2016 to 51% (244/475) in 2023. Similarly, the percentage of participants who felt their sleep improved due to using a WAT rose from 22% (52/237) in 2016 to 42% (200/475) in 2023.

Table 4. Perceived change in lifestyle behaviors since using a wearable activity tracker (percentage reporting somewhat agree or agree strongly).

Activity	2023 survey (n=475), n (%)	2016 survey (n=237), n (%)	*P* value	Chi-square (*df*)
Physical activity	300 (63)	182 (77)	<.001	13.4 (1)
Diet	244 (51)	85 (36)	<.001	15.2 (1)
Sleep	200 (42)	52 (22)	<.001	28.1 (1)

Social Features and Data Sharing

There has been a marked increase in the use of social media platforms for sharing WAT data (Table 5). In 2023, Instagram was used most by 44% (171/387) of participants, a sharp rise from just 1% (2/200) in 2016. Facebook and Twitter saw similar surges, with 36% (141/387) using Facebook (up from 7/200, 4% in 2016) and 35% (134/387) using Twitter (up from 1/200, 1% in 2016). All these increases were statistically significant. Conversely, the proportion of participants not sharing their activity data dropped significantly from 65% (130/200) in 2016 to 27% (104/387) in 2023.

The motivations behind sharing data have also evolved. In 2023, common reasons included sharing progress (145/387, 38%, up from 18/200, 9% in 2016), receiving encouragement (137/387, 35%, up from 13/200, 7% in 2016), and motivating others (138/387, 36%, up from 17/200, 8.5% in 2016). Competing with friends was noted by 35% (134/387) in 2023, a significant increase from 17% (33/200) in 2016.

Table 5. Sharing platforms and reasons for sharing data[a].

	2023 survey (n=387), n (%)	2016 survey (n=200), n (%)	*P* value	Chi-square (*df*)
Sharing platform				
Instagram	171 (44.1)	2 (1)	<.001	118.3 (1)
Facebook	141 (36.4)	7 (3.5)	<.001	75.8 (1)
Twitter	134 (34.6)	1 (0.5)	<.001	125.8 (1)

To share progress	145 (37.5)	18 (9)	<.001	53.2 (1)
To get encouragement from others	137 (35.4)	13 (6.5)	<.001	57.8 (1)
To motivate others	138 (35.6)	17 (8.5)	<.001	50 (1)
To compete with friends	134 (34.6)	33 (16.5)	<.001	21.2 (1)
I don’t share data	104 (26.9)	154 (77)	<.001	78.6 (1)
Other (please specify)	7 (1.8)	4 (2)	.87	0.2 (1)

[a]Participants were allowed to select multiple responses, and percentages reflect the number of participants who selected each response option as a portion of all participants in that survey sample.

Technical Issues and Barriers

The majority of 2023 respondents agreed that they had an overall positive experience using their WAT (322/475, 68% somewhat agree or agree strongly), though this was a decrease compared with 2016 when 212 of 237 (89%) reported an overall positive experience (χ^2_1= 36.2; *P*<.001). The most common complaints in 2023 were short battery life (reported by 201/475, 21% of participants), technical issues (cited by 91/475, 19%), and general wear and tear (mentioned by 86/475, 18%; Table 6). Generally, 2023 participants appeared to report slightly more

XSL•FO
RenderX

complaints than 2016 respondents. In contrast to this trend, problems with data uploading and inaccurate data recording have decreased slightly over time, from 19% (45/237) in 2016 to 10% (47/475) in 2023, and from 17% (39/237) in 2016 to 7% (32/475) in 2023, respectively.

Table 6. Complaints about wearable activity tracker (WAT)[a].

Complaint	2023 survey (n=475), n (%)	2016 survey (n=237), n (%)	*P* value	Chi-square (*df*)
None	162 (34.1)	71 (30)	.26	1.2 (1)
Short battery life	102 (21.4)	48 (20)	.7	0.1 (1)
Technical issues	91 (19.1)	29 (12.2)	.02	5.4 (1)
General wear and tear	86 (18.1)	32 (13.5)	.11	2.4 (1)
It was or is uncomfortable	77 (16.2)	20 (8.4)	<.01	8.1 (1)
It fell or falls off	75 (15.7)	17 (7.2)	<.001	10.4 (1)
It didn't or doesn't fit	71 (14.9)	—[b]	<.001	39.3 (1)
It often didn't or doesn't match my outfit	64 (13.5)	44 (18.6)	.07	3.1 (1)
Problems with the screen	58 (12.2)	10 (4.2)	<.001	11.6 (1)
Lost it	47 (9.9)	5 (2.1)	<.001	14.1 (1)
Problems uploading the data to supporting software	47 (9.9)	45 (19)	<.001	11.6 (1)
Problems interpreting the data	41 (8.6)	10 (4.2)	.03	4.6 (1)
Problems with navigation of supporting website and technology	35 (7.4)	16 (6.8)	.76	0.9 (1)
Inaccurate at recording data	32 (6.7)	39 (16.5)	<.001	16.6 (1)
Other (please specify)	21 (4.4)	27 (11.4)	<.001	12.2 (1)

[a]Participants were allowed to select multiple responses, and percentages reflect the number of participants who selected each response option as a portion of all participants in that survey sample.

[b]Not available.

Former users were asked to identify why they no longer used their WAT (Table 7). Among former WAT users in the 2023 survey, the main reasons for ceasing use were that their WAT was broken (29/88, 33%), they did not like it (22/88, 25%), or that it was lost (15/88, 17%), difficult to understand (15/88, 17%), or technical difficulties (15/88, 17%). This was different from the 2016 survey, where the main reasons former users ceased using their WATs were that they felt they had learned everything they could from their WAT (11/37, 30%), their WAT was broken (8/37, 22%), or their WAT was not helping them achieve their goals (5/37, 14%). The findings appear to indicate a shift in why users discontinue WAT usage, with increasing reports of disliking the device (up from 2/37, 5% in 2016 to 22/88, 25% in 2023) and understanding difficulties (up to 2/37, 5% in 2016 to 15/88, 17% in 2023), and fewer users stopping because they felt they had learned all they could from the device (down from 11/37, 30% in 2016 to 5/88, 6% in 2023).

Discussion

Principal Findings

This study set out to explore changes in user experiences, preferences, and perceived impacts of WATs from 2016 to 2023. We found significant shifts in brand preferences, with Apple overtaking Fitbit as the most popular WAT brand by 2023. The study found that, in general, WATs are now being used for a longer period compared with the previous survey. The sharing of WAT data on social media platforms has surged, indicating a greater integration of these devices into social connectivity and community engagement. While there was a decrease in the perceived effectiveness of WATs in enhancing physical activity, users reported increased positive impacts on diet and sleep management. However, this was tempered by increased complaints about technical issues and discomfort, as well as a decline in overall positive user experience with WATs. In addition, we observed a shift in reasons for discontinuing WAT use, with more users in 2023 ceasing usage due to dissatisfaction with the device or its complexity. Possible reasons for the key differences between responses in 2016 and responses in 2023 (P<.001) are summarized in Multimedia Appendix 2 and further discussed below.

The majority of current users in the 2023 survey reported that they had worn their WAT for a median duration of 18 months and were planning on using their WATs indefinitely. This was significantly greater than that of users in 2016, who reported that they had worn their WATs for 7 months and were planning on using them for >3 years. This is likely due to WATs having existed for a longer period, with more metrics and features available, potentially increasing appeal and, therefore, long-term usage. Most former users in 2023 wore their WATs for a median duration of 9 months, with just over one-third reporting that their device breaking was their main reason for ceasing use. These findings confirm evidence that suggests WATs are often abandoned due to technical malfunctions, including broken WATs or battery issues [28]. In contrast, former users of the 2016 survey reported that they had worn their WAT for a median duration of 5 months, with the main reason for ceasing use being that they had learned everything they could. It is possible that enhancements in WATs over time, such as improved health monitoring capabilities and integration with smartphones, have increased the perceived value of the devices and made them more valuable in people's lives [18]. These findings suggest that continuous innovation in WAT features may play a crucial role in sustaining user interest and reducing disinterest or apathy over time.

Despite the increase in duration of use, fewer users in 2023 reported having a positive experience with their WAT than in 2016, and in general, reported a greater number of complaints. Short battery life was the most reported complaint in both 2016 and 2023, which remains consistent with research that suggests battery capacity is one of the main user complaints and reasons for abandonment [29]. In addition, complaints such as technical issues, wear and tear, comfort, the WAT falling off, problems with the screen, and the ability to interpret the data were more commonly reported in 2023. This increase in complaints seems counterintuitive, given that WATs are now more advanced with more features. Rising expectations may be behind this–as WATs have become more advanced, user expectations might have risen correspondingly, leading users to be more critical of their devices. An alternative explanation is that the inclusion of more features can make WATs more complex to use. This complexity might lead to frustrations, especially among users who prefer simpler, more intuitive interfaces. More advanced devices that offer enhanced features may also explain a shift in user preferences for Apple WATs, with features like call and text, smart pay, and safety functions easily integrated into users' Apple technology ecosystems.

Whilst WATs track various health behaviors like physical activity, diet, and sleep, physical activity remained the most monitored behavior in both the 2016 and 2023 surveys. It was

XSL•FO
RenderX

also the behavior most frequently reported as improved due to WAT use, consistent with research highlighting WAT's effectiveness in increasing physical activity across different populations [14]. In 2023, there was an increase in perceived change in diet and sleep since using a WAT, suggesting that WATs have the potential to influence a range of lifestyle behaviors, and users may benefit more from the advanced features included in more recent models.

Interestingly, although the perceived change in diet and sleep since using a WAT increased between 2016 and 2023, and the perceived usefulness of energy consumed also increased, sleep was considered less useful in 2023. Heart rate monitoring was considered the most useful feature in 2023, a shift from 2016 when step count was rated highest. These findings may reflect the increased popularity of fitness activities emphasizing heart rate, such as high-intensity interval training, or other activities that do not record steps, such as strength training. Previous research suggests that resting and exercise-related heart rate measures are considered useful as they provide noninvasive and time-efficient insights into aerobic fitness, recovery, and performance [30]. This trend in the evolving usage of WATs, with a focus on heart rate monitoring over steps, suggests a broader shift in user health priorities and fitness trends, mirroring the advancements in wearable technology and its increased capability to provide detailed, fitness-specific metrics that cater to modern exercise regimens and health awareness.

Participants in the 2023 survey were notably more inclined to share data on mainstream social networks like Instagram, Facebook, and Twitter, a change from the 2016 survey. This shift contrasts with earlier research suggesting a preference for sharing on niche physical activity social networks [31,32]. This increase in sharing on broader platforms may be attributed, at least in part, to a continued increase in social media usage from 2.73 billion users in 2017 to 4.59 billion users in 2023 [33]. In particular, Instagram has a strong fitness subculture [34]. The rise of fitness influencers and communities on these platforms may also encourage users to share their data more openly. In addition, there seems to be an evolving perception of sharing fitness data, now viewed as a motivational and supportive tool, possibly amplified by the COVID-19 pandemic's push for social connectedness during periods of isolation [35].

Strengths and Limitations

This study has several strengths. First, the longitudinal, cross-sectional design allowed us to compare WAT user experience from 2016 to 2023, offering a valuable perspective on the evolution of user preferences and practices over time. The 2023 study attracted a large and diverse sample, enhancing the generalizability of our findings. We considered the perspectives of both current and former WAT users and examined various facets of WAT usage, including brand preference, feature utility, motivations, social sharing behaviors, and technical issues. In addition, our study was rigorous in its methodology, using an existing survey tool, conducting test-retest analysis, and implementing extensive data quality checks.

Limitations must also be acknowledged. As a survey, data are self-reported, which introduces the possibility of biases as participants may over or underestimate their usage or satisfaction with their WATs due to factors such as factors such as misremembering past experience, social desirability, or acquiescence. Nonresponse bias could also be present. Response options for the item "How long did you use your wearable?" differed between the 2016 and 2023 surveys, which may have introduced some bias. Although the sample was large and diverse, the findings may not be entirely generalizable to all WAT users, especially those in different geographical locations or demographic groups not adequately represented in the sample. There was a very low representation of older adults in both the 2016 and 2023 surveys. This differs from other studies, where older adults are among the most studied groups for acceptability studies. This discrepancy may be explained by our recruitment methods, which utilized social media and MTurk to recruit existing users of WATs. These platforms potentially reach younger and middle-aged adults more readily than older adults. In contrast, many evaluations of mHealth acceptability in older adults are linked to interventional studies where devices are provided directly to participants by researchers. This approach might better engage older adults, who may be less likely to participate in online surveys but more receptive to direct intervention studies. In addition, there were some demographic differences between the survey years that could have impacted the findings. For example, the 2023 survey involved an international sample, whereas the 2016 survey involved only Australians. The 2023 survey also had proportionally more males than the 2016 survey. The use of multivariable analysis methods would have enabled examination of the effects of these cohort differences but was not possible due to the unavailability of the individual-level data from the 2016 survey. We conducted our analyses using the summary data available, which still offers valuable insights into the trends and changes over time. Another limitation of the study includes the presence of numerous internet bots from MTurk that had completed the 2023 survey. Although we conducted data quality checking, concerns have been raised about MTurk, including self-misrepresentation, self-selection bias, English language fluency, and inattention, which may impact a study's validity [36].

Implications for Research and Practice

A key overall finding in this study is that the use of WATs is shifting—including a shift in brand preference toward Apple, a shift in the metrics valued by users away from simple physical activity monitoring features, and toward more detailed metrics such as heart rate tracking, diet, and sleep tracking. People are also sharing their data differently, with increased sharing of WAT data on social media platforms like Instagram. These findings could inform behavioral health interventions. Health promotion researchers might consider integrating WATs into health promotion and disease prevention strategies, given their potential to positively influence lifestyle behaviors. There is also the potential for including sedentary behavior as a metric for users to track, given its importance for health and inclusion in physical activity guidelines. In addition, if patients are willing to discuss their WAT information with health professionals, there is the potential for integrating WATs into health care, providing insights into how different activities and behaviors affect health and well-being and facilitating shared goal setting

XSL•FO
RenderX

and monitoring. However, researchers and health professionals seeking to use WATs with research participants and patients should be cognizant of the common usability complaints, such as battery life and ease of use, since these aspects may be crucial in the long-term adherence to WAT-based programs.

Future research should look to examine WAT user preferences and practices with diverse populations, including different age groups, geographical locations, and health statuses, to provide a more comprehensive understanding of WAT usage patterns and preferences across a broader demographic. In addition, given the recent increase in sharing WAT data on social media between 2016 and 2023, studies investigating the psychological and behavioral impacts of sharing WAT data on social media platforms would be valuable. Research could explore how social sharing influences motivation, behavior change, and community building in the context of health and fitness. Such findings could influence the development of interventions incorporating the use of WATs for healthy lifestyle behaviors. In addition, given the increase in complaints about technical issues and device comfort, research focusing on user interface design and ergonomic improvements in WATs could be beneficial. This would need to be done in partnership with WAT manufacturers to inform future product development.

Implications for WAT Design

Our study highlights several key insights that are highly relevant for companies involved in the design and development of WATs. The most common complaint from users at both time points was short battery life. Manufacturers should prioritize advancements in battery technology to extend the life of WATs between charges to enhance user satisfaction and device adherence. In addition, more users in 2023 reported discomfort and issues with the fit of their devices than in 2016. This could be due to increased battery size or change in device shape due to, for example, the addition of heart rate monitors in more models. Companies should focus on ergonomic designs that offer better comfort for long-term wear, such as adjustable bands, lightweight materials, and options for different wrist sizes.

Technical reliability also emerged as a crucial area for improvement. Although less common in 2023 than in 2016, users frequently mentioned issues with data accuracy and connectivity problems. Improving the reliability and accuracy of WAT sensors and ensuring seamless connectivity with other devices are essential for maintaining user trust and encouraging continued usage. Furthermore, the shift in user preference toward advanced health metrics like heart rate monitoring over basic step counts indicates that users are seeking more sophisticated health insights. Companies should continue to develop and highlight features that provide deeper health analytics, such as heart rate variability, stress levels, and sleep quality.

To address these needs effectively, manufacturers should invest in user education and support. Providing comprehensive tutorials, user guides, and customer support can help mitigate issues related to device complexity and usability, enabling users to understand and make the most of their WAT features. By addressing key areas such as battery life, comfort, technical reliability, and advanced health metrics, companies can enhance the user experience and ensure long-term device adoption, positioning WATs as valuable tools for health and fitness.

Conclusions

In conclusion, this study has provided insights into the evolving landscape of WAT usage from 2016 to 2023. The shift in brand preference toward Apple and the longer usage duration indicate a maturing market and evolving user needs. Notably, the surge in sharing WAT data on platforms like Instagram highlights the increasing social aspect of health monitoring. However, despite technological advancements, the rise in user complaints and the shift in reasons for discontinuation emphasize the need for improvements in WAT design and functionality. These trends underscore the growing importance of integrating sophisticated health metrics such as heart rate monitoring, which aligns with the rising popularity of specific fitness activities and a broader shift in health and wellness culture. As WATs become more embedded in users' daily lives, their role in health promotion and behavioral change becomes increasingly significant. Future research should continue to explore these dynamics, particularly focusing on diverse populations and the psychological impacts of social sharing, to further understand and optimize the potential of WATs in supporting users' health and well-being.

Abstract

Background: The emergence of eHealth services could contribute to improving individuals' quality of life by optimizing effective and efficient care. However, various challenges might limit some older adults' use of eHealth services.

Objective: This study aimed to understand the perspectives of older adults (aged ≥65 years) of different backgrounds regarding eHealth services. We explored the experiences of Iranian immigrant and nonimmigrant older adults with eHealth services to identify their perceived challenges, emotions, and wishes. Immigrants face more challenges, and there is a need to understand their perspectives in addition to those of nonimmigrants. Iranians are one important immigrant group, as their number is limited and their specific needs are less well understood compared to those of the bigger immigrant groups.

Methods: This study used a qualitative explorative research design. Semistructured interviews were conducted between February 2023 and May 2023. The participants were 25 older adults: nonimmigrants residing in cities (n=8, 32%), nonimmigrants residing in rural areas (n=9, 36%), and Iranian immigrants residing in cities (n=8, 32%). Data were analyzed through inductive and deductive content analysis and interpreted through self-determination theory.

Results: Interacting with eHealth services was challenging for some older adults. They perceived several difficulties, with the most obvious ones being related to values and preferences, as some older adults did not value eHealth services (16/25, 64%), had insufficient digital skills (15/25, 60%), and experienced usability issues (15/25, 60%). The first two challenges were more pronounced among immigrants. In contrast, nonimmigrants from cities, being more familiar with the services, shared more usability issues. These identified challenges prevented older adults from satisfying their basic psychological needs of being competent and autonomous users and having a sense of belonging (aspects of self-determination theory), which were the main source of negative emotions. A common negative feeling was confusion (16/25, 64%) among those with limited experience using smart devices and those with poor self-reported digital skills. Conversely, older adults' interaction with eHealth services generated positive emotions that were connected to the satisfaction of their basic psychological needs. Being interested in using eHealth services was a common feeling among most participants regardless of their background and was connected to satisfying their need for being competent and autonomous. The positive emotions could be supported by applying older adults' needs to the design of eHealth services (10/25, 40%) and by supporting their digital skills (19/25, 76%).

Conclusions: Some older adults value eHealth services and see their added benefits. However, various challenges limit their use of these services. The analysis of older adults' needs yielded several practical ideas that could improve the user-friendliness of the services and highlighted the importance of sufficient support services tailored to the cultural needs of specific groups of older adults.

eHealth services; older adults; immigrant; usability; user experience; emotion; self-determination theory

Introduction

Background

The growing number of older adults is a significant socioeconomic trend [1]. Over the next 3 decades, the number of older adults—individuals aged ≥65 years—is projected to double [2]. The proportion of older adults in Europe will reach 35% in 2050 [3]. As people age, they may become more susceptible to different diseases, leading to high demand for health care services [4]. However, several barriers limit some older adults from properly managing their health conditions using traditional health care services. These include reduced mobility [5] and residing in rural locations with limited access to physical health care facilities [6]. Furthermore, the number of physical health care facilities is limited and does not match growing needs [7].

To overcome such barriers, digital solutions have been mobilized to deliver eHealth services [8,9], which are defined as "the use of information and communication technologies for health" [10]. eHealth services are transformative solutions in the context of demographic aging, urban normativity, and austerity politics as they aim to enhance health care quality and equality, especially for people in sparsely populated areas [11].

The use of eHealth services can be expected to facilitate communication with health care providers [8] and allow older adults to control their health status at their own pace as they can read their medical records on electronic patient portals [12]. Furthermore, eHealth services could be useful in supporting and managing a healthy diet and lifestyle among older adults [13]. Moreover, eHealth has proven useful in promoting medication adherence as well as effective in preventing disease among older adults [14]. For example, using mobile health can potentially improve health outcomes among older adults with chronic diseases by supporting symptom control [15]. Mobile health refers to the use of mobile phones and other wireless technology for medical purposes, which is a recent technological evolution in eHealth [16].

Despite these benefits, several difficulties hinder some older adults from fully using eHealth services. For example, older adults with limited financial resources might have limited access to smart devices or the internet [17]. Furthermore, some older adults might lack the proper digital skills to use smart devices or e-services [18] and might not be confident in using technology for critical issues such as health [17]. Security issues and privacy concerns are recognized as factors that limit older adults' willingness to use eHealth services [19,20].

Moreover, these services are often designed without considering older adults' specific features, such as physical difficulties or low digital skills [21]. Thus, older adults might face several usability issues, such as navigation difficulties [22]. Usability is defined by the International Organization for Standardization 9241-11 standard as the "extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [23]. In addition, immigrant older adults might face more barriers that are related to their backgrounds, such as lower socioeconomic status, low language proficiency, and comparatively lower levels of social inclusion [24]. The perceived difficulties might lead to negative emotions [25,26], lack of interest, and unequal use of eHealth services among older adults, which might increase the risk of inequities and social exclusion [27].

Finland is a very high-income country with advanced health policy programs that ensure citizens' well-being [28]. To support equal access to public health services, Finnish law supports the provision of e-services to promote the availability, quality, security, and equality of eHealth services for everyone [29]. However, inequalities still exist, especially among vulnerable groups such as older adults and immigrants [17].

To achieve a socially sustainable society in which everyone is treated equally and individuals' health and functional capacity are supported, it is necessary for people to have a high capability to take responsible action for their health. This can be supported by, for example, tackling the challenges that older adults face in the use of eHealth services and involving older adults from different backgrounds and their specific needs in the design process and delivery strategies of these services [30-32]. This study aimed to understand the perspectives of older adults (aged ≥65 years) from different backgrounds regarding eHealth services to identify their challenges, emotions, and wishes. Achieving this aim could result in ideas for improving the usability of eHealth services for older adults with different backgrounds, generating positive emotions regarding eHealth services among older adults, and encouraging them to use these services.

To achieve the aim of this study, a qualitative analysis of immigrant and nonimmigrant older adults' experiences with eHealth services was conducted to uncover the challenges they might face, identify the sources of their perceived feelings, and find out their wishes regarding these services. To focus more deeply and consider individuals' basic psychological needs, this study applied self-determination theory (SDT) to interpret the findings and answer the research questions. SDT is a psychological framework that explains the mechanisms through which individuals develop the ability and motivation to take active roles in various behaviors, such as health care [33].

Theoretical Framework

SDT suggests 3 basic psychological needs for individuals' motivation, behavior, and well-being: autonomy, competence, and relatedness [33]. Autonomy refers to self-endorsed reasons and intrinsic motivations, such as enjoyment or perceived benefits, and alignment with one's core goals for behavioral engagement. Competence refers to a feeling of having the ability and efficacy for development, learning, and expertise. Relatedness is defined as a sense of belonging and having connections with others [31].

XSL•FO
RenderX

SDT can explain support for older adults' motivation to use eHealth services [34]. Regarding autonomy, eHealth services must provide meaningful choices [35]. According to the concept of competence, older adults must feel able to attain better health outcomes by using eHealth services [36], and the complexity of the services should be appropriate for them [31]. Relatedness refers to fostering meaningful relationships with peers and clinicians, such as being in a short feedback loop with health care providers [37].

SDT has been frequently applied to eHealth adoption [38,39]. For instance, Yuen et al [38] found that individuals' eHealth adoption is affected by their emotions. The 3 constructs of SDT significantly impact emotions, and emotions are known to act as one of the main sources of human motivation [40]. To elaborate, individuals experience heightened positive emotions when they perceive a sense of control over their circumstances, possess the requisite skills and knowledge to engage proficiently with eHealth services, and feel a strong connection with and care for others [33].

Research Questions

To achieve the aim of this study, we formulated 3 research questions. The questions explore perspectives of immigrant and nonimmigrant older adults (aged ≥65 years) regarding eHealth services, focusing on their challenges, emotions, and wishes through the lens of SDT. Identifying challenges helps understand barriers preventing older adults from using eHealth services. Recognizing their wishes reveals their needs and expectations. Designing eHealth services based on wishes increases the likelihood of use. Furthermore, by addressing emotions, it is possible to foster positive feelings and encourage greater adoption among older adults. The research questions are as follows: (1) What challenges do older adults face in using eHealth services? (2) What emotions do older adults have regarding eHealth services? (3) What wishes do older adults have regarding eHealth services?

Methods

Study Design

This was an explorative qualitative study based on semistructured interviews with 25 older adults aged ≥65 years conducted between February 2023 and May 2023. This study is part of the DigiIN project and was carried out to generate solutions to ensure that social welfare and health care provided via eHealth services are available and accessible to everyone equally and that everyone can use these services. Therefore, we assessed experiences, feelings, and expectations regarding eHealth services among older adults from different backgrounds in Finland.

We selected participants from different backgrounds: nonimmigrant older adults from cities and rural areas and Iranian immigrants residing in cities. The rationale for this selection was to explore and compare the perspectives of different vulnerable groups. Immigrants face more challenges, and there is a need to understand their perspectives in addition to those of nonimmigrants. In addition, compared to the largest immigrant groups in Finland, Iranians are fewer, which limits their access to similar levels of public and peer support to those available for larger groups. Being fewer, their specific needs are likely to be less well understood within the health care system. Therefore, these individuals are one of the key vulnerable groups as per the major demographic change in Western societies [41].

To maintain a balance in participant recruitment based on their living areas, we aimed to recruit Iranian immigrants and nonimmigrants from rural and urban areas. However, this effort was unsuccessful, and we could not recruit immigrant participants from rural areas. We discovered that most immigrants reside in urban areas. This trend is influenced by Finland's immigration policies and the personal preferences of immigrants.

We used a semistructured interview guide designed for this study by the main researcher and revised with the coauthors (Multimedia Appendix 1). This qualitative study was conducted and reported following the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines where applicable [42] (Multimedia Appendix 2).

Study Setting and Participant Recruitment

We applied the convenience sampling method to recruit the participants. People were eligible if they (1) were aged ≥65 years; (2) were originally from Finland or Iran; and (3) could read and write in Finnish, Swedish, English, or Persian. We excluded people with dementia; those who were too frail or ill; and those who were in active care, such as in hospitals or older adult centers, to reduce possible risks.

We recruited older adults from nonprofit organizations in the Turku and Helsinki regions, including the Turun Seudun Vanhustuki ry (Turku Region Elderly Support Association), Enter Association, Valli Association, and Varissuo Library. These organizations support diversity, inclusion, and the digital empowerment of older adults while fostering intergenerational collaboration. They organize various events and workshops for older adults, giving them access to a broad network within this demographic.

Multiple strategies were used to recruit participants. First, the first author attended events at the aforementioned organizations and directly invited potential participants. Second, the organizations promoted the study to target groups during events, through informal interactions with older adults visiting their facilities, or via social media platforms. Finally, the organizations reached out to potential participants directly to promote the study.

Interested older adults contacted the first author, or the organizations delivered their contact information to her with their permission. The first author then called everyone and inquired about their interest in participating and agreed on the interview time and place. One of the older adults, who was initially interested in participating, did not answer their phone, and 2 refused to participate because of personal issues.

This study included 25 participants, comprising nonimmigrants residing in cities (n=8, 32%), nonimmigrants residing in rural areas (n=9, 36%), and Iranian immigrants residing in cities (n=8,

XSL•FO
RenderX

32%). Most participants were female (17/25, 68%). In total, 56% (14/25) of the participants were aged 65 to 75 years, whereas the remaining 44% (11/25) were aged >75 years. The participants had diverse educational backgrounds: elementary education (5/25, 20%), upper secondary education (1/25, 4%), vocational education (7/25, 28%), and higher education (13/25, 52%). In addition, 6 participants had medical education: 5 (83%) were nonimmigrants, and 1 (17%) had an immigrant background.

Collecting Data

To collect data, we used the designed semistructured interview guide. We collected information about the participants' backgrounds, including their age, gender, and educational level. Moreover, we asked questions about participants' experiences with eHealth services, including whether they perceived any benefits or reasons for not benefiting. We also inquired about their emotions while interacting with these services and their suggestions for improving eHealth services.

We piloted the designed interview guide with 1 immigrant and 1 nonimmigrant older adult. As no major revisions were necessary, we included the pilot interviews in the study with participants' consent. All interviews with immigrant and nonimmigrant older adults from rural areas (17/25, 68%) were conducted over the phone. A total of 50% (4/8) of the interviews with nonimmigrant older adults in the cities were conducted on the web via Zoom (Zoom Video Communications), and the other 50% (4/8) were conducted face-to-face in the Turun Seudun Vanhustuki ry premises.

All interviews were conducted by the first author between February 2023 and May 2023. Participants were interviewed in their preferred languages: English, Swedish, Finnish, or Persian. The interviews were digitally audio recorded with the participants' permission. After each interview, the audio files were transcribed into text files and then deleted. All interviews were translated from Finnish, Swedish, and Persian into English for further analysis. We used transcription and translation services for transcribing and translating the recorded files, resulting in a total of 318 pages. The transcribed files and findings of the study were not revised by the participants.

The average length of the interviews was 35 (SD 8.54) minutes. We continued with the interviews until we reached the saturation point—when we had collected sufficient data to answer the research question or objective and data collection did not result in new analytic codes or themes [43].

Data Analysis

The data were analyzed using a combination of both inductive and deductive content analysis to understand the information domains better [44]. The combination of inductive and deductive content analysis is widely used across various research areas [17,45] and is considered the most realistic approach for incorporating theory and literature into the analysis [44]. To analyze the data, 3 iterative coding steps—reduction, grouping, and abstraction—proposed by Elo and Kyngäs [44] were applied.

The unit of analysis comprised a collection of ideas in which participants detailed the challenges they faced with eHealth services along with their emotions and wishes regarding these services. During the data reduction process, all researchers thoroughly read through the transcripts and used open coding to accurately summarize the set of ideas. All researchers had previous experience in qualitative research. The interview transcripts were then coded collaboratively by all the researchers. The codes were then grouped based on similarity and given descriptive names. These subcategories were reviewed by the main researcher, who further organized them into higher-level categories: challenges (n=7 main themes), emotions (n=2 main themes), and wishes (n=2 main themes). All subcategories were then linked to the 3 basic psychological needs based on SDT where applicable [33]. The ATLAS.ti software (version 24; ATLAS.ti Scientific Software Development GmbH) facilitated the analysis of the data.

Ethical Considerations

The Aalto University ethics review board granted the ethical permission to conduct this study (reference D/1220/03.04/2022). Participation was voluntary, and participants were informed of their right to withdraw from the study at any time without providing a reason. No previous relationships existed between the researchers of the study and the participants.

Before the interviews, we provided participants with oral information about the study, its aims, ethical processing, data collection, preservation of data, and reporting of results. To ensure that the participants were informed, we provided them with a written information sheet. Written informed consent was sought from all participants. Participants received the information in their preferred languages: English, Swedish, Finnish, or Persian.

We anonymized the data to protect the interviewees' information and stored them on a secure local server with strong password protection. All participants were offered a small thank-you gift. The gift was a water bottle provided by the DigiIN project valued at <€20 (US $20.90).

Results

Challenges of Using eHealth Services

Overview

The participants had different experiences with eHealth services. Some of those with medical education shared that they had no major issues using eHealth services for personal purposes, but the rest considered eHealth services challenging and reported several problems, explained in the following sections and summarized in Table 1. In the participant IDs, *C* refers to participants from cities, *R* refers to participants from rural areas, and *I* refers to Iranian immigrants.

[a]Not applicable.

Barriers Related to Values and Preferences

Some participants (16/25, 64%), even those with successful experiences using eHealth services, reported a preference for face-to-face visits or using eHealth services along with in-person visits, especially for important issues. The participants found it challenging to interact with health care providers and express their issues via web-based health platforms. Therefore, face-to-face visits were assumed to be more effective and reliable in reducing the risk of misdiagnosis. The communication-related challenges were stronger among immigrants because they missed the possibility of using translation services or body language during online visits:

> *When doctors visit, I feel they understand health problems better. Explaining health issues over the phone or via text is not enough; I might miss sharing some of the symptoms, or there might be misunderstandings. I don't want to end up eating the wrong medicines.* [R2]

Some participants reported that the use of eHealth services could decrease their human-based interactions in general, so they preferred to avoid it. They referred to their loneliness and noted that visiting health care providers, often due to their illness, was their main form of face-to-face interaction:

> *I am sick and can't go out alone. Going to hospitals is my only chance to be outdoors and meet people. If I use eHealth, I'll lose this chance.* [C4]

Some participants did not see the added value of eHealth services and, therefore, lacked interest in using them. They mentioned that these services did not match their needs or that identifying a suitable e-service required more time and energy than they could manage. They also noted that not all medical needs could be treated on the web, at least not for their generation.

Furthermore, some participants felt that eHealth services were designed for sick people. Given their self-identification as healthy individuals, they perceived such services as unnecessary and preferred not to use them. In addition, some immigrants noted their preferences for delegating their health care responsibilities to family members as they assumed themselves to be old and incapable of managing health issues, especially in their nonnative languages. In addition, they believed that, just as they had cared for their parents, their children should take care of them. Therefore, they did not feel the need to use eHealth services:

> *I don't know where to go or what to do. I don't even know the language very well. It is better if my kids handle things. When my mother was old and sick, I was taking care of her, and my kids are doing the same for me.* [I4]

Usability Issues

Some participants (15/25, 60%), especially nonimmigrants residing in cities, raised several usability issues. The primary usability concern was the intricate nature of these services and their improper interface design, which resulted in the overload of information, hidden information, and navigation difficulties. Participants reported several navigation challenges, including difficulty distinguishing between clickable and nonclickable elements in some health-related web pages:

> *On some pages, it's hard to know where to click, where not to click, or even when clicking is an option.* [R1]

The usability issues reported mainly concerned My Kanta, the Finnish national patient portal. Regarding complexity, the participants noted that the main page of My Kanta is overloaded with extra information, which makes it hard to find relevant information. They also added that clicking on certain elements on My Kanta often led to new pages overloaded with excessive details, which they found overwhelming:

> *I clicked on a link it opened another window with much information. Made it even more difficult to find what I need.* [R3]

Furthermore, some participants raised concerns about navigating back to the home page, stating that, after several clicks, they found it challenging to return to the home page quickly. Another important usability issue was related to the language. Immigrants said that their effective use of eHealth services was diminished by the lack of services in their native languages, whereas nonimmigrants considered medical or technical terminologies to be barriers to their efficient use.

Some participants, especially those with memory issues, reported that the log-in process to My Kanta was difficult and time-consuming. They also expressed frustration with being required to log in again due to session timeouts or opening another window.

Some nonimmigrants in cities also expressed discontent caused by the lack of functionality for leaving comments on or rectifying errors in physicians' notes on patient portals. This problem was said to limit users' autonomy in managing the trustworthiness of their information. In addition, participants reported feeling disconnected from health care providers. The same participants also shared that the lack of possibility to contact health care providers directly through My Kanta further contributed to this sense of disconnection:

XSL•FO
RenderX

> *I had an accident a few weeks ago and went to the hospital. A couple of days after my visit, I checked My Kanta to read the doctors' notes. There was false information, and I couldn't get rid of it or leave a comment on it. The note said that I had fainted when I went to the hospital, but I hadn't. With this wrong information, what's the point of using My Kanta then?* [C6]

Lack of Digital Skills

Some participants (15/25, 60%) reported challenges due to their lack of the adequate digital skills needed to use smart devices and the internet for critical issues such as health. The participants reported using smart devices and the internet to meet their daily needs, such as contacting their networks or using social media, but not for serious matters. They felt that using eHealth services required a high level of digital skills compared to using other e-services:

> *I have a smartphone, I call people, and I am active on Facebook, but I don't use digital health services. You must be good enough with computers to use them for health issues. I am not.* [R5]

Furthermore, some participants, especially immigrants, reported that their insufficient digital skills caused them difficulties navigating eHealth platforms. This perceived difficulty led to issues with finding information:

> *I can't find the information I need on My Kanta; I don't have skills for that.* [I3]

Some nonimmigrant participants expressed that their lack of adequate digital skills made it challenging to follow updates in eHealth services or health apps. They considered themselves slow adopters of technology. Moreover, 25% (2/8) of the immigrants reported having difficulties dealing with smart devices in general due to their lack of experience with technology-based tools.

Lack of Support

The lack of support was a prevalent concern among some participants (14/25, 56%). The lack of support, they said, could create the impression that these services are not intended for older adults, especially for those who are not capable of using smart devices. Some nonimmigrants cited a lack of family support. They either lacked a family member to turn to with their queries or hesitated to seek assistance believing that their family members could not satisfy their learning needs. Furthermore, nonimmigrants in cities mentioned that either they were unfamiliar with the available support or the available support did not satisfy their needs. Nonimmigrants in rural areas reported a lack of support close to their living areas, and immigrants noted a lack of support in their native languages.

Lack of Self-Efficacy

A total of 44% (11/25) of the participants reported a fear of making serious mistakes while using eHealth services. They were afraid that something irreversible might happen, leading to unwanted and unpleasant results with long-term consequences, such as the nonrenewal of prescriptions or the deletion of important information. They were worried and doubted their capabilities to manage the situation:

> *I use computers for writing emails or watching videos, but I never dare to use eHealth services alone. I don't want to make any mistakes or cause any problems. Not for me not for doctors.* [I2]

Furthermore, some immigrants, even those with a good understanding of the Finnish language, mentioned a lack of trust in their Finnish-language proficiency. This lack of trust prevented them from using the eHealth service in Finnish.

Health-Related Challenges

Health-related challenges such as memory or vision problems were common among 36% (9/25) of the participants and caused difficulties remembering log-in passwords, navigating, or using e-services on mobile phones with small screens. Some participants also mentioned that shaky hands caused difficulty holding phones or tablets or typing text.

Lack of Access to Digital Resources

Some participants shared basic challenges that prevented them from using eHealth services. For example, 25% (2/8) of the immigrants reported a lack of access to smart devices (eg, computers or smartphones) and the internet. In total, 62% (5/8) of the immigrants noted their lack of familiarity with the available eHealth services. However, the lack of general familiarity was only an issue among immigrant older adults. Participants from all groups mentioned a lack of familiarity with the functionalities and benefits of eHealth services:

> *I know about this Kanta; I have heard from my children. But I don't know what exactly it has for me.* [R6]

Moreover, 25% (2/8) of the immigrants and 11% (1/9) of the nonimmigrants in rural areas shared that they did not have a strong e-ID code, which is a prerequisite for using public e-services in Finland. Therefore, they could not use some e-services such as My Kanta.

Emotional Experiences Using eHealth Services

Overview

Participants' experiences with eHealth services generated positive and negative emotions, which are analyzed and summarized in Tables 2 and 3.

XSL•FO
RenderX

Table 2. Immigrant and nonimmigrant older adults' positive emotions regarding eHealth services in Finland and the links to the basic psychological needs introduced in self-determination theory (SDT).

Positive emotion	Definition	Link to SDT	Nonimmigrants in cities	Nonimmigrants in rural areas	Iranian immigrants
Trust	Feeling that eHealth services are safe, secure, and reliable	—[a]	✓	✓	✓
Interest	Willingness to learn how to use eHealth services as people understand their usefulness or consider them easy to use	Competence	✓	✓	✓
Interest	Willingness to use eHealth services as they offer meaningful choices to satisfy patients' needs and people feel that they have enough skills to use these services	Autonomy and competence	✓	✓	✓
Being empowered	Having more control over their health situation, making independent decisions, and being more involved in their health care management	Autonomy and competence	✓	✓	✓
Being less worried	Being less worried about their health condition	—	✓	✓	✓
Being connected	Being connected to health care providers	Relatedness	✓	✓	✓
Hope	Reduction in migration rate from rural areas for health care purposes and hoping to save their community	—		✓	
Peace of mind	Access to health care services in rural areas; freedom to live in their favorite places	Autonomy		✓	
Equality	Equal access to health care services in the country	—		✓	

[a]Not applicable.

Table 3. Immigrant and nonimmigrant older adults' negative emotions regarding eHealth services in Finland and the links to the basic psychological needs introduced in self-determination theory (SDT).

Negative emotion	Definition	Link to SDT	Nonimmigrants in cities	Nonimmigrants in rural areas	Iranian immigrants
Confusion	Dealing with the complicated interface design of eHealth services was confusing	Lack of competence	✓	✓	✓
Lack of interest	Not willing to use eHealth services as they are complex and the use of such services could limit in-person interactions with health care providers	Lack of competence and lack of relatedness	✓	✓	✓
Lack of interest	Not willing to learn how to use eHealth services for different reasons, such as being old and incapable of learning	Lack of competence	✓	✓	✓
Frustration	Feeling frustrated with learning and using complex eHealth services	Lack of competence	✓	✓	✓
Stress	Feeling stress when using complex eHealth services	Lack of competence	✓	✓	
Dependency and shame	Feeling shame of being dependent on others and asking questions even regarding simple issues	Lack of autonomy and lack of competence	✓	✓	✓
Use by force	Feelings of being forced to use eHealth services	Lack of autonomy	✓	✓	
Alienation	Feelings of being excluded due to lack of services in their native languages	Lack of relatedness			✓
Disconnection	Lack of direct connection with health care providers via My Kanta to discuss recorded notes	Lack of relatedness	✓	✓	

Positive Emotions

Our participants shared several positive emotions. Most (19/25, 76%) expressed a prominent level of trust in eHealth services in Finland and the security of their online medical records. This was attributed to trust in the authorities and the Finnish government:

> *I believe that the Finnish government is taking care of the security of our health data.* [C2]

Some participants (13/25, 52%) reported an interest in learning about and using eHealth services. They found the services easy to understand and use. The nonimmigrant participants attributed eHealth services' perceived ease of use to their previous experience with computers and the internet. In addition, 47% (8/17) of the nonimmigrants found the services useful and appreciated the convenience and time savings they offered. They believed that these services provided meaningful options to satisfy different health-related needs, for example, booking appointments or adhering to the treatment process:

> *I like these digital health services; they help me a lot. I have an app on my phone that reminds me to take my medications. Without the app, I might miss to take my pills. Or...this hospital app that I use [Terveystalo], I text doctors. The same app helps me book appointments.* [C2]

The immigrant participants also shared their interest in learning about and using the services but without giving any specific reasons. However, some of them expressed interest in learning

XSL•FO
RenderX

about and using these services after we provided them with information on their usefulness.

Some participants (9/25, 36%) reported feeling empowered by using eHealth services for different reasons. First, they said that having access to their medical records enabled them to control their health situation, such as renewing prescriptions and making informed decisions such as booking or canceling an appointment:

> *By using My Kanta, I control my medicines and renew my prescriptions if I need them. I read my lab results or doctors' notes carefully, then I decide to book or cancel an appointment. And sometimes, I prepare some questions to ask in my visits based on my medical records.* [R1]

Second, some participants described feeling empowered by the possibility of contacting health care providers at any time through the chat option. This functionality allowed them to be more actively involved in managing their health care.

Furthermore, 36% (9/25) of the participants found that access to their medical records helped them enhance their understanding of their health status and reduced their worries. Some participants, especially those living far from physical health care facilities, reported positive feelings about being connected to health care providers via chat or phone calls. Nonimmigrants in rural areas shared 3 positive feelings: equality in terms of using health care services in the country, hope that the use of eHealth services could save their community by reducing the migration rate from rural to urban areas for health care purposes, and peace of mind to live alone in rural areas due to access to eHealth services from their home. The availability of eHealth services was said to offer the autonomy to choose preferred living arrangements:

> *I live in an archipelago alone, far from hospitals. I have appointments with doctors online when the issue is not urgent. I don't need to travel to cities for that reason. People used to move to cities when they were old or sick, but nowadays it is possible to do things online and live in archipelagos, at home.* [R4]

Negative Emotions

Our participants reported several negative emotions regarding eHealth services, with confusion being the most frequently mentioned. A total of 64% (16/25) of the participants, especially those with limited experience using smart devices and those with poor self-reported digital skills, reported that the interface design of eHealth services was complex and confused them, at least in their first experience:

> *In my first experiences with My Kanta, I found it very complex and confusing. I had no idea where the information was or what to do. It is still confusing but not like the first time.* [C6]

The complexity of the services made some participants (7/25, 28%) feel that these services were not designed for people of their age and could not satisfy their needs. Thus, they did not like to interact with such services. In addition, they were afraid of missing in-person interactions with health care providers. Moreover, 28% (7/25) of the participants were not interested in learning new skills as they assumed themselves to be very old and incapable of learning how to use eHealth services. Even those who aimed to learn about eHealth services found it frustrating and noted that the complexity of the services made the learning process more challenging:

> *I am too old and don't want to learn new things; even if I want to, I can't. It is hard for me to memorize and remember. I just want you to make things that I know how to use easier.* [I5]

In total, 28% (7/25) of the participants, those with experience using eHealth services, experienced stress or were irritated when interacting with such complex services. Furthermore, some participants (6/25, 24%) reported that the use of eHealth services made them dependent on others and feel ashamed. As they did not have enough digital skills or experience with computers or e-services, they found the services complex and had to ask for help constantly.

Moreover, 35% (6/17) of the nonimmigrants felt that engaging with eHealth services was somehow obligatory. Despite their initial reluctance, they perceived an external force to adopt these services to remain connected with their community, avoid falling behind youth, and keep pace with developments in health technology:

> *When my kids told me about these digital health services, I found them very difficult to learn, but I said I had to learn them. If I don't learn now, I will be an outsider soon. I think everything will be digitalized soon.* [C5]

In addition, most immigrants (5/8, 62%) reported feelings of being excluded as the available eHealth services were not in their native languages. Nonimmigrant participants expressed a different concern regarding being disconnected. They mentioned that the lack of possibility to contact health care providers directly through My Kanta to discuss recorded notes caused feelings of disconnection:

> *I feel like these services aren't meant for me. If they wanted me to use these eHealth services, they would make them available in my language.* [I7]

Wishes Regarding eHealth Services

Overview

Participants' interactions with eHealth services and their perceived challenges shaped their wishes regarding these services. The identified wishes are explained in the following sections and summarized in Table 4.

XSL•FO
RenderX

Table 4. Immigrant and nonimmigrant older adults' wishes regarding eHealth services in Finland and the links to the basic psychological needs introduced in self-determination theory (SDT).

Wish	Definition	Link to SDT	Nonimmigrants in cities	Nonimmigrants in rural areas	Iranian immigrants
Wishes for all kinds of eHealth services					
User-friendly design	Simple interface	Competence	✓	✓	✓
Support services	Improve digital skills and efficacy	Competence	✓	✓	✓
Unified platform	A single local system	Competence	✓	✓	
Language	eHealth services without technical terminology	Competence	✓	✓	
Language	eHealth services in users' native languages	Competence and autonomy			✓
Facilitate log-in	Log in to eHealth services without an e-ID	Competence		✓	✓
Fewer updates	Zero to few updates	Competence	✓	✓	
Wishes only for My Kanta					
Speed up access	Upload medical records on My Kanta immediately	—[a]	✓	✓	
Notification	Sending notifications to users' mobile phones when new records are uploaded	—	✓		
Edit or comment	Possibility to edit or comment on physicians' notes on My Kanta	Autonomy	✓	✓	
Direct contact	Discuss queries on the recorded health data with health care providers via My Kanta directly	Relatedness	✓	✓	

[a]Not applicable.

Identified Wishes

In Finland, several similar eHealth platforms offer the same services, leading to confusion among users. To address this issue, 40% (10/25) of the participants suggested creating a unified platform that consolidates these services:

> *It is confusing when different sites are giving the same services. It takes time and energy to learn how to use them. It's good if, in one place, you can do very many different things.* [R4]

This single platform was expected to have a user-friendly design for all user groups. Our participants shared several suggestions, such as having only main headlines with big font sizes on the home page; using icons alongside each heading to facilitate information seeking; and minimizing the use of large images on the home page as it might cause navigation difficulties, especially on mobile devices. In addition, some participants emphasized incorporating color into the design. The coloring system was suggested as a potential aid for navigation, especially for people with vision impairments.

Several suggestions were given specifically for My Kanta. These included adding the possibility of listening to the medical records or physicians' notes, the possibility of navigating back to the home page by clicking on the large Kanta icon in the corner of the web page, sharing medical records without any delay, sending notifications to users' mobile phones for new or unchecked records, and the availability of a hotline or chat option as a channel to contact health care providers directly to discuss queries or share worriers about the recorded medical data. These participants wished to have the possibility to edit or comment on physicians' notes, too:

> *Sometimes when I read doctors' notes, I find them hard to understand or I disagree. I wish there was a direct channel to call or text the same doctor who has written the notes and discuss.* [C3]

Furthermore, due to the importance of completely understanding health information, immigrants wished to have at least critical health information in their native languages, and nonimmigrants suggested that health information should be free of medical terminology. In addition, some participants shared the idea of having the possibility to log in without an e-ID. In Finland, to increase security, an e-ID is necessary to log in to public e-services; however, some participants, especially immigrants, found this challenging. Moreover, some participants wished for services without any updates or that, in the case of changes, there should be announcements and proper support. Tailored support in individuals' native languages and close to their living areas was requested by most participants (19/25, 76%).

XSL•FO
RenderX

Discussion

Principal Findings and Comparison With Prior Work

This study used a qualitative exploratory approach to investigate the perspectives of immigrant and nonimmigrant older adults on eHealth services, focusing on their perceived challenges, emotions, and wishes. In addition, it highlighted the role of the basic psychological needs of competence, autonomy, and relatedness, as outlined in SDT, in shaping these perspectives. To support the use of eHealth services by older adults regardless of their background, our findings outline several practical recommendations for developing user-friendly eHealth services and digital supports.

We found that the most common barriers among immigrant and nonimmigrant participants were their values and preferences, inadequate digital skills, and usability issues. Immigrants faced more challenges related to personal values and preferences and inadequate digital skills, whereas nonimmigrants complained that their eHealth use was mainly diminished by usability issues.

We found that barriers related to values and preferences hindered older adults' use of eHealth services for different reasons. First, some participants were reluctant to use eHealth services as they did not understand their added value or highly valued in-person visits to overcome web-based communication challenges. Communication issues varied among participants by background. Although a common problem was the fear of losing human-based interactions, the difficulty in using translation services or body language hindered immigrants without proficiency in the local language from using eHealth services. These findings align with the findings of Wang et al [46]. We showed that the communication-related barriers prevented older adults from satisfying their need for a sense of belonging, reflected in the relatedness aspect of SDT.

Second, participants preferred to use only physical health care facilities or eHealth services aligned with existing in-person services to avoid misdiagnoses, which is in line with previous studies [47,48]. Third, our findings add to the body of knowledge regarding the fact that some Iranian older adults intentionally preferred to delegate their health care responsibilities to their family members and were reluctant to be involved in their health care. Therefore, they did not feel a need to learn about eHealth services. They justified their behavior with their lack of familiarity with the local health care system, language issues, and their own culture. This finding suggests that, even if issues related to language barriers and familiarity with the local health care system are resolved, some Iranian older adults may still prefer to rely on caregivers such as their children. This preference is rooted in their cultural values, which emphasize that older adults should be cared for by younger family members.

The importance of culture has been highlighted previously. Previous studies have considered culture an enabler of learning and using eHealth technologies among some older adults, especially immigrants. The literature shows that older adults' use or nonuse of eHealth services relates to their technology-related cultural perceptions and the contextual factors of their environment and lifestyle [30,49,50]. DeLange Martinez et al [51] identified ethnicity and culture as significant predictors of technology use among Asian immigrant older adults.

Another important group of challenges related to digital skills. Participants' challenges with inadequate digital skills manifested in various ways. Most nonimmigrants and some immigrants felt that their digital skills did not ensure their proficiency in using eHealth services; however, they could use smart devices and search the internet for noncritical topics. In contrast, some immigrants faced greater challenges; they had not been taught the basic digital skills required to use smart devices and the internet in general. These findings are in line with those of previous studies [17,18]. We found that all types of difficulties in terms of digital skills prevented older adults from satisfying their need for a feeling of being competent users of eHealth services (competence aspect of SDT).

Moreover, we identified several usability issues raised mainly by nonimmigrant participants residing in cities. This group of participants had more experience with eHealth services; therefore, they had more knowledge regarding usability issues. A commonly identified usability issue among participants regardless of their immigrant or nonimmigrant status was the complexity of eHealth services and their intricate interfaces. This challenge has been highlighted in previous research [12,17,52,53]. However, the perceived complexity was dependent on other background characteristics; for instance, participants with medical backgrounds found these services less complicated than other participants.

The perceived complexity of eHealth services coupled with inadequate digital skills prevented older adults from satisfying their basic psychological needs outlined by SDT and generated feelings of confusion, stress, and frustration when interacting with eHealth services. Similarly to the study by Chen et al [24], we showed that failure to satisfy the psychological need for being competent users of eHealth services (competence aspect of SDT) led to negative feelings of frustration and anxiety among older adults. Moreover, we add to the literature that the 2 aforementioned challenges of perceived complexity and inadequate digital skills led some participants to repeatedly seek assistance when using the services. On the basis of SDT, these challenges hindered older adults from satisfying their basic psychological need for feelings of being autonomous and competent users of eHealth services (autonomy and competence aspects of SDT), resulting in feelings of shame and reliance on others.

The second most common usability issue—language-related challenges—varied among immigrant and nonimmigrant older adults. Medical terminology use was challenging for nonimmigrants, whereas immigrants faced a lack of eHealth services in their native languages, similar to the findings of Kaihlanen et al [17]. Lack of services in immigrants' native languages leads to the experience of alienation and exclusion (ie, hindering them from meeting their basic psychological need for a sense of belonging [relatedness aspect of SDT]). This discovery aligns with the findings of Safarov [54]. Our findings contribute to the literature by revealing that other usability issues

XSL•FO
RenderX

prevented the satisfaction of the basic psychological need for a sense of belonging among nonimmigrant participants. Nonimmigrants felt disconnected due to the lack of functionality for leaving comments correcting errors in physicians' notes on My Kanta or contacting health care providers directly through My Kanta to discuss their medical records.

Our findings highlight other differences between immigrant and nonimmigrant groups. We found that, despite the perceived challenges and initial reluctance to use eHealth services, some nonimmigrant older adults felt obligated to use these services as a means of staying connected with their community and keeping pace with younger generations. The sense of obligation to adopt innovations may be influenced by Finnish culture or social norms, although we lack concrete evidence to substantiate this claim. This feeling prevented some nonimmigrant older adults from satisfying their psychological need for the feeling of having freedom of choice in using eHealth services (autonomy aspect of SDT). Moreover, Kaihlanen et al [17] showed that not possessing an e-ID was a barrier for immigrants to access eHealth services. Our study added to their findings in that some nonimmigrants residing in rural areas had the same issue.

In addition to the perceived challenges and negative emotions, older adults' interactions with eHealth services generated several positive emotions. Fostering them could support older adults' motivations to use eHealth services. We found that some older adults were interested in learning about eHealth services and using them. However, only nonimmigrants described reasons for their interest. First, they perceived such services as easy to interact with to manage some of their health care needs. This perception signals their basic psychological need for a feeling of being competent users of eHealth services (competence aspect of SDT) being satisfied. Second, nonimmigrants justified their interest as eHealth services giving them access to different meaningful options to satisfy their health care needs independently, which was linked in the analysis to the satisfaction of their psychological need for autonomy. These findings regarding reasons supporting nonimmigrants' interest in eHealth services confirm those of previous studies [55,56].

Moreover, we found that nonimmigrants residing in rural areas expressed more positive feelings compared to others, including equality, hope, and peace of mind, which in the analysis was considered to stem from the satisfaction of their basic psychological need for autonomy in selecting their living places due to the possibility of using eHealth services from rural areas. In addition, satisfaction with being able to contact health care providers (relatedness aspect of SDT) led to the positive feeling of being connected, for example, through the possibility of using chat or phone call options to contact health care professionals for nonemergencies.

Overall, the conducted interviews with older adults yielded several insights for supporting their use of eHealth services that are tied to supporting their basic psychological needs. The first suggestion was related to the design of the services. The participants complained about various available eHealth platforms offering similar services and mentioned being confused. Thus, they suggested that a concrete improvement could be to develop a unified eHealth platform that consolidates multiple services. This suggestion has been made previously [56,57]. However, instead of developing a completely new platform, we recommend that this could be realized through complementing existing patient portals with missing features beyond those available in their current versions. Our key recommendations are to include within such portals options for direct web-based connections with health care providers to discuss older adults' queries about their medical records and the possibility of commenting on their medical records. Such options could satisfy the psychological need to feel connected (relatedness aspect of SDT) among older adults. To satisfy the need for autonomy (as per SDT), we suggest developing the services in multiple languages and using plain terminology. In addition, the platform should have a user-friendly interface design by incorporating visualization tools such as icons alongside each heading, using coloring systems that facilitate navigation, simplifying log-in procedures, and minimizing the frequency of changes to the user interfaces. Adding these features could support satisfying the need to feel competent among older adults.

The second recommendation was to support older adults' digital skills considering their backgrounds. The importance of digital support has been well documented in previous studies [24,30]. Our findings confirm this need, highlighting that existing support services remain insufficient or unsuitable for the diverse needs of older adults, especially immigrants. Our findings confirm that digital support services should be provided in multiple languages considering the cultural differences and needs of different groups of older adults. Similarly, Anand et al [58] highlighted the importance of considering the country of origin and cultural factors in educating older adults. As a practical solution to promote culturally oriented digital support for immigrants, we recommend that translators assigned by the local health care system to assist immigrant older adults during health care visits also be trained to provide digital support services tailored to their specific needs and culture. However, before introducing digital support services, we suggest raising awareness among older adults, particularly immigrants, about the benefits of independently managing health issues via eHealth services. This foundational information can be disseminated through multiple channels. For example, the government agencies responsible for administering national social security programs with contact to all residents could serve as an effective channel. Moreover, to address the identified issue of older adults' reluctance to use eHealth services, which they view as replacing personal interactions that serve a vital social function for lonely individuals, we suggest that society prioritize combating loneliness as a significant and separate social challenge.

Limitations

This study's major limitation lies in its sample selection as it exclusively included immigrants from Iran, who are ranked 13th on the list of the most populous groups of immigrants in Finland [57]. Several reasons supported this selection. First, the first author was proficient in Persian, enabling effective communication with immigrant participants. Second, this group of immigrants has never been the focus of similar studies in

XSL•FO
RenderX

Finland; therefore, their perspectives and needs regarding the Finnish health care system were unknown. This limitation impacts the generalizability of the findings to other immigrant groups in Finland and elsewhere even if we find it plausible that the observed challenges are not limited to Iranians in Finland. For the future, we recommend a larger study with participants from various countries.

Another limitation is the lack of focus on a specific eHealth service. Instead, we allowed participants to raise their most important challenges concerning any type of eHealth service, which allowed us to survey the eHealth landscape more broadly from the user perspective. In addition, this study only compared results based on participants' background information regarding their rural or urban residency and whether they were immigrants. To gain a deep understanding of the background information, we recommend conducting a study that compares the use of eHealth services based on other background information, such as educational level or occupation. It is worth noting that some participants had a medical background. Furthermore, this study collected data solely through interviews and self-reports without conducting usability tests. We recommend a similar study with a follow-up usability test.

Conclusions

The results of 25 interviews with immigrant and nonimmigrant older adults indicate that, while the use of eHealth services is easy for minority groups with medical backgrounds, others face several difficulties. Personal values and preferences, insufficient digital skills, and usability issues were common challenges. The first 2 challenges were more obvious among immigrant older adults, whereas nonimmigrants shared more usability issues due to their familiarity with the available eHealth services. The perceived challenges prevented older adults from satisfying their basic psychological needs for competence, autonomy, and relatedness and generated negative emotions. The Iranian immigrant participants shared more negative feelings regarding eHealth services as they faced more challenges.

To support older adults in the pursuit of well-being via eHealth services, users' basic psychological needs and their wishes regarding eHealth services should be considered from the design stage to the development and implementation processes. To meet this goal, developing a unified eHealth platform with a user-friendly design that consolidates multiple services is of crucial importance to mitigate perceived complexity and the need for advanced digital skills to use such a service because most older adults are concerned that their digital skills are not enough to use complex eHealth services. In addition, a tailored digital support service considering the cultural diversity of users should be available and accessible in multiple languages for older adults. However, before offering digital support, it is essential to promote the importance of managing health issues independently, particularly for those who prefer to delegate their health care responsibilities to their caregivers. These actions could foster positive feelings and support older adults' motivation to use eHealth services.

Abstract

Background: Ureteral stents, such as double-J stents, have become indispensable in urologic procedures but are associated with complications like hematuria and pain. While the advancement of artificial intelligence (AI) technology has led to its increasing application in the health sector, AI has not been used to provide information on potential complications and to facilitate subsequent measures in the event of such complications.

Objective: This study aimed to assess the effectiveness of an AI-based prediction tool in providing patients with information about potential complications from ureteroscopy and ureteric stent placement and indicating the need for early additional therapy.

Methods: Overall, 28 patients (aged 20-70 years) who underwent ureteral stent insertion for the first time without a history of psychological illness were consecutively included. A “reassurance-call” service was set up to equip patients with details about the procedure and postprocedure care, to monitor for complications and their severity. Patients were randomly allocated into 2 groups, reassurance-call by AI (group 1) and reassurance-call by humans (group 2). The primary outcome was the level of satisfaction with the reassurance-call service itself, measured using a Likert scale. Secondary outcomes included satisfaction with the AI-assisted reassurance-call service, also measured using a Likert scale, and the level of satisfaction (Likert scale and Visual Analogue Scale [VAS]) and anxiety (State-Trait Anxiety Inventory and VAS) related to managing complications for both groups.

Results: Of the 28 recruited patients (14 in each group), 1 patient in group 2 dropped out. Baseline characteristics of patients showed no significant differences (all $P>.05$). Satisfaction with reassurance-call averaged 4.14 (SD 0.66; group 1) and 4.54 (SD 0.52; group 2), with no significant difference between AI and humans ($P=.11$). AI-assisted reassurance-call satisfaction averaged 3.43 (SD 0.94). Satisfaction about the management of complications using the Likert scale averaged 3.79 (SD 0.70) and 4.23 (SD 0.83), respectively, showing no significant difference ($P=.14$), but a significant difference was observed when using the VAS ($P=.01$), with 6.64 (SD 2.13) in group 1 and 8.69 (SD 1.80) in group 2. Anxiety about complications using the State-Trait Anxiety Inventory averaged 36.43 (SD 9.17) and 39.23 (SD 8.51; $P=.33$), while anxiety assessed with VAS averaged 4.86 (SD 2.28) and 3.46 (SD 3.38; $P=.18$), respectively, showing no significant differences. Multiple regression analysis was performed on all

XSL•FO
RenderX

outcomes, and humans showed superior satisfaction than AI in the management of complications. Otherwise, most of the other variables showed no significant differences (*P*.>05).

Conclusions: This is the first study to use AI for patient reassurance regarding complications after ureteric stent placement. The study found that patients were similarly satisfied for reassurance calls conducted by AI or humans. Further research in larger populations is warranted to confirm these findings.

KEYWORDS

artificial intelligence; AI; ureteral stent; complications; randomized controlled trial; urologic procedures; urology; patients; information resources

Introduction

The initial stents designed for use in the ureter were the double-J stent and single pigtail stent [1-3]. Following their innovation, ureteric stents have become an essential component of urologic procedures; their applications include safeguarding against renal obstruction caused by stone fragment residues, edema, or blood clots; preventing the extravasation of urine; and for analgesia [4,5].

A number of pharmaceutical agents have been used in order to decrease the complications associated with ureteric stents and assessed in randomized controlled trials (RCTs). These include α-blockers, anticholinergic drugs, β-3 agonists, pregabalin, phosphodiesterase-5 inhibitors, antispasmodics, analgesics, anti-inflammatory drugs, and botulinum A toxin [6]. No studies have been carried out in order to predict the likely complications that may occur and to provide patients with this information, to offer individuals receiving stents reassurance, or to ensure that they receive timely follow-up appointments for any additional therapy required.

The concept of artificial intelligence (AI) was introduced during the 1950s, referring to the potential of machines to demonstrate human intelligence traits, such as being able to learn, reason, and solve problems [7]. The application of AI within health systems has now become a reality, owing to the rapid growth of computational resources, diminished data storage expenses, advanced complexity of algorithms, and widely available electronic health data [8-10]. Instruments facilitated by AI have made positive contributions in a number of health contexts to diagnostic work [11] and treatments [12], as well as to the provision of prognostic information, for example, mortality rates [13]. In renal stone pathologies, most researchers have evaluated the use of AI in terms of the precision of the diagnosis or in order to forecast the clinical results of therapy. The use of AI has infrequently been used in order to provide patients with data, before a ureteric stent intervention, regarding the possible complications that may arise and whether they would benefit from prompt adjunctive therapy.

In order to examine the efficacy of an AI-based prediction that could potentially provide patients with reassurance regarding the complications occurring in association with lithotomy and ureteric stent placement performed through ureteroscopy and to indicate the need for early additional therapy following the intervention, a pilot RCT was carried out. This is the initial study to investigate this topic within this clinical discipline.

Methods

Study Population

From October 2022 to December 2023, a total of 28 patients who underwent ureteral stent insertion with ureteroscopic ureterolithotomy were consecutively included in this single-institution study at the Department of Urology, Soonchunhyang University Hospital, Seoul, South Korea.

Patients were approached during their preoperative consultations and informed about the study. Patients who underwent ureteral stent insertion with ureteroscopic ureterolithotomy, patients who received intervention about urinary stone for the first time, patients who can communicate and are aged between 20 and <70 years, patients without history of psychologic illness, and patients without cognitive problems were included. Patients who were judged to be unsuitable for participation in the study, patients with cognitive impairment, and patients who had undergone the same procedure in the past were excluded. Korean version of the Alzheimer Disease-8, a brief informant-based measure designed to distinguish individuals with very mild dementia and mild cognitive impairment from those with normal cognition, was performed on all patients. Patients with cognitive impairment who had not been previously diagnosed and those with a score of 2 or higher were excluded from the study.

Study Procedure

A call service named “reassurance-call” had been established to provide patients with information about the procedure and postprocedure care, to check for the presence and severity of complications, and to guide future treatments in case of complications. The algorithm of the reassurance-call can be found in Multimedia Appendix 1.

The included 28 patients who underwent ureteroscopic ureteral stent insertion were divided into 2 groups of 14 people each [14]. The power was determined to be 14, considering a dropout rate of 10% based on the minimum target number of 12 to confirm significance [15]. The 2 groups were reassurance-call service group by AI (group 1) and reassurance-call service group by humans (group 2). Allocation was performed with random permutation. JHK generated the random allocation sequence, YNG enrolled participants, and JYH randomly assigned patients

XSL•FO
RenderX

into 2 groups. A complete list of patient characteristics can be found in Multimedia Appendix 2.

Operation agreement and cognitive questionnaire were obtained before the surgery. When patients were discharged, α-blockers and anticholinergics were prescribed to relieve irritation of the ureteral stent, and painkillers were prescribed as needed. On the day after discharge and on the 8th day, group 1 or 2 were randomly assigned and provided reassurance-call. Satisfaction with reassurance-call service was assessed on the 14th day after discharge.

"Reassurance-call" is a voice recognition-based AI service that relies on natural language processing technology, rather than a large language model, to reduce hallucinations and conduct surveys accurately. It leverages natural language understanding (NLU) technology to comprehend user intent and uses dialogue management techniques to facilitate smooth communication with patients. The "reassurance-call" service is trained in the following ways: voice recognition training, NLU training, and dialogue management training. First, the "reassurance-call" service improves its ability to recognize patients' voices through voice recognition training. This process involves analyzing patients' voices to update the voice recognition model. In the pilot trial using "reassurance-call," accurate recognition of numbers was crucial due to the use of the Likert scale. SK Telecom, with experience in providing voice-based services like Tmap (navigation; Tmap Mobility) and Btv (media; SK Broadband), brought expertise in number recognition. However, for this pilot, additional training and tuning were conducted using voices from various age groups and genders. Second, the "reassurance-call" service enhances its ability to understand patients' intentions through NLU training. This involves analyzing patients' speech to update the NLU model. During the pilot trial, additional intent lists were defined and trained to accurately handle responses when patients answered with text rather than numbers (eg, if the first option for a question about pain frequency was "often," and the patient responded with "often," "first one," etc, instead of "1"). Third, the "reassurance-call" service improves its ability to manage conversations with patients through dialogue management training. This involves understanding the patient's intent to provide appropriate responses. In the pilot trial, scenarios were additionally defined for situations where patients wanted to revise a previously answered question, and the dialogue algorithm was trained to handle these scenarios smoothly.

Statistics

The primary outcome was satisfaction with reassurance-call service assessed with a 5-point Likert scale. Secondary outcomes were satisfaction with how complications were handled and anxiety about complications. Satisfaction was scored with a 5-point Likert scale and 10-point Visual Analogue Scale (VAS), and anxiety was assessed with the State-Trait Anxiety Inventory (STAI), which is a 20-item self-report measure of anxiety using a 4-point Likert-type for each item, and the VAS.

Continuous variables were represented by mean and SD, and categorical variables were represented by frequency and percentage. We performed chi-square tests and *t* tests to confirm no significant selection bias at baseline between AI (group 1) and humans (group 2). To identify the variables that affected between 2 groups, we first examined each outcome (*reassurance-call by AI satisfaction.Likert*, *Complication.satisfaction.Likert*, *Complication.satisfaction.VAS*, *Complication.anxiety.STAI*, and *Complication.anxiety.VAS*) using *t* tests. Due to the small sample size per group, nonparametric tests (Mann-Whitney *U* test) were also conducted. Multiple regression analysis was then performed to identify the factors associated with satisfaction and anxiety outcomes. The significance of multicollinearity was assessed by comparing the variance inflation factors between independent variables. Statistical analysis was performed using R version 4.2.1 (The R Foundation for Statistical Computing). All statistics were 2-tailed, and *P* values <.05 were considered significant. In addition, the CONSORT-EHEALTH checklist can be found in Multimedia Appendix 3.

Ethical Considerations

This study underwent a thorough ethical review and was approved by the institutional review board of Soonchunhyang University Hospital (IRB No. SCHUH 2022-07-013-001). Written informed consent was obtained from all patients, and the study data were deidentified. Participants received no compensation for their involvement in the study, and no participant images were uploaded.

Results

In total, 28 patients gave informed consent and were enrolled in the study. The study population was randomly assigned into 2 groups. One patient in group 2 was excluded because he refused to answer the reassurance-call after the first call (Figure 1). Baseline characteristics of patients are shown in Table 1. The mean height and weight of group 1 was 167.38 cm and 67.86 kg, while group 2 had a mean height of 166.81 cm and weight of 69.56 kg, respectively. Also, mean age was 55.14 years and 53.64 years, respectively. Among 14 patients in group 1, a total of 10 were male and 4 were female, while 8 were male and 6 were female in group 2. In group 1, the upper ureter stone was the most common (5/14, 36%), and in group 2, the distal ureter stone was the most common location of urinary stone (7/14, 50%). Mean stone size was 5.12 mm in group 1 and 6.26 mm in group 2, but grade-1 hydronephrosis was the most common in both groups (11/14, 79% and 12/14, 86%, respectively). In both groups, procedures were usually finished with a semirigid ureteroscope (9/14, 64% in both groups), and only 1 patient in group 2 underwent PCNL with a nephroscope. All the characteristics were statistically insignificant (all *P*>.05).

Primary and secondary outcomes are presented in Table 2. Satisfaction of reassurance-call showed a mean of 4.14 (SD 0.66) in group 1 and a mean of 4.54 (SD 0.52) in group 2. There was no significant difference between satisfaction for reassurance-call by AI and humans (*P*=.11). Satisfaction for reassurance-call by AI showed a mean of 3.43 (SD 0.94). Satisfaction about the management of complications using the Likert scale scored a mean of 3.79 (SD 0.70) in group 1 and a mean of 4.23 (SD 0.83) in group 2, which was not significantly different (*P*=.14), but it showed a significant difference when using VAS (*P*=.01), with a mean of 6.64 (SD 2.13) in group 1

XSL•FO
RenderX

and mean 8.69 (SD 1.80) in group 2. Anxiety about complications using STAI scored a mean of 36.43 (SD 9.17) in group 1 and a mean of 39.23 (SD 8.51) in group 2, and anxiety assessed with VAS scored a mean of 4.86 (SD 2.28) in group 1 and a mean of 3.46 (SD 3.38) in group 2. There were no significant differences (*P*=.33 and *P*=.18, respectively). The outcomes were presented using box plots in Figure 2.

Multiple regression analysis was performed on all outcomes and presented in Multimedia Appendix 4. Regarding satisfaction with the reassurance-call service using the Likert scale, there was no variable that showed a significant difference (all *P*>.05). However, in the analysis about satisfaction for management of complications using the Likert scale, reassurance-call by AI showed significantly lower satisfaction than reassurance-call by humans (*P*=.03), and satisfaction significantly increased as stone size increased (*P*=.03). Similarly, in the analysis about satisfaction for the management of complications using the VAS, reassurance-call by AI showed significantly lower satisfaction than reassurance-call by humans (*P*=.02). There was no variable that showed a significant difference in the analysis of anxiety for complications (all *P*>.05).

Discussion

Principal Findings

Hypothetically, a reassurance call generated by AI within a specific clinical context may provide patients with some knowledge regarding the expected complications following the insertion of a ureteric stent and therefore make them more satisfied with the outcome of the procedure. As anticipated, in some instances, human monitoring calls provided a higher satisfaction rating, but in general, it was established that safety data provided by an AI-based intervention could be used to substitute information provided by humans. This is the first research to demonstrate this outcome.

In our study, when comparing group 1 (AI) and group 2 (human), patients were more satisfied with calls made by a human than those made by AI. However, group 1 also received a score exceeding 4 out of 5, achieving a sufficiently high score on the Likert scale. Regarding complications, group 2 showed a significantly higher satisfaction score by the VAS than group 1; however, there was no significant difference between the 2 groups by other measurement tools including Likert-scale anxiety scores. This implies the possibility that AI can replace human calls to some extent.

Discomfort and the presence of blood in the urine are the most frequently occurring side effects following ureteric stent insertion, both of which patients find worrisome and may induce anxiety. The evidence base suggests that symptoms arising in this situation should be approached using combination therapy, for example, α-blockers, anticholinergic agents, anti-inflammatory drugs, and opiates. The rationale underlying the symptoms of loin and suprapubic discomfort, and urine-related issues, for example, frequency, urgency, incontinence, or pain, is not entirely clear. It has been proposed that the stent may act as a mechanical irritant, and that reflux may generate raised pressures within the urinary tract. These issues have not been resolved by either stent design modifications or the administration of pharmaceutical agents either during or following stent insertion. It is essential from the patient's perspective to administer the appropriate medications to address likely complications following the procedure, as well as to be able to provide them with reassurance regarding their symptoms and to monitor for more serious adverse events.

Patient care quality can be enhanced by the application of AI, which enables algorithms pertaining to diagnosis and therapy to be generated for use in patients with renal lithiasis. To date, AI has been used to determine the constituents of renal stones with some precision, to support a diagnosis of lithiasis, and to forecast clinical endpoints following operative interventions [16]. There are, however, further aspects of this clinical domain that have the potential to be assisted by AI.

The widespread use of tools based on AI in routine clinical work has been described in a recent publication by Lam et al [17], with applications identified in 13 clinical disciplines. The majority of relevant RCTs were performed in gastroenterology; 15 studies examined the use of AI to support endoscopic procedures.

Instruments incorporating biosignal-based AI were used in a high proportion of RCTs. In a study of patients with malignancy, those individuals offered a de novo smartphone intervention based on AI demonstrated lower pain scores and were less likely to have a negative mindset toward oncotherapy than control subjects [18].

In some cases, operative procedures for renal stones can be carried out as day cases or in an outpatient facility. In this setting, there should be a consensus on how care is offered to patients who develop postoperative issues. Typically, this is provided by making telephone contact with the patient on the day after the procedure in order to monitor their recovery process and to establish whether they are experiencing any complications [19]. The number of patients requiring same-day procedures, however, is increasing, and this method of follow-up is labor-intensive and takes time that could otherwise be used for clinical patient care. The French Society of Anesthesia and Intensive Care is conducting a study (OPERA) throughout France in order to determine the way in which ambulatory interventions are organized. They established that no calls are made to approximately 15% of patients; this figure may be as high as 55% on Saturday mornings [20]. The majority of follow-up calls, that is, 70%, are made by nursing staff; secretaries and doctors carry out 5% and 1%, respectively. These statistics therefore provide an incentive to develop automated systems to review patients. It is essential that patients remain satisfied with the use of AI, as opposed to a human, to assess their safety, as demonstrated in this study. This is a more advanced system than automated text messages and has the ability to converse with patients.

Although our study is the first to show the potential for safe calls using AI, there are some limitations. The first is that, even if AI is introduced, it is not in the form of conversation. A conversation was had with the patient, during which their symptoms were assessed according to a predetermined script, regardless of whether this was carried out by a human or an AI-based tool. Generative AI was not used in this study, and so, as expected, patients felt less satisfied than if they had conversed with a human. Generative AI is not feasible at present in clinical medicine, but despite this potential shortfall, the outcome of the study was extremely promising. A point was made of specifically enquiring about symptoms of major complications, for example, difficulty passing urine, evident hematuria, and marked pyrexia, and to note if these were absent. A further benefit of this study was that patients could be reassured regarding any potential complications that were arising. We checked for complications by directly asking patients about predictable important complications, such as high fever, severe pain, and hematuria, and guided them to return to the hospital in cases of high fever, so that serious urinary tract infections could be treated early.

Conclusions

Through our study, we have confirmed for the first time that AI can replace humans in identifying complications that occur after ureteral stent insertion and can also play a role in

XSL•FO
RenderX

alleviating anxiety. Although this pilot study included only a small number of participants, the outcomes demonstrated similar satisfaction rates among patients regardless of whether they received a follow-up call made by the tool based on AI or a human. Additional prospective research is therefore merited in larger populations in order to substantiate these findings.

Abstract

Background: Clinical decision support systems leveraging artificial intelligence (AI) are increasingly integrated into health care practices, including pharmacy medication verification. Communicating uncertainty in an AI prediction is viewed as an important mechanism for boosting human collaboration and trust. Yet, little is known about the effects on human cognition as a result of interacting with such types of AI advice.

Objective: This study aimed to evaluate the cognitive interaction patterns of pharmacists during medication product verification when using an AI prototype. Moreover, we examine the impact of AI's assistance, both helpful and unhelpful, and the communication of uncertainty of AI-generated results on pharmacists' cognitive interaction with the prototype.

Methods: In a randomized controlled trial, 30 pharmacists from professional networks each performed 200 medication verification tasks while their eye movements were recorded using an online eye tracker. Participants completed 100 verifications without AI assistance and 100 with AI assistance (either with black box help without uncertainty information or uncertainty-aware help, which displays AI uncertainty). Fixation patterns (first and last areas fixated, number of fixations, fixation duration, and dwell times) were analyzed in relation to AI help type and helpfulness.

Results: Pharmacists shifted 19%-26% of their total fixations to AI-generated regions when these were available, suggesting the integration of AI advice in decision-making. AI assistance did not reduce the number of fixations on fill images, which remained the primary focus area. Unhelpful AI advice led to longer dwell times on reference and fill images, indicating increased cognitive processing. Displaying AI uncertainty led to longer cognitive processing times as measured by dwell times in original images.

Conclusions: Unhelpful AI increases cognitive processing time in the original images. Transparency in AI is needed in "black box" systems, but showing more information can add a cognitive burden. Therefore, the communication of uncertainty should be optimized and integrated into clinical workflows using user-centered design to avoid increasing cognitive load or impeding clinicians' original workflow.

Introduction

Clinical decision support systems (CDSS) are tools that use medical knowledge and health information to aid clinicians' decision-making to provide enhanced patient care [1,2]. CDSS can be classified into 2 types: knowledge-based and non–knowledge-based [2]. In knowledge-based CDSS, relevant information is evaluated by a set of IF-THEN rules, and recommendations are generated. Non–knowledge-based CDSS use artificial intelligence (AI) and machine learning (ML) methods rather than rules to evaluate information and generate recommendations [3]. Various CDSS have been designed to aid pharmacists' clinical work, including checking for drug-drug interactions [4], antibiotics stewardship [5], and drug utilization review [6].

Pharmacists' medication product verification is an example of a pivotal yet time-consuming and vigilant process. During medication product verification, pharmacists compare the contents of a filled medication bottle to professional, close-up images of medication that are integrated into the dispensing platform. Although most pharmacists are checking a physical bottle with the pills inside, the industry is moving toward verification using images of filled medication bottles. Pharmacists spend 30%-48% of their time verifying and dispensing medications [7,8]. Multiplying the time by the mean salary of a pharmacist [9], this equals US $38,823-US $62,117 per pharmacist per year. While some states in the United States have implemented a technician final product verification (tech-check-tech), the cost is still significant as the mean annual wage for a pharmacy technician in 2023 was US $43,330.[10] Furthermore, the tech-check-tech workflow does not eliminate the potential for human error.

Product verification is not only time-consuming and costly, but it also requires pharmacists to be vigilant, which can cause fatigue, cognitive overload, and even result in verification and dispensing errors. Medication dispensing error can be defined as "any deviations of the prescription order," including but not limited to dispensing the wrong dosage, strength, dose form, or pharmaceutical ingredient [11]. The estimated rate of medication dispensing errors is 2.4 in 100 prescriptions [12] in community pharmacies, with the most common types being wrong ingredients, wrong strength, and labeling errors [12,13]. These errors can result in unfavorable therapeutic outcomes, which can have adverse effects on patient safety and outcomes.

Leveraging its capability to process large amounts of data, AI-based CDSS can help pharmacists reduce cognitive load and maintain vigilance. The term vigilance is used to describe the level of maintaining focus and alertness over a prolonged period of time [14]. Human vigilance tends to decrease over time, and multiple theories explain the phenomenon, including the overload theory (reduction of information-processing abilities), underload theory (mindlessness due to repetitive nature), and fatigue [15-17]. Since AI has the power to process large amounts of information, it can reduce humans' cognitive load and maintain their information-processing ability. However, balancing transparency and information load is necessary to avoid cognitive overload. Providing too much information can come at the expense of making the task more cognitively demanding. Marusich et al [18] found increasing information in safety-critical situations decreased users' situational awareness and performance. Similarly, Wu et al [19] examination of high, moderate, and low-complexity user interfaces found significant differences between high- and low-complexity interfaces. Low-complexity interfaces significantly increased users' attention and decreased cognitive load compared with high-complexity interfaces ($P<.05$). Furthermore, cognitive load is not static. Experts and novices at a given task have different levels of cognitive overload; expert users have significantly less cognitive load than novices when using an interface of the same level of complexity [19]. Therefore, it is critical to meet the information needs of users in the design of AI advice.

AI and ML–based CDSS are often "black box" systems, where there is a lack of insight into the AI and ML prediction. As a result, there is an increasing call for greater AI transparency among medical professionals, emphasizing the need to display the uncertainty of AI-generated results [20,21]. While presenting this uncertainty may initially confuse users and require more cognitive effort to make decisions [22], it has significant benefits. Displaying uncertainty helps mitigate issues with AI and ML like overreliance and bias, which fosters better human-AI collaboration and trust [22,23]. This transparency enables users to recognize that AI and ML predictions are not definitive, encouraging them to incorporate their judgment into decision-making. In addition, showing uncertainty serves as a new stimulus that maintains user vigilance, preventing boredom or mindlessness as suggested by the underload theory [17].

AI and ML–based CDSS have the potential to improve medical care if the systems perform well and are appropriately implemented [24]. However, when the AI provides inaccurate, unreliable, and biased results, it can lead users to decision errors due to mechanisms such as automation bias and algorithmic aversion [25]. Automation bias is defined as people's heuristic belief that automation's performance is consistent when the system's performance is not always perfect, which can lead to users accepting incorrect advice or rejecting correct advice [25]. Conversely, algorithmic aversion reflects the tendency of users to not trust the algorithm's performance after seeing it make mistakes, even when its performance is better than humans [26]. In a study of users' assessments of AI and human errors in high-stakes situations (ie, medical and legal), users rated AI errors significantly more harshly and less fair than human errors ($P<.001$) [25]. This result was echoed by Dietvorst et al [26], who studied the effect of AI errors on participants' correctly predicting outcomes. Despite the AI significantly outperforming

XSL•FO
RenderX

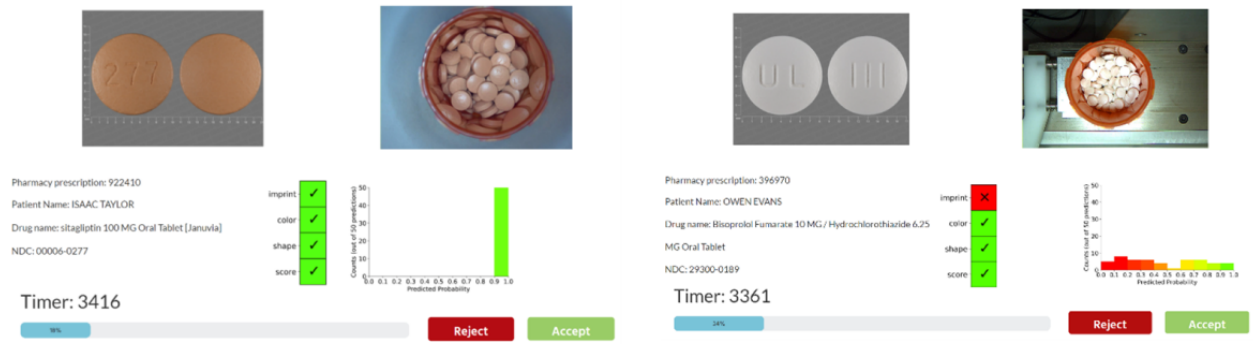
the humans, participants were significantly less likely to trust the AI's prediction and their confidence in the AI significantly decreased after seeing an AI error. To prevent such human errors in clinical decision-making with the help of AI, high-performing and reliable systems are pivotal. In this study, we assess the impact of helpful and unhelpful AI on user cognitive workload.

Previously, our group developed an AI prototype aiming to help pharmacists with medication product verification and reduce dispensing errors. Using the participatory design method, researchers conducted focus groups with pharmacists who had medication verification experience to understand the workflow, difficulties, and concerns of the current process, and ideas about incorporating AI to aid this process. Based on pharmacists' feedback, a user-centered AI interface emphasizing clarity and accessibility was developed. The development of the AI help software is detailed in previous research by Zheng et al [27]. The purpose of this paper is to establish how pharmacists cognitively incorporate and use an AI prototype during the medication product verification process by analyzing eye-tracking fixation data.

Methods

Participants and Trial Design

This study was a randomized controlled trial. We recruited 30 pharmacists to participate in a single, remote study visit. Out of 2 listservs for professional pharmacists, the Minnesota Pharmacy Practice-Based Research Network and the University of Michigan College of Pharmacy Preceptor Network were used to recruit participants. The listserv managers sent a recruitment email instructing interested pharmacists to contact the study team to schedule a screening phone call. The study's inclusion criteria were (1) a licensed pharmacist in the United States, (2) at least 18 years old at the time of screening, and (3) access to a laptop or desktop computer with a webcam to complete the experiment. The exclusion criteria were (1) require assistive technology to use the computer, (2) need eyeglasses with more than 1 power (eg, bifocals) to complete the experiment, (3) have uncorrected cataracts, intraocular implants, glaucoma, or permanently dilated pupils, or (4) eye movement or alignment abnormalities. A random number generator created in R (R Core Team) assigned each participant to receive black box or uncertainty-aware help. The probability of being assigned to black box help trials or uncertainty-aware help trials was equal for all participants as was the probability of completing the first 100 trials with AI help or without AI help. In each trial, participants would check the images on the screen and decide whether it was a good fill (the medication in the fill image is identical to the medication in the reference image) or a bad fill (the medication in the fill image and the reference image are different) and hit either the reject or the accept button.



To ensure confidence in the quality of the remote data collection, all participants met online with a researcher before performing any study activities. The purpose of the online meeting was to ensure the study setup was consistent (eg, adequate lighting and no glare) and participants had the required materials (ie, ruler or tape measure, and standard ID) to conform with Labvanced's eye-tracking and calibration requirements. After meeting with the researcher, all participants watched an orientation video which provided a detailed overview of the study including an explanation of how the AI software makes its predictions and an introduction on how to use the interface to perform the verifications.

The Task: Pharmacists' Medication Verification

Overview

Pharmacists are responsible for dispensing the correct medication to patients to ensure optimal therapeutic outcomes. Before dispensing medications to patients, pharmacists must visually inspect the medication being filled and compare them to the prescribed drugs. This process is called medication product verification. In the study, each participant performed 200 medication product verification tasks, where their eye movement was recorded using an eye tracker. Each participant conducted 100 medication verifications without AI assistance and 100 verifications according to their assigned AI help group. A screenshot of the participants' view is in Figure 1. To avoid the carry-over effect, the medications being verified in no AI help trials were different from those with AI help. However, the medications were identical in trials with black box AI help and trials with uncertainty-aware AI help.

Figure 1. The medication verification system interface with AI Help. In trials without AI assistance, pharmacists only have access to the reference image (refImage) and fill image. With black box AI help, pharmacists saw an AI match plot, which shows the AI's stance on the match status for 4 key medication characteristics (imprint, color, shape, and score). In uncertainty-aware AI help, in addition to the match plot, pharmacists also saw the AI histogram, which displays the probability distribution from 50 predictions, indicating the uncertainty of the prediction. Examples of high certainty (left-hand image) and low certainty (right-hand image) are shown. AI: artificial intelligence.

XSL•FO
RenderX

Trial Type

Each trial was configured with specific variables, including type of AI assistance, case type, and participant performance. There were 3 categories of AI assistance (1) no help, (2) black box help, and (3) uncertainty-aware help. In all 3 categories, 76 of the 100 (76%) trials displayed correctly filled medications. In the no-help condition, participants used only the reference image and filled the image and text. Black box help added an AI-generated match plot, while uncertainty-aware help also included an AI-generated probability histogram. The case type, relevant only when AI assistance was provided, referred to the alignment between the AI's recommendation and the correct answer. The AI accurately recommended the correct action (accept or reject) 79% of the time. There were 2 scenarios: (1) helpful advice, where the AI's guidance matched the correct action (accept or reject), and (2) unhelpful advice, where the AI's suggestion opposed the correct answer.

The AI Help Software

We previously developed an automated tool using a Bayesian neural network [28] to predict the National Drug Code (NDC), color, and shape of medications using images of pills in a prescription bottle [29]. In this study, we modified the Bayesian model [30] to predict the dispensed pills' NDC and the associated model's uncertainty of the predictions. This was accomplished by applying the random dropout technique [30] to the ResNet-34 [31] convolutional neural network. The dropout technique is realized by a layer in the neural network called the dropout layer, which activates connections in the layer with certain probabilities. As such, the output of the layer is random every time it predicts, which we use to measure the uncertainty of the prediction. In our research, the model generated 50 potential probabilities for every image. Because the distribution of predicted probabilities could not be written mathematically in close forms, it was approximated using samples drawn from the distribution.

A sample size of 50 was used to balance between computational cost and goodness of approximation. The AI software then compares the predicted NDC and the reference image NDC to generate insights on the match status. The final interface had 2 AI-generated regions that were designed to aid pharmacists' medication verification the AI match plot and AI histogram. The AI match plot showed the match status of 4 characteristics between the AI-predicted NDC and the expected NDC on the prescription which were (1) imprint, (2) color, (3) shape, and (4) score. The unmatched characteristics were denoted by a red "X," while matched ones by a green check. Figure 1 shows a prediction with 4 green checks.

The AI histogram displayed the probability distribution from 50 AI predictions, each representing the AI's estimated likelihood that its predicted NDC matches the expected NDC. These probabilities form the histogram, illustrating the AI software "confidence" in the match status. A green peak in the histogram indicates consistent results across the 50 simulations, suggesting high confidence. Conversely, a flat, colorful distribution signifies low confidence. In Figure 1, the left-hand image shows a highly confident prediction and the right-hand image shows a low confidence prediction.

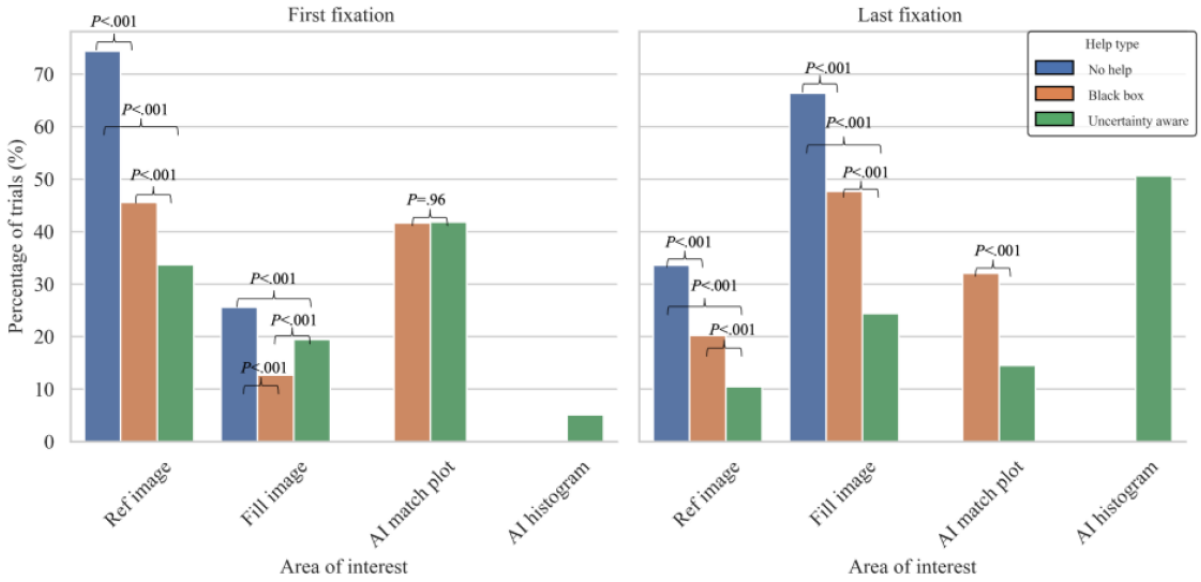
A crucial component of this study was to examine how pharmacists interact with AI-generated errors. The model's overall accuracy is 98.46%. For the purpose of this study, errors were oversampled to obtain a sufficient number of mistakes which lowered the model's accuracy to 79% for the experiment. At 79% accuracy, our model is above the 0.70 reliability threshold wherein imperfect automation is preferable to no automation [32]. Lowering the accuracy balanced the number of trials and participants' time commitment to the study.

Eye-Tracking Data

Eye-tracking data were collected using software from Labvanced (Paderborn). Labvanced uses deep learning models to process webcam videos, allowing online eye movement tracking. The accuracy and precision are comparable to in-laboratory "gold standard" eye trackers and are verified in a peer-reviewed paper [33]. Participants logged on to the Labvanced Trials website. First, they verified the webcam accurately captured their face and agreed to the recording and data use policy before starting the trial. Participants were then prompted to complete a demographics questionnaire that included questions such as age, gender, race, pharmacy practice experience level, practice setting, and trust level in automated systems.

The first phase of the trial was the calibration. During calibration, participants were first asked to measure the distance of their face to the screen and set the center pose that worked best. The actual calibration included 2 parts: (1) the position and orientation and (2) fixation (ie, focused gaze) to certain points on the screen. Participants were asked to follow and fixate on 2 series of red dots on the screen while maintaining their faces at the center pose. After the calibration was completed, participants started the medication verification trials. The system continuously monitored participants' facial position and orientation. If participants moved out of the center pose, they were prompted to re-align their face to the center pose and rerun the fixation calibration. The raw eye-tracking data were processed by the Labvanced algorithm [34] to fixation data. Our analyses were based on the fixation data and excluded eye movement known as saccades, where participants were simply transitioning from 1 fixation to the next and not necessarily fixating in the region.

Data Analysis and Preprocessing



Fixation analysis is the most common metric for analyzing eye-tracking data. The fixation rate, fixation duration, and dwell time have been proposed to reflect human cognitive interest in certain areas of interest [35-37]. Higher fixation rates and longer dwell times indicate repeated interest in a certain area. The longer fixation duration indicates a higher cognitive load. To characterize the use pattern, we were also interested in the order in which pharmacists use these images. Thus, we report the first fixation region, the last fixation region, the number of fixations in each region, the average fixation duration of each fixation, and the dwell time, which was calculated by the sum of the duration of all fixations in each region in each trial. We further stratified the data based on different AI help types (ie, black box versus uncertainty-aware help), and case types (helpful versus unhelpful advice).

XSL•FO
RenderX

To eliminate calibration failure and measurement error, we calculated the modified *z* score of each region's dwell time in each trial. The modified *z* score method is more robust in detecting outliers since it uses median instead of mean in the calculation of *z* scores. If the modified *z* score of the dwell time in that region is greater than 3.5, we labeled that observation as an outlier and excluded it from our analyses.

For all help type pairs, 2-tailed *z* tests were run for the first and last fixation area to determine if differences among categories were statistically significant (Figure 2). *P* values were also calculated to show if the proportions being compared were statistically significant. Statistical significance between help types was calculated for fixation duration, number of durations, time of fixations per area, and total dwell time by case type using the Mann-Whitney *U* test with the *P* values adjusted using the Bonferroni correction.

Figure 2. Percentage of trials by region of interest and AI help type. Left: first fixation; right: last fixation. *P* values were calculated for the 2-tailed z tests to determine the significance of the observed differences and are displayed above respective brackets. AI histogram was only present in the uncertainty-aware condition. No comparative statistics exist in this case. AI: artificial intelligence.

Ethical Considerations

This study did not meet the National Institutes of Health's definition of a clinical trial and the University of Michigan's Institutional Review Board determined this research is exempt from institutional review board oversight under federal Exemption 3(i)(A) and/or 3(i)(B) at 45 CFR 46.104(d).

Results

Overview

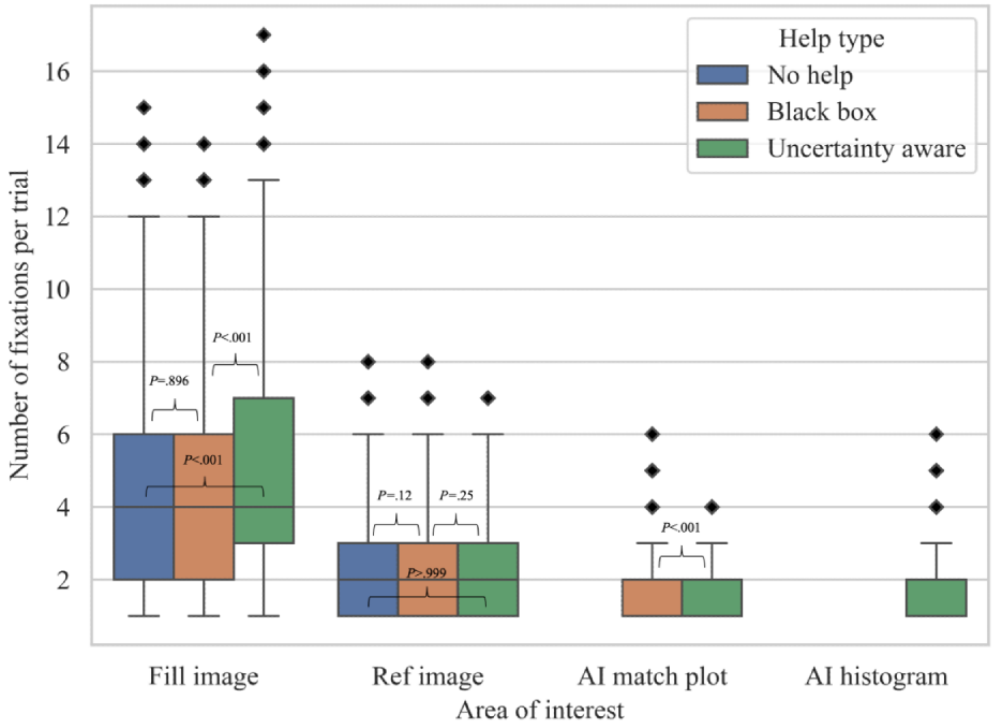
In total, 31 participants were randomized to receive black box or uncertainty-aware AI help. One participant experienced technical difficulties and was unable to complete any trials. Fifteen subjects in each condition completed the experiment and were included in the final analysis. Demographic variables of age, gender, race, practice settings, and working years were well-balanced (*P*>.05). Full details of demographic variables are reported elsewhere [38]. After outlier removal, the dataset comprises 2449 trials without AI assistance, 1365 with black box AI help, and 1391 with uncertainty-aware AI help.

The effects of AI assistance on pharmacists' decision-making and reaction time are reported in full elsewhere [38]. In summary, performance and reaction times varied by AI type and AI accuracy. In general, uncertainty-aware AI led to faster decision-making and protected against bad AI advice to approve a misfiled medication whereas black box AI increased reaction times and bad AI advice resulted in lower accuracy.

First and Last Fixation Area

Overview

In trials without AI help, the first fixation area (Figure 2, left) was either (1) the reference image (1822/2449, 74.4%) or (2) the fill image (627/2449, 25.6%). In the black box help condition, the first fixation area was either (1) the reference image (622/1365, 45.6%), (2) the fill image (174/1365, 12.7%), or (3) the AI match plot (569/1365, 41.7%). In uncertainty-aware help, it was (1) the reference image (469/1391, 33.7%), (2) the fill image (270/1391, 19.4%), (3) the AI match plot (581/1391, 41.8%), and (4) the AI histogram (71/1391, 5.1%). For trials without AI help, the last fixation area (Figure 2, right) was either (1) the reference image (822/2449, 33.6%) or (2) the fill image (1627/2449, 66.4%). In the black box help condition, it was (1) the reference image (276/1365, 20.2%), (2) the fill image (651/1365, 47.7%), and (3) the AI match plot (438/1365, 32.1%). In uncertainty-aware help, it was (1) the reference image (146/1391, 10.5%), (2) the fill image (339/1391, 24.4%), (3) the AI match plot (202/1391, 14.5%), and (4) the AI histogram (704/1391, 50.6%). All of these comparisons, with one exception, showed statistically significant differences between help types. The *P* values were calculated to be *P*<.05 (*z* score>1.96 or <–1.96), thus rejecting the null hypothesis and suggesting there is a significant difference in proportions



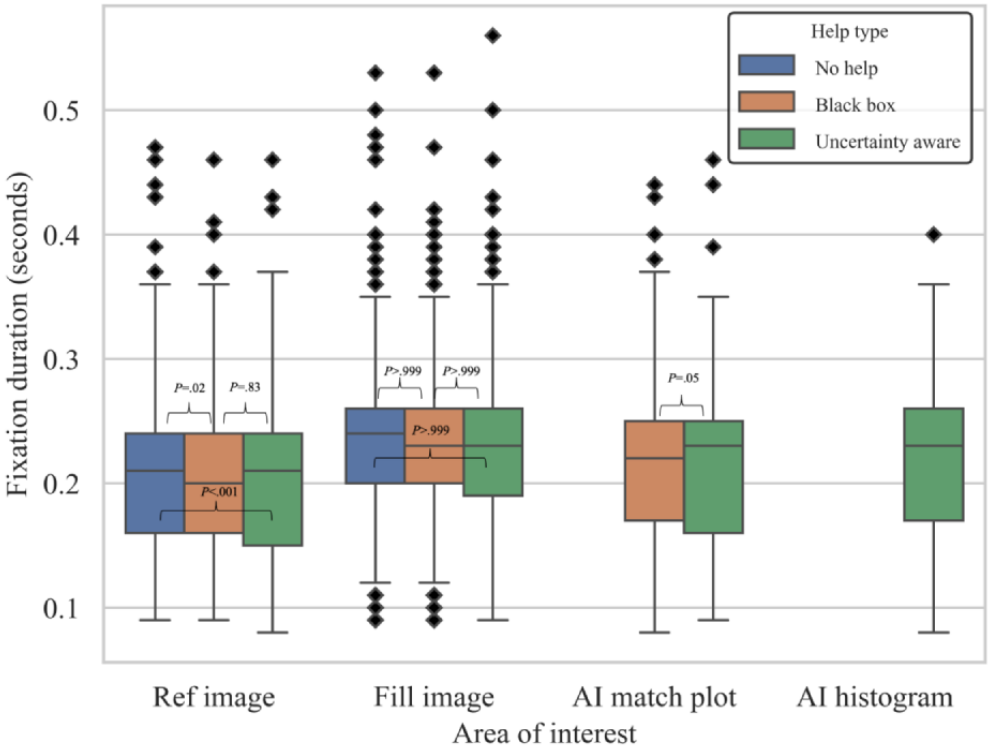
XSL•FO
RenderX

between each 2. The one exception to this was the pair for first fixation being AI match plot with black box help versus uncertainty-aware help, where the *z* test was –.45 and the *P* value was .97, suggesting that these values were not statistically significantly different.

Number of Fixations

Irrespective of help type, fill images had the highest number of fixations in a trial, and the number of fixations per trial did not decrease after the introduction of AI-generated areas (number of fixations: mean [SD], median [IQR]): (1) no help, mean 4.44 (SD 2.92), median 4.0 (IQR 2.0-6.0); (2) black box help, mean 4.33 (SD 2.90), median 4.0 (IQR 2.0-6.0); and (3) uncertainty-aware help, mean 5.14 (SD 3.43), median 4.0 (IQR 3.0-7.0). Reference images received fewer fixations, with the averages and range being (1) no help: mean 2.47 (SD 1.4), median 2.0 (IQR 1.0-3.0), (2) simple help mean 2.38 (SD 1.4), median 2.0 (IQR 1.0-3.0), and (3) advanced help mean 2.45 (SD 1.4), median 2.0 (IQR 1.0-3.0). The AI match plot and AI histogram received a lower number of fixations. The mean (SD) and median (IQR) for the number of fixations in AI match plots in black box and uncertainty-aware help trials are mean 1.91 (SD 1.12), median 2.0 (IRQ 1.0-2.0), and mean 1.65 (SD 0.82), median 1.0 (IQR 1.0-2.0), and in AI histogram in uncertainty-aware help trials, they are mean 1.69 (SD 0.87), median 1.0 (IQR 1.0-2.0), respectively. The numbers are visualized in a box plot in Figure 3. Bonferroni adjusted *P* values comparing no help with black box for fill image and all 3 comparisons for reference image were observed to be greater than .05. Therefore, we do not reject the null hypothesis of the groups being statistically similar. The comparisons of no help and uncertainty-aware and black box with uncertainty-aware advice for fill image, and black box with uncertainty-aware for AI match plot showed significance (Mann-Whitney U=1088528.5, 507726.0, and 381013.0, respectively; all P<.05).

Figure 3. Boxplot representation of the number of fixations in each area per trial, categorized by help type. Bonferroni adjusted *P* values were calculated alongside Mann-Whitney *U* tests, and these statistics are displayed above respective brackets. AI histogram was only present in the uncertainty-aware condition. No comparative statistics exist in this case. AI: artificial intelligence.



Fixation Duration

The fixation duration in each region was similar, regardless of help type. The median duration of fixation was around 0.22 seconds, with an IQR of approximately 0.75 seconds. This indicates that the cognitive load for processing information in each area was similar. The boxplot of the finding is in Figure 4. One adjusted *P* value was below .05, with a *U* value of 29067652, comparing no help to uncertainty-aware advice for the fill image. This indicates a meaningful statistical difference between these 2 groups.

XSL•FO
RenderX

Figure 4. Boxplot representation of fixation duration in each area, categorized by help type. Bonferroni adjusted *P* values were calculated alongside Mann-Whitney *U* tests, with a Bonferroni correction, and these statistics are displayed above respective brackets. AI histogram was only present in the uncertainty-aware condition. No comparative statistics exist in this case. AI: artificial intelligence.

Dwell Times

Participants consistently spent the most time on fill images. The median (IQR) fill image dwell times (in seconds) were: (1) no help trials, median 0.80 (IQR 0.48-1.36), (2) black box help, median 0.80 (IQR 0.47-1.26), and (3) uncertainty-aware help, median 0.92 (IQR 0.53-1.54). For the reference image, the median (IQR) dwell times (in seconds) were (1) no-help, median, 0.44 (0.26-0.66), (2) black box help, median 0.42 (0.24-0.64), and (3) uncertainty-aware help, median 0.43 (IQR 0.26-0.65). The AI match plots had median (IQR) dwell times of 0.33 (IQR 0.22-0.51) and 0.27 (IQR 0.22-0.47) seconds in black box and uncertainty-aware help trials, respectively. The AI histograms had a median (IQR) dwell time of 0.27 (IQR 0.23-0.48) seconds in uncertainty-aware help trials (Figure 5).

The Mann-Whitney *U* test result showed no significant difference between the dwell time in reference images. There was a significant difference in dwell times for fill images with uncertainty-aware help trials compared with no-help trials (*U* value=1113203.0, Bonferroni adjusted *P*<.05) and black box help trials (*U* value=517551.5, Bonferroni adjusted *P*<.05); and for AI match plot from black box to uncertainty-aware (*U* value=375591.0, Bonferroni adjusted *P*<.05). The difference in fill image dwell times was nonsignificant between no help and black box help (Figure 5). Dwell times in fill images and reference images were significantly longer in trials with unhelpful advice compared with helpful advice (the fill image, median: 1.30 vs 0.81 seconds, *U* value 238928.0, *P*<.05; ref image, median: 0.54 vs 0.41 seconds, *U* value 264560.5, *P*<.05; Figure 6).

Discussion

Principal Results

Our study presents critical insights into the interaction between pharmacists and an AI-based CDSS. Our findings highlight a shift in the visual and cognitive engagement of pharmacists when AI-driven tools are used. Although communicating the uncertainty of AI has been shown to have benefits such as preventing overreliance and fostering trust in AI [20,22], our study found that it resulted in a longer cognitive processing time of the core task image (ie, filled medication images), though primarily in situations where the AI provided unhelpful advice. The criticality of AI accuracy is underscored by our findings, as AI advice of varying correctness significantly impacts the cognitive processing time of users. These findings suggest the potential of human-AI collaboration to enhance health care delivery if AI is accurate, reliable, and deployed properly without interfering with health care professionals' existing workflow or increasing their cognitive load.

Irrespective of AI intervention, participants allocated the majority of their fixation time to fill images. The fact that pharmacists need to inspect pills from various angles to verify color, shape, and imprint for accurate identification may give rise to longer cognitive processing times. On the other hand, AI-generated regions have shorter dwell times. This might stem from the graphical simplicity of these images [39] or indicate that users correctly perceive the AI-generated regions as supportive in completing the task. Compared with not showing AI outputs' uncertainty (ie, black box AI help), we found that displaying uncertainty results in significantly longer dwell times in the original (fill) images, especially when the AI advice was unhelpful. This may suggest that users are confused or second-guess the AI's correctness when they see the uncertainty histogram, leading to a need to go back to the fill images and verify the correctness of the advice. The shorter dwell times observed with black box AI advice may be attributed to overreliance on automation, resulting in missed errors in the filled medication.

AI-based CDSS influenced participants' drug verification processes. When participants had access to AI, 19% to 26% of total fixations were shifted to AI regions, and there was a decrease in fixation in the original (fill and reference) images. This indicates that the AI tool changed how participants process information, and participants incorporate AI-generated information in their decision-making process. The decrease in fixation counts in original images and the shift to AI-generated regions indicate that AI may support users in completing the task. When AI help is available, users tend to look at the AI match plot first, and then move on to the fill and reference images. This suggests that providing a simple graphical "summary" of the AI advice may aid users in their decision-making and help them maintain vigilance.

Comparison With Previous Work

Our finding demonstrates the need for well-designed AI that balances transparency and information load. Since many AI algorithms are essentially a "black box," there is a demand for AI transparency [23,40]. However, displaying more information about the advice can decrease user vigilance since more information needs to be processed. In designing AI-based systems, there is a need to balance the transparency and explainability of AI output and the amount of information presented to the users. Previous research has shown that high-complexity interfaces significantly increase cognitive workload compared with low-complexity interfaces [19]. Together, our findings and the previous research support the use of our graphically simple, black box AI help over to the histogram which may be overloading the users.

According to Prabhudesai et al [22], users develop their expertise in explaining the uncertainty plot over time, which resolves the initial confusion. In addition to users developing an explanation over time, the user's expertise with a task impacts the level of cognitive load. Wu et al [19] found at the same level of information load, experts at a task experience significantly less cognitive load than novices. Too much complexity, such as an uncertainty histogram, might not be suitable for the relatively simple medication verification task especially since pharmacists are often tasked with additional responsibilities, which interfere with their vigilance in performing the verification task [41]. Simplifying the communication of the uncertainty might balance the benefits of this kind of advice from AI.

The results revealed that AI's correctness (ie, helpfulness) had a significant impact on users' cognitive processing time. Helpful advice resulted in significantly shorter dwell times in reference images and fill images compared with unhelpful advice. This finding supports that users are susceptible to automation bias, the heuristic tendency of users to favor the suggestion made by automated systems [25], and underlines the importance of AI's correctness and performance. Developers should validate AI's accuracy and reliability before implementing it in the real world, for the underperformance of AI can introduce new user errors through mechanisms such as automation bias, slowing users down. An important way to do this is through the development of standards and guidelines, as well as assessing accuracy, reliability, and other performance metrics [40]. Park et al [42], introduced a framework for AI-based medical products, emphasizing phases akin to drug trials which are (1) balancing benefits and risks, (2) confirming usability through methods like AB testing, (3) conducting large-scale trials to validate effectiveness, and (4) ongoing monitoring for self-improvement. Like medications, AI-driven CDSS can profoundly impact patient care, necessitating rigorous pre- and post-deployment validation.

How AI and CDSS can be used in medication dispensing is under-researched. A systematic review of CDSS and medication use found that while CDSS is used in the prescribing, administrating, and monitoring phases of medication use, CDSS has not been deployed for medication dispensing [43]. To the best of our knowledge, our innovative study is the first to examine how a CDSS impacts cognitive workload for medication verification and dispensing. Our study adds important insights into supporting pharmacists who are experiencing high levels of burnout. A nationwide survey of community pharmacists found that 74.9% of pharmacists have experienced burnout [44]. Furthermore, high prescription

XSL•FO
RenderX

volumes and inadequate pharmacist coverage are contributing factors to dispensing errors [45]. This is concerning as nearly a third (32.1%) of community pharmacists work alone [46], and community pharmacists spend nearly half their work hours (48%) verifying prescriptions [47]. Wash et al [48] narrative review of pharmacists' well-being and burnout found a lack of research into interventions to assist pharmacists with burnout. AI tools such as ours offer a potential solution to alleviate burnout and prevent dispensing errors by providing a second opinion and decreasing cognitive workload.

The use of user-centered design is becoming increasingly prominent in CDSS development [49-53]. A 2024 review of CDSS highlighted the importance of user-centered design to foster the trustworthiness, usability, and acceptability of CDSS tools by health care providers [54]. CDSS tools should fit into current workflows and address health care providers' needs and preferences [54]. During the user-centered design phase of developing our AI prototype, pharmacists emphasized the need for simple and accessible information to guide them in completing the task [27]. To avoid overwhelming pharmacists with redundant information, the match plot only displays AI's stance on color, shape, imprint, and score, which pharmacists identified as the most important information during the medication verification process [27]. Our study adds to the literature a pharmacy-based user-centered design use case underscoring the importance of incorporating user feedback and preferences into the design process. Developers of CDSS should focus on creating systems that align closely with user needs and preferences which can enhance usability and effectiveness. By prioritizing user-centered design principles, developers can improve the performance of AI-based systems and ensure that these systems effectively augment rather than disrupt user workflows.

Limitations and Future Work

Several other eye-tracking metrics have been proposed to assess cognitive load. Voluntary movements such as saccade length and saccade velocity, and involuntary movements such as pupil dilation can reflect cognitive load. Due to the lack of data availability, we did not include these metrics in our analysis. Future studies can include these eye-tracking metrics to further understand users' cognitive workload.

This study showcases the need for well-designed AI that balances transparency and information load. Future research should focus on conducting user-center design and usability testing before implementation to understand the benefits and drawbacks of using the AI tool. Also, qualitative methods, such as interviews, and quantitative methods, such as surveys, can incorporated throughout the design and testing phases to allow for design revision based on participants' perceptions of the AI tools. This may help inform the design and implementation of AI tools in augmenting health care professionals' workflow. As Wu et al [19] described, the interaction between a user's level of expertise and the complexity of an AI tool has a significant impact on the user's cognitive load. Future research should consider allowing users to customize the AI display based on their expertise with the task and comfort with the AI tool. Future studies can include qualitative and quantitative methods to further understand user experiences.

Pharmacists routinely perform a variety of tasks concurrently with the medication verification including checking for drug-drug interactions, confirming the medication count is correct, and verifying patient directions are accurate, complete, and written in patient-friendly language. Pharmacy-specific future research should explore new designs to support dispensing tasks and reduce cognitive load.

Conclusions

The goal of this study was to assess how pharmacists cognitively incorporate and use an AI prototype during the medication product verification process, using eye-tracking data to analyze their interaction with the system. The study revealed that AI-based CDSS can alter traditional workflow and cognitive engagement, with pharmacists allocating significant focus to AI-generated regions, which indicates the integration of AI advice in decision-making. However, communicating AI uncertainty by displaying a probability histogram increased cognitive processing time for original images. The correctness of AI suggestions directly affects cognitive processing, with helpful AI advice reducing and unhelpful AI advice increasing it. The findings underscore the importance of accurate, reliable AI in health care and suggest that user-centered design and AI transparency are crucial for effective human-AI collaboration. Future research should assess additional eye-tracking metrics to determine users' cognitive load, incorporate user-centered design to inform the CDSS design, use qualitative and quantitative methods throughout the design and testing phases to better understand users' experiences, and focus on assisting pharmacists with the varied tasks involved in medication dispensing.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Editorial notice: This randomized study was only retrospectively registered, explained by authors as follows: this benign behavioral intervention using mock data did not meet the NIH definition of a clinical trial and the University of Michigan Institutional Review Board determined it was exempt from ongoing IRB review, under federal EXEMPTION 3(i)(A) and/or 3(i)(B) at 45 CFR 46.104(d). The editor granted an exception from ICMJE rules mandating prospective registration of randomized trials, because

XSL•FO

Abstract

Background: Violence and abuse exert extensive health, social, and economic burdens on adolescents in low- and middle-income countries. Digital parenting interventions are promising for mitigating risks at scale. However, their potential for public health impact hinges on meaningful engagement with the digital platform.

Objective: The objective of this study was to evaluate the impact of 3 intervention design and implementation factors aimed at increasing engagement with a noncommercialized, offline-first smartphone app for caregivers of adolescents in Tanzania, in partnership with the United Nations Children's Fund, the World Health Organization, and the Tanzanian national government.

Methods: Following Multiphase Optimization Strategy (MOST) principles, we conducted a 2×2×2 cluster randomized factorial trial involving caregivers of adolescents aged 10 to 17 years. Caregivers were recruited by community representatives from 16 urban and periurban communities (ie, clusters) in the Mwanza region of Tanzania. Each cluster was randomized to 1 of 2 levels of each factor: *guidance* (self-guided or guided via facilitator-moderated WhatsApp groups), *app design* (structured or unstructured), and preprogram *digital support* (basic or enhanced). Primary outcomes were automatically tracked measures of engagement (app launches, modules completed, and home practice activities reviewed), with secondary outcomes including modules started, time spent in the app, and positive behaviors logged. Generalized linear mixed-effects models assessed the impact of experimental factors on engagement.

XSL•FO
RenderX

Results: Automatically tracked engagement data from 614 caregivers were analyzed, of which 205 (33.4%) were men. Compared to self-guided participants, receiving guidance alongside the app led to significantly more app launches (mean ratio [MR] 2.93, 95% CI 1.84-4.68; *P*<.001), modules completed (MR 1.29, 95% CI 1.05-1.58; *P*=.02), modules started (MR 1.20, 95% CI 1.02-1.42; *P*=.03), time spent in the app (MR 1.45, 95% CI 1.39-1.51; *P*<.001), and positive behavior logs (MR 2.73, 95% CI 2.07-3.60; *P*<.001). Compared to the structured design, unstructured design use resulted in significantly more modules completed (MR 1.49, 95% CI 1.26-1.76; *P*<.001), home practice activity reviews (MR 7.49, 95% CI 5.19-10.82; *P*<.001), modules started (MR 1.27, 95% CI 1.06-1.52; *P*=.01), time spent in the app (MR 1.84, 95% CI 1.70-1.99; *P*<.001), and positive behavior logs (MR 55.68, 95% CI 16.48-188.14; *P*<.001). While analyses did not detect an effect of enhanced digital support on directly observed engagement, the combination of enhanced digital support and guidance positively influenced engagement across a range of outcomes.

Conclusions: This study is the first to systematically optimize engagement with a digital parenting intervention in a low- and middle-income country. Our findings offer important learnings for developing evidence-based, scalable digital interventions in resource-constrained settings.

Introduction

Background

Violence against children (VAC) has far-reaching individual and societal consequences. Beyond physical harm, violence during childhood negatively impacts brain development and increases risks of poor educational attainment, substance use, and adverse mental and physical health conditions [1,2]. These impacts cascade into broader societal costs, including reduced social participation, unemployment, crime, and intergenerational transmission of violence [2-5], with global economic costs approximating US $7 trillion annually [6].

While VAC occurs in many settings, it is most prevalent within the home environment, where it is typically perpetrated by parents or other caregivers [7]. It spans physical, emotional, and sexual abuse, with disproportionately higher rates in low- and middle-income countries (LMICs), particularly in Africa [8,9]. In Tanzania, national survey data [10] revealed that >70% of respondents aged 13 to 24 years had experienced physical violence from parents, relatives, or guardians before the age of 18 years, including being slapped, kicked, beaten, pushed, or threatened with a weapon. Moreover, approximately 80% of those experiencing sexual violence reported physical violence, while emotional abuse was nearly universal among those who experienced physical violence [10]. A more recent nationally representative study by Nkuba et al [11] found even higher rates, with >90% of secondary school students reporting violent discipline from parents or primary caregivers and 80% of parents acknowledging such practices. This widespread prevalence is associated with limited knowledge of nonviolent parenting alternatives, high caregiver stress, and cultural norms emphasizing child obedience and respect, male honor, and family privacy [10,11].

Parenting interventions, identified by the World Health Organization as a key VAC prevention strategy [12], aim to strengthen parent-child relationships and replace harsh, abusive practices with developmentally appropriate, nonviolent discipline strategies [7]. These interventions are effective in preventing VAC globally [13], particularly when they incorporate skill-building in nonviolent discipline, positive reinforcement, emotion regulation, proactive parenting, and protective relationship promotion [14-16]. However, scaling traditional in-person delivery in LMICs, such as Tanzania, faces significant barriers, including prohibitive delivery costs, extensive human resource requirements, limited geographic accessibility for families, and competing work and childcare demands [17-20].

Digital delivery via smartphone apps offers a promising solution to these implementation and access barriers, particularly in LMIC regions, such as sub-Saharan Africa, where mobile phone penetration is rapidly increasing [21]. The success of mobile health interventions in delivering health care services in sub-Saharan Africa [22] and improving health outcomes across LMICs [23,24] further supports this potential. However, systematic reviews [25-31] show that digital parenting research is almost exclusively concentrated in high-income countries (HICs), with interventions predominantly focusing on child behavior management rather than violence prevention. Moreover, these interventions typically experience poor participant engagement [32], defined as both the extent of program usage (eg, amount, frequency, duration, and depth) and subjective user experience (eg, attention, interest, and affect) [33].

Poor engagement undermines an intervention's impact at both individual and population levels. At the individual level, participants fail to acquire essential skills needed to prevent VAC and improve child well-being, while at the population

XSL•FO
RenderX

level, governments and policy makers are unlikely to implement programs widely when only a small proportion of participants engage with and benefit from them [34]. Consequently, poor engagement severely limits the potential public health impact of digital parenting interventions [35,36]. Understanding and optimizing engagement in LMIC contexts is thus critical for establishing digital parenting interventions as a scalable violence prevention strategy.

Existing studies examining engagement with digital parenting interventions in HICs have largely been descriptive [37,38] or focus on sociodemographic and behavioral characteristics associated with engagement [39-42]. A recent review of technology-assisted parenting interventions has advanced this literature by identifying several potential engagement-promoting components, including practical technology support, interactive program features, tailoring, and control features [43]. Similar components have been identified across the broader mobile health literature, such as personalized content and feedback [44-46], user-friendliness [47], a visually appealing layout and the integration of a tutorial on how to use the app [44], human guidance [48-50], peer-based asynchronous communication features [51], and reminders [33,44,52]. However, experimental evidence for these components remains limited; to date, only 1 known trial has experimentally evaluated engagement strategies for digital parenting interventions [53], with no such trials conducted in LMICs. This gap is particularly significant given that digital interventions and their delivery strategies comprise multiple components, each with potentially different effects on engagement. Furthermore, findings from HICs may not generalize to LMIC settings, such as Tanzania, where technological infrastructure, digital literacy, and cultural contexts differ substantially.

Objectives

In response to the need for scalable violence prevention in LMICs, the Global Parenting Initiative, a 5-year research-within-implementation collaboration between universities, foundations, and implementing partners, is developing and evaluating open-source digital parenting programs based on the Parenting for Lifelong Health (PLH) intervention suite. One of these interventions is ParentApp, a smartphone app designed to address adolescent exposure to VAC. Using the Multiphase Optimization Strategy (MOST) framework [54] for systematic intervention optimization, we conducted a cluster randomized factorial trial to identify optimal components for maximizing engagement with ParentApp among socioeconomically disadvantaged caregivers of adolescents in Tanzania. The trial examined 3 factors: *guidance*, *app design*, and *digital support*. Our primary objective was to determine the independent effects of these factors on primary and secondary engagement outcomes. An exploratory objective was to identify potential interaction effects between the factors.

Methods

Trial Design

The trial used a cluster randomized factorial design with three experimental factors: (1) *guidance* (self-guided or guided; factor A), (2) *app design* (structured or unstructured; factor B), and (3) *digital support* (basic or enhanced; factor C). Each factor was varied at 2 levels (lower dose or inactive vs higher dose or active), yielding an 8-condition (2×2×2) trial. A full factorial design was used, allowing all clusters to potentially be randomized to all combinations of factors and their corresponding levels. Further details on the study design are provided in the published protocol [55]. The trial was preregistered on the Pan-African Clinical Trial Registry (PACTR202210657553944) on October 11, 2022. The CONSORT (Consolidated Standards of Reporting Trials) 2010 extension for randomized factorial trials [56] and the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist [57] were used for reporting.

Setting and Participants

Target communities were urban and periurban sub-wards characterized by high rates of poverty in the Mwanza region, Tanzania. Eligible clusters were sub-wards that (1) were located within 3 selected low-income wards, (2) had no previous involvement in ParentApp testing, and (3) contained at least 40 smartphone-owning households. Within each cluster, participants were primary caregivers of at least 1 adolescent aged 10 to 17 years. Caregivers were eligible if they (1) were aged ≥18 years, (2) lived in the same household as their adolescent for at least 4 nights per week in the previous month, (3) had regular access to an Android smartphone, and (4) provided written informed consent. Participants were excluded from the study if they were unable to read or had a severe learning disability that affected their ability to provide informed consent.

Recruitment, Enrollment, and App Onboarding

Following a 2-week community mapping period conducted by Tanzania's National Institute for Medical Research (NIMR) in October 2022, the fieldwork team, in collaboration with Tanzania-based nongovernmental organization (NGO) Investing in Children and Strengthening Their Societies (ICS), initiated recruitment procedures in 3 low-income wards. Centralized stakeholder meetings were held in 2 wards, while in the third ward, sub-ward-level consultations took place due to logistical constraints. A total of 31 community leaders, including ward executive officers, community development officers, and local representatives, were briefed about the study. Those who agreed to support the study were tasked with identifying and contacting potential eligible families within their respective sub-wards over an 8-week recruitment period. Community leaders provided standardized information about the study purpose and intervention content and invited interested families to attend orientation and onboarding sessions.

These sessions were organized by study cluster and held at accessible locations, such as schools and community centers. Sessions were cofacilitated by NIMR research assistants and ICS facilitators. Families first attended a group orientation where they received detailed information about the program objectives, study procedures, data collection requirements, and time commitments. Research assistants then conducted one-on-one eligibility screening using an Open Data Kit checklist. Written

XSL•FO
RenderX

informed consent was obtained from caregivers who met all eligibility criteria.

The subsequent app onboarding lasted approximately 90 minutes and was conducted in small groups of 5 to 10 participants. This included guided assistance with app installation via Google Play (Google LLC), technical troubleshooting, and an orientation to app features. Facilitators demonstrated key functionalities, such as module navigation, activity completion, and resource access. Participants then practiced these skills by completing the app's first module, which concluded with an integrated baseline assessment.

Intervention

Overview

ParentApp is a smartphone app adapted from PLH Teens, an in-person, group-based program originally developed in South Africa to address the need for cost-effective, culturally appropriate violence prevention [58]. Initial evaluations of PLH Teens demonstrated significant improvements in positive parenting practices, along with reductions in child maltreatment, parental depression, stress, substance use, and financial stress [58]. PLH Teens has since been adapted and widely implemented across >18 LMICs [59], including a large-scale delivery in Tanzania to >75,000 caregivers and adolescents [60]. Building on this strong, emerging evidence, ParentApp was developed to address access and scalability challenges associated with in-person delivery. The development and delivery of ParentApp in Tanzania were jointly led by the Universities of Oxford and Cape Town; PLH; Innovations in Development, Education and the Mathematical Sciences; Clowns Without Borders South Africa; NIMR; and ICS, in collaboration with the United Nations Children's Fund, the World Health Organization, and the Tanzanian national government. The intervention content is described in accordance with the TIDieR (Template for Intervention Description and Replication) checklist (Multimedia Appendices 1 and 2).

ParentApp Development

ParentApp underwent systematic development through four phases: (1) initial adaptation and codevelopment with researchers, program specialists, technical experts, and PLH Teens participants in South Africa; (2) user testing with 24 participants across 9 African countries [61]; (3) feasibility testing of self-guided delivery with 107 caregivers in South Africa; and (4) pre- and postpilot testing with 103 caregiver-adolescent dyads in Tanzania, which included remote guidance via phone calls or WhatsApp (Meta Platforms, Inc). Iterative refinements to content, design, and delivery approach across these phases produced the version of ParentApp evaluated in this trial.

ParentApp Design and Content

ParentApp is an open-source, offline-first Android app (compatible with version 5.5.1 or later) comprising 12 modules that integrate text, images, and audio to deliver a condensed version of the in-person program (Table 1). The introductory module focuses on parental self-care and stress reduction, concluding with a welcome survey that collects baseline data and enables users to select their preferred delivery format (individual or group) and engagement schedule. The core intervention consists of 10 modules covering evidence-based practices shown to effectively reduce harsh and abusive parenting [7]. A final module consolidates learning and includes a postintervention assessment.

Each module uses recurring activities to reinforce learning and practical skill building. Modules begin with mindfulness activities featuring emotional check-ins and relaxation exercises, followed by comics that illustrate positive and negative caregiver-adolescent scenarios with reflection questions. Audio testimonials from Tanzanian parents share benefits and experiences, while *Essential Tools* summaries provide quick access to key skills and examples. Modules conclude with home practice assignments that include structured activities and a follow-up *Home Practice Review* for activity reflection. Throughout the app, users can log their skill implementation through *ParentPoints*, a behavioral tracking system for monitoring 10 evidence-based practices that promote positive parenting and mental health (Multimedia Appendix 2). Beyond module activities, users have access to a library with essential parenting tips, local support resources, and technical support. To encourage ongoing engagement, automated push notifications are triggered at 1, 6, and 30 days following the user's last app launch.

XSL•FO
RenderX

Table 1. ParentApp module content and learning objectives.

Module	Core skills and objectives	Home practice[a]
1. Parental self-care and stress reduction	Developing essential mental and physical well-being skills to strengthen parents' capacity to support their families	Practice daily relaxation techniques, identify moments of achievement, and reward successes.
2. One-on-one time	Spending meaningful time with adolescents, using active listening to foster trust, communication, and positive relationships	Schedule and spend 5 to 20 min of focused time with adolescents daily.
3. Praise and positive reinforcement	Using effective praise techniques to encourage positive behavior in adolescents	Practice praising adolescents daily.
4. Positive instructions	Providing clear, specific, and positive directions to improve communication and cooperation	Use positive instructions with adolescents daily.
5. Managing stress	Enhancing emotional awareness and communication skills to support mental well-being and reduce the risk of violent reactions during challenging situations	Practice breathing exercises before reacting.
6. Family budgeting	Identifying strategies for managing and saving money to reduce financial stress and establish achievable family goals	Create a budget with adolescents and other family members.
7. Establishing rules and routines	Engaging adolescents in establishing household rules and routines to foster compliance and build a safe, supportive, and consistent home environment	Practice making rules together with adolescents.
8. Consequences and accepting responsibility	Promoting shared parent-adolescent responsibilities; applying realistic, appropriate consequences for noncompliance; and emphasizing positive discipline over punitive measures	Discuss negative and positive consequences with adolescents.
9. Problem-solving	Building family collaboration skills to identify, address, and resolve challenges through joint problem-solving	Teach adolescents 4-step problem-solving: know it, solve it, try it, and test it.
10. Teen safety in the community and online	Mapping risks in community and online environments to establish protective rules for adolescents	Map safe and unsafe spaces with adolescents and create a family safety plan.
11. Dealing with crisis	Remaining calm in crisis situations and developing immediate and long-term plans to respond effectively, using available support services	Discuss crisis scenarios with adolescents and create family crisis response plans.
12. Celebration and next steps	Reflecting on key learning and solidifying plans for ongoing peer support	Review key skills learned.

[a]Modules 2 to 11 include home practice assignments with follow-up reviews for activity reflection.

Experimental Factors

Overview

Table 2 presents an overview of the core features associated with each factor level. Justification for the selection of factors is also provided in the published protocol [55].

XSL•FO
RenderX

Table 2. Experimental factors, levels, and their core features.

Factor	Description	Core features
Guidance		
Self-guided	Participants accessed ParentApp's full content throughout the study.	• ParentApp without human support
Guided	Participants accessed ParentApp's full content throughout the study and received WhatsApp group guidance.	• ParentApp • WhatsApp groups moderated by 1 lead facilitator and 1 cofacilitator • Facilitators monitored discussions and shared tips and reminders • Facilitators led a weekly 1-hour live-chat session per group
App design		
Structured	ParentApp content followed a sequential, weekly format.	• 12 modules • First module available immediately, with 1 new module unlocked every 7 days • Sequential module order • Content-related notifications • Images featuring generic blue amorphous cartoon characters
Unstructured	ParentApp content followed an open, nonsequential format.	• 12 modules • All modules available immediately • Nonsequential module order • Modules divided into shorter tasks and activities • Content-related notifications disabled • Culturally adapted images featuring humanlike figures
Digital support		
Basic	Participants received an in-app navigation tour at first app launch, followed by a group-based orientation of the app.	• Brief built-in app navigation tour showing core app features • Group orientation on core features led by trained research assistants
Enhanced	Participants received an in-app navigation tour at first app launch, followed by a group-based orientation of the app and a supplementary training session focusing on broader smartphone skills.	• Brief built-in app navigation tour showing core app features • Group orientation on core features led by trained research assistants • Supplementary group training (15 to 20 min) on general smartphone skills led by trained research assistants

Factor A: Guidance (Self-Guided or Guided)

During formative testing, WhatsApp groups showed promise for enhancing app-based delivery. In this trial, half of the clusters received no human support after app onboarding, while the remaining half received guidance via facilitator-moderated WhatsApp groups. The purpose of these groups was to promote social connection and sustain engagement with ParentApp. Each cluster in the guided condition had a corresponding WhatsApp group, overseen by a female-male facilitator pair (totaling 8 groups and 4 facilitator pairs). Following a standardized manual, facilitators shared tips and reminders, monitored discussions, addressed questions, and led weekly 1-hour live-chat sessions to encourage discussion and reflection. The facilitators, who were locally recruited paraprofessionals with previous experience supporting caregivers remotely during the Tanzanian pilot, received training from Clowns Without Borders South Africa, an NGO experienced in training PLH program facilitators.

Factor B: App Design (Structured or Unstructured)

ParentApp was originally designed with a sequential progression to match PLH Teens' learning objectives and time frame. The original design also featured generic blue cartoon characters intentionally designed to facilitate global implementation. However, early testing highlighted 2 potential areas for improvement: some participants found the fixed weekly module releases limiting, while others questioned the acceptability of the generic illustrations. In response, this trial evaluated 2 versions of the app's design (refer to Figures 1 and 2 for screenshot examples). Half of the clusters received the structured design, which maintained sequential module delivery at 7-day intervals over 12 weeks. This version included automated content notifications aligned with module releases, scheduled unlocking of home practice reviews for modules 2 to 11 at the end of each 7-day cycle, and the original generic illustrations. The remaining clusters received the unstructured design, which offered immediate access to all modules and activities after installation. This version incorporated several modifications: users could navigate the 12 modules at their own pace and in their preferred sequence; modules were subdivided into shorter tasks for easier navigation, with home practice review as the final task for modules 2 to 11; automated content notifications were disabled to accommodate flexible access; and generic cartoon images were replaced with culturally adapted illustrations featuring humanlike characters tailored to the Tanzanian context.

Factor C: Digital Support (Basic or Enhanced)

During formative testing, digital literacy challenges emerged as a critical consideration for app engagement. Consequently, this trial evaluated 2 levels of digital support during the onboarding session. Basic support, offered to all clusters, included an embedded ParentApp navigation tour followed by a group-based orientation of the app with demonstrations and practice opportunities. Half of the clusters received enhanced support, which included an additional 15- to 20-minute session focused on improving general smartphone literacy and user confidence. This supplementary training was developed by Innovations in Development, Education and the Mathematical Sciences Kenya, an NGO providing technical support during trial implementation. The training covered essential smartphone skills, including app installation, effective internet use, and online safety, and was delivered by research assistants at the end of the onboarding session. Both levels of digital support were optional.

Measures and Assessment

Overview

Engagement was operationalized across three phases: (1) initial, (2) ongoing, and (3) quality, aligning with established digital intervention literature [33,43,62,63]. Engagement data were collected through automated tracking each time a participant interacted with ParentApp. Use records, including module completion rates, content viewing patterns, and responses to in-app tasks and the baseline assessment, were uploaded to a Metabase cloud server (Metabase, Inc) whenever a device accessed the internet. Additional use data were automatically captured through Matomo Analytics (InnoCraft Ltd), including visit timestamps, session duration, and the frequency of actions or pages viewed. Data monitoring protocols were implemented to ensure accurate tracking and verify that participants received the correct app version based on their cluster allocation. The final dataset was extracted from Metabase and Matomo Analytics in March 2023, approximately 4 months after the last cluster of participants enrolled in the study. Research assistants and facilitators reported estimated attendance rates and session durations for the enhanced digital support training and WhatsApp live-chat sessions, respectively.

Primary Outcomes

Three primary engagement outcomes were evaluated: (1) the number of *app launches* throughout the intervention period (initial engagement), (2) the number of *modules completed* out of 12 (ongoing engagement), and (3) the number of *home practice activities reviewed* out of 10 (quality of engagement). The home practice review outcome underwent a post hoc modification from the protocol, evaluating user initiation of postactivity reviews rather than access to the home practice tab for activity instructions.

Secondary Outcomes

Secondary engagement outcomes included (1) the number of *modules started* out of 12 (initial engagement), (2) the total *time spent in the app* during the intervention period (ongoing engagement), and (3) the number of self-reported *positive parenting and mental health–promoting behaviors logged* throughout the intervention period (quality of engagement).

Baseline Sociodemographic and Behavioral Measures

Baseline demographic and behavioral data were collected using a self-administered questionnaire embedded within the app's welcome survey in the first module. The questionnaire included multiple response formats: demographic questions primarily used binary choice buttons (eg, gender: woman or man) or number entry fields (eg, age), while behavioral measures used frequency scales. Participants could navigate between pages to review and modify their responses, with the assessments taking approximately 10 to 15 minutes to complete. All behavioral measures were nonproprietary, freely available, and recommended by the Global Parenting Initiative. Given the trial's focus on engagement rather than caregiver outcomes, abbreviated scales were used to minimize participant burden. All measures were translated into Kiswahili and back translated and were previously used in Tanzania [60].

Demographic variables included caregiver age and gender, household structure, orphanhood status, and 2 items adapted from the Financial Self-Efficacy Scale on financial stress and food insecurity (1 item each) [64]. Child maltreatment was assessed using 4 items from the International Society for the Prevention of Child Abuse and Neglect Screening Tool-Trial Version [65]. This included subscales for physical abuse (2 items; eg, "How many times in the past month did you hit, spank or slap your child with a hand or object?") and emotional abuse (2 items; eg, "How many times in the past month did you shout, scream or yell at your child?"), rated on a 0 to ≥8 frequency scale. Positive parenting was measured using 5 items from the Alabama Parenting Questionnaire [66], assessing involvement (2 items; eg, "How many times in the past month did you praise your teen?") and supervision (3 items; eg, "How many times in the past month did your teen stay out past their curfew?"), rated on a 0 to ≥8 frequency scale. Parental depression was measured using 3 items from the Centre for Epidemiologic Studies Depression Scale [67]. Items were rated on a 0- to 7-day frequency scale (eg, "How often did you feel that everything you did was an effort?"). Parenting stress was assessed using 1 item adapted from the Parental Stress Scale [68], "How many times in the past month did caring for your children make you feel very stressed?" rated on a 0 to ≥8 frequency scale.

Power

An a priori simulation–based power analysis determined that 640 caregivers across 16 clusters (40 per cluster) were needed for adequate statistical power [55]. This cluster size was selected for future scalability, as larger WhatsApp groups offer greater reach and cost-effectiveness. Simulations accounted for clustering at the sub-ward level, participant-level covariates, and an α level of .05.

Randomization

The factorial experiment was conducted at the cluster level for logistical efficiency, streamlining screening, enrollment, and baseline data collection for participants receiving the same experimental conditions. Community representatives compiled lists of potentially eligible families within their designated

XSL•FO
RenderX

sub-wards. Fieldwork coordinators then formed clusters by grouping geographically proximate sub-wards to minimize the risk of cross contamination. An off-site research team member performed single-stage randomization, assigning each eligible cluster to 1 of the 8 experimental condition combinations using a randomization algorithm in R (R Foundation for Statistical Computing). Final cluster sizes ranged from 32 to 49 caregivers (mean 38.38, SD 6.20).

Blinding

Blinding was not feasible for the in-country research team and facilitators due to their involvement in implementation. Participants were only informed about the experimental conditions to which their cluster was assigned. The data analyst was blinded to cluster allocation but not to condition assignment due to effect coding [69].

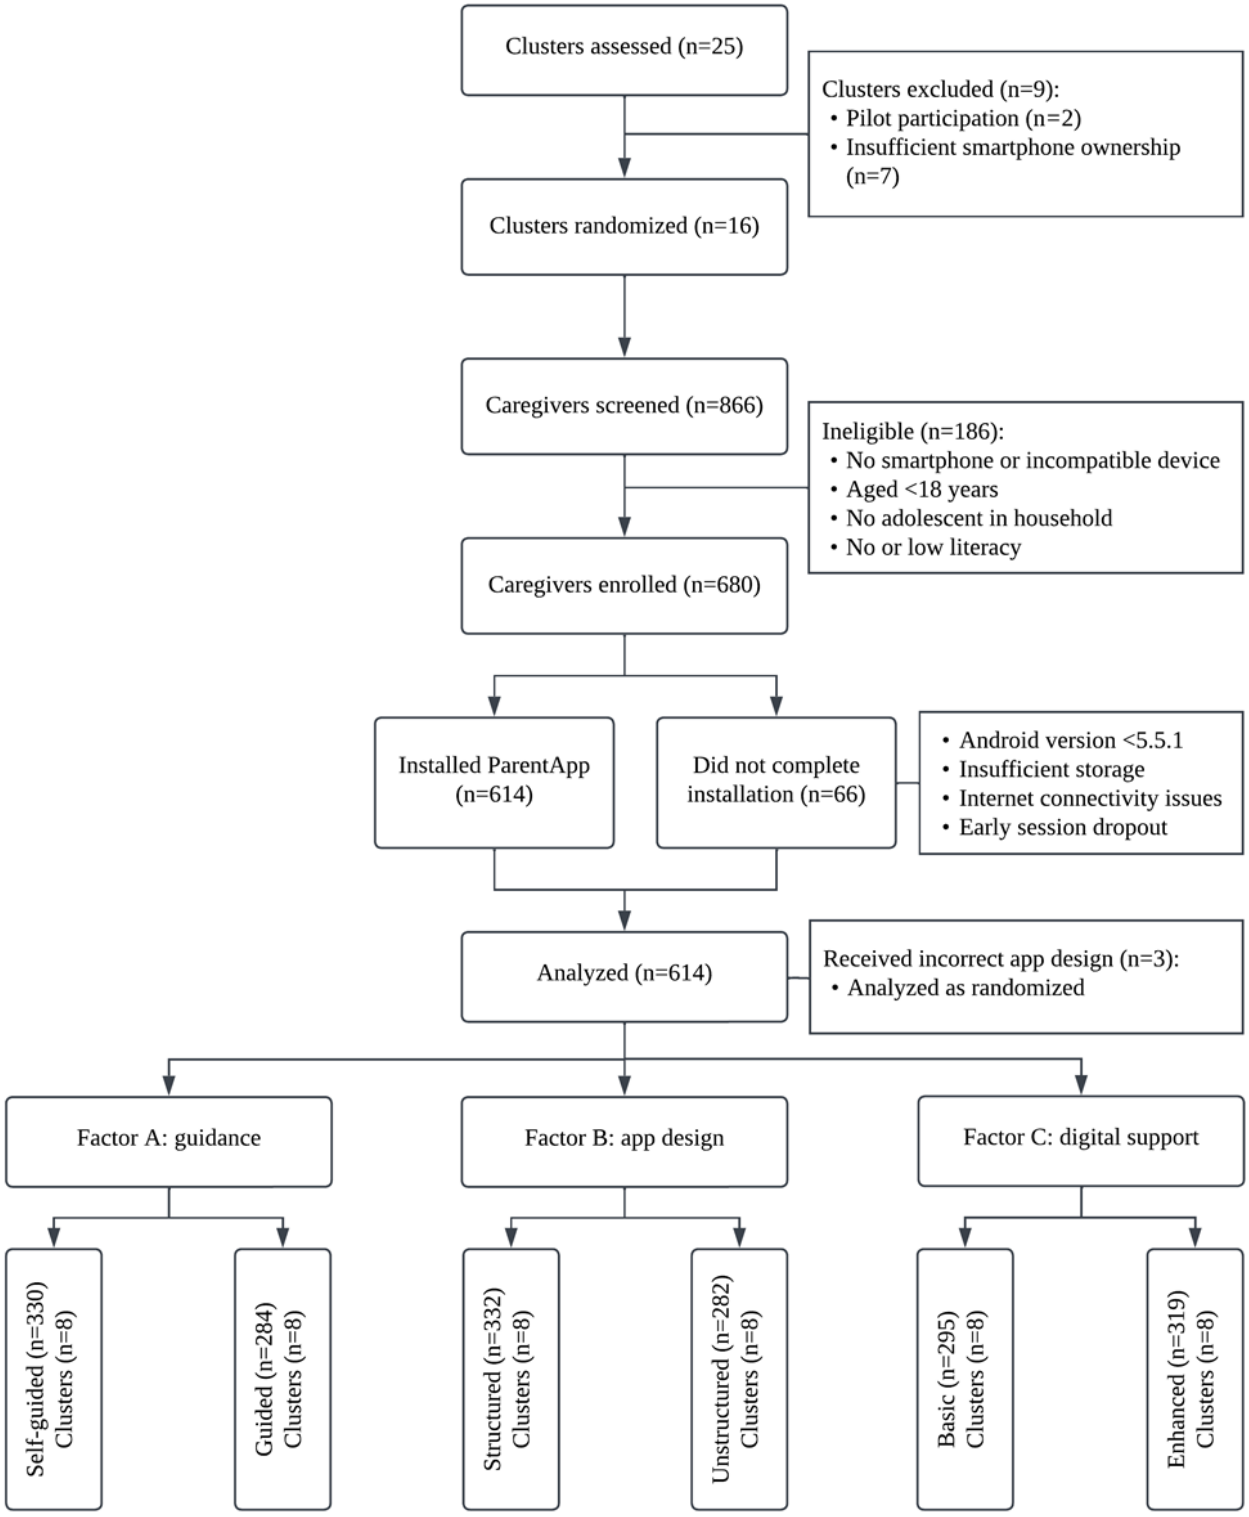
Statistical Analysis

Analyses used generalized linear mixed-effects models with a Poisson distribution to estimate the impact of experimental factors on engagement. Models included a random intercept term to account for the nesting of participants within clusters. Intention-to-treat analyses were conducted but included only participants who successfully installed ParentApp, as data collection was contingent upon app installation. Supplementary analyses found no significant effect of cluster randomization to experimental conditions on app installation status (Table S1 in Multimedia Appendix 3). Missingness in engagement outcomes was minimal, affecting only 2 variables: app launches (6/614, 1%) and time spent on the app (11/614, 1.8%). Multiple imputation with fully conditional specification [70] was used to address missingness in caregiver baseline data (5% to 7.5% at item level). A total of 10 imputations were conducted using predictive mean matching. Clustering was accounted for by specifying –2 in the predictor matrix. Imputation at the item level was passive, summing behavioral items to generate total scores within the imputation process. Following imputation, caregiver baseline data were sample-mean centered within each of the 10 imputed datasets. Analyses were conducted in R (version 4.3.1), using the glmer function from the *lme4* package for generalized linear mixed-effects models [71], and imputations were performed using the *mice* package [72].

In primary analyses, each factor's individual effect on primary and secondary outcomes was evaluated separately. Models were adjusted for the prespecified covariates: caregiver age, caregiver gender, financial stress, food insecurity, child maltreatment (physical and emotional abuse), positive parenting involvement and supervision, parental depression, and parenting stress. In exploratory analyses, all 3 factors were included as main effects alongside their 2-way interactions, while adjusting for baseline characteristics. The inclusion of interaction terms followed recent recommendations for factorial designs to account for potential interdependencies between factors [73]. All main and 2-way interaction effects were estimated using the full sample. Assuming similar effect sizes, this provided equally high power to detect all effects [54]. Estimates for each model were pooled across the 10 imputed datasets using Rubin's rules [72]. Factors were effect-coded, assigning –1 to inactive or lower-dose levels and 1 to active or higher-dose levels (Multimedia Appendix 4). This coding scheme calculates the difference between levels as (+1 – (–1) = 2), whereas with dummy codes, it is simply (1 – 0 = 1) [69]. To ensure an accurate representation of the effect of a 1-unit change in the predictor variable within the effect coding scheme, unstandardized regression coefficients and their SEs were multiplied by a scaling constant of 2. Poisson regression coefficients (which represent the log of the expected change in the outcome per 1-unit increase in the predictor while holding other variables constant) and 95% CIs were exponentiated for easier interpretation. The main effects were interpreted as the ratio of mean event counts or mean ratio (MR), comparing participants in clusters randomized to the higher-dose factor level to those randomized to the contrasting factor level. Interaction terms were interpreted as the additional effect of 1 factor level in the presence of another.

Ethical Considerations

Ethics approval was granted by NIMR (NIMR/HQ/R.8s/Vol.IX/3856) and the University of Oxford Departmental Research Ethics Committee (R69744/RE001). Written informed consent was obtained from all study participants at the onboarding session. Participants also accepted the app's terms and conditions and privacy policy, which detailed how personal information from ParentApp would be collected, used, and shared. After completing the onboarding session, participants received a US $2 honorarium and monthly 1 GB internet bundles for 4 months to support data synchronization with study servers and WhatsApp group participation where applicable. No additional incentives or compensation were provided.



Results

Participant Flow

Participant recruitment and onboarding activities began on October 24, 2022, and concluded on December 1, 2022, coinciding with Tanzania's short rainy season. Of 866 caregivers screened for eligibility, 680 (78.5%) met the inclusion criteria and consented to participate. Among enrolled participants, 66 (9.7%) did not complete app installation due to technical difficulties, including phone-to-app incompatibility, insufficient storage capacity, and internet instability, while others left the onboarding session prematurely due to poor weather conditions and scheduling conflicts. The final sample included 614 participants (90.3% of those enrolled) who successfully installed the app, all of whom were included in intention-to-treat analyses. A CONSORT diagram illustrating participant flow through the study is presented in Figure 3.

XSL•FO
RenderX

Figure 3. CONSORT (Consolidated Standards of Reporting Trials) diagram of participant flow through the 2×2×2 factorial trial.

Participant Characteristics

Participant baseline characteristics, summarized in Table 3, showed a comparable distribution across the 3 factors' levels and the overall sample. Caregiver age ranged from 18 to 75 (mean 35.94, SD 11.84) years. One-third (205/614, 33.4%) of the caregivers were men, which is notable given the challenges parenting programs typically face in engaging fathers [74]. Households comprised an average of 3 (SD 1.80) adults and 3.61 (SD 2.12) children aged between 0 and 17 years. Most caregivers (485/576, 84.2%) reported experiencing food insecurity at least once in the past month, with 35.1% (202/576) reporting ≥7 instances during this period. Nearly half (276/576, 47.9%) of the sample reported that their adolescents had experienced the loss of a primary caregiver during their lifetime. Among these, 72.1% (199/276) reported that the death had occurred within the past 3 years, a trend likely influenced by the COVID-19 pandemic.

Past 3 years, n (%)	199 (72.1)	117 (73.1)	82 (70.7)	108 (70.6)	91 (74)	95 (69.3)	104 (74.8)

[a]Sample sizes vary due to item nonresponse.

[b]Missing caregiver gender data were supplemented with information from the screening questionnaires, resulting in 614 complete observations.

[c]Cases missing all household size data were excluded from the analysis.

[d]Past 3-year orphanhood percentages were calculated using lifetime orphanhood as the denominator.

Intervention Exposure and Engagement

Exposure

Among the 614 participants who successfully installed the app, 600 (97.7%) engaged with at least some of the module content throughout the study, while 14 (2.3%) did not access any content. On average, participants visited the app 3.69 (SD 4.73) times, where a visit was defined as either the initial app launch or visiting a page after a 30-minute interval since the last page view. Each visit involved approximately 20.75 (SD 17.10) actions or page views, totaling 63.81 (SD 85.54) actions on average throughout the study.

For the guidance factor, 53.7% (330/614) of the participants were in self-guided clusters, while 46.2% (284/614) were in clusters allocated to WhatsApp groups. WhatsApp groups averaged 35.5 (SD 6.03) caregivers per group. Half (4/8, 50%) of the WhatsApp groups experienced delayed initiation due to rolling recruitment and the December 2022 Christmas break, with 2 groups postponed until January 2023. These delays likely contributed to participant attrition from the groups. Facilitators reported moderate WhatsApp message participation, but live-chat engagement was low, with attendance ranging from 1 to 16 participants per session (mean 2, SD 2.65).

For the app design factor, 54.1% (332/614) of the participants were in clusters allocated to the structured design and 45.9% (282/614) were in clusters allocated to the unstructured design. Research assistants activated the assigned design on participants' phones based on their respective cluster. In 4 cases, the structured design was mistakenly activated; 3 of these participants did not respond to follow-ups and were treated as randomized in the analyses.

For the digital support factor, clusters assigned to basic support included 48% (295/614) of the participants, and enhanced support 52% (319/614). Given that participation was optional, attendance was not systematically recorded. Research assistants and fieldwork coordinators estimated that 67.1% (214/319) of the participants in enhanced support clusters attended training sessions. Nonattendance was primarily attributed to scheduling conflicts. Session duration varied, lasting anywhere from 5 to 20 minutes, depending on the group size and the number of questions asked.

Engagement

Table 4 summarizes the raw mean comparison of engagement outcomes for the entire sample and each factor level. Module completion rates among the 614 participants who successfully installed ParentApp were as follows: 38.4% (n=236) completed at least 25% (3/12) of the modules, 21.5% (n=132) completed at least 50% (6/12) of the modules, 13.8% (n=85) completed at least 75% (9/12) of the modules, and 8% (n=49) completed 100% (12/12) of the modules. Among the 600 participants who

XSL•FO
RenderX

engaged with some module content, the average content completion rate across all 12 modules was 35.57% (SD 33.10%). This rate varied by factor levels: *guidance* (self-guided: mean 32.8%, SD 31.34% vs guided: mean 38.7%, SD 34.79%), *app design* (structured: mean 34.6%, SD 31.73% vs unstructured: mean 36.7%, SD 34.65%), and *digital support* (basic: mean 34.3%, SD 32.48% vs enhanced: mean 36.8%, SD 33.69%). For participants who started at least 1 module, survival analysis estimated a median retention time of 31 days (95% CI 25-36) from enrollment to last synchronization with the cloud server.

Table 4. Mean comparison of primary and secondary engagement outcomes.

Outcome	Total	Factor A: guidance		Factor B: app design		Factor C: digital support	
		Self-guided (n=330)	Guided (n=284)	Structured (n=332)	Unstructured (n=282)	Basic (n=295)	Enhanced (n=319)
Primary engagement outcomes, mean (SD)							
App launches[a]	17.00 (22.59)	15.87 (20.93)	20.44 (24.18)	20.62 (26.81)	14.91 (15.86)	17.82 (23.67)	18.13 (21.56)
Modules completed[b]	3.40 (3.64)	3.09 (3.41)	3.77 (3.85)	2.91 (3.04)	3.99 (4.16)	3.26 (3.51)	3.54 (3.75)
Activity reviews[c]	1.62 (3.02)	1.39 (2.75)	1.88 (3.30)	0.49 (1.33)	2.95 (3.82)	1.48 (2.90)	1.74 (3.13)
Secondary engagement outcomes, mean (SD)							
Modules started[d]	4.57 (4.13)	4.22 (3.92)	4.99 (4.33)	4.34 (4.03)	4.84 (4.23)	4.43 (4.04)	4.71 (4.21)
Time spent in the app (min)[e]	54.99 (52.48)	48.79 (43.33)	62.22 (60.77)	51.46 (51.54)	59.19 (53.37)	53.39 (48.88)	56.49 (55.71)
Positive behavior logs[f]	38.96 (104.07)	30.70 (75.52)	48.56 (129.06)	32.35 (66.25)	46.74 (135.44)	32.67 (89.18)	44.78 (115.99)

[a]Total app launches during the intervention period.

[b]Number of completed modules (0 to 12).

[c]Number of home practice activities reviewed (0 to 10).

[d]Number of modules started (0 to 12).

[e]Total minutes spent in the app.

[f]Number of self-reported positive parenting and mental health–promoting behaviors logged.

Factor Effects on Primary and Secondary Outcomes

The main effect results for primary and secondary outcomes by factor are provided in Table 5. Following adjustments for baseline characteristics, caregivers who received WhatsApp group guidance in combination with ParentApp demonstrated significantly higher levels of engagement compared to those who were self-guided. Guided caregivers launched the app 2.93 times more (95% CI 1.84-4.68; *P*<.001), completed 1.29 times more modules (95% CI 1.05-1.58; *P*=.02), started 1.20 times more modules (95% CI 1.02-1.42; *P*=.03), spent 1.45 times more time in the app (95% CI 1.39-1.51; *P*<.001), and logged positive behaviors 2.73 times more frequently (95% CI 2.07-3.60; *P*<.001) than self-guided participants. Although guided caregivers initiated more home practice activity reviews compared to those who were self-guided, this difference was not statically significant (MR 2.17, 95% CI 0.84-5.63; *P*=.11).

The unstructured app design significantly outperformed the structured app design across all but 1 engagement outcome. App launch frequency did not differ significantly between designs (MR 0.88, 95% CI 0.70-1.11; *P*=.28). However, caregivers using the unstructured design completed 1.49 times more modules (95% CI 1.26-1.76; *P*<.001), initiated 7.49 times more home practice activity reviews (95% CI 5.19-10.82; *P*<.001), started 1.27 times more modules (95% CI 1.06-1.52; *P*=.01), and spent 1.84 times more time in the app (95% CI 1.70-1.99; *P*<.001) compared to those using the structured design. Notably, users of the unstructured design also logged 55.68 times more positive behaviors (95% CI 16.47-188.27; *P*<.001) compared to those using the structured design. A sensitivity analysis was conducted to address potential biases arising from extreme values in the positive behavior logs outcome (range 0-1342), where 10.4% (64/614) of the sample logged values exceeding 80 (deemed excessive in the study context). Models were rerun with positive behavior logs capped at 80. The results remained consistent with the original analyses (Table S2 of Multimedia Appendix 3).

RenderX

Table 5. Main effects of experimental factors on engagement: unadjusted and adjusted results (N=614).

Factor level and outcomes	Unadjusted		Adjusted[a]	
	MR[b] (95% CI)	*P* value	MR (95% CI)	*P* value
Guided versus self-guided				
App launches	2.90 (1.85-4.54)	<.001	2.93 (1.84-4.68)	<.001
Modules completed	1.29 (1.06-1.57)	.01	1.29 (1.05-1.58)	.02
Activity reviews	2.23 (0.89-5.59)	.09	2.17 (0.84-5.63)	.11
Modules started	1.23 (1.04-1.46)	.02	1.20 (1.02-1.42)	.03
Time spent in the app	1.48 (1.44-1.52)	<.001	1.45 (1.39-1.51)	<.001
Positive behavior logs	2.65 (2.03-3.45)	<.001	2.73 (2.07-3.60)	<.001
Unstructured versus structured				
App launches	0.87 (0.69-1.10)	.25	0.88 (0.70-1.11)	.28
Modules completed	1.45 (1.23-1.72)	<.001	1.49 (1.26-1.76)	<.001
Activity reviews	6.84 (4.73-9.73)	<.001	7.49 (5.19-10.82)	<.001
Modules started	1.24 (1.02-1.51)	.03	1.27 (1.06-1.52)	.01
Time spent in the app	1.72 (1.67-1.77)	<.001	1.84 (1.70-1.99)	<.001
Positive behavior logs	53.48 (17.44-164.03)	<.001	55.68 (16.47-188.27)	<.001
Enhanced versus basic				
App launches	1.02 (0.78-1.32)	.91	1.01 (0.79-1.27)	.97
Modules completed	1.09 (0.88-1.36)	.42	1.09 (0.87-1.36)	.45
Activity reviews	1.15 (0.41-3.24)	.79	1.15 (0.39-3.34)	.80
Modules started	1.07 (0.88-1.29)	.51	1.06 (0.88-1.27)	.53
Time spent in the app	1.07 (0.87-1.30)	.53	1.07 (0.87-1.30)	.53
Positive behavior logs	1.39 (0.78-2.48)	.27	1.44 (0.82-2.54)	.21

[a]Adjusted models included the following covariates: caregiver age, gender, financial stress, food insecurity, parenting stress, caregiver depression, overall child maltreatment, and overall positive parenting. All covariates were sample-mean centered.

[b]MR: mean ratio: estimated effects calculated as MR = exp (2β), where β is the unstandardized regression coefficient derived from the effect-coded experimental factors.

For the digital support factor, although enhanced support showed higher average engagement levels than basic support, these differences were not statistically significant (app launches: MR 1.01, 95% CI 0.79-1.27; *P*=.97; modules completed: MR 1.09, 95% CI 0.87-1.36; *P*=.45; home practice activity reviews: MR 1.15, 95% CI 0.39-3.34; *P*=.80; modules started: MR 1.06, 95% CI 0.88-1.27; *P*=.53; time spent in the app: MR 1.07, 95% CI 0.87-1.30; *P*=.53; and positive behavior logs: MR 1.44, 95% CI 0.82-2.54; *P*=.21).

Factor Interaction Effects on Primary and Secondary Outcomes

Table 6 shows the main and 2-way interaction effects. Results for each outcome were derived from the same fitted model, adjusted for the same sample-mean centered covariates as the main effects analyses.

Although none of the factors showed significant main effects on app launches, a significant interaction between guidance and enhanced digital support (MR 1.69, 95% CI 1.06-2.71; *P*=.04) indicated that their combined effect positively influenced each other's impact on the number of times a participant launched the app. For modules completed, all 3 factors showed significant main effects. In addition, guidance and enhanced digital support showed a significant interaction (MR 1.17, 95% CI 1.07-1.28; *P*<.001), suggesting a mutual positive influence on the number of modules completed. In the model analyzing home practice activity reviews, guidance and app design factors had significant main effects, while digital support did not. A significant interaction between guidance and the unstructured app design (MR 0.77, 95% CI 0.63-0.92; *P*=.004) indicated a decrease in activity reviews, while a significant interaction between guidance and enhanced digital support (MR 1.38, 95% CI 1.21-1.58; *P*<.001) indicated an increase in activity review rates.

[a]WhatsApp group guided versus self-guided.

[b]Unstructured app design versus structured app design.

[c]Enhanced digital support versus basic digital support.

[d]MR: mean ratio: estimated effects calculated as MR = exp (2β), where β is the unstandardized regression coefficients derived from the effect-coded experimental factors.

Among secondary outcomes, the joint influence of guidance and enhanced digital support on modules started was significant (MR 1.24, 95% CI 1.11-1.38; *P*<.001), despite the digital support factor showing no significant main effect. Similarly, the unstructured design and enhanced digital support showed significant interaction effects for the time spent in the app, despite neither factor individually showing significance. However, their combined effects were attenuated (MR 0.36, 95% CI 0.31-0.42; *P*<.001), suggesting that their synergy led to a reduction in participants' app use time.

Discussion

Principal Findings

This is the first known factorial trial of a digital parenting intervention for families with adolescents in an LMIC. It follows MOST principles [54] to optimize engagement with an app targeting socioeconomically disadvantaged families in Tanzania. Findings offer important insights into engagement-enhancing intervention design and implementation strategies for digital parenting interventions tailored to the unique contexts and needs of LMIC settings.

Receiving guidance through moderated WhatsApp groups significantly increased participant engagement across a wide range of engagement metrics. Compared to self-guided participants, those in WhatsApp groups launched the app more frequently, started and completed more program modules, spent more time in the app, and logged more positive parenting and mental health behaviors. These findings align with meta-analytic research on mental health apps and the broader digital health literature, which consistently shows that interventions incorporating some form of human guidance yield higher engagement rates compared to self-guided interventions [44,46,48-50]. However, our study advances this literature in 2 distinct ways. First, we directly compared self-guided and guided conditions within the same trial, whereas previous research has largely relied on cross-study comparisons [48-50]. Second, we implemented a group-based guidance model rather than individual approaches (eg, one-on-one phone consultations, videoconferencing, or email) commonly used in previous studies [26]. This shift toward a less resource-intensive delivery model enhances potential for future scalability.

The mechanisms through which human guidance facilitates engagement with digital interventions are not fully understood. One possible explanation is the role of the relationship quality between facilitators and participants [75]. Alternatively, guided participants may feel an increased sense of accountability in the presence of a facilitator [76]. The group-based format may also be important, as it enables interaction among caregivers. For instance, this setting allows participants with shared experiences to offer emotional and informational support [77] potentially enhancing engagement through social connection and community building. Indeed, a recent systematic review on peer-based features in digital interventions highlighted the importance of asynchronous communication features in

XSL•FO
RenderX

supporting program engagement [51]. In addition to peer support benefits, findings from a systematic review of digital mental health interventions suggest that peer-to-peer groups are particularly effective in promoting engagement and retention when moderated by trained professionals [78]. Nevertheless, contact with facilitators or fellow participants may not be universally desirable or beneficial, as evidenced by participants who left WhatsApp groups prematurely in this study. These findings align with a systematic review showing that synchronous communication features, such as online video calls or chat rooms, were associated with reduced engagement [51]. Understanding which participants benefit from group-based support remains a critical direction for future research.

The unstructured app design, which featured flexible content access and culturally adapted, humanlike illustrations, significantly increased engagement compared to the structured design. Participants using the unstructured design completed more program modules, initiated more home practice reviews, started more modules, spent more time in the app, and logged more positive behaviors compared to those using the structured design. These findings align with research showing that user experience design, including app navigation and appearance, influences motivation and engagement with digital interventions [45,63]. However, as this study evaluated 2 app design packages rather than distinct components, it remains unclear which specific aspect of the unstructured design contributed to enhanced engagement. Future research would benefit from more granular testing and analysis of these design components to determine their individual impact. Enhanced engagement might be attributed to the flexible content progression, which allowed participants to move through the program at their preferred pace. Alternatively, increased engagement could reflect the greater relatability of culturally adapted images, which may have improved app acceptability among caregivers [26] and consequently boosted motivation to engage. While developing a universal app with content tailored for low-income contexts aimed to enhance scalability and reduce adaptation costs, our findings suggest that scalability alone does not ensure acceptability. Culturally adapted visual elements may therefore be crucial in fostering engagement with digital interventions.

A notable finding was the significant increase in home practice activity reviews among participants using the unstructured design. While the reason for this increase remains unclear, it could be attributed to the modular format of the design, which allowed participants to access home practice reviews without waiting for the 7-day cycle to be completed. Given that home practice of program skills is a key mechanism linking program implementation to behavioral outcomes in parenting interventions [79], including home practice engagement as an outcome is a study strength. However, the study does not establish a direct link between engaging in home practice reviews within the app and the actual application of these skills at home. Furthermore, this study only measured when participants initiated home practice reviews in the app, without capturing related measures such as self-reports of activity completion.

A surprising finding was the limited effectiveness of the digital support factor on engagement, which tended to have MRs close to 1 across most engagement outcomes. This suggests that augmenting app-specific assistance with general smartphone support may not yield additional benefits for participants. Unlike recent systematic reviews which assessed baseline digital literacy and its association with engagement [44,48], our study experimentally examined the provision of preprogram digital support. This was an important implementation consideration given our target population's relatively low exposure to digital technology. While systematic reviews indicate that app literacy, defined as technological competency in using a smartphone app, is important for both uptake and engagement [46,80], it is plausible that the basic digital support module in our study adequately contributed to participants' competency and perceived digital skills. Another potential reason could be that the enhanced digital training may have inadvertently reduced ParentApp engagement by introducing participants to competing apps and features, particularly among those with limited previous digital experience.

The impact of digital support on engagement might also have been influenced by various individual factors. The relatively young age of the sample (mean 35.94, SD 11.84 years) and their previous smartphone ownership may suggest sufficient baseline digital literacy. Moderator analyses could reveal whether factors such as caregiver age and other demographic characteristics influenced the results. If digital support proves effective only for specific participants, tailoring the type and intensity of support to individuals would be advantageous. Furthermore, it is essential to highlight that both digital support trainings were optional. The fieldwork team reported that while attendance was high for the basic training, some participants allocated to the enhanced training left the onboarding session early to resume economic and caregiving responsibilities. This reduced exposure could have attenuated the effects of the enhanced training; consideration is thus warranted when interpreting the results.

Interaction analyses found evidence that combining enhanced digital support with guidance led to increased engagement across 4 of the 6 measured outcomes. These interaction effects suggest the importance of smartphone literacy in promoting engagement, although enhanced digital support training alone may not be sufficient to sustain engagement. The combination of enhanced digital support and the unstructured design appeared to reduce app use time, possibly because increased navigation confidence paired with a simplified design allowed more efficient use. Further research is needed to help explain these findings.

Limitations

Several limitations should be considered when interpreting the results. First, as this trial focused on engagement outcomes, we did not assess how the design and implementation factors influenced caregiver or adolescent outcomes. However, this trial serves as the optimization phase of the MOST framework within the broader ParentApp study, laying the groundwork for a comprehensive evaluation of the app's effectiveness in the forthcoming randomized controlled trial [81]. Second, while the study's focus on broader implementation strategies provides valuable insights for implementers and researchers, the generalizability of results to different LMIC settings or populations remains unclear. Further investigation into the

XSL•FO
RenderX

factors influencing uptake and engagement across diverse behavioral domains, digital platforms, and delivery contexts is needed.

Third, data collection via automated tracking required internet access for synchronization with the cloud servers. As a result, participant engagement data may have been incomplete for those whose 1 GB monthly internet bundles depleted before data synchronization occurred, potentially leading to an underestimation of engagement rates. Efforts to address this included sending participants an SMS text message reminder toward the end of the study, along with an additional data bundle. However, it remains unclear to what extent these measures resolved the issue. Fourth, technical challenges hindered app installation and use. Despite enrolling 680 caregivers, surpassing the desired sample size of 640, installation difficulties affected 66 (9.7%) participants, and 14 (2.1%) did not to access any core intervention content after installation. These challenges stemmed primarily from internet and phone-to-app compatibility issues. Forthcoming qualitative research conducted in parallel to this study highlighted additional barriers to uptake and retention, including the selling of phones due to financial needs, deleting the app due to storage constraints, and program dropout due to severely damaged screens. Despite these challenges, overall content completion rates for participants who started at least 1 module was 35.57% of the program. While only 8% (49/614) of participants completed all 12 modules, completion rates were consistent with other digital parenting intervention studies in HICs, such as the 7.5% completion rate found in a large-scale study of the web-based ParentWorks program in Australia [39]. Nonetheless, investigating patterns of early dropout and identifying opportunities for keeping caregivers engaged throughout program delivery remain crucial areas for investigation.

Strengths

This study has several notable strengths. A key strength is the application of a randomized factorial experiment to identify the combination of candidate factor levels that, while remaining feasible and acceptable, most effectively promoted engagement with ParentApp. Findings from this experiment played a pivotal role in selecting which factor levels to include in the forthcoming randomized controlled trial in Tanzania [81]. Following MOST framework decision-making guidelines [82], significant main effects guided the selection of effective factor levels, while lower-dose factor levels were retained when effects were null. Cost-effectiveness analysis and qualitative feedback then helped assess feasibility and acceptability of retained factor levels for the optimized intervention package. In addition, the findings from this experiment have contributed to the development and refinement of other digital parenting interventions, including in South Africa [83] and Malaysia [84].

Another key strength is the study context. Recruitment through local gatekeepers and community leaders yielded a large community sample in an LMIC. This approach aligns with how the intervention could be disseminated in the future and enhances the sustainability of the program. The sample also included 33.4% (205/614) men, a demographic typically underrepresented in parenting interventions [74]. This high proportion of male caregivers not only extends the generalizability of the results but also represents significant strides toward understanding how to engage underrepresented groups in digital parenting interventions in LMIC contexts. A forthcoming subgroup analysis of engagement predictors will provide further insights into this aspect of engagement.

Finally, unlike many digital intervention trials that provided participants with digital devices, this study's sample consisted of participants who used their own smartphones, including older and low-cost models. This approach demonstrates the feasibility of implementing digital interventions in real-world, low-income settings and highlights the potential for cost-effective scale-up. Furthermore, by including participants with varying levels of technological access and proficiency, this study establishes a model for inclusive digital intervention design, particularly relevant in regions such as Tanzania, where smartphone access is expanding but still limited [85].

Conclusions

While digital interventions hold immense promise for addressing health and service needs in LMICs, their effectiveness critically depends on ensuring meaningful engagement. This trial is the first of its kind to use a randomized factorial experiment to optimize participant engagement with an app-based parenting intervention in an LMIC. Moreover, this study adds to the paucity of research addressing the need for effective and accessible violence prevention interventions for adolescents in LMICs. While further investigation is needed to understand the impact of experimental factors on parenting and adolescent outcomes, our findings demonstrate that facilitator-moderated WhatsApp group guidance; an unstructured, culturally adapted app design; and preprogram digital support can enhance engagement with app-based parenting interventions. Continued exploration and refinement of these approaches is needed for developing evidence-based, scalable digital interventions capable of addressing parenting challenges and fostering positive outcomes for families in resource-constrained contexts.

Acknowledgments

This study was funded by the UK Research and Innovation Global Challenges Research Fund Accelerating Achievement for Africa's Adolescents (Accelerate) Hub (ES/S008101/1), the Wellspring Philanthropic Foundation (16204), the European Research Council under the Proof of Concept 2022 Call (101067451), and a private family trust which wishes to remain anonymous. This study is also part of the Global Parenting Initiative, which is funded by the LEGO Foundation and Oak Foundation. The authors would like to thank all members of the ParentApp Tanzania Optimization Trial team. Innovations in Development, Education and the Mathematical Sciences provided technical leadership and conceptual partnership throughout the development of the intervention, including app design and coding; building digital data collection and monitoring systems; and technical support during study implementation. The Tanzanian National Institute for Medical Research fieldwork team conducted community mapping, recruitment, and participant onboarding. Facilitators from Investing in Children and Strengthening Their Societies conducted onboarding sessions and led the delivery of the WhatsApp groups. Clowns Without Borders South Africa conducted local adaptation and contextualization of content, curriculum development, and facilitator training. The authors would also like to thank Vodacom Tanzania for providing low-cost data bundles for participants. The authors would especially like to acknowledge the many families whose participation and input were instrumental in developing ParentApp.

Data Availability

The datasets generated or analyzed during this study are not currently publicly available due to ongoing analyses but will be made available via the Open Science Framework upon study completion. In the interim, datasets are available from the corresponding author on reasonable request.

Authors' Contributions

RJ led the study conceptualization and design, with contributions from LDC, JW, DS, L Clements, LB, ETW, AB, and JML. Trial implementation and data collection were managed by RJ, with project administration support from JW, MW, AO, ANC, L Christine, AM, and GM. DS, L Clements, and ETW led app development and app-generated data management. RJ conducted statistical analyses with guidance from GJM-T and L Clements. RJ drafted the manuscript, which was reviewed and edited by LDC, YS, L Clements, GJM-T, LB, ANC, JK, ETW, and JML. All authors approved the submitted manuscript.

Conflicts of Interest

ParentApp was developed and implemented by members of the research team. RJ's doctoral research is based on this trial. JML is the chief executive officer, and LDC is a voluntary trustee of Parenting for Lifelong Health (PLH), a charity based in the United Kingdom and South Africa. JML receives occasional fees for providing training and supervision for PLH programs. Members of the research team have worked on other studies of PLH, which contributed funding to their respective universities but not directly to them.
